(57) L'invention porte sur des mélanges de poudre et sur un procédé de production et de façonnage de ces mélanges. Ce procédé consiste à mélanger les composants des matériaux en poudre, un liant, un solvant pour le liant, un tensioactif et un non solvant vis à vis d'au moins un liant, le solvant et les matériaux en poudre. Le non solvant a une viscosité inférieure à celle du liant combiné au solvant. Le solvant est présent dans une quantité inférieure à la quantité habituelle. Les composants sont mélangés et plastifiés, puis façonnés pour former une ébauche crue. Le choix des composants confère à l'ébauche crue une meilleure résistance initiale à l'état mouillé. Ce procédé est notamment utilisé dans le traitement par extrusion de systèmes de liants aqueux tels que l'eau et des éthers de cellulose et des non solvants hydrophobes de façon à former des structures telles que des nids d'abeille. Dans l'ébauche, le rapport, lors de la cuisson ultérieure, de la résistance isostatique à la résistance de l'axe A est d'au moins environ 20 % supérieur à celui des ébauches fabriquées sans la composition de mélange de l'invention. L'invention porte également sur une ébauche en nid d'abeille dont le rapport de la résistance isostatique à la résistance de l'axe A est d'au moins environ 0,33 pendant la cuisson.

(57) Powder mixtures and a method of forming and shaping the mixtures. The method involves compounding the components of powder materials, binder, solvent for the binder, surfactant, and non-solvent with respect to at least the binder, the solvent, and the powder materials. The non-solvent is lower in viscosity than the binder combined with the solvent. The solvent is present in an amount that is less than the amount that would be present otherwise. The components are mixed and plasticized, and shaped to form a green body. The choice of components results in improved wet green strength in the green body. The method is especially useful for extrusion processing of aqueous binder systems such as water and cellulose ethers and hydrophobic non-solvents, to form structures such as honeycombs. In the body, the ratio, upon subsequent firing, of the isostatic strength to the A-axis strength is at least about 20 % higher than in bodies made without the mixture composition of the invention. A honeycomb body having a ratio of the isostatic strength to the A-axis strength of at least about 0.33 upon firing.

(54) Title: IMPROVED METHOD OF FORMING AND SHAPING PLASTICIZED MIXTURES AND THE GREEN BODIES MADE THEREFROM

(57) Abstract

Powder mixtures and a method of forming and shaping the mixtures. The method involves compounding the components of powder materials, binder, solvent for the binder, surfactant, and non-solvent with respect to at least the binder, the solvent, and the powder materials. The non-solvent is lower in viscosity than the binder combined with the solvent. The solvent is present in an amount that is less than the amount that would be present otherwise. The components are mixed and plasticized, and shaped to form a green body. The choice of components results in improved wet green strength in the green body. The method is especially useful for extrusion processing of aqueous binder systems such as water and cellulose ethers and hydrophobic non-solvents, to form structures such as honeycombs. In the body, the ratio, upon subsequent firing, of the isostatic strength to the A-axis strength is at least about 20 % higher than in bodies made without the mixture composition of the invention. A honeycomb body having a ratio of the isostatic strength to the A-axis strength of at least about 0.33 upon firing.

15 Field of the Invention

This invention relates to a method for forming and
shaping stiff plasticized powder mixtures containing a
binder, solvent for the binder, surfactant, and a
component in which at least the binder, its solvent, and
20 the powder materials are insoluble, referred to as the
non-solvent. The solvent is present in an amount that is
less than would be present without the non-solvent. The
combinations of mixture components result in improved wet
green strength in the green body than otherwise occurs.
25 Furthermore, this increase in wet green strength occurs
without proportional increases in pressure or torque.

-2-

Also, in extrusion of the above mixtures, the shape of the extrudate or green body is retained at the very instant it exits the die, with no time delay.

5

Background of the Invention

Powder mixtures having a cellulose ether binder are used in forming articles of various shapes. For example ceramic powder mixtures are formed into honeycombs which are used as substrates in catalytic and adsorption applications. The mixtures must be well blended and homogeneous in order for the resulting body to have good integrity in size and shape and uniform physical properties. The mixtures have organic additives in addition to the binders. These additives can be surfactants, lubricants, and dispersants and function as processing aids to enhance wetting thereby producing a uniform batch.

A major and ongoing need in extrusion of bodies from highly filled powder mixtures, especially multicellular bodies such as honeycombs is to extrude a stiffer body without causing proportional increase in pressures. The need is becoming increasingly critical as thinner walled higher cell density cellular structures are becoming more in demand for various applications. Thin walled products with current technology are extremely difficult to handle without causing shape distortion.

Rapid-setting characteristics are important for honeycomb substrates. If the cell walls of the honeycomb can be solidified quickly after forming, the dimension of the greenware will not be altered in subsequent cutting and handling steps. This is especially true for a fragile thin-walled or complex shaped product, or a product having a large frontal area.

Prior rapid stiffening methods involve time-delayed stiffening using rapid set waxes as disclosed, for example in U.S. patent 5,568,652, and/or applying an external

-3-

field such as an electrical, ultrasonic, or RF field at the die exit. All of these methods involve extrusion of soft batches. Historically, for highly filled ceramic mixtures, soft batches have lead to better extrusion quality. Attempts to extrude stiffer ceramic batches with the current batch components, i.e. cellulose ether binder, lowering the amount of water and/or additives such as sodium tallowate or sodium stearate have not been very successful because of the higher extrusion pressures resulting from collision of finer particles, and the abrasiveness of the materials involved.

The growing need for thinner webs (1-2 mil)/high density cellular products to be extruded to shape necessitates stiffening at the very instant the batch exits the die.

The present invention fills the need for instantaneous forming of stiff batches which is especially beneficial for extrusion of thin walled honeycombs, and shape retention of extruded bodies at the very instant the batch exits the die.

Summary of the Invention

In accordance with one aspect of the invention, there is provided powder mixtures and a method of forming and shaping the mixtures. The method involves compounding the components of powder materials, binder, solvent for the binder, surfactant, and non-solvent with respect to at least the binder, the solvent, and the powder materials. The non-solvent is lower in viscosity than the binder combined with the solvent. The solvent is present in an amount that is less than the amount that would be present otherwise. The components are mixed and plasticized, and shaped to form a green body. The choice of components results in improved wet green strength in the green body.

The method is especially useful for extrusion processing of aqueous binder systems such as water and

- 4 -

cellulose ethers and hydrophobic non-solvents, to form structures such as honeycombs.

5 In accordance with another aspect of the invention, there is provided a honeycomb body having a ratio of the isostatic strength to A-axis strength of at least about 0.33, upon firing.

Brief Description of the Drawing

10 Figure 1 is a graph showing stiffness/deformation data representative of inventive and non-inventive examples.

Detailed Description of the Invention

15 This invention relates to a method for forming and shaping stiff plasticized powder mixtures containing a binder, solvent for the binder, surfactant, and a component in which at least the binder, its solvent, and the powder materials are essentially insoluble. This latter component is referred to as the non-solvent, 20 although in actuality, there can be some solubility of the binder and the solvent in the non-solvent as long as the viscosity of the non-solvent is not changed significantly, and the gel that forms as a result of combining the binder and solvent does not become weak as a result of some 25 dissolution in the non-solvent. It is preferred that the binder and its solvent be completely insoluble in the non-solvent. The combinations of mixture components result in improved wet green strength in the green body than otherwise occurs. Furthermore, this increase in wet green 30 strength occurs without proportional increases in forming pressure or mixing torque. Also, in extrusion of the above mixtures, the shape of the extrudate or green body is retained at the very instant it exits the die, with no time delay.

35 Historically, a mixture or batch of a given composition can be made stiff by removing liquids. But

- 5 -

extrusion of such stiff batches results in proportional increase in extrusion pressures and torque with enhanced flow defects such as e.g. swollen or deformed webs (in honeycombs). The method of the present invention enables forming e.g. extrusion of a stiff batch without adversely affecting performance such as pressures, torque, and the flow characteristics.

The method involves forming a stiff batch instantaneously during the plasticization stage of mixing the batch. Stiff batches are formed during plasticization by increasing the binder to solvent ratio in the batch. This is done by partial removal of the solvent which contributes plasticity to the batch. The batch is supplemented with a component in which at least the binder, the solvent, and the powder materials are essentially insoluble, which is termed the non-solvent. The non-solvent does not contribute plasticity to the batch. The non-solvent compensates for the lost solvent. The non-solvent provides the fluidity necessary for shaping, while maintaining stiff batches. This is unlike the solvent which provides both fluidity and acts as a medium for the binder to dissolve in, which results in a soft batch.

The increased stiffness is brought about by increasing the gel strength of the binder in the solvent and the batch. By gelling here is meant thickening that occurs when the binder and its solvent are combined. The gel strength of the binder is increased by increasing the weight ratio of the binder to the solvent by partial removal of the solvent from the batch that would historically be present.

Prior to this invention, if the solvent content were to be reduced, the binder and the batch would be deprived of solvent necessary for complete plasticization of the binder, which is necessary to form a very stiff strong binder gel in the solvent and the batch. This increase in

- 6 -

the effective concentration of the binder in the solvent would lead to a proportional increase in pressures, torques, and flow defects when these batches are shaped.

5 In the present invention, formability of the solvent-deprived stiff batches is enhanced by the use of the non-solvent. The non-solvent component of the batch provides the fluidity necessary for extrusion while maintaining the stiffness of the binder gel in the solvent. While not
10 wishing to be bound by theory, it is believed that the formability is enhanced by the non-solvent being at two critical interfaces: (1) at the interface between the batch and the wall of the shaping apparatus, e.g. in extrusion this is the die/extruder wall, front end hardware (screen pack, homogenized flow control device),
15 and (2) at the interfaces between the individual powder particles.

By highly filled mixtures is meant a high solid to liquid content in the mixture. For example, the powder material content in the mixture is typically at least
20 about 45% by volume, and most typically at least about 55% by volume.

As mentioned previously, the components of the highly filled mixture or batch are (1) powders or mixtures of powders, (2) binder to bind the particles, (3) solvent for
25 the binder which imparts plasticity (binder dissolves in the solvent to provide plasticity), (4) the non-solvent with respect to at least the binder, the solvent, and the powder materials, and (5) surfactant which functions as a lubricant/dispersant to disperse the powders in the
30 plasticized mixture. When the binder dissolves in a solvent, the resulting gel is visco-elastic, i.e. the gel is characterized by an elastic component which is a measure of stiffness, and a viscous component which is a measure of the fluidity of the system. Elastic component
35 is typical of a solid-like behavior, and viscous component is typical of a fluid-like behavior. In the present

-7-

invention, partial removal of the solvent results in a significant improvement in the elastic component of the binder-solvent gel compared to historic batches.

5

The powder material

Typical powders are inorganics such as ceramic, glass ceramic, glass, molecular sieve, metal, or combinations of these.

10

The invention is especially suitable for use with ceramic, particularly with cordierite and/or mullite-forming raw material powders.

15

By ceramic, glass ceramic and glass ceramic powders is meant those materials as well as their pre-fired precursors. By combinations is meant physical or chemical combinations, e.g., mixtures or composites. Examples of these powder materials are cordierite, mullite, clay, talc, zircon, zirconia, spinel, aluminas and their precursors, silicas and their precursors, silicates, aluminates, lithium aluminosilicates, feldspar, titania, fused silica, nitrides, carbides, borides, e.g., silicon carbide, silicon nitride, soda lime, aluminosilicate, borosilicate, soda barium borosilicate or mixtures of these, as well as others.

20

25

Especially suited are ceramic materials, such as those that yield cordierite, mullite, or mixtures of these on firing, some examples of such mixtures being about 2% to about 60% mullite, and about 30% to about 97% cordierite, with allowance for other phases, typically up to about 10% by weight. Some ceramic batch material compositions for forming cordierite that are especially suited to the practice of the present invention are those disclosed in U.S. patent 3,885,977 which is herein incorporated by reference as filed.

30

35

In accordance with a preferred embodiment, one composition which ultimately forms cordierite upon firing is as follows in percent by weight, although it is to be

- 8 -

understood that the invention is not limited to such:
about 33 to about 41, and most preferably about 34-40 of
aluminum oxide, about 46-53 and most preferably about 48-
52 of silica, and about 11-17 and most preferably about
5 12-16 magnesium oxide.

The powders can be synthetically produced materials
such as oxides, hydroxides, etc., or they can be naturally
occurring minerals such as clays, talcs, or any
combination of these. The invention is not limited to the
10 types of powders or raw materials. These can be chosen
depending on the properties desired in the body.

Some typical kinds of powder materials are given
below. The particle size is given as median particle
diameter by Sedigraph analysis, and the surface area is
15 given as N₂ BET surface area.

Some types of clay are non-delaminated kaolinite raw
clay, such as Hydrite MPTM clay, or Hydrite PXTM clay,
delaminated kaolinite, such as KAOPAQUE-10TM (K10) clay,
and calcined clay, such as Glomax LL. All of the above
20 named materials are sold by Dry Branch Kaolin, Dry Branch,
Georgia.

Some typical kinds of talc are those having a surface
area of about 5-8 m²/g, such as supplied by Barretts
Minerals, under the designation MB 96-67.

25 Some typical aluminas are coarse aluminas, for example,
Alcan C-700 series, such as C-701TM, or fine aluminas such
as A-16SG from Alcoa.

One typical kind of silica is that having a particle
size of about 9-11 micrometers, and a surface area of
30 about 4-6 m²/g, such as IMSILTM sold by Unimin
Corporation.

In filter applications, such as in diesel particulate
filters, it is customary to include a burnout agent in the
mixture in an amount effective to subsequently obtain the
35 porosity required for efficient filtering. A burnout agent
is any particulate substance (not a binder) that burns out

- 9 -

of the green body in the firing step. Some types of burnout agents that can be used, although it is to be understood that the invention is not limited to these, are non-waxy organics that are solid at room temperature, elemental carbon, and combinations of these. Some examples are graphite, cellulose, flour, etc. Elemental particulate carbon is preferred. Graphite is especially preferred because it has the least adverse effect on the processing. In an extrusion process, for example, the rheology of the mixture is good when graphite is used. Typically, the amount of graphite is about 10% to about 30%, and more typically about 15% to about 30% by weight based on the powder material.

Molecular sieves can also be shaped into bodies in accordance with this invention. Molecular sieves are crystalline substances having pores of size suitable for adsorbing molecules. The molecular sieve can be in the crystallized form or in the ammonium form or hydrogen form, or ion-exchanged with or impregnated with a cation. The molecular sieves can be provided in ion exchanged form or impregnated with cations either before forming into a body or after the product body has formed. The ion-exchange and impregnation methods are well known processes. Such treatments are within the scope of this invention.

Some types of molecular sieves which are preferred for the practice of the present invention are carbon molecular sieves, zeolites, metallophosphates, silicoaluminophosphates, and combinations of these. Carbon molecular sieves have well defined micropores made out of carbon material.

The molecular sieves that are especially suited to the invention are the zeolites. Some suitable zeolites are pentasil, such as ZSM-5, Y, such as ultrastable Y, beta, mordenite, X, such as 13X, or mixtures thereof.

-10-

Any sinterable metal or metal composition can be used in the practice of the present invention. Especially suited are iron group metal, chromium, and aluminum compositions, with the preferred iron group metal being iron. Especially preferred is Fe, Al, and Cr. For example, Fe5-20Al5-40Cr, and Fe7-10Al10-20Cr powders with other possible additions are especially suited. Some typical compositions of metal powders are disclosed in U.S. Patents 4,992,233, 4,758,272, and 5,427,601 which are herein incorporated by reference as filed. U.S. patent 4,992,233 relates to methods of producing porous sintered bodies made from metal powder compositions of Fe and Al with optional additions of Sn, Cu, and Cr. U.S. patent 5,427,601 relates to porous sintered bodies having a composition consisting essentially of in percent by weight about 5-40 chromium, about 2-30 aluminum, 0-about 5 of special metal, 0-about 4 of rare earth oxide additive and the balance being iron group metal, and unavoidable impurities such as e.g., Mn or Mo, with the preferred iron group metal being iron. When rare earth oxide is present, the special metal is at least one of Y, lanthanides, Zr, Hf, Ti, Si, alkaline earth metal, B, Cu, and Sn. When no rare earth oxide is present, the special metal is at least one of Y, lanthanides, Zr, Hf, Ti, Si, and B, with optional additions of alkaline earths, Cu, and Sn.

In general, the powder material is fine powder (in contrast to coarse grained materials) some components of which can either impart plasticity, such as clays, when mixed with water for example, or which when combined with the organic binder can contribute to plasticity.

The weight percents of the binder, solvent, and non-solvent are calculated as superadditions with respect to the non-organic solids by the following formula:

$$\frac{\text{weight of binder, solvent, non-solvent, or other additives}}{\text{weight units of powder materials}} \times 100.$$

- 11 -

The Binder

The function of the binder is to bind the inorganic powders and impart plasticity to the batch when mixed with a solvent. The preferred binders used in this invention are aqueous based, that is, capable of hydrogen bonding with polar solvents. Examples of binders are cellulosics, starches, poly(vinyl alcohol), poly(vinyl pyrrolidone), gums such as guar gum, xanthan gum, carageenan, etc., alginates, polyethylene oxides, polyamides, and/or polyacrylates. A combination of binder and cross-linking agent can also be used as a binder component (e.g. polyvinyl alcohol with borax, polyacrylates with poly(vinyl alcohol). Hydrophobically modified aqueous binders can also be used.

Especially useful in the practice of this invention are cellulose ether binders for aqueous systems.

Some typical cellulose ether binders according to the present invention are methylcellulose, ethylhydroxy ethylcellulose, hydroxybutyl methylcellulose, hydroxymethylcellulose, hydroxypropyl methylcellulose, hydroxyethyl methylcellulose, hydroxybutylcellulose, hydroxyethylcellulose, hydroxypropylcellulose, sodium carboxy methylcellulose, and mixtures thereof. Methylcellulose and/or methylcellulose derivatives are especially suited as organic binders in the practice of the present invention with methylcellulose, hydroxypropyl methylcellulose, or combinations of these being preferred. Preferred sources of cellulose ethers are Methocel A4M, F4M, F240, and K75M cellulose products from Dow Chemical Co. Methocel A4M cellulose is a methylcellulose. Methocel F4M, F240, and K75M cellulose products are hydroxypropyl methylcellulose.

The properties of preferred cellulose ether binders such as methylcellulose are water retention, water solubility, surface activity or wetting ability, thickening of the mixture, providing wet and dry green

-12-

strength to the green bodies, thermal gelation and hydrophobic association in an aqueous environment. Cellulose ether binders that promote hydrophobic association with the non-solvent and hydrogen bonding interaction with the solvent are desirable. Examples of substituent groups that provide hydrophobic association with the non-solvent are methoxy, propoxy, and butoxy groups. These substituents which provide the hydrophobic association also contribute to the gel strength of the binder. The substituent groups that maximize the hydrogen bonding interaction with polar solvents e.g. water, are hydroxypropyl and hydroxyethyl groups, and to a smaller extent hydroxybutyl groups. This combination of properties enables binders to be at the interface between the solvent and non-solvent.

Cellulose ethers that provide especially good hydrophobic-hydrophilic balance are hydroxypropyl methylcellulose, hydroxyethylcellulose, hydroxyethyl methylcellulose, a combination of hydroxyethyl or hydroxypropyl with methyl, ethyl, propyl, and butyl cellulose.

The distribution (random vs. blocking) of the substituent groups along the polymer chain also plays a critical role in determining the gel strength of the binder. Blocky substitution contributes to higher gel strength relative to random substitution.

Gel strength increases also with an increase in concentration of the binder in the solvent. The increase in concentration of the binder in the solvent lowers the thermal gelation temperature.

The organic binder makes up typically about 2-12% by weight, and more typically about 2-4% by weight of the powder materials.

-13-

The Solvent

5 The solvent provides a medium for the binder to dissolve in thus providing plasticity to the batch and wetting of the powders. The solvent can be aqueous based, which are normally water or water-miscible solvents; or organically based. Most useful are aqueous based solvents which provide hydration of the binder and powder particles.

10 The non-solvent

15 The non-solvent is not a solvent for at least the binder, the solvent, and the powder materials. The non-solvent is lower in viscosity than the binder-solvent combination. Partial solubility of cellulose ether binders in the non-solvent would result in increase of viscosity of the non-solvent, and loss of lubricating properties needed to shape a stiff batch. This would result in an increase in shaping pressures and torques. The function of the non-solvent is to provide the fluidity necessary for shaping, while maintaining the strength of the binder in the solvent. The non-solvent can have dissolved surfactants, secondary binders, lubricants, and additives that enhance the rheological performance. The amount of dissolved substances should be so as to not adversely impact the rheology of the mixture.

25 In case of an aqueous binder system, the non-solvent is hydrophobic relative to binder in the solvent e.g. water. One preferred binder-solvent combination is cellulose ether in water. In this combination, the non-solvent hydrophobically associates through the methoxy substituent of the binder. This combination is especially advantageous for cordierite and/or mullite-forming raw material powders.

30 With aqueous-based binder solvents, such as water, non solvents can be chosen from both synthetic and natural substances.

-14-

5 Examples of such non-solvents are hydrocarbons, silicones, fluorine compounds, phosphate esters, esters, liquid CO₂, supercritical fluids e.g. supercritical CO₂, and hot water at a temperature above the thermal gelation temperature for a given cellulose ether, and combinations of these. When hot water is used as a non-solvent, it is in combination with at least one other non-solvent component.

10 Examples of useful hydrocarbons are alkanes, alkenes, alkynes, cycloaliphatics, synthetic lubricant base stocks (industrial, automotive, agricultural), polyolefins, and aromatics. Examples of these types of materials are paraffinic oils, e.g. mineral oil, hydrogenated polybutenes, alpha olefins, internal olefins, polyphenyl
15 ethers, polybutenes, and polyisobutylene.

20 Examples of esters are synthetic mono and diesters, and natural fatty acid esters (glycerides). Examples of mono and diesters are adipates, phthalates, polyol esters such as trimethylolpropane, and pentaerythritol. Examples of fatty acid esters are natural plant and animal
25 glycerides such as soybean oil, sunflower, palm, corn, coconut, cottonseed, castor oil, peanut oil, essential oils (rose, jasmine, orange, lime, etc.) soya fatty acid, tallow, bacon grease, lard, and fish oil.

30 Non-solvents can also be solids as long as they are processed at or above the melt point of the solid. For example, fatty acids and fatty alcohols of carbon chain length greater than 22 can be used alone or in combination with other non-solvent components.

35 Some especially useful non-solvents are hydrocarbons, fatty acids having greater than 22 carbon atoms in their chains, fatty alcohols having greater than 22 carbon atoms in their chains, natural esters having 14 or more carbon atoms in their chains, synthetic esters, and combinations of these.

-15-

More advantageous non-solvents are mineral oil, fatty acid glycerides, monoesters, diesters, and combinations of these.

5 Most preferred are light mineral oil, corn oil, high molecular weight polybutenes, polyol esters, a blend of light mineral oil and wax emulsion, a blend of paraffin wax in corn oil, and combinations of these.

10 The solvent for the binder can also be made to function as a partial non-solvent and a partial solvent for the binder through use of additives in the batch. For example, in the case of aqueous based solvents such as water and a cellulose ether binder, additives that have greater affinity for water than for the cellulose ether binder, dehydrate the cellulose ether. The additives can
15 be used to shift the solvent-non-solvent character of the water. The extent of dehydration is dependent on the additive concentration. The solvent/non-solvent balance of water can be adjusted with the type and concentration of additives such as glycerin, corn syrup, maple syrup,
20 sucrose, sorbitol, and electrolytes such as the salts of alkali and alkaline earth metals.

The Surfactant

25 The surfactant plays an important role in determining the interfacial properties between the inorganic powders, between the inorganics and organics, and between the components of the organic system. The surfactant has the greatest influence in determining the gel strength of the binder, adhesion of the binder gel to the inorganics, and
30 adhesion of the non-solvent to the binder. It promotes emulsification between the solvent and non-solvent. The preferred surfactants co-exist with the binder at the interface between the solvent and non-solvent. In the formed mixture, the surfactant is at least partially
35 miscible in both the solvent and the non-solvent. It disperses/wets the inorganic powders.

-16-

Typically, the surfactant is suitable if, by itself without other substances, it is insoluble in the solvent at room temperature.

5 Some surfactants that can be used in the practice of the present invention are C₈ to C₂₂ fatty acids and/or their derivatives. Additional surfactant components that can be used with these fatty acids are C₈ to C₂₂ fatty esters, C₈ to C₂₂ fatty alcohols, and combinations of these. Preferred surfactants are stearic, lauric, oleic,
10 linoleic, palmitoleic acids, and their derivatives, stearic acid in combination with ammonium lauryl sulfate, and combinations of all of these. Most preferred surfactants are lauric acid, stearic acid, oleic acid, and combinations of these. An especially preferred non-solvent
15 for use with this latter group of surfactants is light mineral oil.

The main interactions contributing to stiffness are the interactions of the binder with the (1) solvent, (2) surfactant, (3) surfactant-solvent, (4) inorganics-solvent, and (5) inorganics-surfactant-solvent.
20

Binder-Solvent

Stiffening from the binder-solvent interaction is observed when the concentration of the binder in the
25 solvent is increased. The binder concentration can be increased by partial removal of the solvent or by further increasing the amount of binder. In this invention, increasing the binder concentration is done typically by partial removal of the solvent. When the solvent is
30 partially removed, the binder is deprived of the solvent necessary for complete plasticization. This results in a very strong binder gel which is very stiff and not overly plastic. Binding of the inorganic particles with the strong binder gel results in a very stiff batch.

- 17 -

Binder-Surfactant and Binder-Surfactant-Solvent

The type and amount of surfactant is important in determining the amount of solvent required to plasticize the binder. If the surfactant makes the binder too soluble in the solvent, it results in a weak gel. A weak gel can also be formed when the surfactant hinders the binder (chemically, mechanically, or thermally) from solubilizing in the solvent. This leads to an unplasticized batch.

Binder-Inorganics-Solvent and
Binder-Inorganics-Surfactant-Solvent

The type and concentration of inorganics also has an impact on the total liquid demand, which in turn affects the amount of solvent available to the binder. Also, the type of surfactant plays a significant role in dispersing the particles and affects the total solvent demand for the batch.

Some useful mixture compositions are in percent by weight based on the powder materials, about 2% to 50% non-solvent, about 0.2% to 10% surfactant, about 2% to 10% cellulose ether binder, and about 6% to 50% water. More advantageous mixture compositions are in percent by weight based on the powder materials, about 5% to 10% non-solvent, about 0.2% to 2% surfactant, about 2.5% to 5% cellulose ether binder, and about 8% to 25% water. It is to be understood that for powder materials of very high surface area, e.g. $>20 \text{ m}^2/\text{g}$, more water is required. However, according to this invention, the amount of water needed is less than the amount that would be needed otherwise.

Batch-Forming Mechanics

For best results, the sequence of addition of the various batch components is important. It is preferred

-18-

that batch formation take place in two stages prior to the shaping step.

5 In the first stage or wetting stage of batch formation, the powder particles, surfactant, and binder are dry mixed followed by addition of the solvent such as in a Littleford mixer. The solvent is added in an amount that is less than is needed to plasticize the batch. With water as the solvent, the water hydrates the binder and the powder particles. The non-solvent is then added to the
10 mix to wet out the binder and powder particles. The non-solvent typically has lower surface tension than water. As a result, it wets out the particles much more readily than the solvent. At this stage, the powder particles are coated and dispersed by the surfactant, solvent, and non-
15 solvent.

It is preferred that plasticization take place in the second stage. In this stage the wet mix from the first stage is sheared in any suitable mixer in which the batch will be plasticized, such as for example in a twin-screw
20 extruder/mixer, auger mixer, muller mixer, or double arm, etc. During plasticization, the binder dissolves in the solvent and a gel is formed. The gel that is formed is stiff because the system is very solvent-deficient. The surfactant enables the binder-gel to adhere to the powder
25 particles. The non-solvent partially migrates to the exterior of the particle agglomerates (inter-particle region) and to the interface between the batch and the walls of the vessel containing it, e.g. mixer, or extruder, or die wall. This results in a batch that is
30 stiff in its interior and lubricated on its exterior.

Thus the batch is a system of particles separated by the solvent/surfactant/non-solvent bound/glued with the binder gel which is further coated with a film of the non-solvent and surfactant. Without wishing to be bound by
35 theory, it is thought that the most important part of the system is for the binder/surfactant to co-exist at the

-19-

interface between the solvent and the non-solvent lubricating fluid. The binder and the surfactant at the interface hydrogen-bond with the solvent and hydrophobically associate with the non-solvent. If the
5 surfactant displaces the binder from the interface, it results in a soft batch or an unplasticized batch.

The resulting stiff batch is then shaped into a green body by any known method for shaping plasticized mixtures, such as e.g. extrusion, injection molding, slip casting, centrifugal casting, pressure casting, dry pressing, etc.
10 The invention is best suited for extrusion through a die.

The extrusion operation can be done using a hydraulic ram extrusion press, or a two stage de-airing single auger extruder, or a twin screw mixer with a die assembly
15 attached to the discharge end. In the latter, the proper screw elements are chosen according to material and other process conditions in order to build up sufficient pressure to force the batch material through the die. The extrusion can be vertical or horizontal.

20 The total extrusion pressure through the die is composed of the pressure to enter the die and the pressure drop through the die. The higher entrance pressure due to the stiff batch is offset by a much larger pressure drop through the die. As a result, the total extrusion pressure
25 through the die is no greater than it would be in historic batches.

As the stiff batch is passed through the extruder and the die, the film of lubricating fluid in the inter-particle region and at the interface between the batch and the extruder/die wall provides the lubrication necessary
30 to maintain a lower total extrusion pressure for a stiff batch. If the mixing process is not high shear in the second or plasticization stage, the plasticization will occur during extrusion through the die because of high
35 shear through the die, e.g. in forming a honeycomb, through the slots and holes.

-20-

5 The lubrication provided by the non-solvent enables
the stiff batch to slip at the wall of the die/extruder.
As the stiff batch is extruded, at points of high shear
through the die, the non-solvent is partially squeezed out
10 of the batch to the interface between the batch and the
wall of the die/extruder. The driving force for the
preferential migration of the non-solvent versus solvent
to the interface is due to (1) the viscosity of the non-
solvent being significantly lower than the viscosity of
15 the binder-solvent gel or mixture, (2) the non-solvent
being incompatible with the solvent, i.e. hydrophobic
relative to it in the case of aqueous based solvents, and
(3) the solvent being held by the binder and inorganics by
hydration as opposed to the non-solvent which is free to
migrate.

20 An unexpected benefit of this invention is that shaping
e.g. extrusion can be done at significantly lower
temperatures, i.e. at least about 25% lower, than was
previously possible. Among other advantages of lower
temperature processing, the lower temperatures in the case
of the present invention enable extrusion at higher feed
rates (at least 2 times, and generally about 2-2.5 times
higher) than with historic batches. The temperature
reduction observed is due to lower mixing torques. The
25 lower mixing torques are due to lower inter-particle
friction and lower friction of the batch with the
extruder/die wall. Lower temperatures enable the cellulose
ether binders to be processed well below thermal gelation
temperature (at least 25% lower). An unexpected advantage
30 of this invention is that it provides a method in which
cellulose ether binders (in water as the solvent) can be
processed with higher gel strength at higher throughputs.
This is in direct contrast to the historical batches where
the higher throughput capability was achieved through the
35 use of cellulose ethers with low gel strength, which
translates to drying blisters during dielectric drying. In

-21-

addition, the heating rate of the batch, with an increase in throughput, is significantly lower than in historic batches.

5 The extrudability benefits of this invention are (1) cell orthogonality at the perimeter of the shaped body, and (2) smooth skin.

10 The stiff batches of this invention exhibit good shape retention at the die. In the case of multicellular structures, the cell orthogonality at the perimeter of the part closer to the skin is greatly improved.

15 A component of extrudability that is affected by the stiff batches is skin deterioration. Very stiff batches at lower extrusion velocities (<1.52 cm/sec or $< 0.6''$ /sec) tend to diverge and split apart as the batch exits the die. Skin deterioration can be overcome by increasing the shear rate for both the twin screw and RAM extrusion. Shear rate can be increased in the twin screw by increasing the extrusion velocity (feed rate and/or screw rpm). In the RAM, extrusion velocity can be increased by increasing the piston speed.

20 The higher shear rate/extrusion velocity is the driving force for the non-solvent to partially migrate to the batch-wall interface providing smooth skin. Very stiff batches from this invention show superior smooth skin flow at higher extrusion velocities, that is >1.52 cm/sec ($>.6''$ /sec).

25 The present invention is especially advantageous for RAM and twin screw extrusion of honeycombs at velocities of typically about 2.54-12.7 cm/sec (1-5''/sec).

30 The bodies of this invention can have any convenient size and shape and the invention is applicable to all processes in which plastic powder mixtures are shaped. The process is especially suited to production of cellular monolith bodies such as honeycombs. Cellular bodies find use in a number of applications such as catalytic, adsorption, electrically heated catalysts, filters such as

35

-22-

diesel particulate filters, molten metal filters, regenerator cores, etc.

Generally honeycomb densities range from about 235 cells/cm² (1500 cells/in²) to about 15 cells/cm² (100 cells/in²). Examples of honeycombs produced by the process of the present invention, although it is to be understood that the invention is not limited to such, are those having about 94 cells/cm² (about 600 cells/in²), or about 62 cells/cm² (about 400 cells/in²) each having wall thicknesses of about 0.1 mm (4 mils). Typical wall thicknesses are from about 0.07 to about 0.6 mm (about 3 to about 25 mils), although thicknesses of about .02-.048 mm (1-2 mils) are possible with better equipment. The method is especially suited for extruding thin wall/high cell density honeycombs.

The intrinsic material stiffness or wet green strength of this invention is typically about 2-2.5 times greater than with historic mixtures.

Stiffening is important for honeycombs having a large frontal area. For example, honeycombs of typically about 12.7-22.9 cm (5-9") diameter and lower cell density and very thin walls, e.g. .07-.12 mm (3-5 mils) are more vulnerable to deformation as they leave the extrusion die. In accordance with this invention, there is no cell distortion at the perimeter, and there is significant improvement in shape. Therefore the rapid stiffening effects of the present invention are especially advantageous for those types of structures.

In addition to the stiffness of the batches, another important advantage of this invention is that there is improved shape retention of the green body. Shape retention is especially advantageous in forming complex structures. Shape of thin-wall cellular substrates e.g. 3-6 mil or less, is maintained typically at 2-2.5 times the

-23-

feed rates for twin screw extrusion and higher extrusion velocities for ram extrusion.

5 The bodies made by the present invention, when fired, exhibit higher strength values than bodies made from historic batches, that is without the combination of non-solvent, surfactant, and binder in the composition of the present invention. This is particularly evident in the ratio of ISO strength (isostatic strength) to A-axis strength measurements of honeycombs. The isostatic strength measurements in the practice of this invention are 3-D isostatic strength and the tests were carried out hydraulically. The A-axis is that axis along the axial direction. The A-axis strength is a crush strength measurement. Generally, this ratio is at least about 20% and more typically about 20% to 50% higher than those made from historic batches. Typically the ratio of ISO strength (isostatic strength) to A-axis strength is at least about 0.33.

20 Another advantage of the invention is that it decreases the wear on the extrusion die, and screw elements, thus extending their life.

25 The green body can then be dried and fired according to known techniques except that drying times will be shorter due to less water in the green body. Also, less drying energy is required than for historic batches. This is especially advantageous in dielectric drying operations.

30 The firing conditions of temperature and time depend on the composition and size and geometry of the body, and the invention is not limited to specific firing temperatures and times. For example, in compositions which are primarily for forming cordierite, the temperatures are typically from about 1300°C to about 1450°C, and the holding times at these temperatures are from about 1 hour to about 6 hours. For mixtures that are primarily for forming mullite, the temperatures are from about 1400°C to

-24-

about 1600°C, and the holding times at these temperatures are from about 1 hour to about 6 hours. For cordierite-mullite forming mixtures which yield the previously described cordierite-mullite compositions, the
5 temperatures are from about 1375°C to about 1425°C. Firing times depend on factors such as kinds and amounts of materials and nature of equipment but typical total firing times are from about 20 hours to about 80 hours. For metal
10 bodies, the temperatures are about 1000°C to 1400°C in a reducing atmosphere preferably hydrogen. Firing times depend on factors as discussed above but are typically at least 2 hours and typically about 4 hours. For zeolite
bodies, the temperatures are about 400°C to 1000°C in air. Firing times depend on factors as discussed above but are
15 typically about 4 hours.

To more fully illustrate the invention, the following non-limiting examples are presented. All parts, portions, and percentages are on a weight basis unless otherwise
20 stated.

Example 1 Various non-solvents, surfactants, and binders.

Various homogeneous mixture compositions were made of the components listed in Tables 1, 2, and 3, and extruded into ribbons and rods. The parameters used for comparing
25 the examples of this invention to historical batches are mixing torques of a Brabender mixer, extrusion pressures of a rod and ribbon, and ribbon stiffness (Load/Deformation (L/D)). Brabender mixing torques are expressed as "Peak" and "End" torques. Peak torques are a
30 measure of the ease of wetting of the powders or the initial torque during mixing, and the end torques are representative of the torques at steady state, and are usually correlated to the torques observed in a twin screw extrusion or single screw extrusion process.

35 The intrinsic material stiffness or wet green strength used in this invention is referred to as the Load versus

-25-

Deformation (L/D). Stiffness (L/D) was measured by first extruding ribbons about 3.1 mm (1/8") thick using a capillary rheometer. The ribbon stiffness was then measured by applying a load to a piston at a given velocity and measuring the deformation of the ribbon. The ratio of the load to deformation is a measure of intrinsic material stiffness. The higher the L/D, the stiffer the batch.

A second measure of stiffness used for measuring the wet strength of honeycombs is referred to as the ball drop stiffness. The ball drop test was carried out using a Fischer Scientific Penetrometer which was adapted for this test. A ball of a given weight which is fastened to the bottom of the plunger rod is released and allowed to drop onto the test sample. The indentation made by the ball on the sample is measured. The degree of indentation is an indication of the stiffness or lack thereof of the sample. Lower ball drop numbers at a given load correspond to stiffer batches, with numbers less than about 80 being considered a stiff batch.

The results are summarized in Tables 1, 2, and 3 for each composition.

Table 1 shows examples of non-solvents used in this invention. The historic or non-inventive batch is referred to as the "Control." The results show that the mixing torques, both peak and end torques, are lower than the control within experimental error. In other words, the processing torques and pressures are equal to or lower than the control, even though stiffness of the ribbon (L/D) is higher than the control (by at least about 25%).

The surfactant examples of this invention are compared to the historical or non-inventive example (sodium tallowate) referred to as the "Control" (Table 2). Even though sodium tallowate can also be used as a surfactant in this invention to provide the stiffness, the extrusion quality of the ribbons was inferior (characterized by

-26-

presence of serrations in the ribbons), compared to the other surfactant examples. Examples of saturated fatty acids with chain length of C₈ to C₁₈ are shown in addition to unsaturated fatty acids, e.g. oleic acid. The fatty acids, unlike the sodium tallowate, showed good extrusion quality (characterized by no serrations in the ribbons) and stiffness. In all the surfactant examples, the extrusion pressures are equal to or lower than the control, while higher stiffness is maintained. Although the torque increases with an increase in carbon chain length in the total surfactant content as shown in examples 7, 3, 2, and 4, the overall benefit of higher stiffness at equal or lower extrusion pressure is maintained.

Table 3 shows examples of other water-soluble binders that can be used in combination with cellulose ether binders. The results again show that in all cases, the stiffness is higher than the control at lower or equal extrusion pressures and torques.

Figure 1 shows stiffness and deformation data that is representative of inventive as well as non-inventive examples for extruded wet honeycombs, e.g. 62 cells/cm² with 0.1 mm thick wall (400 cells/in² and 4 mil wall), measured at the very instant the batch exited the die. Comparison of ball drop data shows that the deformation of the inventive examples (wet) is significantly lower than that of the non-inventive examples at equal or lower pressures and torques. Furthermore, the cell collapse at the perimeter of the honeycomb showed significant improvement over the non-inventive example.

Example 2 Strength measurements on the fired body in comparison with prior art fired bodies

5 Compositions were extruded into honeycombs as shown in
Table 4. Each of the prior art (comparative) and inventive
compositions contained substantially the same quantities
of calcined kaolin clay, talc, delaminated kaolin clay,
alumina, and silica, and each contained methylcellulose as
the binder. However, while the liquid vehicle in the
10 comparative batch consisted essentially of water as a
solvent for the methylcellulose, the liquid vehicle in the
inventive batch consisted of a combination of water and a
hydrocarbon oil non-solvent. The amount of non-solvent was
about 6% based on the inorganic powders. The inventive
15 batch contained an organic acid surfactant at a level of
about 0.5% based on the inorganic powders. The comparative
batch contained sodium stearate (or tallowate) at a level
of about 0.75% based on the inorganic powders.

- 31 -

**Table 4: Average Strength and Other Property Comparisons
for inventive and comparative fired bodies**

	Comparative	Inventive
Product Cell Density*	350 cpsi	350 cpsi
Product Web Thickness	.12 mm (5.8 mil)	.11 mm (5.4 mil)
Water Absorption	9.02%	10.4%
Total Intrusion – Hg Porosity	0.126 cc/g	0.142 cc/g
CTE	4.18 cm/cm/°C	3.15 cm/cm/°C
A-Axis Strength**	4370 psi	2900 psi
B-Axis Strength**	669 psi	628 psi
C-Axis Strength**	47 psi	32 psi
Isostatic Strength (to Destruction)	1224 psi	1226 psi
Ratio: ISO/A-Axis	.2801	.4228

5 * Square cell honeycomb

10 ** A-Axis strength - measured by applying a downward
force to a slice of the honeycomb (crush strength)
B-Axis strength - measured by applying a force applied
parallel to the cell walls (crush strength)
C-Axis strength - measured by applying a force in a
direction along the diagonal of a cell (crush
strength)

15 Despite the disadvantages of higher porosity, lower
CTE (which is likely the result of increased microcracking
and, in turn, reduced material strength), and lower web or
wall thickness - all of which lowered A-axis (and other)
crush strengths, ISO strength was maintained at the same
level.

20 It should be understood that while the present invention
has been described in detail with respect to certain
illustrative and specific embodiments thereof, it should
not be considered limited to such but may be used in other
ways without departing from the spirit of the invention
25 and the scope of the appended claims.

-32-

What is claimed is:

1. A method for forming and shaping plasticized powder mixtures, the method comprising:

5 a) compounding components comprising

i) powder materials,

ii) binder,

iii) solvent for the binder,

iv) surfactant, and

10 v) non-solvent with respect to at least the binder, the solvent, and the powder materials, wherein the non-solvent is lower in viscosity than the binder combined with the solvent,

15 the components being chosen to result improved wet green strength in the subsequently formed green body;

b) mixing and plasticizing said components to form a plasticized mixture; and

c) shaping the plasticized mixture to form a green body.

20

2. A method of claim 1 wherein step b is carried out by the steps of:

i) dry-mixing the powder materials, surfactant and binder to form a uniform blend thereof;

25 ii) adding the solvent to the resulting dry blend; and thereafter

iii) adding the non-solvent to the blend resulting from step ii.

30

3. A method of claim 1 wherein the solvent for the binder is aqueous-based and the non-solvent is hydrophobic with respect to the solvent.

4. A method of claim 3 wherein the solvent is water.

35

-33-

5. A method of claim 3 wherein the binder comprises a cellulose ether.

5 6. A method of claim 5 wherein the cellulose ether is selected from the group consisting of methylellulose, methylcellulose derivatives, and combinations thereof.

7. A method of claim 3 wherein the binder comprises a cellulose ether, and the solvent is water.

10

8. A method of claim 7 wherein the binder comprises additional components selected from the group consisting of starch, poly(vinyl alcohol), poly(acrylic acid), and combinations thereof.

15

9. A method of claim 3 wherein the non-solvent comprises components selected from the group consisting of hydrocarbons, fatty acids with chain length of greater than C₂₂, fatty alcohols with chain length of greater than C₂₂, natural esters with chain length of C₁₄ or greater, synthetic esters, and combinations thereof.

20

10. A method of claim 9 wherein the non-solvent comprises components selected from the group consisting of mineral oil, fatty acid glycerides, monoesters, diesters, and combinations thereof.

25

11. A method of claim 9 wherein the non-solvent comprises components selected from the group consisting of light mineral oil, corn oil, high molecular weight polybutenes, polyol esters, wax emulsion-light mineral oil blend, paraffin wax in corn oil, and combinations thereof.

30

12. A method of claim 7 wherein the non-solvent comprises water, the water having dissolved additives selected from

35

-34-

the group consisting of sugar, glycerin, and combinations thereof.

5 13. A method of claim 3 wherein the surfactant comprises components selected from the group consisting of fatty acids of C₈ to C₂₂ chain length, derivatives of fatty acids of C₈ to C₂₂ chain length, and combinations thereof.

10 14. A method of claim 13 wherein the surfactant is selected from the group consisting of stearic acid, stearic acid and ammonium lauryl sulfate, lauric acid, oleic acid, and combinations thereof.

15 15. A method of claim 13 wherein the surfactant comprises additional components selected from the group consisting of fatty esters of C₈ to C₂₂ chain length, fatty alcohols of C₈ to C₂₂ chain length, and combinations thereof.

20 16. A method of claim 3 wherein the non-solvent is light mineral oil and the surfactant is selected from the group consisting of lauric acid, stearic acid, oleic acid, and combinations thereof.

25 17. A method of claim 7 wherein the mixture comprises in percent by weight based on the powder materials, about 2% to 50% non-solvent, about 0.2% to 10% surfactant, about 2% to 10% binder, and about 6% to 50% water.

30 18. A method of claim 17 wherein the mixture comprises in percent by weight based on the powder materials, about 5% to 10% non-solvent, about 0.2% to 2% surfactant, about 2.5% to 5% binder, and about 8% to 25% water.

35 19. A method of claim 7 wherein the powder materials are cordierite-forming raw materials.

- 35 -

20. A method of claim 1 wherein the shaping is done by passing the mixture through an extruder and then through a die to form a green extrudate.

5 21. A method of claim 20 wherein the mixture is plasticized within and extruded from a twin screw extruder.

10 22. A method of claim 21 wherein the temperature of the mixture being extruded is at least about 25% lower than it would be otherwise, whereby the rate of extrusion is at least twice as great as it would be otherwise.

15 23. A method of claim 22 wherein when the binder is a cellulose ether and the solvent is water, for a given powder material, the pressure of the mixture entering the die is higher than it would be and the wall shear stress through the die is lower than it would be absent the binder, solvent, non-solvent, and surfactant of claim 1, step a, whereby the total extrusion pressure is no greater than it would be absent the binder, solvent, non-solvent, and surfactant of claim 1, step a.

20 24. A method of claim 21 wherein the extrusion is done at an increased shear rate, whereby the skin of the green extrudate is free of deterioration for the duration of the extrusion process.

25 25. A method of claim 20 wherein the mixture is extruded into a honeycomb structure.

30 26. A method of claim 20 wherein the stiffness of extrudate is at least about 25% greater than would be otherwise at equal or lower extrusion torques and pressures.

35

-36-

27. A plasticized mixture comprising the components of

- i) powder materials,
- ii) binder,
- iii) solvent for the binder,
- iv) surfactant, and

5

v) non-solvent with respect to at least the binder, the solvent, and the powder materials, wherein the non-solvent is lower in viscosity than the binder combined with the solvent,

10

the components being chosen to result improved wet green strength in a green body subsequently formed therefrom.

28. A plasticized mixture comprising

15

- i) powder materials,
- ii) cellulose ether binder,
- iii) water as solvent for the binder,
- iv) surfactant, and

20

v) non-solvent with respect to at least the binder, the solvent, and the powder materials, wherein the non-solvent is lower in viscosity than the binder combined with the solvent,

25

the components being chosen to result improved wet green strength in a green body subsequently formed therefrom.

29. A method for forming and shaping plasticized powder mixtures, the method comprising:

a) compounding components comprising

30

- i) powder materials,
- ii) cellulose ether binder,
- iii) water solvent for the binder,
- iv) surfactant, and

35

v) non-solvent with respect to at least the binder, the solvent, and the powder materials, wherein

-37-

the non-solvent is lower in viscosity than the binder combined with the solvent,

the components being chosen to result improved wet green strength in the subsequently formed green body;

5 b) mixing and plasticizing said components to form a plasticized mixture; and

c) shaping the plasticized mixture to form a green body.

10 30. A method for making a honeycomb structure, the method comprising:

a) compounding components comprising

i) powder materials,

ii) cellulose ether binder,

15 iii) water solvent for the binder,

iv) surfactant, and

v) non-solvent with respect to at least the binder and the solvent, wherein the non-solvent is lower in viscosity than the binder combined with the solvent,

20 the components being chosen to result improved wet green strength in the subsequently formed green body;

b) mixing and plasticizing said components to form a plasticized mixture; and

25 c) extruding the plasticized mixture through a honeycomb extrusion die.

31. A body made by the method of claim 1 in the shape of a honeycomb having an A, B, and C axis, wherein, upon firing, the ratio of the isostatic strength to the A-axis strength is at least about 20% higher than that in bodies, upon firing, made without the mixture composition of claim 1.

32. A honeycomb body having a ratio of the isostatic strength to the A-axis strength of at least about 0.33 upon being fired.
