METHODS FOR DIAGNOSING IRRITABLE BOWEL SYNDROME

The invention provides novel biomarkers, kits, and methods of diagnosing, prognosing, and subtyping IBS. Also provided are methods for aiding in the diagnosis of irritable bowel syndrome by detecting the serum level of novel IBS biomarkers identified herein.
METHODS FOR DIAGNOSING IRRITABLE BOWEL SYNDROME

CROSS-REFERENCES TO RELATED APPLICATIONS

BACKGROUND OF THE INVENTION

[0002] Irritable bowel syndrome (IBS) is the most common of all gastrointestinal disorders, affecting 10-20% of the general population and accounting for more than 50% of all patients with digestive complaints. However, studies suggest that only about 10% to 50% of those afflicted with IBS actually seek medical attention. Patients with IBS present with disparate symptoms such as, for example, abdominal pain predominantly related to defecation, diarrhea, constipation or alternating diarrhea and constipation, abdominal distention, gas, and excessive mucus in the stool. More than 40% of IBS patients have symptoms so severe that they have to take time off from work, curtail their social life, avoid sexual intercourse, cancel appointments, stop traveling, take medication, and even stay confined to their house for fear of embarrassment. The estimated health care cost of IBS in the United States is $8 billion per year (Talley et al, Gastroenterol, 109:1736-1741 (1995)).

[0003] IBS patients are classified into three groups according to their predominant bowel symptoms: constipation-predominant IBS (IBS-C), diarrhea-predominant IBS (IBS-D) and IBS with alternating symptoms of diarrhea and constipation (IBS-M). In current clinical practice, diagnosis of IBS is based on the Rome III criteria and according to the symptoms presented by the patients plus the exclusion of other GI disorders. There are no specific biological, radiographic, endoscopic or physiological biomarkers that can be used to identify this disorder.

[0004] Irritable bowel syndrome is a heterogeneous gastrointestinal (GI) function disorder. There is increasing evidence pointing to the involvement of the immune system in its
pathogenesis. GI infection may be a triggering factor for causing the onset of IBS symptoms. On the other hand, IBS is often described as a "brain-gut disorder". Alterations in GI motility and secretion mediated by dysregulation of the 5-HT signaling pathway may underlie the irregularities in bowel habits. Activation of mast cells in proximity to colonic nerves correlated with the abnormal pain experienced by patients with IBS. Mast cells are well known to be capable of producing and releasing a variety of inflammatory mediators upon activation. However, it is not clear how these different pathways communicate with each other and whether their interactions behave in the same manner in IBS patients as it is in healthy subjects.

[0005] The precise pathophysiology of IBS is not well understood. Nevertheless, there is a heightened sensitivity to visceral pain perception, known as peripheral sensitization. This sensitization involves a reduction in the threshold and an increase in the gain of the transduction processes of primary afferent neurons, attributable to a variety of mediators including monoamines (e.g., catecholamines and indoleamines), substance P, and a variety of cytokines and prostanoids such as E-type prostaglandins (see, e.g., Mayer et al, Gastroenterol, 107:271-293 (1994)). Also implicated in the etiopathology of IBS is intestinal motor dysfunction, which leads to abnormal handling of intraluminal contents and/or gas (see, e.g., Kellow et al., Gastroenterol., 92:1885-1893 (1987); Levitt et al., Ann. Int. Med., 124:422-424 (1996)). Psychological factors may also contribute to IBS symptoms appearing in conjunction with, if not triggered by, disturbances including depression and anxiety (see, e.g., Drossman et al., Gastroenterol. Int., 8:47-90 (1995)).

[0006] The causes of IBS are not well understood. The walls of the intestines are lined with layers of muscle that contract and relax as they move food from the stomach through the intestinal tract to the rectum. Normally, these muscles contract and relax in a coordinated rhythm. In IBS patients, these contractions are typically stronger and last longer than normal. As a result, food is forced through the intestines more quickly in some cases causing gas, bloating, and diarrhea. In other cases, the opposite occurs: food passage slows and stools become hard and dry causing constipation.

[0007] The precise pathophysiology of IBS remains to be elucidated. While gut dysmotility and altered visceral perception are considered important contributors to symptom pathogenesis (Quigley, Scand. J. Gastroenterol., 38(Suppl. 237):1-8 (2003); Mayer et al., Gastroenterol., 122:2032-2048 (2002)), this condition is now generally viewed as a disorder of the brain-gut axis. Recently, roles for enteric infection and intestinal inflammation have also been proposed. Studies have documented the onset of IBS following bacteriologically
confirmed gastroenteritis, while others have provided evidence of low-grade mucosal inflammation (Spiller et al., Gut, 47:804-811 (2000); Dunlop et al., Gastroenterol., 125:1651-1659 (2003); Cumberland et al., Epidemiol. Infect., 130:453-460 (2003)) and immune activation (Gwee et al., Gut, 52:523-526 (2003); Pimentel et al., Am. J. Gastroenterol., 95:3503-3506 (2000)) in IBS. The enteric flora has also been implicated, and a recent study demonstrated the efficacy of the probiotic organism Bifidobacterium in treating the disorder through modulation of immune activity (O'Mahony et al., Gastroenterol., 128:541-551 (2005)).

[0008] The hypothalamic-pituitary-adrenal axis (HPA) is the core endocrine stress system in humans (De Wied et al., Front. Neuroendocrinol., 14:251-302 (1993)) and provides an important link between the brain and the gut immune system. Activation of the axis takes place in response to both physical and psychological stressors (Dinan, Br. J. Psychiatry, 164:365-371 (1994)), both of which have been implicated in the pathophysiology of IBS (Cumberland et al., Epidemiol. Infect., 130:453-460 (2003)). Patients with IBS have been reported as having an increased rate of sexual and physical abuse in childhood together with higher rates of stressful life events in adulthood (Gaynes et al., Baillieres Clin. Gastroenterol., 13:437-452 (1999)). Such psychosocial trauma or poor cognitive coping strategy profoundly affects symptom severity, daily functioning, and health outcome.

[0009] Although the etiology of IBS is not fully characterized, the medical community has developed a consensus definition and criteria, known as the Rome II criteria, to aid in the diagnosis of IBS based upon patient history. The Rome II criteria requires three months of continuous or recurrent abdominal pain or discomfort over a one-year period that is relieved by defecation and/or associated with a change in stool frequency or consistency as well as two or more of the following: altered stool frequency, altered stool form, altered stool passage, passage of mucus, or bloating and abdominal distention. The absence of any structural or biochemical disorders that could be causing the symptoms is also a necessary condition. As a result, the Rome II criteria can be used only when there is a substantial patient history and is reliable only when there is no abnormal intestinal anatomy or metabolic process that would otherwise explain the symptoms. Similarly, the Rome III criteria recently developed by the medical community can be used only when there is presentation of a specific set of symptoms, a detailed patient history, and a physical examination.

[0010] It is well documented that diagnosing a patient as having IBS can be challenging due to the similarity in symptoms between IBS and other diseases or disorders. In fact, because the symptoms of IBS are similar or identical to the symptoms of so many other
intestinal illnesses, it can take years before a correct diagnosis is made. For example, patients who have inflammatory bowel disease (IBD), but who exhibit mild signs and symptoms such as bloating, diarrhea, constipation, and abdominal pain, may be difficult to distinguish from patients with IBS. As a result, the similarity in symptoms between IBS and IBD renders rapid and accurate diagnosis difficult. The difficulty in differentially diagnosing IBS and IBD hampers early and effective treatment of these diseases. Unfortunately, rapid and accurate diagnostic methods for definitively distinguishing IBS from other intestinal diseases or disorders presenting with similar symptoms are currently not available. The present invention satisfies this need and provides related advantages as well.

**BRIEF SUMMARY OF THE INVENTION**

[0011] The present invention provides methods, assays, systems, and code for accurately classifying whether a sample from an individual is associated with irritable bowel syndrome (IBS). As a non-limiting example, the present invention is useful for classifying a sample from an individual as an IBS sample using a statistical algorithm and/or empirical data. Similarly, the present invention also provides methods, assays, systems, and code for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject. The present invention is also useful for ruling out one or more diseases or disorders that present with IBS-like symptoms and ruling in IBS using a combination of statistical algorithms and/or empirical data. Thus, the present invention provides an accurate diagnostic prediction of IBS and prognostic information useful for guiding treatment decisions.

[0012] In one aspect, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, the method comprising: (a) contacting a blood or serum sample from the subject with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; and (b) determining the level of the complex, thereby determining the level of the IBS marker present in the sample.

[0013] In one aspect, the present invention provides a method for monitoring the progression or regression of irritable bowel syndrome (IBS) in a subject, the method comprising: (a) contacting a first blood or serum sample taken from the subject at a first time with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; (b) determining the level of the complex, thereby determining the level of the IBS marker present in the first sample; (c) contacting a second blood or serum sample taken from
the subject at a second time with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; (d) determining the level of the complex, thereby determining the level of the IBS marker present in the second sample; and (e) comparing the level of the IBS marker present in the first sample to the level of the IBS marker present in the second sample, wherein a higher level of the IBS marker in the second sample relative to the first sample is indicative of the progression of IBS in the subject and a lower level of the IBS marker in the second sample relative to the first sample is indicative of the regression of IBS in the subject.

[0014] In one aspect, the present invention provides a computer-readable medium comprising code for controlling one or more processors to classify whether a serum or blood sample from a subject is associated with irritable bowel syndrome (IBS), the code comprising instructions to apply a statistical process to a data set comprising a diagnostic marker profile to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile, wherein the diagnostic marker profile indicates the level of at least IBS diagnostic marker provided herein.

[0015] In another aspect, the present invention provides a system for classifying whether a serum or blood sample from a subject is associated with irritable bowel syndrome (IBS), the system comprising: (a) a data acquisition module configured to produce a data set comprising a diagnostic marker profile, wherein the diagnostic marker profile indicates the presence or level of at least one IBS diagnostic marker provided herein; (b) a data processing module configured to process the data set by applying a statistical process to the data set to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile; and (c) a display module configured to display the statistically derived decision.

[0016] In one aspect, the present invention provides a method for classifying whether a sample from an individual is associated with IBS, the method comprising: (a) determining a diagnostic marker profile by detecting the presence or level of at least one diagnostic marker in the sample; and (b) classifying the sample as an IBS sample or non-IBS sample using an algorithm based upon the diagnostic marker profile.

[0017] In certain embodiments of the diagnostic methods provided herein, the IBS marker is selected from the group consisting of a cytokine, growth factor, anti-neutrophil antibody, anti-Saccharomyces cerevisiae antibody (ASCA), antimicrobial antibody, mast cell marker, stress marker, gastrointestinal hormone, serotonin metabolite, serotonin pathway marker,
carbohydrate deficient transferrin (CDT), lactoferrin, anti-tissue transglutaminase (tTG) antibody, lipocalin, matrix metalloproteinase (MMP), tissue inhibitor of metalloproteinase (TIMP), alpha-globulin, actin-severing protein, S100 protein, fibrinopeptide, calcitonin gene-related peptide (CGRP), tachykinin, ghrelin, neurotensin, corticotropin-releasing hormone, serine protease, prostaglandin, histamine, and combinations thereof.

[0018] In preferred embodiments of the diagnostic methods provided herein, the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocrtin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A, and combinations thereof.

[0019] In preferred embodiments of the various methods and assays of the present invention, the presence or level of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, or more of the biomarkers shown in Table 1 is detected to generate a diagnostic marker profile that is useful for predicting IBS. In certain instances, the biomarkers described herein are analyzed using an immunoassay such as an enzyme-linked immunosorbent assay (ELISA) or an immunohistochemical assay.

Table 1. Exemplary diagnostic markers suitable for use in IBS classification.

**BRIEF DESCRIPTION OF THE DRAWINGS**

[0020] Figure 1 illustrates a dose response curve in one embodiment of the present invention.

[0021] Figure 2 illustrates a dose response curve in one embodiment of the present invention.

[0022] Figure 3 illustrates a standard curve in one embodiment of the present invention. Rabbit anti-human tryptase was coated onto an immunoassay plate and blocked with assay buffer (5%BSA in PBS). Different concentrations of human tryptase (Standard curve) or human serum samples (diluted in assay buffer 1:5 and 1:10) were added to the wells and incubated for 2 hours at RT. The plate was washed and alkaline phosphatase (AP) labeled McAb against tryptase (G3) were added and incubated for 2 hours at RT. The plate was washed and AP substrate (CSPD) was added to each well. A luminescence plate reader was used to detect the luminescent light. Serum tryptase concentration was calculated using the standard curve. (Tryptase detection range 0.019-5000 ng/ml. EC50 = 65 ng/ml; Recovery 81.5% with 20 ng/ml of tryptase spiked in normal pooled serum). See Example 1.

[0023] Figure 4 illustrates a bar graph with tryptase concentrations in serum of GI control, IBS-C and IBS-D.

[0024] Figure 5 illustrates a bar graph with tryptase log value distribution.
[0025] Figure 6 illustrates a density analysis for tryptase data.

[0026] Figure 7 illustrates a bar graph with tryptase concentrations in serum of GI control, IBS-C, IBS-D and IBS-A.

[0027] Figure 8 illustrates the dose response curve of human tryptase in one embodiment of the present invention.

[0028] Figure 9 illustrates the optimization of the tryptase ELISA. (A) Comparison of tryptase standard curve with different amount of capture antibody. (B) Optimization of detecting antibody dilutions. (C) Comparison of tryptase standard curves in the presence of different amounts of normal human serum (NHS).

[0029] Figure 10 illustrates tryptase levels in serum from healthy controls (n=139) and from subjects with IBS (n=378).

[0030] Figure 11 illustrates the increased serum level of histamine and PGE$_2$ in IBS patients versus healthy controls.

[0031] Figure 12 illustrates one embodiment of a molecular pathway derived from the IBS markers identified and disclosed herein.

[0032] Figure 13 illustrates a disease classification system (DCS) according to one embodiment of the present invention.

[0033] Figure 14 provides representative chromatographs demonstrating that the identified metabolites are present at different concentrations in the serums of individuals with IBS as compared to the serums of non-IBS individuals.

[0034] Figure 15 illustrates the increased serum level of the identified metabolites in IBS patients versus healthy controls.

[0035] Figure 16 illustrates the top variables identified in the IBS prediction.

[0036] Figure 17 provides representative chromatographs showing that tryptophan and 5-HT metabolite production is increased in response to TNFa treatment of whole blood.

[0037] Figure 18 illustrates (A) TPH1 and (B) MAO expression in whole blood treated with various inflammatory cytokines.

[0038] Figure 19 illustrates Urocortin (Ucn) levels (Y-axis) in whole blood treated with various inflammatory cytokines.
[0039] **Figure 20** illustrates the levels of the mast cell markers (A) histamine, (B) PGE2, and (C) tryptase in whole blood treated with various inflammatory cytokines.

[0040] **Figure 21** illustrates the interplay between leukocytes, enterochromaffin cells, mast cells and platelets in the gastrointestinal system mediated by some of the markers provided herein.

[0041] **Figure 22** provides representative chromatograms obtained from the HPLC analysis of serum samples from IBS patients and healthy control (HC) subjects.

[0042] **Figure 23** illustrates serum levels (AUC) of the 7.5 min peak, the 13.5 min peak and the 17.2 min peak determined by HPLC analysis of samples from IBS patients (IBS-C = 12, IBS-D = 24, IBS-M = 14) and healthy control subjects (HC = 38).

[0043] **Figure 24** provides structure elucidation of the 7.5 min peak by mass spectrometry. The molecular mass of the compound present in the 7.5 min peak was determined to be 181.9 m/z (panel A), which corresponds to the molecular mass of the amino acid tyrosine. That the identity of this peak is tyrosine was further verified by the results in panel B, which shows a prominent mass peak at m/z 164.9 corresponding to the loss of a OH group (17 m/z) from the molecular ion (181.9 m/z); by panel C, which shows a prominent mass peak at m/z 146.9 corresponding to the loss of H₂O (18 m/z) and NH₃ (17 m/z) from the molecular ion and panel D, which shows a prominent mass peak at m/z 119 corresponding to the loss of HCOOH (m/z 46) and a OH group (17 m/z) from the molecular ion.

[0044] **Figure 25** provides structure elucidation of the 13.5 min peak by mass spectrometry. The molecular mass of the compound present in the 13.5 min peak was determined to be 165.9 m/z (panel A), which corresponds to the molecular mass of the amino acid phenylalanine. That the identity of this peak is phenylalanine was further verified by the results in panel B, which shows a prominent mass peak at m/z 131.0 corresponding to the loss of H₂O (18 m/z) and NH₃ (17 m/z) from the molecular ion (165.9 m/z); and by panel C, which shows a prominent mass peak at m/z 120.0 corresponding to the loss of HCOOH (46 m/z) from the molecular ion.

[0045] **Figure 26** illustrates the dose-dependent response of spiked in D-tyrosine to serum samples determined by HPLC analysis.

[0046] **Figure 27** illustrates the dose-dependent response of spiked in L-phenylalanine to serum samples determined by HPLC analysis.
[0047] Figure 28 illustrates the serotonin pathway and its participation in the pathophysiology of IBS.

[0048] Figure 29 illustrates the transcript levels of 5-HT pathway metabolic enzymes produced by cytokine treatment of whole blood cells.

[0049] Figure 30 illustrates the normalized levels of mast cell activation markers produced by cytokine treatment of whole blood cells.

[0050] Figure 31 illustrates the levels of urocortin (Ucn) produced by cytokine treatment of whole blood cells.

10 DETAILED DESCRIPTION OF THE INVENTION

1. Introduction

[0051] Diagnosing a patient as having irritable bowel syndrome (IBS) can be challenging due to the similarity in symptoms between IBS and other diseases or disorders. For example, patients who have inflammatory bowel disease (IBD), but who exhibit mild signs and symptoms such as bloating, diarrhea, constipation, and abdominal pain can be difficult to distinguish from patients with IBS. As a result, the similarity in symptoms between IBS and IBD renders rapid and accurate diagnosis difficult and hampers early and effective treatment of the disease.

[0052] Although the pathology of irritable bowel syndrome (IBS) is not completely understood, many studies have led to the hypothesis that IBS is a disorder caused by the dysregulation of the brain-gut axis (for review, see, Öhman and Simren, Nat Rev Gastroenterol Hepatol. 2010 Mar;7(3): 163-73). One observation that supports this theory is the repeated finding that an increased number of mast cells can be found in the intestinal mucosa of patients diagnosed with IBS (Guilarte, M. et al, Gut 56, 203-209 (2007); Walker, M. M. et al, Pharmacol. Ther. 29, 765-773 (2009); Akbar, A. et al, Gut 57, 923-929 (2008); Barbara, G. et al, Gastroenterology 126, 693-702 (2004); Barbara, G. et al, Gastroenterology 132, 26-37 (2007); Cremon, C. et al, Am. J. Gastroenterol. 104, 392-400 (2009); and O'Sullivan, M. et al, Neurogastroenterol. Motil., 12, 449-457 (2000)). Similarly, some studies have also found that levels of mediators released from these cells, including histamine and serine proteases (e.g., tryptase), are found in the colonic mucosa of IBS patients (Buhner et al, Gastroenterology 2009 Oct; 137(4); Barbara et al., Gastroenterology, Volume: 122 , Number: 4 Suppl. 1, Page: A-276, April 2002). However, this finding remains controversial,
as other studies have reported that no such correlation exists (Guilarte et al, *Gut* 2007 Feb;56(2):203-9).

Regardless of the existence of increased levels of mast cell mediators in the colonic mucosa of IBS patients, such a correlation has a limited diagnostic value since colonic biopsies are invasive procedures. While researchers have looked for similar patterns in the blood/serum of IBS patients, fluids well suited for non-invasive diagnostics, no correlation has been reported to date (Lessof *et al.*, *Ann Allergy.* 1983 Aug;51(2 Pt 2):249-50; Guilarte, M. *et al.*, *Gut* 56, 203-209 (2007); Öhman and Simren, *Nat Rev Gastroenterol Hepatol.* 2010 Mar;7(3): 163-73).

Advantageously, the present invention provides, among other aspects, non-invasive methods and assays for the diagnosis and classification of irritable bowel syndrome (IBS). In certain embodiments, these methods and assays are related to the detection of the presence or concentration level of various IBS biomarkers in the blood and/or serum of subjects suspected of, or previously diagnosed as having IBS. In preferred embodiments, the methods comprise the detection of one or more IBS markers identified in Table 1, in blood and/or serum samples from a subject. Additional markers can also be used.

The present invention is based, in part, upon the surprising discovery that the accuracy of classifying a biological sample from an individual as an IBS sample can be substantially improved by detecting the presence or level of certain diagnostic markers *(e.g., β-tryptase, prostaglandin E₂, histamine, cytokines, growth factors, anti-neutrophil antibodies, *anti-Saccharomyces cerevisiae* antibodies, antimicrobial antibodies, mast cell markers, stress markers, gastrointestinal hormones, serotonin metabolites, serotonin pathway markers, carbohydrate deficient transferrin (CDT), lactoferrin, *etc.*), alone or in combination with identifying the presence or severity of IBS-related symptoms based upon the individual's response to one or more questions *(e.g., "Are you currently experiencing any symptoms?"). Figure 12 shows a non-limiting example of a molecular pathway derived from the IBS markers identified and disclosed herein. In some aspects, the present invention uses statistical algorithms to aid in the classification of a sample as an IBS sample or non-IBS sample. In other aspects, the present invention uses statistical algorithms for ruling out other intestinal disorders *(e.g., IBD)*, and then classifying the non-IBD sample to aid in the classification of IBS.
II. Definitions

[0056] As used herein, the following terms have the meanings ascribed to them unless specified otherwise.

[0057] The term "classifying" includes "to associate" or "to categorize" a sample with a disease state. In certain instances, "classifying" is based on statistical evidence, empirical evidence, or both. In certain embodiments, the methods and systems of classifying use a so-called training set of samples having known disease states. Once established, the training data set serves as a basis, model, or template against which the features of an unknown sample are compared, in order to classify the unknown disease state of the sample. In certain instances, classifying the sample is akin to diagnosing the disease state of the sample. In certain other instances, classifying the sample is akin to differentiating the disease state of the sample from another disease state.

[0058] The term "irritable bowel syndrome" or "IBS" includes a group of functional bowel disorders characterized by one or more symptoms including, but not limited to, abdominal pain, abdominal discomfort, change in bowel pattern, loose or more frequent bowel movements, diarrhea, and constipation, typically in the absence of any apparent structural abnormality. There are at least three forms of IBS, depending on which symptom predominates: (1) diarrhea-predominant (IBS-D); (2) constipation-predominant (IBS-C); and (3) IBS with alternating stool pattern (IBS-A). IBS can also occur in the form of a mixture of symptoms (IBS-M). There are also various clinical subtypes of IBS, such as post-infectious IBS (IBS-PI).

[0059] The term "transforming the sample" includes a physical and/or chemical change of the sample to extract a marker or to change or modify a marker as defined herein. An extraction, a manipulation, a chemical precipitation, an ELISA, a complexation, an immuno-extraction, a physical or chemical modification of the sample or marker to measure a level or concentration of a marker all constitute a transformation. As long as the sample or marker is not identical before and after the transformation step, the change or modification is a transformation.

[0060] The term "sample" includes any biological specimen obtained from an individual. Suitable samples for use in the present invention include, without limitation, whole blood, plasma, serum, saliva, urine, stool (i.e., feces), tears, and any other bodily fluid, or a tissue sample (i.e., biopsy) such as a small intestine or colon sample, and cellular extracts thereof (e.g., red blood cellular extract). In a preferred embodiment, the sample is a blood, plasma,
or serum sample. In a more preferred embodiment, the sample is a serum sample. The use of samples such as serum, saliva, and urine is well known in the art (see, e.g., Hashida et al, J. Clin. Lab. Anal, 11:267-86 (1997)). One skilled in the art will appreciate that samples such as serum samples can be diluted prior to the analysis of marker levels.

[0061] The term "biomarker" or "marker" includes any diagnostic marker such as a biochemical marker, serological marker, genetic marker, or other clinical or echographic characteristic that can be used to classify a sample from an individual as an IBS sample or to rule out one or more diseases or disorders associated with IBS-like symptoms in a sample from an individual. The term "biomarker" or "marker" also encompasses any classification marker such as a biochemical marker, serological marker, genetic marker, or other clinical or echographic characteristic that can be used to classify IBS into one of its various forms or clinical subtypes. Non-limiting examples of diagnostic markers suitable for use in the present invention are described below and include cytokines, growth factors, anti-neutrophil antibodies, anti-Saccharomyces cerevisiae antibodies, antimicrobial antibodies, mast cell markers, stress markers, gastrointestinal hormones, serotonin metabolites, serotonin pathway markers, carbohydrate deficient transferrin (CDT), anti-tissue transglutaminase (tTG) antibodies, lipocalins, matrix metalloproteinases (MMPs), tissue inhibitor of metalloproteinases (TIMPs), alpha-globulins, actin-severing proteins, S100 proteins, fibrinopeptides, calcitonin gene-related peptide (CGRP), tachykinins, ghrelin, neurotensin, corticotropin-releasing hormone (CRH), serine proteases (e.g., tryptase, elastase), prostaglandin (e.g., PGE_2_), histamine, C-reactive protein (CRP), lactoferrin, anti-lactoferrin antibodies, calprotectin, hemoglobin, NOD2/CARD15, serotonin reuptake transporter (SERT), tryptophan hydroxylase-1, 5-hydroxytryptamine (5-HT), lactulose, and the like. Examples of classification markers include, without limitation, leptin, SERT, tryptophan hydroxylase-1, 5-HT, antrum mucosal protein 8, keratin-8, claudin-8, zonulin, corticotropin releasing hormone receptor-1 (CRHR1), corticotropin releasing hormone receptor-2 (CRHR2), tryptase, histamine, prostaglandin E_2_ (PGE_2_) and the like. In some embodiments, diagnostic markers can be used to classify IBS into one of its various forms or clinical subtypes. In other embodiments, classification markers can be used to classify a sample as an IBS sample or to rule out one or more diseases or disorders associated with IBS-like symptoms. One skilled in the art will know of additional diagnostic and classification markers suitable for use in the present invention.

[0062] In certain instances, the presence or level of at least one diagnostic marker is determined using an assay such as a hybridization assay or an amplification-based assay.
Examples of hybridization assays and amplification-based assays suitable for use in the methods of the present invention are described above. In certain other instances, the presence or level of at least one diagnostic marker is determined using an immunoassay or an immunohistochemical assay. Non-limiting examples of immunoassays and immunohistochemical assays suitable for use in the methods of the present invention are described herein.

[0063] As used herein, the term "binding moiety" refers to any class of molecules capable of specifically recognizing a biomarker of interest. Non-limiting examples of binding moieties that are well suited for use in the methods provided herein include proteins, such as monoclonal or polyclonal antibodies and functional fragments thereof (e.g., minibodies, diabodies, triabodies, single chain Fv, F(ab)′, and the like), combinatorially derived proteins from phage display or ribosome display, peptides, nucleic acids, such as aptamers, and other molecules that are capable of specifically recognizing a biomarker of interest.

[0064] As used herein, the term "profile" includes any set of data that represents the distinctive features or characteristics associated with a disease or disorder such as IBS or IBD. The term encompasses a "diagnostic marker profile" that analyzes one or more diagnostic markers in a sample, a "symptom profile" that identifies one or more IBS-related clinical factors (i.e., symptoms) an individual is experiencing or has experienced, and combinations thereof. For example, a "diagnostic marker profile" can include a set of data that represents the presence or level of one or more diagnostic markers associated with IBS and/or IBD. Likewise, a "symptom profile" can include a set of data that represents the presence, severity, frequency, and/or duration of one or more symptoms associated with IBS and/or IBD.

[0065] In some embodiments, a panel for measuring one or more of the diagnostic markers and/or diagnostic profiles described above can be constructed and used for classifying the sample as an IBS sample or non-IBS sample. One skilled in the art will appreciate that the presence or level of a plurality of diagnostic markers can be determined simultaneously or sequentially, using, for example, an aliquot or dilution of the individual's sample. In certain instances, the level of a particular diagnostic marker in the individual's sample is considered to be elevated when it is at least about 10%, 15%, 20%, 25%, 50%, 75%, 100%, 125%, 150%, 175%, 200%, 250%, 300%, 350%, 400%, 450%, 500%, 600%, 700%, 800%, 900%, or 1000% greater than the level of the same marker in a comparative sample (e.g., a normal, GI control, IBD, and/or Celiac disease sample) or population of samples (e.g., greater than a median level of the same marker in a comparative population of normal, GI control, IBD,
and/or Celiac disease samples). In certain other instances, the level of a particular diagnostic marker in the individual's sample is considered to be lowered when it is at least about 5%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, or 95% less than the level of the same marker in a comparative sample (e.g., a normal, GI control, IBD, and/or Celiac disease sample) or population of samples (e.g., less than a median level of the same marker in a comparative population of normal, GI control, IBD, and/or Celiac disease samples).

[0066] The term "individual," "subject," or "patient" typically refers to humans, but also to other animals including, e.g., other primates, rodents, canines, felines, equines, ovines, porcines, and the like.

[0067] As used herein, the term "substantially the same amino acid sequence" includes an amino acid sequence that is similar, but not identical to, the naturally-occurring amino acid sequence. For example, an amino acid sequence that has substantially the same amino acid sequence as a naturally-occurring peptide, polypeptide, or protein can have one or more modifications such as amino acid additions, deletions, or substitutions relative to the amino acid sequence of the naturally-occurring peptide, polypeptide, or protein, provided that the modified sequence retains substantially at least one biological activity of the naturally-occurring peptide, polypeptide, or protein such as immunoreactivity. Comparison for substantial similarity between amino acid sequences is usually performed with sequences between about 6 and 100 residues, preferably between about 10 and 100 residues, and more preferably between about 25 and 35 residues. A particularly useful modification of a peptide, polypeptide, or protein of the present invention, or a fragment thereof, is a modification that confers, for example, increased stability. Incorporation of one or more D-amino acids is a modification useful in increasing stability of a polypeptide or polypeptide fragment.

Similarly, deletion or substitution of lysine residues can increase stability by protecting the polypeptide or polypeptide fragment against degradation.

[0068] The term "monitoring the progression or regression of IBS" includes the use of the methods, systems, and code of the present invention to determine the disease state (e.g., presence or severity of IBS) of an individual. In certain instances, the results of an algorithm (e.g., a learning statistical classifier system) are compared to those results obtained for the same individual at an earlier time. In some embodiments, the methods, systems, and code of the present invention can be used to predict the progression of IBS, e.g., by determining a likelihood for IBS to progress either rapidly or slowly in an individual based on an analysis of diagnostic markers and/or the identification or IBS-related symptoms. In other embodiments,
the methods, systems, and code of the present invention can be used to predict the regression of IBS, e.g., by determining a likelihood for IBS to regress either rapidly or slowly in an individual based on an analysis of diagnostic markers and/or the identification or IBS-related symptoms.

[0069] The term "monitoring drug efficacy in an individual receiving a drug useful for treating IBS" includes the use of the methods, systems, and code of the present invention to determine the effectiveness of a therapeutic agent for treating IBS after it has been administered. In certain instances, the results of an algorithm (e.g., a learning statistical classifier system) are compared to those results obtained for the same individual before initiation of use of the therapeutic agent or at an earlier time in therapy. As used herein, a drug useful for treating IBS is any compound or drug used to improve the health of the individual and includes, without limitation, IBS drugs such as serotonergic agents, antidepressants, chloride channel activators, chloride channel blockers, guanylate cyclase agonists, antibiotics, opioids, neurokinin antagonists, antispasmodic or anticholinergic agents, belladonna alkaloids, barbiturates, glucagon-like peptide-1 (GLP-1) analogs, corticotropin releasing factor (CRF) antagonists, probiotics, free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof.

[0070] The term "therapeutically effective amount or dose" includes a dose of a drug that is capable of achieving a therapeutic effect in a subject in need thereof. For example, a therapeutically effective amount of a drug useful for treating IBS can be the amount that is capable of preventing or relieving one or more symptoms associated with IBS. The exact amount can be ascertainable by one skilled in the art using known techniques (see, e.g., Lieberman, Pharmaceutical Dosage Forms, Vols. 1-3 (1992); Lloyd, The Art, Science arid Technology of Pharmaceutical Compounding (1999); Pickar, Dosage Calculations (1999); and Remington: The Science and Practice of Pharmacy, 20th Edition, Gennaro, Ed., Lippincott, Williams & Wilkins (2003)).

III. Description of the Embodiments

[0071] The present invention provides methods, systems, and code for aiding in the diagnosis of irritable bowel syndrome in a subject. Similarly, the present invention provides methods, systems, and code for accurately classifying whether a sample from an individual is associated with irritable bowel syndrome (IBS). In some embodiments, the present invention relies on the use of a statistical algorithm (e.g., a learning statistical classifier system) and/or empirical data (e.g., the presence or level of an IBS marker). The present invention is also
useful for ruling out one or more diseases or disorders that present with IBS-like symptoms
and ruling in IBS using a combination of statistical algorithms and/or empirical data.
Accordingly, the present invention provides an accurate diagnostic prediction of IBS and
prognostic information useful for guiding treatment decisions.

A. Methods for Aiding in the Diagnosis of Irritable Bowel Syndrome (IBS)

[0072] In one aspect, the present invention provides methods for aiding in the diagnosis of
irritable bowel syndrome in a subject by determining the level of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10,
11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, or more of the biomarkers shown in
Table 1. In preferred embodiments, the methods provided herein rely on the detection of at
least one biomarker selected from the group consisting of carbohydrate deficient transferrin,
urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic
hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal
peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide,
serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide,
tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter,
tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, hydroxytryptamine
(serotonin) receptor 3A, and a combination thereof.

[0073] In certain embodiments, methods are provided for aiding in the diagnosis of irritable
bowel syndrome in a subject by determining the level of at least one biomarker selected from
carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding
protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin
A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary
adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-
hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-
glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1,
monoamine oxidase A, monoamine oxidase B, hydroxytryptamine (serotonin) receptor 3A,
and a combination thereof in conjunction with at least one IBS biomarker selected from the
group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-
Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-
Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1 β), Tissue Inhibitor of
Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-
CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-
Human Tissue Transglutaminase IgA (tTG), β-tryptase, histamine, prostaglandin E₂ (PGE₂), and a combination thereof.

[0074] In yet other embodiments, methods are provided for aiding in the diagnosis of irritable bowel syndrome in a subject by determining the level of at least one biomarker selected from carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, hydroxytryptamine (serotonin) receptor 3A, and a combination thereof in conjunction with at least one biomarker selected from the group consisting of a cytokine (e.g., IL-8, IL-1β, TWEAK, leptin, OPG, MIP-3β, GROα, CXCL4/PF-4, and/or CXCL7/NAP-2), growth factor (e.g., EGF, VEGF, PEDF, BDNF, and/or SDGF), anti-neutrophil antibody (e.g., ANCA, pANCA, cANCA, NSNA, and/or SAPPa), ASCA (e.g., ASCA-IgA, ASCA-IgG, and/or ASCA-IgM), antimicrobial antibody (e.g., anti-OmpC antibody, anti-flagellin antibody, and/or anti-I2 antibody), lactoferrin, anti-tTG antibody, lipocalin (e.g., NGAL, NGAL/MMP-9 complex), MMP (e.g., MMP-9), TIMP (e.g., TIMP-1), alpha-globulin (e.g., alpha-2-macroglobulin, haptoglobin, and/or orosomucoid), actin-severing protein (e.g., gelsolin), S100 protein (e.g., calgranulin), fibrinopeptide (e.g., FIBA), CGRP, tachykinin (e.g., Substance P), ghrelin, neurotensin, corticotropin-releasing hormone, and combinations thereof. In yet other embodiments, the presence or level of other diagnostic markers such as, for example, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-Ul-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, gastrin, β-tryptase, histamine, prostaglandin E₂ (PGE₂), and a combination thereof may also be detected.

[0075] In another aspect, the present invention provides a method for classifying whether a sample from an individual is associated with IBS, the method comprising: (a) determining a diagnostic marker profile by detecting the presence or level of at least one diagnostic marker in the sample; (b) classifying the sample as an IBD sample or non-IBD sample using a first statistical algorithm based upon the diagnostic marker profile; and if the sample is classified as a non-IBD sample, (c) classifying the non-IBD sample as an IBS sample or non-IBS
sample using a second statistical algorithm based upon the same diagnostic marker profile as
determined in step (a) or a different diagnostic marker profile.

[0076] The diagnostic markers used for ruling out IBD can be the same as the diagnostic
markers used for ruling in IBS. Alternatively, the diagnostic markers used for ruling out IBD
can be different than the diagnostic markers used for ruling in IBS.

[0077] In some embodiments, the method of first ruling out IBD (i.e., classifying the
sample as an IBD sample or non-IBD sample) and then ruling in IBS (i.e., classifying the
non-IBD sample as an IBS sample or non-IBS sample) comprises determining a diagnostic
marker profile optionally in combination with a symptom profile, wherein the symptom
profile is determined by identifying the presence or severity of at least one symptom in the
individual; classifying the sample as an IBD sample or non-IBD sample using a first
statistical algorithm based upon the diagnostic marker profile and the symptom profile; and if
the sample is classified as a non-IBD sample, classifying the non-IBD sample as an IBS
sample or non-IBS sample using a second statistical algorithm based upon the same profiles
as determined in step (a) or different profiles. One skilled in the art will appreciate that the
diagnostic marker profile and the symptom profile can be determined simultaneously or
sequentially in any order.

[0078] In additional embodiments, the methods of the present invention further comprise
ruling out intestinal inflammation. Non-limiting examples of intestinal inflammation include
acute inflammation, diverticulitis, ileal pouch-anal anastomosis, microscopic colitis,
infectious diarrhea, and combinations thereof. In some instances, the intestinal inflammation
is ruled out based upon the presence or level of C-reactive protein (CRP), lactoferrin,
calprotectin, or combinations thereof.

[0079] As described herein, the methods of the present invention can further comprise
sending the IBS classification results to a clinician, e.g., a gastroenterologist or a general
practitioner. The methods can also provide a diagnosis in the form of a probability that the
individual has IBS. For example, the individual can have about a 0%, 5%, 10%, 15%, 20%,
25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, or
greater probability of having IBS. In some instances, the methods of the present invention
further provide a prognosis of IBS in the individual. For example, the prognosis can be
surgery, development of a category or clinical subtype of IBS, development of one or more
symptoms, or recovery from the disease.
1. IBS Markers

[0080] In one aspect, a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject is provided, the method comprising: (a) contacting a blood or serum sample from the subject with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; and (b) determining the level of the complex, thereby determining the level of the IBS marker present in the sample, wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A. In one embodiment, the method further comprises: (c) comparing the level of the IBS marker present in the sample to a control level, wherein a difference in the level of the IBS marker present in the sample relative to the control level is indicative of an increased likelihood of the subject having IBS.

[0081] In a specific embodiment, the present invention provides an assay to aid in the diagnosis of IBS, the assay comprising: (a) contacting a sample having an IBS marker contained therein under conditions suitable to transform the IBS marker into a complex comprising the IBS marker and a capture anti-IBS marker antibody; (b) contacting the complex with an enzyme labeled indicator antibody to transform the complex into a labeled complex; (c) contacting the labeled complex with a substrate for the enzyme; and (d) detecting the presence or level of the IBS marker in the sample, wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.
In certain embodiments, a control level is the level of the IBS marker present in a blood or serum sample from a healthy subject or an average level of the IBS marker present in blood or serum samples from a cohort of healthy subjects. In other embodiments, a control level is the level of the IBS marker present in a blood or serum sample from a non-IBS subject or an average level of the IBS marker present in blood or serum samples from a cohort of non-IBS subjects. In another embodiment, a control level is the level of the IBS marker present in a blood or serum sample from a diseased subject or an average level of the IBS marker present in blood or serum samples from a cohort of diseased subjects. Non-limiting examples of diseased subjects that are useful for determining a control level from include subjects with IBS, subjects with a non-IBS gastrointestinal disease, subjects with inflammatory bowel disease (IBD), subjects with ulcerative colitis (UC), subjects with Crohn's disease (CD), subjects with celiac disease, subjects with gastroesophageal reflux disease (GERD), subjects with cancer, subjects with a cancer of the gastrointestinal tract, subjects with a cancer of the stomach, subjects with a cancer of the small or large bowel, and the like.

In cases where the control level is a level of the IBS marker in a blood or serum sample of a healthy subject or healthy subjects, an increased level of the IBS marker present in a sample from a subject, relative to the control level, is indicative of an increased likelihood of the subject having IBS. Conversely, where the control is a healthy subject or subjects, a similar or reduced level of the IBS marker present in a sample from a subject, relative to the control level, is indicative of an increased likelihood of the subject not having IBS.

In cases where the control level is a level of the IBS marker in a blood or serum sample of a subject or subjects with IBS, a similar or increased level of the IBS marker present in a sample from a subject, relative to the control level, is indicative of an increased likelihood of the subject having IBS. Conversely, where the control is a subject or subjects with IBS, a reduced level of the IBS marker present in a sample from a subject, relative to the control level, is indicative of an increased likelihood of the subject not having IBS.

In certain aspects of the invention, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject comprising the detection of an IBS marker in a blood or serum sample and at least one additional blood or serum biomarker selected from β-tryptase, histamine and prostaglandin E₂ (PGE₂). In one embodiment, the method comprises detecting or determining the level of the IBS marker and β-tryptase from a blood or serum sample from a subject. In another embodiment, the method comprises detecting or
determining the level of the IBS marker and PGE$_2$ from a blood or serum sample from a subject. In a third embodiment, the method comprises detecting or determining the level of the IBS marker and histamine from a blood or serum sample from a subject. In yet another embodiment, the method comprises detecting or determining the level of the IBS marker, $\beta$-tryptase, histamine, and PGE$_2$ from a blood or serum sample from a subject. Preferably, the IBS marker, $\beta$-tryptase, histamine, and/or PGE$_2$ are detected from the same blood or serum sample, although in certain instances the biomarkers may be detected in different blood or serum samples taken from the same individual, for example, at the same time or at different times. In certain embodiments, the biomarkers may be detected in separate assays performed with different aliquots of a blood or serum sample from a subject. In other embodiments, the biomarkers may be detected in a single multiplex detection assay, for example, in a Luminex® xMAP® assay.

[0086] In yet other aspects of the invention, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject comprising the detection of the IBS marker in a blood or serum sample and at least one additional biomarker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-$\alpha$), Interleukin-1 Beta (IL-1$\beta$), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), $\beta$-tryptase, histamine, PGE$_2$, and a combination thereof. In certain embodiments, at least 2 of the additional biomarkers may be detected. In other embodiments, at least 3, 4, 5, 6, 7, 8, 9, or 10 of the additional biomarkers may be detected.

[0087] The sample used for detecting or determining the presence or level of at least one diagnostic marker is typically whole blood, plasma, serum, saliva, urine, stool (i.e., feces), tears, and any other bodily fluid, or a tissue sample (i.e., biopsy) such as a small intestine or colon sample. Preferably, the sample is serum, whole blood, plasma, stool, urine, or a tissue biopsy. In certain instances, the methods of the present invention further comprise obtaining the sample from the individual prior to detecting or determining the presence or level of at least one diagnostic marker in the sample. In a preferred embodiment, the additional biomarker may be detected from a blood or serum sample. In other embodiments, the additional biomarker may be detected from a stool sample or a biopsy from the bowel of the subject.
In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Brain-Derived Neurotropic Factor (BDNF) from a biological sample. In a preferred embodiment, Brain-Derived Neurotropic Factor (BDNF) is detected in a blood or serum sample from the subject. In another preferred embodiment, Brain-Derived Neurotropic Factor (BDNF) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Neutrophil Gelatinase-Associated Lipocalin (NGAL) from a biological sample. In a preferred embodiment, Neutrophil Gelatinase-Associated Lipocalin (NGAL) is detected in a blood or serum sample from the subject. In another preferred embodiment, Neutrophil Gelatinase-Associated Lipocalin (NGAL) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and TNF-related Weak Inducer of Apoptosis (TWEAK) from a biological sample. In a preferred embodiment, TNF-related Weak Inducer of Apoptosis (TWEAK) is detected in a blood or serum sample from the subject. In another preferred embodiment, TNF-related Weak Inducer of Apoptosis (TWEAK) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Growth-Related Oncogene Alpha (GRO-a) from a biological sample. In a preferred embodiment, Growth-Related Oncogene Alpha (GRO-a) is detected in a blood or serum sample from the subject. In another preferred embodiment, Growth-Related Oncogene Alpha (GRO-a) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Interleukin-1 Beta (IL-1β) from a biological sample. In a preferred embodiment, Interleukin-1 Beta (IL-1β) is detected in a blood or serum sample from the subject. In another preferred embodiment, Interleukin-1 Beta (IL-1β)
is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0093] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Tissue Inhibitor of Metalloproteinaske-1 (TIMP-1) from a biological sample. In a preferred embodiment, Tissue Inhibitor of Metalloproteinaske-1 (TIMP-1) is detected in a blood or serum sample from the subject. In another preferred embodiment, Tissue Inhibitor of Metalloproteinaske-1 (TIMP-1) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0094] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA) from a biological sample. In a preferred embodiment, Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA) is detected in a blood or serum sample from the subject. In another preferred embodiment, Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0095] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Anti-CBir-1 Antibody (CBirl) from a biological sample. In a preferred embodiment, Anti-CBir-1 Antibody (CBirl) is detected in a blood or serum sample from the subject. In another preferred embodiment, Anti-CBir-1 Antibody (CBirl) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0096] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Anti-Human Neutrophil Cytoplasmic Antibody (ANCA) from a biological sample. In a preferred embodiment, Anti-Human Neutrophil Cytoplasmic Antibody (ANCA) is detected in a blood or serum sample from the subject. In another preferred embodiment, Anti-Human Neutrophil Cytoplasmic Antibody (ANCA) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0097] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and Anti-Human Tissue Transglutaminase IgA (tTG) from a biological sample. In a preferred embodiment, Anti-Human Tissue Transglutaminase IgA (tTG) is detected in a blood or serum sample from the subject. In
another preferred embodiment, Anti-Human Tissue Transglutaminase IgA (tTG) is detected in a stool sample or a biopsy from the bowel of the subject. In other embodiments, at least one additional biomarker is also detected.

[0098] In one embodiment, the method comprises detecting or determining the level of the IBS marker from a blood or serum sample and all of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-α), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), and Anti-Human Tissue Transglutaminase IgA (tTG) from a blood or serum sample, a stool sample, or a biopsy from the bowel of the subject.

[0099] In certain embodiments, the presence or level of at least one diagnostic marker is determined using an assay such as a hybridization assay or an amplification-based assay. Examples of hybridization assays suitable for use in the methods of the present invention include, but are not limited to, Northern blotting, dot blotting, RNase protection, and a combination thereof. A non-limiting example of an amplification-based assay suitable for use in the methods of the present invention includes a reverse transcriptase-polymerase chain reaction (RT-PCR).

[0100] In certain other embodiments, the presence or level of at least one diagnostic marker is determined using an immunoassay or an immunohistochemical assay. A non-limiting example of an immunoassay suitable for use in the methods of the present invention includes an enzyme-linked immunosorbent assay (ELISA). Examples of immunohistochemical assays suitable for use in the methods of the present invention include, but are not limited to, immunofluorescence assays such as direct fluorescent antibody assays, indirect fluorescent antibody (IFA) assays, anticomplement immunofluorescence assays, and avidin-biotin immunofluorescence assays. Other types of immunohistochemical assays include immunoperoxidase assays.

[0101] In a preferred embodiment, the presence or level of the IBS marker is determined using a sandwich enzyme-linked immunosorbent assay (ELISA). Any suitable antibody pair may be used for the capture and detecting antibodies in a sandwich ELISA. One of skill in the art will know and appreciate how to select an appropriate antibody pair for the assay. Generally, two antibodies are selected that bind to the target of interest, e.g., the IBS marker, at different epitopes such that the binding of the first (capture) antibody does not interfere
with the second (detecting) antibody. In certain embodiments, the detecting antibody will be conjugated to an enzyme, for example, alkaline phosphatase, to aid in the detection of the complex. In other embodiments, a secondary antibody conjugated to an enzyme (e.g., alkaline phosphatase), which binds to the detecting antibody, may be used in the assay.

Generally, the complex will then be detected by the use of a luminescent substrate, for example, Ultra LITE™ (NAG Research Laboratories); SensoLyte® (AnaSpec); SuperSignal ELISA Femto Maximum Sensitivity Substrate (Thermo Scientific); SuperSignal ELISA Pico Chemiluminescent Substrate (Thermo Scientific); CPSD (disodium 3-(4-methoxySpiro{1,2-dioxetane-3,2'-(5'-chloro)tricyclo[3.3.1.13,7]decan}-4-yl)phenyl phosphate; Tropix, Inc). In a preferred embodiment, the β-tryptase sandwich ELISA comprises the use of an alkaline phosphatase conjugated anti-tryptase antibody as the detecting antibody and a CPSD containing luminescent substrate to enhance the assay sensitivity. The CPSD substrate can be found in chemiluminescent detection systems, such as the ELISA-Light™ System (Applied Biosystems).

[0102] In some embodiments, the methods provided herein further include the step of determining a symptom profile for the subject, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the subject. In a preferred embodiment, the method comprises: (d) determining a symptom profile for the subject, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the subject; and (e) diagnosing the subject as having IBS or not having IBS using an algorithm based upon the level of an IBS biomarker and the system profile. In a preferred embodiment, the method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject comprises determining a diagnostic marker profile, for example for the IBS marker or a combination thereof as described herein, optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and classifying the sample as an IBS sample or non-IBS sample using an algorithm based upon the diagnostic marker profile and the symptom profile.

[0103] The symptom profile is typically determined by identifying the presence or severity of at least one symptom selected from the group consisting of chest pain, chest discomfort, heartburn, uncomfortable fullness after having a regular-sized meal, inability to finish a regular-sized meal, abdominal pain, abdominal discomfort, constipation, diarrhea, bloating, abdominal distension, negative thoughts or feelings associated with having pain or discomfort, and combinations thereof.
In preferred embodiments, the presence or severity of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or more of the symptoms described herein is identified to generate a symptom profile that is useful for predicting IBS. In certain instances, a questionnaire or other form of written, verbal, or telephone survey is used to produce the symptom profile. The questionnaire or survey typically comprises a standardized set of questions and answers for the purpose of gathering information from respondents regarding their current and/or recent IBS-related symptoms.

In some embodiments, the symptom profile is produced by compiling and/or analyzing all or a subset of the answers to the questions set forth in the questionnaire or survey. In other embodiments, the symptom profile is produced based upon the individual's response to the following question: "Are you currently experiencing any symptoms?" The symptom profile generated in accordance with either of these embodiments can be used in combination with a diagnostic marker profile in the algorithmic-based methods described herein to improve the accuracy of predicting IBS.

In some embodiments, the methods provided herein further include providing a probability that a subject has IBS. In certain embodiments, the method may comprise providing a probability that the subject is highly unlikely, unlikely, likely, or highly likely has IBS. In related embodiments, methods are provided that further include providing a probability that a sample classified as an IBS sample or a non-IBS sample is from a subject with IBS. In certain embodiments, the method may comprise providing a probability that the sample is from a subject that is highly unlikely, unlikely, likely, or highly likely has IBS.

In other embodiments, the methods provided herein further include classifying a diagnosis of IBS as IBS-constipation (IBS-C), IBS-diarrhea (IBS-D), IBS-mixed (IBS-M), IBS-alternating (IBS-A), or post-infectious IBS (IBS-PI). In related embodiments, methods are provided herein to further classify a sample as an IBS-constipation (IBS-C), IBS-diarrhea (IBS-D), IBS-mixed (IBS-M), IBS-alternating (IBS-A), or post-infectious IBS (IBS-PI) sample.

In one embodiment, the present invention provides an assay to aid in the differentiation of IBS-D and IBS-A from IBS-C, the assay comprising: (a) contacting a sample having an IBS marker contained therein under conditions suitable to transform the IBS marker into a complex comprising the IBS marker and a capture anti-IBS marker antibody; (b) contacting the complex with an enzyme labeled indicator antibody to transform
the complex into a labeled complex; (c) contacting the labeled complex with a substrate for
the enzyme; and (d) detecting the presence or level of the IBS marker in the sample.

[0109] In some instances, the assay to aid in the differentiation of IBS-D and IBS-A from
IBS-C further comprises detecting the presence or level of β-tryptase, a prostaglandin (e.g.,
PGE₂), and/or histamine in the sample.

[0110] In yet other embodiments, methods provided herein further include diagnosing a
subject not having IBS as having IBD, as not having IBD, as having celiac disease, as not
having celiac disease, as being a healthy subject, or as not having a gastrointestinal disease.
In a related embodiment, methods are provided herein that further classify a non-IBS sample
as an IBD sample, a non-IBD sample, a healthy sample, a non-gastrointestinal disease
sample, a celiac sample, and the like.

[0111] In one embodiment, the methods provided herein comprise the use of an algorithm
based upon the level of an IBS biomarker. In certain embodiments, the algorithm is further
based upon the system profile. In a preferred embodiment, the algorithm comprises a
statistical algorithm, for example a learning statistical classifier system. In a more preferred
embodiment, the algorithm comprises a combination of at least two learning statistical
classifier systems. In a most preferred embodiment, the combination of at least two learning
statistical classifier systems comprises a random forest classifier and a neural network
classifier.

2. Stress Markers

[0112] In one embodiment, the present invention provides a method for aiding in the
dagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration
of a stress marker in a biological sample from the subject (e.g., a blood or serum sample).
The level or concentration of the stress marker may be determined by various methods known
in the art, including without limitation, immunoassays, for example, enzyme immunoassays
(EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked
immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody
capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary
electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric
assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence
assays (CL); marker purification, for example, by high pressure liquid chromatography
(HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-
TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including,
without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0113] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a stress marker binding moiety under conditions suitable to transform the stress marker present in the sample into a complex comprising the stress marker and the stress marker binding moiety; and determining the level of said complex, thereby determining the level or concentration of the stress marker present in the sample. In a preferred embodiment, the stress marker is selected from urocortin (Ucn), corticotrophin-releasing hormone-binding protein (CRFBP), Cortisol, adrenocorticotropic hormone, and a combination thereof.

[0114] In one embodiment, the method provided above, further comprises a step of comparing the level or concentration of the stress marker present in the sample to a control level or concentration, wherein a difference in the level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0115] In one embodiment, wherein the control level or concentration is the level or concentration of the stress marker present in a blood or serum sample from a healthy subject, an increased level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while the same or a reduced level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0116] In another embodiment, wherein the control level or concentration is the level or concentration of the stress marker present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0117] In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a stress marker and at least one additional IBS marker selected from Brain-Derived Neurotropic...
Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1\(\beta\)), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, \(\beta\)-tryptase, prostaglandin \(E_2\) (PGE\(_2\)), and a combination thereof.

[0118] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a urocortin binding moiety under conditions suitable to transform urocortin present in the sample into a complex comprising urocortin and the urocortin binding moiety; and determining the level of said complex, thereby determining the level or concentration of urocortin present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1\(\beta\)), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, \(\beta\)-tryptase, and prostaglandin \(E_2\) (PGE\(_2\)).

[0119] In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a corticotrophin-releasing hormone-binding protein binding moiety under conditions suitable to transform corticotrophin-releasing hormone-binding protein present in the sample into a complex comprising corticotrophin-releasing hormone-binding protein and the corticotrophin-releasing hormone-binding protein binding moiety; and determining the level of said complex, thereby determining the level or concentration of corticotrophin-releasing hormone-binding protein present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1\(\beta\)), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic
Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0120] In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a Cortisol binding moiety under conditions suitable to transform Cortisol present in the sample into a complex comprising Cortisol and the Cortisol binding moiety; and determining the level of said complex, thereby determining the level or concentration of Cortisol present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-α), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirI), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0121] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with an adrenocorticotropin hormone binding moiety under conditions suitable to transform adrenocorticotropin hormone present in the sample into a complex comprising adrenocorticotropin hormone and the adrenocorticotropin hormone binding moiety; and determining the level of said complex, thereby determining the level or concentration of adrenocorticotropin hormone present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-α), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirI), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

3. Gastrointestinal Hormones

[0122] In one embodiment, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or
concentration of a gastrointestinal hormone in a biological sample from the subject (e.g., a blood or serum sample). The level or concentration of the gastrointestinal hormone may be determined by various methods known in the art, including without limitation, immunoassays, for example, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL); marker purification, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including, without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0123] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a gastrointestinal hormone binding moiety under conditions suitable to transform the gastrointestinal hormone present in the sample into a complex comprising the gastrointestinal hormone and the gastrointestinal hormone binding moiety; and determining the level of said complex, thereby determining the level or concentration of the gastrointestinal hormone present in the sample. In a preferred embodiment, the gastrointestinal hormone is selected from substance P, nerve growth factor (NGF), neurokinin A, neurokinin B, vasoactive intestinal peptide (VIP), glucagon-like peptide 2 (GLP-2), motilin, pituitary adenylate cyclase-activating peptide (PACAP), and a combination thereof.

[0124] In one embodiment, the method provided above, further comprises a step of comparing the level or concentration of the gastrointestinal hormone present in the sample to a control level or concentration, wherein a difference in the level or concentration of the gastrointestinal hormone present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0125] In one embodiment, wherein the control level or concentration is the level or concentration of the gastrointestinal hormone present in a blood or serum sample from a healthy subject, an increased level or concentration of the gastrointestinal hormone present in the sample relative to the control level or concentration is indicative of an increased
likelihood of said subject having IBS, while the same or a reduced level or concentration of the gastrointestinal hormone present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0126] In another embodiment, wherein the control level or concentration is the level or concentration of the gastrointestinal hormone present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of the gastrointestinal hormone present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of the gastrointestinal hormone present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0127] In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a gastrointestinal hormone and at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E\textsubscript{2} (PGE\textsubscript{2}), and a combination thereof.

[0128] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a substance P binding moiety under conditions suitable to transform substance P present in the sample into a complex comprising substance P and the substance P binding moiety; and determining the level of said complex, thereby determining the level or concentration of substance P present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E\textsubscript{2} (PGE\textsubscript{2}).
In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a nerve growth factor binding moiety under conditions suitable to transform nerve growth factor present in the sample into a complex comprising nerve growth factor and the nerve growth factor binding moiety; and determining the level of said complex, thereby determining the level or concentration of nerve growth factor present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a neurokinin A binding moiety under conditions suitable to transform neurokinin A present in the sample into a complex comprising neurokinin A and the neurokinin A binding moiety; and determining the level of said complex, thereby determining the level or concentration of neurokinin A present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a neurokinin B binding moiety under conditions suitable to transform neurokinin B present in the sample into a complex comprising neurokinin B and the neurokinin B binding moiety; and determining the level of said complex, thereby determining the level or concentration of neurokinin B present in the sample. In one
embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-l Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0132] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a vasoactive intestinal peptide binding moiety under conditions suitable to transform vasoactive intestinal peptide present in the sample into a complex comprising vasoactive intestinal peptide and the vasoactive intestinal peptide binding moiety; and determining the level of said complex, thereby determining the level or concentration of vasoactive intestinal peptide present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-l Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0133] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a glucagon-like peptide 2 binding moiety under conditions suitable to transform glucagon-like peptide 2 present in the sample into a complex comprising glucagon-like peptide 2 and the glucagon-like peptide 2 binding moiety; and determining the level of said complex, thereby determining the level or concentration of glucagon-like peptide 2 present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-
1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E$_2$ (PGE$_2$).

[0134] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a motilin binding moiety under conditions suitable to transform motilin present in the sample into a complex comprising motilin and the motilin binding moiety; and determining the level of said complex, thereby determining the level or concentration of motilin present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E$_2$ (PGE$_2$).

[0135] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a pituitary adenylate cyclase-activating peptide binding moiety under conditions suitable to transform pituitary adenylate cyclase-activating peptide present in the sample into a complex comprising pituitary adenylate cyclase-activating peptide and the pituitary adenylate cyclase-activating peptide binding moiety; and determining the level of said complex, thereby determining the level or concentration of pituitary adenylate cyclase-activating peptide present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E$_2$ (PGE$_2$).
4. Serotonin Metabolites

[0136] In one embodiment, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serotonin metabolite in a biological sample from the subject (e.g., a blood or serum sample). The level or concentration of the serotonin metabolite may be determined by various methods known in the art, including without limitation, immunoassays, for example, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL); marker purification, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including, without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0137] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serotonin metabolite binding moiety under conditions suitable to transform the serotonin metabolite present in the sample into a complex comprising the serotonin metabolite and the serotonin metabolite binding moiety; and determining the level of said complex, thereby determining the level or concentration of the serotonin metabolite present in the sample. In a preferred embodiment, serotonin metabolite is selected from serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, and a combination thereof.

[0138] In one embodiment, the method provided above, further comprises a step of comparing the level or concentration of the serotonin metabolite present in the sample to a control level or concentration, wherein a difference in the level or concentration of the serotonin metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0139] In one embodiment, wherein the control level or concentration is the level or concentration of the serotonin metabolite present in a blood or serum sample from a healthy subject, an increased level or concentration of the serotonin metabolite present in the sample
relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while the same or a reduced level or concentration of the serotonin metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0140] In another embodiment, wherein the control level or concentration is the level or concentration of the serotonin metabolite present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of the serotonin metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of the serotonin metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0141] In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serotonin metabolite and at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.

[0142] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serotonin binding moiety under conditions suitable to transform serotonin present in the sample into a complex comprising serotonin and the serotonin binding moiety; and determining the level of said complex, thereby determining the level or concentration of serotonin present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).
In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a tryptophan binding moiety under conditions suitable to transform tryptophan present in the sample into a complex comprising tryptophan and the tryptophan binding moiety; and determining the level of said complex, thereby determining the level or concentration of tryptophan present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1 β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serotonin O-sulfate binding moiety under conditions suitable to transform serotonin O-sulfate present in the sample into a complex comprising serotonin O-sulfate and the serotonin O-sulfate binding moiety; and determining the level of said complex, thereby determining the level or concentration of serotonin O-sulfate present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1 β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a 5-hydroxyindoleacetic acid binding moiety under conditions suitable to transform 5-hydroxyindoleacetic acid present in the sample into a complex comprising 5-hydroxyindoleacetic acid and the 5-hydroxyindoleacetic acid binding moiety; and determining the level of said complex, thereby determining the level or concentration of 5-hydroxyindoleacetic acid present in the sample.
concentration of 5-hydroxyindoleacetic acid present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E_2 (PGE_2).

In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a 5-HT glucuronide binding moiety under conditions suitable to transform 5-HT glucuronide present in the sample into a complex comprising 5-HT glucuronide and the 5-HT glucuronide binding moiety; and determining the level of said complex, thereby determining the level or concentration of 5-HT glucuronide present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E_2 (PGE_2).

5. Serum Metabolites

In one embodiment, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serum metabolite in a biological sample from the subject (e.g., a blood or serum sample). The level or concentration of the serum metabolite may be determined by various methods known in the art, including without limitation, immunoassays, for example, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA);
immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL); marker purification, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including, without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0148] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serum metabolite binding moiety under conditions suitable to transform the serum metabolite present in the sample into a complex comprising the serum metabolite and the serum metabolite binding moiety; and determining the level of said complex, thereby determining the level or concentration of the serum metabolite present in the sample. In a preferred embodiment, the serum metabolite is selected from tyrosine and/or phenylalanine.

[0149] In one embodiment, the method provided above, further comprises a step of comparing the level or concentration of the serum metabolite present in the sample to a control level or concentration, wherein a difference in the level or concentration of the serum metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0150] In one embodiment, wherein the control level or concentration is the level or concentration of the serum metabolite present in a blood or serum sample from a healthy subject, an increased level or concentration of the serum metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while the same or a reduced level or concentration of the serum metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0151] In another embodiment, wherein the control level or concentration is the level or concentration of the serum metabolite present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of the serum metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of the serum metabolite present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.
In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serum metabolite and at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.

In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a tyrosine binding moiety under conditions suitable to transform tyrosine present in the sample into a complex comprising tyrosine and the tyrosine moiety; and determining the level of said complex, thereby determining the level or concentration of tyrosine present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a phenylalanine binding moiety under conditions suitable to phenylalanine present in the sample into a complex comprising phenylalanine and the phenylalanine binding moiety; and determining the level or concentration of phenylalanine present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.
(ANCA), Anti-Human Tissue Transglutaminase IgA (fTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

6. Serotonin Pathway Markers

[0155] In one embodiment, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serotonin pathway marker in a biological sample from the subject (e.g., a blood or serum sample). The level or concentration of the serotonin pathway marker may be determined by various methods known in the art, including without limitation, immunoassays, for example, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL); marker purification, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including, without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0156] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serotonin pathway marker binding moiety under conditions suitable to transform the serotonin pathway marker present in the sample into a complex comprising the serotonin pathway marker and the serotonin pathway marker binding moiety; and determining the level of said complex, thereby determining the level or concentration of the serotonin pathway marker present in the sample. In a preferred embodiment, the serotonin pathway marker is selected from UDP-glucuronosyltransferase 1A6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, hydroxytryptamine (serotonin) receptor 3A, and a combination thereof.

[0157] In one embodiment, the method provided above, further comprises a step of comparing the level or concentration of the serotonin pathway marker present in the sample to a control level or concentration, wherein a difference in the level or concentration of the
serotonin pathway marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0158] In one embodiment, wherein the control level or concentration is the level or concentration of the serotonin pathway marker present in a blood or serum sample from a healthy subject, an increased level or concentration of the serotonin pathway marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while the same or a reduced level or concentration of the serotonin pathway marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0159] In another embodiment, wherein the control level or concentration is the level or concentration of the serotonin pathway marker present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of the serotonin pathway marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of the serotonin pathway marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0160] In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of a serotonin pathway marker and at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.

[0161] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a UDP-glucuronosyltransferase 1-6 binding moiety under conditions suitable to transform UDP-glucuronosyltransferase 1-6 present in the sample into a complex comprising UDP-glucuronosyltransferase 1-6 and the UDP-glucuronosyltransferase 1-6 binding moiety; and determining the level of said complex, thereby determining the level or concentration of UDP-glucuronosyltransferase 1-6 present in the sample. In one embodiment, the method further comprises detecting the level or
concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0162] In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a serotonin reuptake transporter binding moiety under conditions suitable to transform serotonin reuptake transporter present in the sample into a complex comprising serotonin reuptake transporter and the serotonin reuptake transporter binding moiety; and determining the level of said complex, thereby determining the level or concentration of serotonin reuptake transporter present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0163] In another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a tryptophan hydroxylase 1 binding moiety under conditions suitable to transform tryptophan hydroxylase 1 present in the sample into a complex comprising tryptophan hydroxylase 1 and the tryptophan hydroxylase 1 binding moiety; and determining the level of said complex, thereby determining the level or concentration of tryptophan hydroxylase 1 present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-
CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0164] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a monoamine oxidase A binding moiety under conditions suitable to transform monoamine oxidase A present in the sample into a complex comprising monoamine oxidase A and the monoamine oxidase A binding moiety; and determining the level of said complex, thereby determining the level or concentration of monoamine oxidase A present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0165] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a monoamine oxidase B binding moiety under conditions suitable to transform monoamine oxidase B present in the sample into a complex comprising monoamine oxidase B and the monoamine oxidase B binding moiety; and determining the level of said complex, thereby determining the level or concentration of monoamine oxidase B present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

[0166] In yet another specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a hydroxytryptamine (serotonin) receptor 3A binding
moiety under conditions suitable to transform hydroxytryptamine (serotonin) receptor 3A present in the sample into a complex comprising hydroxytryptamine (serotonin) receptor 3A and the hydroxytryptamine (serotonin) receptor 3A binding moiety; and determining the level of said complex, thereby determining the level or concentration of hydroxytryptamine receptor 3A present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E₂ (PGE₂).

7. Carbohydrate Deficient Transferrin (CDT)

[0167] In one embodiment, the present invention provides a method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration carbohydrate deficient transferrin in a biological sample from the subject (e.g., a blood or serum sample). The level or concentration of carbohydrate deficient transferrin may be determined by various methods known in the art, including without limitation, immunoassays, for example, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL); marker purification, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.); and other well known methods including, without limitation, Bradford assays, Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0168] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or serum sample from the subject with a carbohydrate deficient transferrin binding moiety under conditions suitable to transform carbohydrate deficient transferrin present in the sample into a
complex comprising carbohydrate deficient transferrin and the carbohydrate deficient transferrin binding moiety; and determining the level of said complex, thereby determining the level or concentration of carbohydrate deficient transferrin present in the sample.

[0169] In one embodiment, the method provided above further comprises a step of comparing the level or concentration of carbohydrate deficient transferrin present in the sample to a control level or concentration, wherein a difference in the level or concentration of carbohydrate deficient transferrin present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

[0170] In one embodiment, wherein the control level or concentration is the level or concentration of carbohydrate deficient transferrin present in a blood or serum sample from a healthy subject, an increased level or concentration of carbohydrate deficient transferrin present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while the same or a reduced level or concentration of the stress marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0171] In another embodiment, wherein the control level or concentration is the level or concentration of carbohydrate deficient transferrin present in a blood or serum sample from a subject with IBS, the same or an increased level or concentration of carbohydrate deficient transferrin present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS, while a reduced level or concentration of carbohydrate deficient transferrin present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

[0172] In another related embodiment, methods are provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject by detecting the level or concentration of carbohydrate deficient transferrin and at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E$_2$ (PGE$_2$), and a combination thereof.

[0173] In a specific embodiment, a method is provided for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising: contacting a blood or
serum sample from the subject with a carbohydrate deficient transferrin binding moiety under conditions suitable to transform carbohydrate deficient transferrin present in the sample into a complex comprising carbohydrate deficient transferrin and the carbohydrate deficient transferrin binding moiety; and determining the level of said complex, thereby determining the level or concentration of carbohydrate deficient transferrin present in the sample. In one embodiment, the method further comprises detecting the level or concentration of at least one additional IBS marker selected from Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirI), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, and prostaglandin E2 (PGE2).

B. Symptom Profiles

[0174] In some embodiments, the method for aiding in the diagnosis of IBS comprises determining a diagnostic marker profile optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and classifying the sample as an IBS sample or non-IBS sample using an algorithm based upon the diagnostic marker profile and the symptom profile. One skilled in the art will appreciate that the diagnostic marker profile and the symptom profile can be determined simultaneously or sequentially in any order.

[0175] The symptom profile is typically determined by identifying the presence or severity of at least one symptom selected from the group consisting of chest pain, chest discomfort, heartburn, uncomfortable fullness after having a regular-sized meal, inability to finish a regular-sized meal, abdominal pain, abdominal discomfort, constipation, diarrhea, bloating, abdominal distension, negative thoughts or feelings associated with having pain or discomfort, and combinations thereof.

[0176] In preferred embodiments, the presence or severity of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or more of the symptoms described herein is identified to generate a symptom profile that is useful for predicting IBS. In certain instances, a questionnaire or other form of written, verbal, or telephone survey is used to produce the symptom profile. The questionnaire or survey typically comprises a standardized set of questions and answers for the purpose of gathering information from respondents regarding their current and/or recent IBS-related
symptoms. For instance, Example 3 provides exemplary questions that can be included in a questionnaire for identifying the presence or severity of one or more IBS-related symptoms in the individual.

[0177] In certain embodiments, the symptom profile is produced by compiling and/or analyzing all or a subset of the answers to the questions set forth in the questionnaire or survey. In certain other embodiments, the symptom profile is produced based upon the individual's response to the following question: "Are you currently experiencing any symptoms?" The symptom profile generated in accordance with either of these embodiments can be used in combination with a diagnostic marker profile in the algorithmic-based methods described herein to improve the accuracy of predicting IBS.

C. Use of Statistical Algorithms

[0178] In some embodiments, methods for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject is based upon the diagnostic marker profile, alone or in combination with a symptom profile, in conjunction with a statistical algorithm. In certain instances, the statistical algorithm is a learning statistical classifier system. The learning statistical classifier system can be selected from the group consisting of a random forest (RF), classification and regression tree (C&RT), boosted tree, neural network (NN), support vector machine (SVM), general chi-squared automatic interaction detector model, interactive tree, multiadaptive regression spline, machine learning classifier, and combinations thereof. Preferably, the learning statistical classifier system is a tree-based statistical algorithm (e.g., RF, C&RT, etc.) and/or a NN (e.g., artificial NN, etc.). Additional examples of learning statistical classifier systems suitable for use in the present invention are described in U.S. Patent Application No. 11/368,285. In certain embodiments, the methods comprise classifying a sample from the subject as an IBS sample or non-IBS sample.

[0179] In certain instances, the statistical algorithm is a single learning statistical classifier system. Preferably, the single learning statistical classifier system comprises a tree-based statistical algorithm such as a RF or C&RT. As a non-limiting example, a single learning statistical classifier system can be used to classify the sample as an IBS sample or non-IBS sample based upon a prediction or probability value and the presence or level of at least one diagnostic marker (i.e., diagnostic marker profile), alone or in combination with the presence or severity of at least one symptom (i.e., symptom profile). The use of a single learning statistical classifier system typically classifies the sample as an IBS sample with a sensitivity, specificity, positive predictive value, negative predictive value, and/or overall accuracy of at
least about 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%. As such, the classification of a sample as an IBS sample or non-IBS sample is useful for aiding in the diagnosis of IBS in a subject.

[0180] In certain other instances, the statistical algorithm is a combination of at least two learning statistical classifier systems. Preferably, the combination of learning statistical classifier systems comprises a RF and a NN, e.g., used in tandem or parallel. As a non-limiting example, a RF can first be used to generate a prediction or probability value based upon the diagnostic marker profile, alone or in combination with a symptom profile, and a NN can then be used to classify the sample as an IBS sample or non-IBS sample based upon the prediction or probability value and the same or different diagnostic marker profile or combination of profiles. Advantageously, the hybrid RF/NN learning statistical classifier system of the present invention classifies the sample as an IBS sample with a sensitivity, specificity, positive predictive value, negative predictive value, and/or overall accuracy of at least about 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%. In a particularly preferred embodiment, the statistical algorithm is a random forest classifier or a combination of a random forest classifier and a neural network classifier.

[0181] In some instances, the data obtained from using the learning statistical classifier system or systems can be processed using a processing algorithm. Such a processing algorithm can be selected, for example, from the group consisting of a multilayer perceptron, backpropagation network, and Levenberg-Marquardt algorithm. In other instances, a combination of such processing algorithms can be used, such as in a parallel or serial fashion.

[0182] In certain other embodiments, the methods of the present invention further comprise sending the IBS classification results to a clinician, e.g., a gastroenterologist or a general practitioner. In another embodiment, the methods of the present invention provide a diagnosis in the form of a probability that the individual has IBS. For example, the individual can have about a 0%, 5%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95%, or greater probability of having IBS. In yet another embodiment, the methods of the present invention further provide a prognosis of IBS in the individual. For example, the prognosis can be surgery, development of a category or clinical subtype of IBS, development of one or more symptoms, or recovery from the disease.
D. Assays and Kits

[0183] Any of a variety of assays, techniques, and kits known in the art can be used to determine the presence or level of one or more markers in a sample to classify whether the sample is associated with IBS.

[0184] The present invention relies, in part, on determining the presence or level of at least one marker in a sample obtained from an individual. As used herein, the term "determining the presence of at least one marker" includes determining the presence of each marker of interest by using any quantitative or qualitative assay known to one of skill in the art. In certain instances, qualitative assays that determine the presence or absence of a particular trait, variable, or biochemical or serological substance (e.g., protein or antibody) are suitable for detecting each marker of interest. In certain other instances, quantitative assays that determine the presence or absence of RNA, protein, antibody, or activity are suitable for detecting each marker of interest. As used herein, the term "determining the level of at least one marker" includes determining the level of each marker of interest by using any direct or indirect quantitative assay known to one of skill in the art. In certain instances, quantitative assays that determine, for example, the relative or absolute amount of RNA, protein, antibody, or activity are suitable for determining the level of each marker of interest. One skilled in the art will appreciate that any assay useful for determining the level of a marker is also useful for determining the presence or absence of the marker.

[0185] As used herein, the term "antibody" includes a population of immunoglobulin molecules, which can be polyclonal or monoclonal and of any isotype, or an immunologically active fragment of an immunoglobulin molecule. Such an immunologically active fragment contains the heavy and light chain variable regions, which make up the portion of the antibody molecule that specifically binds an antigen. For example, an immunologically active fragment of an immunoglobulin molecule known in the art as Fab, Fab' or F(ab')\textsubscript{2} is included within the meaning of the term antibody.

[0186] Flow cytometry can be used to determine the presence or level of one or more markers in a sample. Such flow cytometric assays, including bead based immunoassays, can be used to determine, e.g., antibody marker levels in the same manner as described for detecting serum antibodies to Candida albicans and HIV proteins (see, e.g., Bishop and Davis, J. Immunol. Methods, 210:79-87 (1997); McHugh et al, J. Immunol. Methods, 116:213 (1989); Scillian et al, Blood, 73:2041 (1989)).
Phage display technology for expressing a recombinant antigen specific for a marker can also be used to determine the presence or level of one or more markers in a sample. Phage particles expressing an antigen specific for, e.g., an antibody marker can be anchored, if desired, to a multi-well plate using an antibody such as an anti-phage monoclonal antibody (Felici et al., "Phage-Displayed Peptides as Tools for Characterization of Human Sera" in Abelson (Ed.), Methods in Enzymol. 267, San Diego: Academic Press, Inc. (1996)).

A variety of immunoassay techniques, including competitive and non-competitive immunoassays, can be used to determine the presence or level of one or more markers in a sample (see, e.g., Self and Cook, Curr. Opin. Biotechnol., 7:60-65 (1996)). The term immunoassay encompasses techniques including, without limitation, enzyme immunoassays (EIA) such as enzyme multiplied immunoassay technique (EMIT), enzyme-linked immunosorbent assay (ELISA), antigen capture ELISA, sandwich ELISA, IgM antibody capture ELISA (MAC ELISA), and microparticle enzyme immunoassay (MEIA); capillary electrophoresis immunoassays (CEIA); radioimmunoassays (RIA); immunoradiometric assays (IRMA); fluorescence polarization immunoassays (FPIA); and chemiluminescence assays (CL). If desired, such immunoassays can be automated. Immunoassays can also be used in conjunction with laser induced fluorescence (see, e.g., Schmalzing and Nashabeh, Electrophoresis, 18:2184-2193 (1997); Bao, J. Chromatogr. B, Biomed. Sci., 699:463-480 (1997)). Liposome immunoassays, such as flow-injection liposome immunoassays and liposome immunosensors, are also suitable for use in the present invention (see, e.g., Rongen et al., J. Immunol. Methods, 204: 105-133 (1997)). In addition, nephelometry assays, in which the formation of protein/antibody complexes results in increased light scatter that is converted to a peak rate signal as a function of the marker concentration, are suitable for use in the present invention. Nephelometry assays are commercially available from Beckman Coulter (Brea, CA; Kit #449430) and can be performed using a Behring Nephelometer Analyzer (Fink et al., J. Clin. Chem. Clin. Biol. Chem., 27:261-276 (1989)).

Antigen capture ELISA can be useful for determining the presence or level of one or more markers in a sample. For example, in an antigen capture ELISA, an antibody directed to a marker of interest is bound to a solid phase and sample is added such that the marker is bound by the antibody. After unbound proteins are removed by washing, the amount of bound marker can be quantitated using, e.g., a radioimmunoassay (see, e.g., Harlow and Lane, Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory, New York, 1988)). Sandwich ELISA can also be suitable for use in the present invention. For
example, in a two-antibody sandwich assay, a first antibody is bound to a solid support, and
the marker of interest is allowed to bind to the first antibody. The amount of the marker is
quantitated by measuring the amount of a second antibody that binds the marker. The
antibodies can be immobilized onto a variety of solid supports, such as magnetic or
chromatographic matrix particles, the surface of an assay plate (e.g., microtiter wells), pieces
of a solid substrate material or membrane (e.g., plastic, nylon, paper), and the like. An assay
strip can be prepared by coating the antibody or a plurality of antibodies in an array on a solid
support. This strip can then be dipped into the test sample and processed quickly through
washes and detection steps to generate a measurable signal, such as a colored spot.

[0190] A radioimmunoassay using, for example, an iodine-125 (125I) labeled secondary
antibody (Harlow and Lane, supra) is also suitable for determining the presence or level of
one or more markers in a sample. A secondary antibody labeled with a chemiluminescent
marker can also be suitable for use in the present invention. A chemiluminescence assay
using a chemiluminescent secondary antibody is suitable for sensitive, non-radioactive
detection of marker levels. Such secondary antibodies can be obtained commercially from
various sources, e.g., Amersham Lifesciences, Inc. (Arlington Heights, IL).

[0191] The immunoassays described above are particularly useful for determining the
presence or level of one or more markers in a sample. As a non-limiting example, an ELISA
using an IL-8-binding molecule such as an anti-IL-8 antibody or an extracellular IL-8-binding
protein (e.g., IL-8 receptor) is useful for determining whether a sample is positive for IL-8
protein or for determining IL-8 protein levels in a sample. A fixed neutrophil ELISA is
useful for determining whether a sample is positive for ANCA or for determining ANCA
levels in a sample. Similarly, an ELISA using yeast cell wall phosphopeptidomannan is
useful for determining whether a sample is positive for ASCA-IgA and/or ASCA-IgG, or for
determining ASCA-IgA and/or ASCA-IgG levels in a sample. An ELISA using OmpC
protein or a fragment thereof is useful for determining whether a sample is positive for anti-
OmpC antibodies, or for determining anti-OmpC antibody levels in a sample. An ELISA
using I2 protein or a fragment thereof is useful for determining whether a sample is positive
for anti-I2 antibodies, or for determining anti-I2 antibody levels in a sample. An ELISA
using flagellin protein (e.g., Cbir-1 flagellin) or a fragment thereof is useful for determining
whether a sample is positive for anti-flagellin antibodies, or for determining anti-flagellin
antibody levels in a sample. In addition, the immunoassays described above are particularly
useful for determining the presence or level of other diagnostic markers in a sample.
Specific immunological binding of the antibody to the marker of interest can be detected directly or indirectly. Direct labels include fluorescent or luminescent tags, metals, dyes, radionuclides, and the like, attached to the antibody. An antibody labeled with iodine-\(^{125}\)\(^{1}\) can be used for determining the levels of one or more markers in a sample. A chemiluminescence assay using a chemiluminescent antibody specific for the marker is suitable for sensitive, non-radioactive detection of marker levels. An antibody labeled with fluorochrome is also suitable for determining the levels of one or more markers in a sample. Examples of fluorochromes include, without limitation, DAPI, fluorescein, Hoechst 33258, R-phycoerythrin, B-phycoerythrin, R-phycoerythrin, rhodamine, Texas red, and lissamine.

Secondary antibodies linked to fluorochromes can be obtained commercially, \textit{e.g.,} goat F(\(\text{ab'}\))\(_2\) anti-human IgG-FITC is available from Tago Immunologicals (Burlingame, CA).

Indirect labels include various enzymes well-known in the art, such as horseradish peroxidase (HRP), alkaline phosphatase (AP), \(\beta\)-galactosidase, urease, and the like. A horseradish-peroxidase detection system can be used, for example, with the chromogenic substrate tetramethylbenzidine (TMB), which yields a soluble product in the presence of hydrogen peroxide that is detectable at 450 nm. An alkaline phosphatase detection system can be used with the chromogenic substrate \(p\)-nitrophenyl phosphate, for example, which yields a soluble product readily detectable at 405 nm. Similarly, a \(\beta\)-galactosidase detection system can be used with the chromogenic substrate \(o\)-nitrophenyl \(-\text{P-D-galactopyranoside}\) (ONPG), which yields a soluble product detectable at 410 nm. An urease detection system can be used with a substrate such as urea-bromocresol purple (Sigma Immunochemicals; St. Louis, MO). A useful secondary antibody linked to an enzyme can be obtained from a number of commercial sources, \textit{e.g.,} goat F(\(\text{ab'}\))\(_2\) anti-human IgG-alkaline phosphatase can be purchased from Jackson ImmunoResearch (West Grove, PA.).

A signal from the direct or indirect label can be analyzed, for example, using a spectrophotometer to detect color from a chromogenic substrate; a radiation counter to detect radiation such as a gamma counter for detection of \(^{125}\)\(^{1}\); or a fluorometer to detect fluorescence in the presence of light of a certain wavelength. For detection of enzyme-linked antibodies, a quantitative analysis of the amount of marker levels can be made using a spectrophotometer such as an EMAX Microplate Reader (Molecular Devices; Menlo Park, CA) in accordance with the manufacturer's instructions. If desired, the assays of the present invention can be automated or performed robotically, and the signal from multiple samples can be detected simultaneously.
Quantitative western blotting can also be used to detect or determine the presence or level of one or more markers in a sample. Western blots can be quantitated by well-known methods such as scanning densitometry or phosphorimaging. As a non-limiting example, protein samples are electrophoresed on 10% SDS-PAGE Laemmli gels. Primary murine monoclonal antibodies are reacted with the blot, and antibody binding can be confirmed to be linear using a preliminary slot blot experiment. Goat anti-mouse horseradish peroxidase-coupled antibodies (BioRad) are used as the secondary antibody, and signal detection performed using chemiluminescence, for example, with the Renaissance chemiluminescence kit (New England Nuclear; Boston, MA) according to the manufacturer's instructions. Autoradiographs of the blots are analyzed using a scanning densitometer (Molecular Dynamics; Sunnyvale, CA) and normalized to a positive control. Values are reported, for example, as a ratio between the actual value to the positive control (densitometric index). Such methods are well known in the art as described, for example, in Parra *et al.*, *J. Vase. Surg.*, 28:669-675 (1998).

Alternatively, a variety of immunohistochemical assay techniques can be used to determine the presence or level of one or more markers in a sample. The term immunohistochemical assay encompasses techniques that utilize the visual detection of fluorescent dyes or enzymes coupled (i.e., conjugated) to antibodies that react with the marker of interest using fluorescent microscopy or light microscopy and includes, without limitation, direct fluorescent antibody assay, indirect fluorescent antibody (IFA) assay, anticomplement immunofluorescence, avidin-biotin immunofluorescence, and immunoperoxidase assays. An IFA assay, for example, is useful for determining whether a sample is positive for ANCA, the level of ANCA in a sample, whether a sample is positive for pANCA, the level of pANCA in a sample, and/or an ANCA staining pattern (e.g., cANCA, pANCA, NSNA, and/or SAPP staining pattern). The concentration of ANCA in a sample can be quantitated, e.g., through endpoint titration or through measuring the visual intensity of fluorescence compared to a known reference standard.

Alternatively, the presence or level of a marker of interest can be determined by detecting or quantifying the amount of the purified marker. Purification of the marker can be achieved, for example, by high pressure liquid chromatography (HPLC), alone or in combination with mass spectrometry (e.g., MALDI/MS, MALDI-TOF/MS, SELDI-TOF/MS, tandem MS, etc.). Qualitative or quantitative detection of a marker of interest can also be determined by well-known methods including, without limitation, Bradford assays,
Coomassie blue staining, silver staining, assays for radiolabeled protein, and mass spectrometry.

[0198] The analysis of a plurality of markers may be carried out separately or simultaneously with one test sample. For separate or sequential assay of markers, suitable apparatuses include clinical laboratory analyzers such as the ElecSys (Roche), the AxSym (Abbott), the Access (Beckman), the ADVIA® (Bayer), and the NICHOLS ADVANTAGE® (Nichols Institute) immunoassay systems. Preferred apparatuses or protein chips perform simultaneous assays of a plurality of markers on a single surface. Particularly useful physical formats comprise surfaces having a plurality of discrete, addressable locations for the detection of a plurality of different markers. Such formats include protein microarrays, or "protein chips" (see, e.g., Ng et al, J. Cell Mol. Med., 6:329-340 (2002)) and certain capillary devices (see, e.g., U.S. Pat. No. 6,019,944). In these embodiments, each discrete surface location may comprise antibodies to immobilize one or more markers for detection at each location. Surfaces may alternatively comprise one or more discrete particles (e.g., microparticles or nanoparticles) immobilized at discrete locations of a surface, where the microparticles comprise antibodies to immobilize one or more markers for detection.

[0199] In addition to the above-described assays for determining the presence or level of various markers of interest, analysis of marker mRNA levels using routine techniques such as Northern analysis, reverse-transcriptase polymerase chain reaction (RT-PCR), or any other methods based on hybridization to a nucleic acid sequence that is complementary to a portion of the marker coding sequence (e.g., slot blot hybridization) are also within the scope of the present invention. Applicable PCR amplification techniques are described in, e.g., Ausubel et al., Current Protocols in Molecular Biology, John Wiley & Sons, Inc. New York (1999), Chapter 7 and Supplement 47; Theophilus et al, "PCR Mutation Detection Protocols," Humana Press, (2002); and Innis et al., PCR Protocols, San Diego, Academic Press, Inc. (1990). General nucleic acid hybridization methods are described in Anderson, "Nucleic Acid Hybridization," BIOS Scientific Publishers, 1999. Amplification or hybridization of a plurality of transcribed nucleic acid sequences (e.g., mRNA or cDNA) can also be performed from mRNA or cDNA sequences arranged in a microarray. Microarray methods are generally described in Hardiman, "Microarrays Methods and Applications: Nuts & Bolts," DNA Press, 2003; and Baldi et al., "DNA Microarrays and Gene Expression: From Experiments to Data Analysis and Modeling," Cambridge University Press, 2002.

[0200] Analysis of the genotype of a marker such as a genetic marker can be performed using techniques known in the art including, without limitation, polymerase chain reaction

[0201] Several markers of interest may be combined into one test for efficient processing of a multiple of samples. In addition, one skilled in the art would recognize the value of testing multiple samples (e.g., at successive time points, etc.) from the same subject. Such testing of serial samples can allow the identification of changes in marker levels over time. Increases or decreases in marker levels, as well as the absence of change in marker levels, can also provide useful information to classify IBS or to rule out diseases and disorders associated with IBS-like symptoms.

[0202] A panel for measuring one or more of the markers described above may be constructed to provide relevant information related to the approach of the present invention for classifying a sample as being associated with IBS. Such a panel may be constructed to determine the presence or level of 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25, 30, 35, 40, or more individual markers. The analysis of a single marker or subsets of markers can also be carried out by one skilled in the art in various clinical settings. These include, but are not limited to, ambulatory, urgent care, critical care, intensive care, monitoring unit, inpatient, outpatient, physician office, medical clinic, and health screening settings.
The analysis of markers could be carried out in a variety of physical formats as well. For example, the use of microtiter plates or automation could be used to facilitate the processing of large numbers of test samples. Alternatively, single sample formats could be developed to facilitate treatment and diagnosis in a timely fashion.

1. Embodiments

In one aspect, the present invention provides an assay for the detection of an IBS marker in a blood or serum sample, the method comprising the steps of: (a) coating a solid phase surface with a first anti-IBS marker capture antibody; (b) contacting the solid phase surface with a blood or serum sample under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the anti-IBS marker capture antibody; (c) contacting the IBS marker and the anti-IBS maker complex with a second detecting antibody under conditions suitable to form a ternary complex; and (d) contacting the ternary complex with a luminescent or chemiluminescent substrate, wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyl transferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.

In one embodiment, the detecting antibody is conjugated to alkaline phosphatase. In other embodiments, the detecting antibody is not conjugated to an enzyme and the method further comprises the steps of (i) contacting the ternary complex with a third antibody conjugated to alkaline phosphatase under conditions suitable to form a quaternary complex and (ii) contacting the quaternary complex with a luminescent or chemiluminescent substrate.

Any suitable antibody pair may be used for the capture and detecting antibodies in a sandwich ELISA. One of skill in the art will know and appreciate how to select an appropriate antibody pair for the assay. Generally, two antibodies are selected that bind to the target of interest, e.g., the IBS marker, at different epitopes such that the binding of the first (capture) antibody does not interfere with the second (detecting) antibody. In certain embodiments, the detecting antibody will be conjugated to an enzyme, for example, alkaline phosphatase, to aid in the detection of the complex. In other embodiments, a secondary
antibody conjugated to an enzyme (e.g., alkaline phosphatase), which binds to the detecting antibody, may be used in the assay.

[0207] Generally, the complex will be detected by the use of a luminescent substrate, for example, a luminescent substrate found in a kit such as Ultra LITE™ (NAG Research Laboratories); SensoLyte® (AnaSpec); SuperSignal ELISA Femto Maximum Sensitivity Substrate (Thermo Scientific); SuperSignal ELISA Pico Chemiluminescent Substrate (Thermo Scientific); or CPSD (disodium 3-(4-methoxyspiro[1,2-dioxetane-3,2’-(5’-chloro)tricyclo[3.3.1.13,7]decan]-4-yl)phenyl phosphate; Tropix, Inc).

[0208] In a preferred embodiment, an assay for detecting the presence or level of an IBS marker comprises a sandwich ELISA that relies on the use of an alkaline phosphatase conjugated anti-IBS marker antibody as the detecting antibody and a CPSD containing luminescent substrate to enhance the assay sensitivity. The CPSD substrate can be found in chemiluminescent detection systems, such as the ELISA-Light™ System (Applied Biosystems).

[0209] In a preferred embodiment of the assay, the detection limit of the IBS marker present in a blood or serum sample is less than about 500 pg/ml. In certain embodiments, the detection limit of the IBS marker present in a blood or serum sample is less than about 500 pg/ml, or less than about 400 pg/ml, 300 pg/ml, 250 pg/ml, 200 pg/ml, 150 pg/ml, 100 pg/ml, 75 pg/ml, 50 pg/ml, 40 pg/ml, 30 pg/ml, 25 pg/ml, 20 pg/ml, 15 pg/ml, or less than about 10 pg/ml. In a preferred embodiment, the detection limit of the IBS marker present in a blood or serum sample is less than about 200 pg/ml. In a more preferred embodiment, the detection limit of the IBS marker present in a blood or serum sample is less than about 100 pg/ml. In a more preferred embodiment, the detection limit of the IBS marker present in a blood or serum sample is less than about 50 pg/ml. In a most preferred embodiment, the detection limit of the IBS marker present in a blood or serum sample is less than about 25 pg/ml.

[0210] In another aspect, the present invention provides an assay to aid in the diagnosis of IBS, the assay comprising: (a) contacting a sample having an IBS marker under conditions suitable to transform the IBS marker into a complex comprising the IBS marker and a capture anti-IBS marker antibody; (b) contacting the complex with an enzyme-labeled indicator antibody to transform the complex into a labeled complex; (c) contacting the labeled complex with a substrate for the enzyme; and (d) detecting the presence or level of the IBS marker in the sample, wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol,
adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxyltryptamine (serotonin) receptor 3A.

[0211] In one embodiment of an assay to aid in the diagnosis of IBS, the sample is human serum.

[0212] In another embodiment of an assay to aid in the diagnosis of IBS, the sample is obtained from a subject suspected of having IBS.

[0213] In another embodiment of an assay to aid in the diagnosis of IBS, a higher level of the IBS marker in the sample relative to healthy controls is indicative of an increased likelihood of the subject having IBS.

[0214] In another embodiment of an assay to aid in the diagnosis of IBS, the assay is an enzyme-linked immunosorvent assay (ELISA).

[0215] In another embodiment of an assay to aid in the diagnosis of IBS, detecting the presence or level of the IBS marker in the sample comprises the use of a detection device.

[0216] In another embodiment of an assay to aid in the diagnosis of IBS, the detection device comprises a luminescence plate reader.

[0217] In another embodiment of an assay to aid in the diagnosis of IBS, the detection device comprises a spectrophotometer.

[0218] In another embodiment of an assay to aid in the diagnosis of IBS, the assay further comprises detecting the presence or level of \( \beta \)-tryptase, prostaglandin E2 (PGE\textsubscript{2}), and/or histamine in the sample.

[0219] In another aspect, the present invention provides an assay to aid in the differentiation of clinical subtypes of IBS, the assay comprising: (a) contacting a sample having an IBS marker under conditions suitable to transform the IBS marker into a complex comprising the IBS marker and a capture anti-IBS marker antibody; (b) contacting the complex with an enzyme-labeled indicator antibody to transform the complex into a labeled complex; (c) contacting the labeled complex with a substrate for the enzyme; and (d) detecting the presence or level of the IBS marker in the sample, wherein the IBS marker is
selected from the group consisting of carbohydrate deficient transferrin, urocortin,
corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone,
substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide,
glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin,
tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine,
phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan
hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine
(serotonin) receptor 3A.

[0220] In one embodiment of an assay to aid in the differentiation of clinical subtypes of
IBS, the assay aids in the differentiation of IBS-D and IBS-A from IBS-C.

[0221] In another embodiment of an assay to aid in the differentiation of clinical subtypes
of IBS, the sample is human serum.

[0222] In another embodiment of an assay to aid in the differentiation of clinical subtypes
of IBS, the assay is an enzyme-linked immunosorbent assay (ELISA).

[0223] In another embodiment of an assay to aid in the differentiation of clinical subtypes
of IBS, detecting the presence or level of the IBS marker in the sample comprises the use of a
detection device.

[0224] In another embodiment of an assay to aid in the differentiation of clinical subtypes
of IBS, the assay further comprises detecting the presence or level of β-tryptase,
prostaglandin E2 (PGE₂), and/or histamine in the sample.

[0225] In certain embodiments, the assays provided herein may further comprise detection
of the presence or level of at least one additional biomarker selected from the group
consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated
Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related
Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-
1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBirl Antibody
(CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue
Transglutaminase IgA (tTG), β-tryptase, prostaglandin E₂, histamine, and a combination
thereof.

[0226] In yet other embodiments, the assays provided herein may further comprise
detection of the presence or level of at least one additional biomarker selected from the group
consisting of a cytokine (e.g., IL-8, IL-1β, TWEAK, leptin, OPG, MIP-3β, GROa,
CXCL4/PF-4, and/or CXCL7/NAP-2), growth factor (e.g., EGF, VEGF, PEDF, BDNF, and/or SDGF), anti-neutrophil antibody (e.g., ANCA, pANCA, cANCA, NSNA, and/or SAPPa), ASCA (e.g., ASCA-IgA, ASCA-IgG, and/or ASCA-IgM), antimicrobial antibody (e.g., anti-OmpC antibody, anti-flagellin antibody, and/or anti-I2 antibody), lactoferrin, anti-tTG antibody, lipocalin (e.g., NGAL, NGAL/MMP-9 complex), MMP (e.g., MMP-9), TIMP (e.g., TIMP-1), alpha-globulin (e.g., alpha-2-macroglobulin, haptoglobin, and/or orosomucoid), actin-severing protein (e.g., gelsolin), S100 protein (e.g., calgranulin), fibrinopeptide (e.g., FIBA), CGRP, tachykinin (e.g., Substance P), ghrelin, neurotensin, corticotropin-releasing hormone, and combinations thereof. In yet other embodiments, the presence or level of other diagnostic markers such as, for example, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-Ul-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, gastrin, and a combination thereof may also be detected.

[0227] In certain embodiments, the assays provided may comprise the detection of at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, or more of the biomarkers described herein.

[0228] In another aspect, kits are provided for aiding in the diagnosis of IBS in a subject, or for classifying a sample as an IBS sample or a non-IBS sample. In certain embodiments, The kits provided herein contain a binding moiety for detecting the presence or level of an IBS biomarker selected from carbohydrate deficient transferrin, urocortin, corticotropin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.

[0229] In other embodiments, the kit will also contain at least one binding moiety for an additional biomarker selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir), Anti-Human Neutrophil Cytoplasmic...
Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), β-tryptase, prostaglandin E₂, histamine, and a combination thereof.

[0230] In yet other embodiments, a kit will contain at least one binding moiety for an additional biomarker selected from the group consisting of a cytokine (e.g., IL-8, IL-1β, TWEAK, leptin, OPG, MIP-3β, GROa, CXCL4/PF-4, and/or CXCL7/NAP-2), growth factor (e.g., EGF, VEGF, PEDF, BDNF, and/or SDGF), anti-neutrophil antibody (e.g., ANCA, pANCA, cANCA, NSNA, and/or SAPP), ASCA (e.g., ASCA-IgA, ASCA-IgG, and/or ASCA-IgM), antimicrobial antibody (e.g., anti-OmpC antibody, anti-flagellin antibody, and/or anti-I2 antibody), lactoferrin, anti-tTG antibody, lipocalin (e.g., NGAL, NGAL/MMP-9 complex), MMP (e.g., MMP-9), TIMP (e.g., TIMP-1), alpha-globulin (e.g., alpha-2-macroglobulin, haptoglobin, and/or orosomucoid), actin-severing protein (e.g., gelsolin), S100 protein (e.g., calgranulin), fibrinopeptide (e.g., FIBA), CGRP, tachykinin (e.g., Substance P), ghrelin, neurotensin, corticotropin-releasing hormone, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-U1-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, gastrin, and combinations thereof.

[0231] In certain embodiments, the kits provided may contain a binding moiety for at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, or more of the biomarkers described herein.

[0232] In a preferred embodiment, a kit is provided for detecting the presence or level of an IBS marker in a blood or serum sample. In one embodiment, the kit contains a first capture antibody, which is optionally attached to a solid surface, and a second detection antibody that binds to a different epitope on the IBS marker than the capture antibody. In certain embodiments, the detection antibody will be conjugated to alkaline phosphatase. In other embodiments, the detection antibody will not be conjugated to an enzyme, i.e., alkaline phosphatase. In certain embodiments, wherein the detection antibody is not enzyme-conjugated, the kit may further comprise a third antibody specific for the detection antibody, the third antibody being conjugated to an enzyme, e.g., alkaline phosphatase.

[0233] In certain embodiments, the kit will also contain a luminescent or chemiluminescent substrate, for example, a luminescent substrate as found in Ultra LITE™ (NAG Research Laboratories); SensoLyte® (AnaSpec); SuperSignal ELISA Femto Maximum Sensitivity Substrate (Thermo Scientific); SuperSignal ELISA Pico Chemiluminescent Substrate (Thermo Scientific); or CPSD (disodium 3-(4-methoxyspiro[1,2-dioxetane-3,2'-5']...
chboro)tricyclo[3.3.1.1^{3},7]decan\text{-}4\text{-}yl)phenyl phosphate; Tropix, Inc). In a preferred embodiment, the luminescent substrate is CPSD (disodium 3-(4-methoxyspiro{\text{[1,2-dioxetane-3,2'-(5'-chloro)tricyclo[3.3.1.1^{3},7]decan\text{-}4-yl]phenyl phosphate.}

[0234] In certain embodiments, the kit for detecting the presence or level of an IBS marker is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 500 pg/ml. In certain embodiments, the kit is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 500 pg/ml, or less than about 400 pg/ml, 300 pg/ml, 250 pg/ml, 200 pg/ml, 150 pg/ml, 100 pg/ml, 75 pg/ml, 50 pg/ml, 40 pg/ml, 30 pg/ml, 25 pg/ml, 20 pg/ml, 15 pg/ml, or less than about 10 pg/ml. In a preferred embodiment, the kit is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 200 pg/ml. In a more preferred embodiment, the kit is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 100 pg/ml. In a more preferred embodiment, the kit is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 50 pg/ml. In a most preferred embodiment, the kit is suitable for detecting the IBS marker present in a blood or serum sample at a concentration of less than about 25 pg/ml.

E. Methods for Monitoring and Assigning Therapy

[0235] In some embodiments, the diagnosis of an individual as having IBS is followed by administering to the individual a therapeutically effective amount of a drug useful for treating one or more symptoms associated with IBS. Suitable IBS drugs include, but are not limited to, serotonergic agents, antidepressants, chloride channel activators, chloride channel blockers, guanylate cyclase agonists, antibiotics, opioid agonists, neurokinin antagonists, antispasmodic or anticholinergic agents, belladonna alkaloids, barbiturates, GLP-1 analogs, CRF antagonists, probiotics, free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof. Other IBS drugs include bulking agents, dopamine antagonists, carminatives, tranquilizers, dextofisopam, phenytoin, timolol, and diltiazem. Additionally, amino acids like glutamine and glutamic acid which regulate intestinal permeability by affecting neuronal or glial cell signaling can be administered to treat patients with IBS.

[0236] In other embodiments, the methods of the present invention further comprise classifying an IBS sample or a diagnosis of IBS as an IBS-constipation (IBS-C), IBS-diarrhea (IBS-D), IBS-mixed (IBS-M), IBS-alternating (IBS-A), or post-infectious IBS (IBS-PI)
sample or diagnosis. In certain instances, the classification of the IBS sample or diagnosis into a category, form, or clinical subtype of IBS is based upon the presence or level of at least one, two, three, four, five, six, seven, eight, nine, ten, or more classification markers provided herein. Preferably, at least one form of IBS is distinguished from at least one other form of IBS based upon the presence or level of one or more IBS markers provided herein. In certain instances, the methods of the present invention can be used to differentiate an IBS-C sample from an IBS-A and/or IBS-D sample in an individual previously identified as having IBS. In certain other instances, the methods of the present invention can be used to classify a sample from an individual not previously diagnosed with IBS as an IBS-A sample, IBS-C sample, IBS-D sample, or non-IBS sample.

[0237] In certain embodiments, the methods further comprise sending the results from the classification to a clinician. In certain other embodiments, the methods further provide a diagnosis in the form of a probability that the individual has IBS-A, IBS-C, IBS-D, IBS-M, or IBS-PI. The methods of the present invention can further comprise administering to the individual a therapeutically effective amount of a drug useful for treating IBS-A, IBS-C, IBS-D, IBS-M, or IBS-PI. Suitable drugs include, but are not limited to, tegaserod (Zelnorm®), alosetron (Lotronex®), lubiprostone (Amitiza™), rifamixin (Xifaxan™), MD-1 100, probiotics, and a combination thereof.

[0238] In instances where the sample is classified as an IBS-A or IBS-C sample and/or the individual is diagnosed with IBS-A or IBS-C, a therapeutically effective dose of tegaserod or other 5-HT₄ agonist (e.g., mosapride, renzapride, AG1-001, etc.) can be administered to the individual. In some instances, when the sample is classified as IBS-C and/or the individual is diagnosed with IBS-C, a therapeutically effective amount of lubiprostone or other chloride channel activator, rifamixin or other antibiotic capable of controlling intestinal bacterial overgrowth, MD-1 100 or other guanylate cyclase agonist, asimadoline or other opioid agonist, or talnetant or other neurokinin antagonist can be administered to the individual. In other instances, when the sample is classified as IBS-D and/or the individual is diagnosed with IBS-D, a therapeutically effective amount of alosetron or other 5-HT₃ antagonist (e.g., ramosetron, DDP-225, etc.), crofelemer or other chloride channel blocker, talnetant or other neurokinin antagonist (e.g., saredutant, etc.), or an antidepressant such as a tricyclic antidepressant can be administered to the individual.

[0239] In yet another aspect, the present invention provides a method for monitoring the progression or regression of IBS in an individual, the method comprising: (a) determining a
diagnostic marker profile by detecting the presence or level of at least one diagnostic marker in the sample; and (b) determining the presence or severity of IBS in the individual using an algorithm based upon the diagnostic marker profile.

[0240] In one embodiment, the method of monitoring the progression or regression of IBS comprises determining a diagnostic marker profile optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and determining the presence or severity of IBS in the individual using an algorithm based upon the diagnostic marker profile and the symptom profile.

[0241] In a related aspect, the present invention provides a method for monitoring drug efficacy in an individual receiving a drug useful for treating IBS, the method comprising: (a) determining a diagnostic marker profile by detecting the presence or level of at least one diagnostic marker in the sample; and (b) determining the effectiveness of the drug using an algorithm based upon the diagnostic marker profile.

[0242] In one embodiment, the method of monitoring IBS drug efficacy comprises determining a diagnostic marker profile optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and determining the effectiveness of the drug using an algorithm based upon the diagnostic marker profile and the symptom profile.

[0243] In one embodiment, the present invention provides a method for monitoring the progression or regression of irritable bowel syndrome (IBS) in a subject, the method comprising: (a) contacting a first blood or serum sample taken from the subject at a first time with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; (b) determining the level of the complex, thereby determining the level of the IBS marker present in the first sample; (c) contacting a second blood or serum sample taken from the subject at a second time with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; (d) determining the level of the complex, thereby determining the level of the IBS marker present in the second sample; and (e) comparing the level of the IBS marker present in the first sample to the level of the IBS marker present in the second sample, wherein a higher level of the IBS marker in the second sample relative to the first sample is indicative of the progression of IBS in the subject and a lower level of the
IBS marker in the second sample relative to the first sample is indicative of the regression of IBS in the subject.

[0244] In certain embodiments of the methods of monitoring and assigning therapy, the method further comprises detecting the presence of level of at least one additional biomarker selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-α), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), β-tryptase, prostaglandin E2, histamine, and a combination thereof. In certain embodiments, the method comprises detecting the presence or level of at least two, three, four, five, six, seven, eight, nine, or all ten of the additional biomarkers provided above.

[0245] In yet other embodiments, the method my further comprises detecting the presence of level of at least one biomarker selected from the group consisting of a cytokine (e.g., IL-8, IL-1β, TWEAK, leptin, OPG, MIP -3β, GROα, CXCL4/PF-4, and/or CXCL7/NAP-2), growth factor (e.g., EGF, VEGF, PEDF, BDNF, and/or SDGF), anti-neutrophil antibody (e.g., ANCA, pANCA, cANCA, NSNA, and/or SAPPA), ASCA (e.g., ASCA-IgA, ASCA-IgG, and/or ASCA-IgM), antimicrobial antibody (e.g., anti-OmpC antibody, anti-flagellin antibody, and/or anti-12 antibody), lactoferrin, anti-tTG antibody, lipocalin (e.g., NGAL, NGAL/MMP-9 complex), MMP (e.g., MMP-9), TIMP (e.g., TIMP-1), alpha-globulin (e.g., alpha-2-macroglobulin, haptoglobin, and/or orosomucoid), actin-severing protein (e.g., gelsolin), S100 protein (e.g., calgranulin), fibrinopeptide (e.g., FIBA), CGRP, tachykinin (e.g., Substance P), ghrelin, neurotensin, corticotropin-releasing hormone, and combinations thereof. In yet other embodiments, the presence or level of other diagnostic markers such as, for example, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-Ul-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, gastrin, and a combination thereof may also be detected.

[0246] In some embodiments, a panel for measuring one or more of the diagnostic markers described above may be constructed and used for determining the presence or severity of IBS or for determining the effectiveness of an IBS drug. One skilled in the art will appreciate that the presence or level of a plurality of diagnostic markers can be determined simultaneously or sequentially, using, for example, an aliquot or dilution of the individual’s sample. As described above, the level of a particular diagnostic marker in the individual’s sample is
generally considered to be elevated when it is at least about 10%, 15%, 20%, 25%, 50%, 75%, 100%, 125%, 150%, 175%, 200%, 250%, 300%, 350%, 400%, 450%, 500%, 600%, 700%, 800%, 900%, or 1000% greater than the level of the same marker in a comparative sample or population of samples (e.g., greater than a median level). Similarly, the level of a particular diagnostic marker in the individual's sample is typically considered to be lowered when it is at least about 5%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, or 95% less than the level of the same marker in a comparative sample or population of samples (e.g., less than a median level).

[0247] In certain embodiments, the method of monitoring the progression or regression of IBS comprises determining a diagnostic marker profile optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and determining the presence or severity of IBS in the individual using an algorithm based upon the diagnostic marker profile and the symptom profile. In certain other embodiments, the method of monitoring IBS drug efficacy comprises determining a diagnostic marker profile optionally in combination with a symptom profile, wherein the symptom profile is determined by identifying the presence or severity of at least one symptom in the individual; and determining the effectiveness of the drug using an algorithm based upon the diagnostic marker profile and the symptom profile. One skilled in the art will appreciate that the diagnostic marker profile and the symptom profile can be determined simultaneously or sequentially in any order.

[0248] In some embodiments, determining the presence or severity of IBS or the effectiveness of an IBS drug is based upon the diagnostic marker profile, alone or in combination with a symptom profile, in conjunction with a statistical algorithm. In certain instances, the statistical algorithm is a learning statistical classifier system. The learning statistical classifier system comprises any of the learning statistical classifier systems described herein.

[0249] In certain embodiments, the methods of the present invention can further comprise comparing the presence or severity of IBS in the individual determined in step (b) to the presence or severity of IBS in the individual at an earlier time. As a non-limiting example, the presence or severity of IBS determined for an individual receiving an IBS drug can be compared to the presence or severity of IBS determined for the same individual before initiation of use of the IBS drug or at an earlier time in therapy. In certain other embodiments, the methods of the present invention can comprise determining the effectiveness of the IBS drug by comparing the effectiveness of the IBS drug determined in
step (b) to the effectiveness of the IBS drug in the individual at an earlier time in therapy. In additional embodiments, the methods can further comprise sending the IBS monitoring results to a clinician, e.g., a gastroenterologist or a general practitioner.

**F. Computer Readable Medium and Systems for Classifying Samples**

[0250] In one aspect, the present invention provides a computer-readable medium comprising code for controlling one or more processors to classify whether a serum or blood sample from an subject is associated with irritable bowel syndrome (IBS), the code comprising instructions to apply a statistical process to a data set comprising a diagnostic marker profile to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile, wherein the diagnostic marker profile indicates the level of at least one diagnostic marker selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A, and a combination thereof.

[0251] In other embodiments, the computer-readable medium for ruling in IBS comprises instructions to apply a statistical process to a data set comprising a diagnostic marker profile optionally in combination with a symptom profile which indicates the presence or severity of at least one symptom in the individual to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile and the symptom profile. One skilled in the art will appreciate that the statistical process can be applied to the diagnostic marker profile and the symptom profile simultaneously or sequentially in any order.

[0252] In a specific embodiment, the present invention provides a computer-readable medium including code for controlling one or more processors to classify whether a sample from an individual is associated with IBS, the code comprising instructions to apply a statistical process to a data set comprising a diagnostic marker profile to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample.
based upon the diagnostic marker profile, wherein the diagnostic marker profile indicates the presence or level of at least one diagnostic marker in the sample.

[0253] In a related aspect, the present invention provides a computer-readable medium including code for controlling one or more processors to classify whether a sample from an individual is associated with IBS, the code comprising: (a) instructions to apply a first statistical process to a data set comprising a diagnostic marker profile to produce a statistically derived decision classifying the sample as an IBD sample or non-IBD sample based upon the diagnostic marker profile, wherein the diagnostic marker profile indicates the presence or level of at least one diagnostic marker in the sample; and if the sample is classified as a non-IBD sample, (b) instructions to apply a second statistical process to the same or different data set to produce a second statistically derived decision classifying the non-IBD sample as an IBS sample or non-IBS sample.

[0254] In one embodiment, the computer-readable medium for ruling in IBS comprises instructions to apply a statistical process to a data set comprising a diagnostic marker profile optionally in combination with a symptom profile which indicates the presence or severity of at least one symptom in the individual to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile and the symptom profile.

[0255] In other embodiments, the computer-readable medium for first ruling out IBD and then ruling in IBS comprises instructions to apply a first statistical process to a data set comprising a diagnostic marker profile optionally in combination with a symptom profile which indicates the presence or severity of at least one symptom in the individual to produce a statistically derived decision classifying the sample as an IBD sample or non-IBD sample based upon the diagnostic marker profile and the symptom profile; and if the sample is classified as a non-IBD sample, instructions to apply a second statistical process to the same or different data set to produce a second statistically derived decision classifying the non-IBD sample as an IBS sample or non-IBS sample. One skilled in the art will appreciate that the first and/or second statistical process can be applied to the diagnostic marker profile and the symptom profile simultaneously or sequentially in any order.

[0256] In one embodiment, the first and second statistical processes are implemented in different processors. Alternatively, the first and second statistical processes are implemented in a single processor. In another embodiment, the first statistical process is a learning statistical classifier system. Examples of learning statistical classifier systems suitable for use in the present invention are described above. In certain instances, the first and/or second
statistical process is a single learning statistical classifier system such as, for example, a RF or C&RT. In certain other instances, the first and/or second statistical process is a combination of at least two learning statistical classifier systems. As a non-limiting example, the combination of learning statistical classifier systems comprises a RF and a NN or SVM, e.g., used in tandem. In some instances, the data obtained from using the learning statistical classifier system or systems can be processed using a processing algorithm.

[0257] In another aspect, the present invention provides a system for classifying whether a serum or blood sample from a subject is associated with irritable bowel syndrome (IBS), the system comprising: (a) a data acquisition module configured to produce a data set comprising a diagnostic marker profile, wherein the diagnostic marker profile indicates the presence or level of at least one diagnostic marker selected from the group consisting of carbohydrate deficient transferrin, urocin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A, and a combination thereof; (b) a data processing module configured to process the data set by applying a statistical process to the data set to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile; and (c) a display module configured to display the statistically derived decision.

[0258] In certain embodiments, the system for classifying whether a serum or blood sample is associated with IBS, aiding in the diagnosis of IBS, or ruling in IBS comprises a data acquisition module configured to produce a data set comprising a diagnostic marker profile optionally in combination with a symptom profile which indicates the presence or severity of at least one symptom in the individual; a data processing module configured to process the data set by applying a statistical process to the data set to produce a statistically derived decision classifying the sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile and the symptom profile; and a display module configured to display the statistically derived decision.

[0259] In a related aspect, the present invention provides a system for classifying whether a sample from an individual is associated with IBS, the system comprising: (a) a data acquisition module configured to produce a data set comprising a diagnostic marker profile,
wherein the diagnostic marker profile indicates the presence or level of at least one diagnostic marker in the sample; (b) a data processing module configured to process the data set by applying a first statistical process to the data set to produce a first statistically derived decision classifying the sample as an IBD sample or non-IBD sample based upon the diagnostic marker profile; if the sample is classified as a non-IBD sample, a data processing module configured to apply a second statistical process to the same or different data set to produce a second statistically derived decision classifying the non-IBD sample as an IBS sample or non-IBS sample; and (c) a display module configured to display the first and/or the second statistically derived decision.

[0260] In one embodiment, the system for first ruling out IBD and then ruling in IBS comprises a data acquisition module configured to produce a data set comprising a diagnostic marker profile optionally in combination with a symptom profile which indicates the presence or severity of at least one symptom in the individual; a data processing module configured to process the data set by applying a first statistical process to the data set to produce a first statistically derived decision classifying the sample as an IBD sample or non-IBD sample based upon the diagnostic marker profile and the symptom profile; if the sample is classified as a non-IBD sample, a data processing module configured to apply a second statistical process to the same or different data set to produce a second statistically derived decision classifying the non-IBD sample as an IBS sample or non-IBS sample; and a display module configured to display the first and/or the second statistically derived decision.

[0261] In certain embodiments the diagnostic marker profile indicates the level of at least one additional diagnostic marker selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E2 (PGE₂), and a combination thereof. In certain embodiments, the method comprises detecting the presence or level of at least two, three, four, five, six, seven, eight, nine, or all ten of the additional biomarkers provided above.

[0262] In yet other embodiments, the diagnostic marker profile indicates the level of at least one additional diagnostic marker selected from the group consisting of a cytokine (e.g., IL-8, IL-1β, TWEAK, leptin, OPG, MIP-3β, GROα, CXCL4/PF-4, and/or CXCL7/NAP-2),
growth factor (e.g., EGF, VEGF, PEDF, BDNF, and/or SDGF), anti-neutrophil antibody (e.g., ANCA, pANCA, cANCA, NSNA, and/or SAPP), ASCA (e.g., ASCA-IgA, ASCA-IgG, and/or ASCA-IgM), antimicrobial antibody (e.g., anti-OmpC antibody, anti-flagellin antibody, and/or anti-I2 antibody), lactoferrin, anti-tTG antibody, lipocalin (e.g., NGAL, NGAL/MMP-9 complex), MMP (e.g., MMP-9), TIMP (e.g., TIMP-1), alpha-globulin (e.g., alpha-2-macroglobulin, haptoglobin, and/or orosomucoid), actin-severing protein (e.g., gelsolin), S100 protein (e.g., calgranulin), fibrinopeptide (e.g., FIBA), CGRP, tachykinin (e.g., Substance P), ghrelin, neurotensin, corticotropin-releasing hormone, and combinations thereof. In yet other embodiments, the presence or level of other diagnostic markers such as, for example, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-Ul-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, gastrin, and a combination thereof may also be detected.

G. Diseases and Disorders with IBS-like Symptoms

[0263] A variety of structural or metabolic diseases and disorders can cause signs or symptoms that are similar to IBS. As non-limiting examples, patients with diseases and disorders such as inflammatory bowel disease (IBD), Celiac disease (CD), acute inflammation, diverticulitis, ileal pouch-anal anastomosis, microscopic colitis, chronic infectious diarrhea, lactase deficiency, cancer (e.g., colorectal cancer), a mechanical obstruction of the small intestine or colon, an enteric infection, ischemia, maldigestion, malabsorption, endometriosis, and unidentified inflammatory disorders of the intestinal tract can present with abdominal discomfort associated with mild to moderate pain and a change in the consistency and/or frequency of stools that are similar to IBS. Additional IBS-like symptoms can include chronic diarrhea or constipation or an alternating form of each, weight loss, abdominal distention or bloating, and mucus in the stool.

[0264] Most IBD patients can be classified into one of two distinct clinical subtypes, Crohn's disease and ulcerative colitis. Crohn's disease is an inflammatory disease affecting the lower part of the ileum and often involving the colon and other regions of the intestinal tract. Ulcerative colitis is characterized by inflammation localized mostly in the mucosa and submucosa of the large intestine. Patients suffering from these clinical subtypes of IBD typically have IBS-like symptoms such as, for example, abdominal pain, chronic diarrhea, weight loss, and cramping.

[0265] The clinical presentation of Celiac disease is also characterized by IBS-like symptoms such as abdominal discomfort associated with chronic diarrhea, weight loss, and
abdominal distension. Celiac disease is an immune-mediated disorder of the intestinal mucosa that is typically associated with villous atrophy, crypt hyperplasia, and/or inflammation of the mucosal lining of the small intestine. In addition to the malabsorption of nutrients, individuals with Celiac disease are at risk for mineral deficiency, vitamin deficiency, osteoporosis, autoimmune diseases, and intestinal malignancies (e.g., lymphoma and carcinoma). It is thought that exposure to proteins such as gluten (e.g., glutenin and prolamine proteins which are present in wheat, rye, barley, oats, millet, triticale, spelt, and kamut), in the appropriate genetic and environmental context, is responsible for causing Celiac disease.

[0266] Other diseases and disorders characterized by intestinal inflammation that present with IBS-like symptoms include, for example, acute inflammation, diverticulitis, ileal pouch-anal anastomosis, microscopic colitis, and chronic infectious diarrhea, as well as unidentified inflammatory disorders of the intestinal tract. Patients experiencing episodes of acute inflammation typically have elevated C-reactive protein (CRP) levels in addition to IBS-like symptoms. CRP is produced by the liver during the acute phase of the inflammatory process and is usually released about 24 hours post-commencement of the inflammatory process. Patients suffering from diverticulitis, ileal pouch-anal anastomosis, microscopic colitis, and chronic infectious diarrhea typically have elevated fecal lactoferrin and/or calprotectin levels in addition to IBS-like symptoms. Lactoferrin is a glycoprotein secreted by mucosal membranes and is the major protein in the secondary granules of leukocytes. Leukocytes are commonly recruited to inflammatory sites where they are activated, releasing granule content to the surrounding area. This process increases the concentration of lactoferrin in the stool.

[0267] Increased lactoferrin levels are observed in patients with ileal pouch-anal anastomosis (i.e., a pouch is created following complete resection of colon in severe cases of Crohn's disease) when compared to other non-inflammatory conditions of the pouch, like irritable pouch syndrome. Elevated levels of lactoferrin are also observed in patients with diverticulitis, a condition in which bulging pouches (i.e., diverticula) in the digestive tract become inflamed and/or infected, causing severe abdominal pain, fever, nausea, and a marked change in bowel habits. Microscopic colitis is a chronic inflammatory disorder that is also associated with increased fecal lactoferrin levels. Microscopic colitis is characterized by persistent watery diarrhea (non-bloody), abdominal pain usually associated with weight loss, a normal mucosa during colonoscopy and radiological examination, and very specific histopathological changes. Microscopic colitis consists of two diseases, collagenous colitis and lymphocytic colitis. Collagenous colitis is of unknown etiology and is found in patients...
with long-term watery diarrhea and a normal colonoscopy examination. Both collagenous colitis and lymphocytic colitis are characterized by increased lymphocytes in the lining of the colon. Collagenous colitis is further characterized by a thickening of the sub-epithelial collagen layer of the colon. Chronic infectious diarrhea is an illness that is also associated with increased fecal lactoferrin levels. Chronic infectious diarrhea is usually caused by a bacterial, viral, or protozoan infection, with patients presenting with IBS-like symptoms such as diarrhea and abdominal pain. Increased lactoferrin levels are also observed in patients with IBD.

[0268] In addition to determining CRP and/or lactoferrin and/or calprotectin levels, diseases and disorders associated with intestinal inflammation can also be ruled out by detecting the presence of blood in the stool, such as fecal hemoglobin. Intestinal bleeding that occurs without the patient's knowledge is called occult or hidden bleeding. The presence of occult bleeding (e.g., fecal hemoglobin) is typically observed in a stool sample from the patient. Other conditions such as ulcers (e.g., gastric, duodenal), cancer (e.g., stomach cancer, colorectal cancer), and hemorrhoids can also present with IBS-like symptoms including abdominal pain and a change in the consistency and/or frequency of stools.

[0269] In addition, fecal calprotectin levels can also be assessed. Calprotectin is a calcium binding protein with antimicrobial activity derived predominantly from neutrophils and monocytes. Calprotectin has been found to have clinical relevance in cystic fibrosis, rheumatoid arthritis, IBD, colorectal cancer, HIV, and other inflammatory diseases. Its level has been measured in serum, plasma, oral, cerebrospinal and synovial fluids, urine, and feces. Advantages of fecal calprotectin in GI disorders have been recognized: stable for 3-7 days at room temperature enabling sample shipping through regular mail; correlated to fecal alpha 1-antitrypsin in patients with Crohn's disease; and elevated in a great majority of patients with gastrointestinal carcinomas and IBD. It was found that fecal calprotectin correlates well with endoscopic and histological gradings of disease activity in ulcerative colitis, and with fecal excretion of indium-111-labelled neutrophilic granulocytes, which is a standard of disease activity in IBD.

[0270] In view of the foregoing, it is clear that a wide array of diseases and disorders can cause IBS-like symptoms, thereby creating a substantial obstacle for definitively classifying a sample as an IBS sample. However, the present invention overcomes this limitation by classifying a sample from an individual as an IBS sample using, for example, a statistical algorithm, or by excluding (i.e., ruling out) those diseases and disorders that share a similar
clinical presentation as IBS and identifying (i.e., ruling in) IBS in a sample using, for example, a combination of statistical algorithms.

H. Diagnostic Markers

A variety of diagnostic markers are suitable for use in the methods, systems, and code of the present invention for classifying a sample from an individual as an IBS sample or for ruling out one or more diseases or disorders associated with IBS-like symptoms in a sample from an individual. Examples of diagnostic markers include, without limitation, cytokines, growth factors, anti-neutrophil antibodies, *Saccharomyces cerevisiae* antibodies, antimicrobial antibodies, anti-tissue transglutaminase (tTG) antibodies, Hpocalins, matrix metalloproteinases (MMPs), complexes of lipocalin and MMP, tissue inhibitor of metalloproteinases (TIMPs), globulins (e.g., alpha-globulins), actin-severing proteins, SIOO proteins, fibrinopeptides, calcitonin gene-related peptide (CGRP), tachykinins, ghrelin, neurotensin, corticotropin-releasing hormone (CRH), serine proteases (e.g., tryptases such as β-tryptase, elastase, etc.), prostaglandin (e.g., PGE₂), histamine, C-reactive protein (CRP), lactoferrin, anti-lactoferrin antibodies, calprotectin, hemoglobin, NOD2/CARD15, serotonin reuptake transporter (SERT), tryptophan hydroxylase-1, 5-hydroxytryptamine (5-HT), lactulose, mast cell marker, stress marker, gastrointestinal hormone, serotonin metabolite, serotonin pathway marker, carbohydrate deficient transferrin (CDT), and combinations thereof. Additional diagnostic markers for predicting IBS in accordance with the present invention can be selected using the techniques described in Example 14 from US Patent Publication No. 2008/0085524, filed August 14, 2007, which is herein incorporated by reference in its entirety for all purposes. One skilled in the art will also know of other diagnostic markers suitable for use in the present invention.

In particular embodiments, a diagnostic marker profile is determined by detecting the presence or level of at least one, two, or all three of the following biomarkers: a serine protease (e.g., a tryptase such as β-tryptase); a prostaglandin (e.g., PGE₂); and/or histamine.

In other embodiments, the presence or level of at least two, three, four, five, six, seven, eight, nine, ten, or more diagnostic markers are determined in the individual’s sample. In certain instances, the cytokine comprises one or more of the cytokines described below. Preferably, the presence or level of IL-8, IL-1β, TNF-related weak inducer of apoptosis (TWEAK), leptin, osteoprotegerin (OPG), MIP-3β, GROα, CXCL4/PF-4, and/or CXCL7/NAP-2 is determined in the individual’s sample. In certain other instances, the growth factor comprises one or more of the growth factors described below. Preferably, the
presence or level of epidermal growth factor (EGF), vascular endothelial growth factor (VEGF), pigment epithelium-derived factor (PEDF), brain-derived neurotrophic factor (BDNF), and/or amphiregulin (SDGF) is determined in the individual's sample.

[0274] In some instances, the anti-neutrophil antibody comprises ANCA, pANCA, cANCA, NSNA, SAPPa, and combinations thereof. In other instances, the ASCA comprises ASCA-IgA, ASCA-IgG, ASCA-IgM, and combinations thereof. In further instances, the antimicrobial antibody comprises an anti-OmpC antibody, anti-flagellin antibody, anti-I2 antibody, and combinations thereof.

[0275] In certain instances, the lipocalin comprises one or more of the lipocalins described below. Preferably, the presence or level of neutrophil gelatinase-associated lipocalin (NGAL) and/or a complex of NGAL and a matrix metalloproteinase (e.g., NGAL/MMP-9 complex) is determined in the individual's sample. In other instances, the matrix metalloproteinase (MMP) comprises one or more of the MMPs described below. Preferably, the presence or level of MMP-9 is determined in the individual's sample. In further instances, the tissue inhibitor of metalloproteinase (TIMP) comprises one or more of the TIMPs described below. Preferably, the presence or level of TIMP-1 is determined in the individual's sample. In yet further instances, the alpha-globulin comprises one or more of the alpha-globulins described below. Preferably, the presence or level of alpha-2-macroglobulin, haptoglobin, and/or orosomucoid is determined in the individual's sample.

[0276] In certain other instances, the actin-severing protein comprises one or more of the actin-severing proteins described below. Preferably, the presence or level of gelsolin is determined in the individual's sample. In additional instances, the S100 protein comprises one or more of the S100 proteins described below including, for example, calgranulin. In yet other instances, the fibrinopeptide comprises one or more of the fibrinopeptides described below. Preferably, the presence or level of fibrinopeptide A (FIBA) is determined in the individual's sample. In further instances, the presence or level of a tachykinin such as Substance P, neurokinin A, and/or neurokinin B is determined in the individual's sample.

[0277] In some instances, the serine protease comprises one or more of the serine proteases described below. Preferably, the presence or level of a serine protease such as tryptase (e.g., \( \beta \)-tryptase) is determined in the individual's sample. In other instances, the prostaglandin comprises one or more of the prostaglandins described below. Preferably, the presence or level of a prostaglandin such as PGE\(_2\) is determined in the individual's sample.
The presence or level of other diagnostic markers such as, for example, anti-lactoferrin antibody, L-selectin/CD62L, elastase, C-reactive protein (CRP), calprotectin, anti-UI-70 kDa autoantibody, zona occludens 1 (ZO-1), vasoactive intestinal peptide (VIP), serum amyloid A, and/or gastrin can also be determined.

1. Serine Proteases

The determination of the presence or level of at least one serine protease in a sample is useful in the present invention. As used herein, the term "serine protease" includes any member of a family of proteases in which one of the amino acids at the active site is serine. Non-limiting examples of serine proteases include trypase (e.g., α-trypase, β-trypase, γ-trypase, and/or Δ-trypase), elastase, chymotrypsin, trypsin, subtilisin, and combinations thereof. Trypsin is an abundant specific neutral protease of human mast cells that can be measured in various biological fluids and can serve as a useful marker for mast cell activation. In fact, trypsin can be used as a marker for mast cell activation in IBS. It is believed that trypsin, possibly by activation of protease-activated receptor-2, is a good candidate to explain the pro-secretory and pro-inflammatory effects of mast cells, however other mast cell mediators could also involved. In a preferred embodiment, β-trypsin (TPB1) is detected in a blood or serum sample from a subject. β-trypsin, also commonly referred to as Tryptase beta-1 or Tryptase 1, is encoded by the trypsin alpha/beta 1 gene (TPSAB1; NM_003294), which is translated to form a 275 amino acid trypsin beta-1 precursor protein (NP_003285). The precursor protein is then processed by the removal of a signal peptide (amino acids 1-18) and activation peptide propeptide (amino acids 19-30) resulting in the mature Tryptase beta-1 polypeptide (amino acids 31-275; UniProt: Q15661).

In certain instances, the presence or level of a particular serine protease such as trypsin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular serine protease such as trypsin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA techniques for determining the presence or level of trypsin in a serum sample are described herein. In a particularly preferred embodiment, the level of β-trypsin is detected in a blood or serum sample using a sandwich ELISA assay in which the detecting antibody is an alkaline phosphatase conjugated anti-β-trypsin antibody, for example, commercial antibody G3. A luminescent substrate, for example, CPSD (disodium
3-(4-methoxyspiro{1,2-dioxetane-3,2'-(5'-chloro)tricyclo[3.3.13,7]decan}-4-yl)phenyl phosphate), can then be used to enhance the sensitivity of the assay.

2. **Prostaglandins**

[0281] The determination of the presence or level of at least one prostaglandin in a sample is also useful in the present invention. As used herein, the term "prostaglandin" includes any member of a group of lipid compounds that are derived enzymatically from fatty acids and have important functions in the animal body. Every prostaglandin contains 20 carbon atoms, including a 5-carbon ring. Prostaglandins, together with the thromboxanes and prostacyclins, form the prostanoid class of fatty acid derivatives. The prostanoid class is a subclass of the eicosanoids. Non-limiting examples of prostaglandins include prostaglandin I_2 (PGI_2), prostaglandin E_2 (PGE_2), prostaglandin F_20 (PGF_20), and combinations thereof. In a preferred embodiment, prostaglandin E_2 (PGE_2) is detected in a blood or serum sample from a subject, for example, a subject suspected of having IBS. In certain embodiments, PGE_2 may be detected by an ELISA or chemiluminescent assay. Suitable ELISA kits for determining the presence or level of PGE_2 in a serum sample are available from, e.g., Cayman Chemical Co. (Ann Arbor, MI).

3. **Histamine**

[0282] The determination of the presence or level of histamine in a sample is also useful in the present invention. As used herein, the term "histamine" includes a biogenic amine involved in local immune responses as well as regulating physiological function in the gut and acting as a neurotransmitter. Histamine triggers the inflammatory response. As part of an immune response to foreign pathogens, histamine is produced by basophils and by mast cells found in nearby connective tissues. Histamine increases the permeability of the capillaries to white blood cells and other proteins, in order to allow them to engage foreign invaders in the affected tissues. It is found in virtually all animal body cells. In a preferred embodiment, histamine is detected in a blood or serum sample from a subject, for example, a subject suspected of having IBS. In certain embodiments, histamine may be detected by an ELISA or chemiluminescent assay. Suitable ELISA kits for determining the presence or level of histamine in a serum sample are available from, e.g., Immunotech (Czech Republic) and Cayman Chemical Co. (Ann Arbor, MI).
4. Cytokines

[0283] The determination of the presence or level of at least one cytokine in a sample is particularly useful in the present invention. As used herein, the term "cytokine" includes any of a variety of polypeptides or proteins secreted by immune cells that regulate a range of immune system functions and encompasses small cytokines such as chemokines. The term "cytokine" also includes adipocytokines, which comprise a group of cytokines secreted by adipocytes that function, for example, in the regulation of body weight, hematopoiesis, angiogenesis, wound healing, insulin resistance, the immune response, and the inflammatory response.

In certain aspects, the presence or level of at least one cytokine including, but not limited to, TNF-a, TNF-related weak inducer of apoptosis (TWEAK), osteoprotegerin (OPG), IFN-a, IFN-β, IFN-γ, IL-1a, IL-1β, IL-1 receptor antagonist (IL-1ra), IL-2, IL-4, IL-5, IL-6, soluble IL-6 receptor (sIL-6R), IL-7, IL-8, IL-9, IL-10, IL-12, IL-13, IL-15, IL-17, IL-23, and IL-27 is determined in a sample. In certain other aspects, the presence or level of at least one chemokine such as, for example, CXCL1/GRO1/GROa, CXCL2/GRO2, CXCL3/GRO3, CXCL4/PF-4, CXCL5/ENA-78, CXCL6/GCP-2, CXCL7/NAP-2, CXCL9/MIG, CXCL10/IP-10, CXCL11/I-TAC, CXCL12/SDF-1, CXCL13/BCA-1, CXCL14/BRAK, CXCL15, CXCL16, CXCL17/DMC, CCL1, CCL2/MCP-1, CCL3/MIP-la, CCL4/MIP-ip, CCL5/RANTES, CCL6/C10, CCL7/MCP-3, CCL8/MCP-2, CCL9/CCL10, CCL11/Eotaxin, CCL12/MCP-5, CCL13/MCP-4, CCL14/HCC-1, CCL15/MIP-5, CCL16/LEC, CCL17/TARC, CCL18/MIP-4, CCL19/MIP-3p, CCL20/MIP-3a, CCL21/SLC, CCL22/MDC, CCL23/MPIF1, CCL24/Eotaxin-2, CCL25/TECK, CCL26/Eotaxin-3, CCL27/CTACK, CCL28/MEC, CL1, CL2, and CX3CL1 is determined in a sample. In certain further aspects, the presence or level of at least one adipocytokine including, but not limited to, leptin, adiponectin, resistin, active or total plasminogen activator inhibitor-1 (PAI-1), visfatin, and retinol binding protein 4 (RBP4) is determined in a sample. Preferably, the presence or level of IL-8, IL-1β, TWEAK, leptin, OPG, MIP-3β, GROa, CXCL4/PF-4, and/or CXCL7/NAP-2 is determined.

[0285] In yet other aspects, the ratio of cytokine levels is determined in a sample. For example, the ratio of the level of TNF-a to the level of IL-10 (TNF-a/IL-10), or the ratio of the level of IL-10 to the level of IL-12 (IL-10/IL-12), may be diagnostic of IBS. In yet other embodiments, the ratio of the level any one cytokine to the level of any other one cytokine may be useful. Non-limiting example of ratios that may be useful in the methods of the
The present invention includes TNF-α/TWEAK, TNF-α/OPG, TNF-α/IFN-α, TNF-α/IFN-β, TNF-α/IFN-γ, TNF-α/IL-1β, TNF-α/IL-1ra, TNF-α/IL-2, TNF-α/IL-4, TNF-α/IL-5, TNF-α/IL-6, TNF-α/sIL-6R, TNF-α/IL-7, TNF-α/IL-8, TNF-α/IL-9, TNF-α/IL-10, TNF-α/IL-12, TNF-α/IL-13, TNF-α/IL-15, TNF-α/IL-17, TNF-α/IL-23, TNF-α/IL-27, TWEAK/OPG, TWEAK/IFN-α, TWEAK/IFN-β, TWEAK/IFN-γ, TWEAK/IL-1α, TWEAK/IL-1β, TWEAK/IL-1ra, TWEAK/IL-2, TWEAK/IL-4, TWEAK/IL-5, TWEAK/IL-6, TWEAK/sIL-6R, TWEAK/IL-7, TWEAK/IL-8, TWEAK/IL-9, TWEAK/IL-10, TWEAK/IL-12, TWEAK/IL-13, TWEAK/IL-15, TWEAK/IL-17, TWEAK/IL-23, TWEAK/IL-27, IL-6/TWEAK, IL-6/OPG, IL-6/IFN-α, IL-6/IFN-β, IL-6/IFN-γ, IL-6/IL-1α, IL-6/IL-1β, IL-6/IL-1ra, IL-6/IL-2, IL-6/IL-4, IL-6/IL-5, IL-6/sIL-6R, IL-6/IL-7, IL-6/IL-8, IL-6/IL-9, IL-6/IL-10, IL-6/IL-12, IL-6/IL-13, IL-6/IL-15, IL-6/IL-17, IL-6/IL-23, IL-6/IL-27, IL-12/TWEAK, IL-12/OPG, IL-12/IFN-α, IL-12/IFN-β, IL-12/IFN-γ, IL-12/IL-1β, IL-12/IL-1ra, IL-12/IL-2, IL-12/IL-4, IL-12/IL-5, IL-12/IL-6, IL-12/sIL-6R, IL-12/IL-7, IL-12/IL-8, IL-12/IL-9, IL-12/IL-10, IL-12/IL-13, IL-12/IL-15, IL-12/IL-17, IL-12/IL-23, IL-12/IL-27, IL-10/TWEAK, IL-10/OPG, IL-10/IFN-α, IL-10/IFN-β, IL-10/IFN-γ, IL-10/IL-1α, IL-10/IL-1β, IL-10/IL-1ra, IL-10/IL-2, IL-10/IL-4, IL-10/IL-5, IL-10/IL-6, IL-10/sIL-6R, IL-10/IL-7, IL-10/IL-8, IL-10/IL-9, IL-10/IL-12, IL-10/IL-13, IL-10/IL-15, IL-10/IL-17, IL-10/IL-23, IL-8/TWEAK, IL-8/OPG, IL-8/IFN-α, IL-8/IFN-β, IL-8/IFN-γ, IL-8/IL-1α, IL-8/IL-1β, IL-8/IL-1ra, IL-8/IL-2, IL-8/IL-4, IL-8/IL-5, IL-8/IL-6, IL-8/sIL-6R, IL-8/IL-7, IL-8/IL-8, IL-8/IL-9, IL-8/IL-10, IL-8/IL-12, IL-8/IL-13, IL-8/IL-15, IL-8/IL-17, IL-8/IL-23, IL-8/IL-27, or any other ratio of one cytokine to another.

[0286] In certain instances, the presence or level of a particular cytokine is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular cytokine is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a cytokine such as IL-8, IL-1β, MCP-3β, GROα, CXCL4/PF-4, or CXCL7/NAP-2 in a serum, plasma, saliva, or urine sample are available from, e.g., R&D Systems, Inc. (Minneapolis, MN), Neogen Corp. (Lexington, KY), Alpcgo Diagnostics (Salem, NH), Assay Designs, Inc. (Ann Arbor, MI), BD Biosciences Pharmingen (San Diego, CA), Invitrogen (Camarillo, CA), Calbiochem (San Diego, CA), CHEMICON International, Inc. (Temecula, CA), Antigenix America Inc. (Huntington Station, NY), QIAGEN Inc. (Valencia, CA), Bio-Rad Laboratories, Inc. (Hercules, CA), and/or Bender MedSystems Inc. (Burlingame, CA).
5. TWEAK

TWEAK is a member of the TNF superfamily of structurally related cytokines. Full-length, membrane-anchored TWEAK can be found on the surface of many cell types and a smaller, biologically active form, generated via proteolytic processing, has also been detected in the extracellular milieu (see, e.g., Chicheportiche et al, J. Biol. Chem., 272:32401-32410 (1997)). TWEAK acts via binding to a TNF receptor superfamily member named fibroblast growth factor-inducible 14 (Fnl4; also known as tumor necrosis factor receptor superfamily member 12A or TNFRSF12A). TWEAK has multiple biological activities, including stimulation of cell growth and angiogenesis, induction of inflammatory cytokines, and stimulation of apoptosis (see, e.g., Wiley et al, Cytokine Growth Factor Rev., 14:241-249 (2003)). In particular, TWEAK has been shown to induce the expression of PGE₂, MMP-1, IL-6, IL-8, RANTES, and IP-10 in fibroblasts and synoviocytes, and to upregulate ICAM-1, E-selectin, IL-8, and MCP-1 expression in endothelial cells (see, e.g., Campbell et al, Front. BioscL, 9:2273-2284 (2004)). It has also been demonstrated that TWEAK binding to the Fnl4 receptor, or constitutive Fnl4 overexpression, activates the NF-κB signaling pathway, which plays an important role in immune and inflammatory processes, oncogenesis, cancer therapy resistance, and tumorigenesis (see, e.g., Winkles et al, Cancer Lett., 235:1 1-17 (2006); and Winkles et al, Front. BioscL, 12:2761-2771 (2007)). One skilled in the art will appreciate that TWEAK is also known as tumor necrosis factor ligand superfamily member 12 (TNFSF12), AP03 ligand (AP03L), CD255, DR3 ligand, FN14, and UNQ181/PRO207.

Suitable ELISA kits for determining the presence or level of TWEAK in a biological sample such as a serum, plasma, saliva, or urine sample are available from, e.g., Antigenix America Inc. (Huntington Station, NY), Bender MedSystems Inc. (Burlingame, CA), Agdia Inc. (Elkhart, IN), American Research Products Inc. (Belmont, MA), Biomedica Corp. (Foster City, CA), BioVision, Inc. (Mountain View, CA), and Kamiya Biomedical Co. (Seattle, WA).

6. Osteoprotegerin (OPG)

OPG is a 401-amino acid member of the TNF superfamily of structurally related cytokines. OPG, which is homologous to the receptor activator of NFκB (RANK), inhibits the differentiation of macrophages into osteoclasts and regulates the resorption of osteoclasts by acting as a soluble decoy receptor for RANK ligand (RANKL; also known as OPG ligand (OPGL)). As a result, the OPG-RANK-RANKL system plays a direct and essential role in
the formation, function, and survival of osteoclasts. The OPG-RANK-RANKL system has also been shown to modulate cancer cell migration, thus controlling the development of bone metastases. One skilled in the art will appreciate that OPG is also known as osteoprotegrin and osteoclastogenesis inhibitory factor (OCIF).

[0290] Suitable ELISA kits for determining the presence or level of OPG in a serum, plasma, saliva, or urine sample are available from, e.g., Antigenix America Inc. (Huntington Station, NY), Immunodiagnostics Systems Ltd. (Boldon, United Kingdom), and BioVendor, LLC (Candler, NC).

7. Leptin

[0291] Leptin, a member of the adipokine family of cytokines, is a 16-kD peptide hormone that plays a critical role in the regulation of body weight by inhibiting food intake and stimulating energy expenditure. It is predominantly synthesized by adipocytes and circulates in the plasma in amounts proportional to body fat content (see, e.g., Maffei et al, Nat. Med., 1:155-1 161 (1995); Considine et al, Diabetes, 45:992-994 (1996)). Leptin displays a high degree of homology among different species and it is also analogous in structure to other cytokines (see, e.g., Madej et al, FEBS Lett., 373:13-18 (1995)). Leptin acts through the leptin receptor, a single-transmembrane-domain receptor of the class I cytokine superfamily of receptors, which are characterized by extracellular motifs of four cysteine residues and a number of fibronectin type III domains (see, e.g., Heim, Eur. J. Clin. Invest., 26: 1-12 (1996)). The leptin receptor is known to exist as a homodimer and is activated by conformational changes that occur following ligand binding to the receptor (see, e.g., Devos et al., J. Biol. Chem., 272:18304-1 8310 (1997)). Six leptin receptor isoforms, generated by alternate slicing, have been identified to date (see, e.g., Wang et al, Nature, 393:684-688 (1998); Lee et al, Nature, 379:632-635 (1996)).

[0292] Suitable ELISA kits for determining the presence or level of leptin in a biological sample such as a serum, plasma, saliva, or urine sample are available from, e.g., R&D Systems, Inc. (Minneapolis, MN), B-Bridge International (Mountain View, CA), Neogen Corp. (Lexington, KY), Assay Designs, Inc. (Ann Arbor, MI), Invitrogen (Camarillo, CA), CHEMICON International, Inc. (Temecula, CA), Antigenix America Inc. (Huntington Station, NY), LINCO Research, Inc. (St. Charles, MO), Diagnostic Systems Laboratories, Inc. (Webster, TX), Immuno-Biological Laboratories, Inc. (Minneapolis, MN), and Cayman Chemical Co. (Ann Arbor, MI).
8. Growth Factors

[0293] The determination of the presence or level of one or more growth factors in a sample is also useful in the present invention. As used herein, the term "growth factor" includes any of a variety of peptides, polypeptides, or proteins that are capable of stimulating cellular proliferation and/or cellular differentiation.

[0294] In certain aspects, the presence or level of at least one growth factor including, but not limited to, epidermal growth factor (EGF), heparin-binding epidermal growth factor (HB-EGF), vascular endothelial growth factor (VEGF), pigment epithelium-derived factor (PEDF; also known as SERPINF1), amphiregulin (AREG; also known as schwannoma-derived growth factor (SDGF)), basic fibroblast growth factor (bFGF), hepatocyte growth factor (HGF), transforming growth factor-a (TGF-a), transforming growth factor-β (TGF-β), bone morphogenetic proteins (e.g., BMP 1-BMP 15), platelet-derived growth factor (PDGF), nerve growth factor (NGF), β-nerve growth factor (β-NGF), neurotrophic factors (e.g., brain-derived neurotrophic factor (BDNF), neurotrophin 3 (NT3), neurotrophin 4 (NT4), etc.), growth differentiation factor-9 (GDF-9), granulocyte-colony stimulating factor (G-CSF), granulocyte-macrophage colony stimulating factor (GM-CSF), myostatin (GDF-8), erythropoietin (EPO), and thrombopoietin (TPO) is determined in a sample. Preferably, the presence or level of EGF, VEGF, PEDF, amphiregulin (SDGF), and/or BDNF is determined.

[0295] In certain instances, the presence or level of a particular growth factor is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular growth factor is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a growth factor such as EGF, VEGF, PEDF, SDGF, or BDNF in a serum, plasma, saliva, or urine sample are available from, e.g., Antigenix America Inc. (Huntington Station, NY), Promega (Madison, WI), R&D Systems, Inc. (Minneapolis, MN), Invitrogen (Camarillo, CA), CHEMICON International, Inc. (Temecula, CA), Neogen Corp. (Lexington, KY), PeproTech (Rocky Hill, NJ), Alpco Diagnostics (Salem, NH), Pierce Biotechnology, Inc. (Rockford, IL), and/or Abazyme (Needham, MA).

9. Lipocalins

[0296] The determination of the presence or level of one or more lipocalins in a sample is also useful in the present invention. As used herein, the term "lipocalin" includes any of a
variety of small extracellular proteins that are characterized by several common molecular recognition properties: the ability to bind a range of small hydrophobic molecules; binding to specific cell-surface receptors; and the formation of complexes with soluble macromolecules (see, e.g., Flowers, Biochem. J., 318:1-14 (1996)). The varied biological functions of lipocalins are mediated by one or more of these properties. The lipocalin protein family exhibits great functional diversity, with roles in retinol transport, invertebrate cryptic coloration, olfaction and pheromone transport, and prostaglandin synthesis. Lipocalins have also been implicated in the regulation of cell homoeostasis and the modulation of the immune response, and, as carrier proteins, to act in the general clearance of endogenous and exogenous compounds. Although lipocalins have great diversity at the sequence level, their three-dimensional structure is a unifying characteristic. Lipocalin crystal structures are highly conserved and comprise a single eight-stranded continuously hydrogen-bonded antiparallel beta-barrel, which encloses an internal ligand-binding site.

[0297] In certain aspects, the presence or level of at least one lipocalin including, but not limited to, neutrophil gelatinase-associated lipocalin (NGAL; also known as human neutrophil lipocalin (HNL) or lipocalin-2), von Ebner’s gland protein (VEGP; also known as lipocalin-1), retinol-binding protein (RBP), purpurin (PURP), retinoic acid-binding protein (RABP), α2α-globulin (A2U), major urinary protein (MUP), bilin-binding protein (BBP), α-crustacyanin, pregnancy protein 14 (PP14), β-lactoglobulin (Big), α1-microglobulin (AIM), the gamma chain of C8 (C8y), Apolipoprotein D (ApoD), lazarillo (LAZ), prostaglandin D2 synthase (PGDS), quiescence-specific protein (QSP), choroid plexus protein, odorant-binding protein (OBP), exi-acid glycoprotein (AGP), probasin (PBAS), aphrodisin, orosomucoid, and progestagen-associated endometrial protein (PAEP) is determined in a sample. In certain other aspects, the presence or level of at least one lipocalin complex including, for example, a complex of NGAL and a matrix metalloproteinase (e.g., NGAL/MMP-9 complex) is determined. Preferably, the presence or level of NGAL or a complex thereof with MMP-9 is determined.

[0298] In certain instances, the presence or level of a particular lipocalin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular lipocalin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a lipocalin such as NGAL in a serum, plasma, or urine sample are available from, e.g., AntibodyShop A/S (Gentofte, Denmark), LabClinics SA (Barcelona,

10. Matrix Metalloproteinases

[0299] The determination of the presence or level of at least one matrix metalloproteinase (MMP) in a sample is also useful in the present invention. As used herein, the term "matrix metalloproteinase" or "MMP" includes zinc-dependent endopeptidases capable of degrading a variety of extracellular matrix proteins, cleaving cell surface receptors, releasing apoptotic ligands, and/or regulating chemokines. MMPs are also thought to play a major role in cell behaviors such as cell proliferation, migration (adhesion/dispersion), differentiation, angiogenesis, and host defense.

[0300] In certain aspects, the presence or level of at least one at least one MMP including, but not limited to, MMP-1 (interstitial collagenase), MMP-2 (gelatinase-A), MMP-3 (stromelysin-1), MMP-7 (matrilysin), MMP-8 (neutrophil collagenase), MMP-9 (gelatinase-B), MMP-10 (stromelysin-2), MMP-11 (stromelysin-3), MMP-12 (macrophage metalloelastase), MMP-13 (collagenase-3), MMP-14, MMP-15, MMP-16, MMP-17, MMP-18 (collagenase-4), MMP-19, MMP-20 (enamelysin), MMP-21, MMP-23, MMP-24, MMP-25, MMP-26 (matrilysin-2), MMP-27, and MMP-28 (epilysin) is determined in a sample. Preferably, the presence or level of MMP-9 is determined.

[0301] In certain instances, the presence or level of a particular MMP is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular MMP is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of an MMP such as MMP-9 in a serum or plasma sample are available from, e.g., Calbiochem (San Diego, CA), CHEMICON International, Inc. (Temecula, CA), and R&D Systems, Inc. (Minneapolis, MN).
11. Tissue Inhibitor of Metalloproteinases

[0302] The determination of the presence or level of at least one tissue inhibitor of metalloproteinase (TIMP) in a sample is also useful in the present invention. As used herein, the term "tissue inhibitor of metalloproteinase" or "TIMP" includes proteins capable of inhibiting MMPs.

[0303] In certain aspects, the presence or level of at least one TIMP including, but not limited to, TIMP-1, TIMP-2, TIMP-3, and TIMP-4 is determined in a sample. Preferably, the presence or level of TIMP-1 is determined.

[0304] In certain instances, the presence or level of a particular TIMP is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular TIMP is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a TIMP such as TIMP-1 in a serum or plasma sample are available from, e.g., Alpco Diagnostics (Salem, NH), Calbiochem (San Diego, CA), Invitrogen (Camarillo, CA), CHEMICON International, Inc. (Temecula, CA), and R&D Systems, Inc. (Minneapolis, MN).

12. Globulins

[0305] The determination of the presence or level of at least one globulin in a sample is also useful in the present invention. As used herein, the term "globulin" includes any member of a heterogeneous series of families of serum proteins which migrate less than albumin during serum electrophoresis. Protein electrophoresis is typically used to categorize globulins into the following three categories: alpha-globulins (i.e., alpha-1-globulins or alpha-2-globulins); beta-globulins; and gamma-globulins.

[0306] Alpha-globulins comprise a group of globular proteins in plasma which are highly mobile in alkaline or electrically-charged solutions. They generally function to inhibit certain blood protease and inhibitor activity. Examples of alpha-globulins include, but are not limited to, alpha-2-macroglobulin (a2-MG), haptoglobin (Hp), orosomucoid, alpha-1-antitrypsin, alpha-1-antichymotrypsin, alpha-2-antiplasmin, antithrombin, ceruloplasmin, heparin cofactor II, retinol binding protein, and transcortin. Preferably, the presence or level of a2-MG, haptoglobin, and/or orosomucoid is determined. In certain instances, one or more
haptoglobin allotypes such as, for example, Hp precursor, Hpβ, Hpal, and Hpα2, are determined.

[0307] In certain instances, the presence or level of a particular globulin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular globulin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a globulin such as α2-MG, haptoglobin, or orosomucoid in a serum, plasma, or urine sample are available from, e.g., GenWay Biotech, Inc. (San Diego, CA) and/or Immundiagnostik AG (Bensheim, Germany).

13. Actin-Severing Proteins

[0308] The determination of the presence or level of at least one actin-severing protein in a sample is also useful in the present invention. As used herein, the term "actin-severing protein" includes any member of a family of proteins involved in actin remodeling and regulation of cell motility. Non-limiting examples of actin-severing proteins include gelsolin (also known as brevin or actin-depolymerizing factor), villin, fragmin, and adseverin. For example, gelsolin is a protein of leukocytes, platelets, and other cells which severs actin filaments in the presence of submicromolar calcium, thereby solating cytoplasmic actin gels.

[0309] In certain instances, the presence or level of a particular actin-severing protein is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular actin-severing protein is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA techniques for determining the presence or level of an actin-severing protein such as gelsolin in a plasma sample are described in, e.g., Smith et al., J. Lab. Clin. Med., 110:189-195 (1987); and Hiyoshi et al., Biochem. Mol Biol. Int., 32:755-762 (1994).

14. S100 Proteins

[0310] The determination of the presence or level of at least one S100 protein in a sample is also useful in the present invention. As used herein, the term "S100 protein" includes any member of a family of low molecular mass acidic proteins characterized by cell-type-specific expression and the presence of 2 EF-hand calcium-binding domains. There are at least 21 different types of S100 proteins in humans. The name is derived from the fact that S100
proteins are 100% soluble in ammonium sulfate at neutral pH. Most S100 proteins are homodimeric, consisting of two identical polypeptides held together by non-covalent bonds. Although S100 proteins are structurally similar to calmodulin, they differ in that they are cell-specific, expressed in particular cells at different levels depending on environmental factors. S-100 proteins are normally present in cells derived from the neural crest (e.g., Schwann cells, melanocytes, glial cells), chondrocytes, adipocytes, myoepithelial cells, macrophages, Langerhans cells, dendritic cells, and keratinocytes. S100 proteins have been implicated in a variety of intracellular and extracellular functions such as the regulation of protein phosphorylation, transcription factors, Ca\textsuperscript{2+} homeostasis, the dynamics of cytoskeleton constituents, enzyme activities, cell growth and differentiation, and the inflammatory response.

[0311] Calgranulin is an S100 protein that is expressed in multiple cell types, including renal epithelial cells and neutrophils, and are abundant in infiltrating monocytes and granulocytes under conditions of chronic inflammation. Examples of calgranulins include, without limitation, calgranulin A (also known as S100A8 or MRP-8), calgranulin B (also known as S100A9 or MRP-14), and calgranulin C (also known as S100A12).

[0312] In certain instances, the presence or level of a particular S100 protein is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular S100 protein is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of an S100 protein such as calgranulin A (S100A8) or calgranulin B (S100A9) in a serum, plasma, or urine sample are available from, e.g., Peninsula Laboratories Inc. (San Carlos, CA) and Hycult biotechnology b.v. (Uden, The Netherlands).

[0313] Calprotectin, the complex of S100A8 and S100A9, is a calcium- and zinc-binding protein in the cytosol of neutrophils, monocytes, and keratinocytes. Calprotectin is a major protein in neutrophilic granulocytes and macrophages and accounts for as much as 60% of the total protein in the cytosol fraction in these cells. It is therefore a surrogate marker of neutrophil turnover. Its concentration in stool correlates with the intensity of neutrophil infiltration of the intestinal mucosa and with the severity of inflammation. In some instances, calprotectin can be measured with an ELISA using small (50-100 mg) fecal samples (see, e.g., Johne et al., Scand J Gastroenterol., 36:291-296 (2001)).
15. **Tachykinins**

The determination of the presence or level of at least one tachykinin in a sample is also useful in the present invention. As used herein, the term "tachykinin" includes amidated neuropeptides that share the carboxy-terminal sequence Phe-X-Gly-Leu-Met-NH?.

Tachykinins typically bind to one or more tachykinin receptors (e.g., TACR1, TACR2, and/or TACR3).

In certain aspects, the presence or level of at least one tachykinin including, but not limited to, substance P, neurokinin A, and neurokinin B is determined in a sample. Preferably, the presence or level of substance P is determined. Substance P is a peptide of 11 amino acids in length that is released by nerve endings in both the central and peripheral nervous systems. Among the numerous biological sites innervated by substance P-releasing neurons are the skin, intestines, stomach, bladder, and cardiovascular system.

In certain instances, the presence or level of a particular tachykinin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of a particular tachykinin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of a tachykinin such as substance P in a serum, plasma, saliva, or urine sample are available from, e.g., MD Biosciences Inc. (St. Paul, MN), Assay Designs, Inc. (Ann Arbor, MI), R&D Systems, Inc. (Minneapolis, MN), Sigma-Aldrich Corp. (St. Louis, MO), and Cayman Chemical Co. (Ann Arbor, MI).

16. **Ghrelin**

The determination of the presence or level of ghrelin in a sample is also useful in the present invention. As used herein, the term "ghrelin" includes a peptide of 28 amino acids that is an endogenous ligand for the growth hormone secretagogue receptor (GHSR) and is involved in regulating growth hormone release. Ghrelin can be acylated, typically with an n-octanoyl group at serine residue three, to form active ghrelin. Alternatively, ghrelin can exist as an unacylated form (i.e., desacyl-ghrelin). Ghrelin is primarily expressed in specialized enterochromaffin cells located mainly in the mucosa of the fundus of the stomach and has metabolic effects opposite to those of leptin. Ghrelin stimulates food intake, enhances the use of carbohydrates and reduces fat utilization, increases gastric motility and acid secretion, and reduces locomotor activity.
[0318] In certain instances, the presence or level of ghrelin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of ghrelin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of active ghrelin or desacyl-ghrelin in a serum, plasma, saliva, or urine sample are available from, e.g., Alpco Diagnostics (Salem, NH), Cayman Chemical Co. (Ann Arbor, MI), LINCO Research, Inc. (St. Charles, MO), and Diagnostic Systems Laboratories, Inc. (Webster, TX).

17. Neurotensin

[0319] The determination of the presence or level of neurotensin in a sample is also useful in the present invention. As used herein, the term "neurotensin" includes a tridecapeptide that is widely distributed throughout the central nervous system and the gastrointestinal tract. Neurotensin has been identified as an important mediator in the development and progression of several gastrointestinal functions and disease conditions, exerting its effects by interacting with specific receptors that act directly or indirectly on nerves, epithelial cells, and/or cells of the immune and inflammatory systems (see, e.g., Zhao et al, Peptides, 27:2434-2444 (2006)).

[0320] In certain instances, the presence or level of neurotensin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of neurotensin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA techniques for determining the presence or level of neurotensin in a sample are described in, e.g., Davis et al, J. Neurosci. Methods, 14:15-23 (1985); and Williams et al, J. Histochem. Cytochem., 37:831-841 (1989).

18. Corticotropin-Releasing Hormone

[0321] The determination of the presence or level of corticotropin-releasing hormone (CRH; also known as corticotropin-releasing factor or CRF) in a sample is also useful in the present invention. As used herein, the term "corticotropin-releasing hormone," "CRH," "corticotropin-releasing factor," or "CRF" includes a 41-amino acid peptide secreted by the paraventricular nucleus of the hypothalamus that mediates the proximal part of the response to stress in mammals such as humans. CRH typically binds to one or more corticotropin-
releasing hormone receptors (e.g., CRHR1 and/or CRHR2). CRH is expressed by the hypothalamus, spinal cord, stomach, spleen, duodenum, adrenal gland, and placenta.

[0322] In certain instances, the presence or level of CRH is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of CRH is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. Suitable ELISA kits for determining the presence or level of CRH in a serum, plasma, saliva, or urine sample are available from, e.g., Alpco Diagnostics (Salem, NH) and Cosmo Bio Co., Ltd. (Tokyo, Japan).

19. Anti-Neutrophil Antibodies

[0323] The determination of ANCA levels and/or the presence or absence of pANCA in a sample is also useful in the present invention. As used herein, the term "anti-neutrophil cytoplasmic antibody" or "ANCA" includes antibodies directed to cytoplasmic and/or nuclear components of neutrophils. ANCA activity can be divided into several broad categories based upon the ANCA staining pattern in neutrophils: (1) cytoplasmic neutrophil staining without perinuclear highlighting (cANCA); (2) perinuclear staining around the outside edge of the nucleus (pANCA); (3) perinuclear staining around the inside edge of the nucleus (NSNA); and (4) diffuse staining with speckling across the entire neutrophil (SAPPA). In certain instances, pANCA staining is sensitive to DNase treatment. The term ANCA encompasses all varieties of anti-neutrophil reactivity, including, but not limited to, cANCA, pANCA, NSNA, and SAPPA. Similarly, the term ANCA encompasses all immunoglobulin isotypes including, without limitation, immunoglobulin A and G.

[0324] ANCA levels in a sample from an individual can be determined, for example, using an immunoassay such as an enzyme-linked immunosorbent assay (ELISA) with alcohol-fixed neutrophils. The presence or absence of a particular category of ANCA such as pANCA can be determined, for example, using an immunohistochemical assay such as an indirect fluorescent antibody (IFA) assay. Preferably, the presence or absence of pANCA in a sample is determined using an immunofluorescence assay with DNase-treated, fixed neutrophils. In addition to fixed neutrophils, antigens specific for ANCA that are suitable for determining ANCA levels include, without limitation, unpurified or partially purified neutrophil extracts; purified proteins, protein fragments, or synthetic peptides such as histone H1 or ANCA-reactive fragments thereof (see, e.g., U.S. Patent No. 6,074,835); histone H1-like antigens, porin antigens, Bacteroides antigens, or ANCA-reactive fragments thereof (see, e.g., U.S.
Patent No. 6,033,864); secretory vesicle antigens or ANCA-reactive fragments thereof (see, e.g., U.S. Patent Application No. 08/804,106); and anti-ANCA idiotypic antibodies. One skilled in the art will appreciate that the use of additional antigens specific for ANCA is within the scope of the present invention.

20. **Anti-Saccharomyces cerevisiae Antibodies**

[0325] The determination of ASCA (e.g., ASCA-IgA and/or ASCA-IgG) levels in a sample is also useful in the present invention. As used herein, the term "anti-Saccharomyces cerevisiae immunoglobulin A" or "ASCA-IgA" includes antibodies of the immunoglobulin A isotype that react specifically with *S. cerevisiae*. Similarly, the term "anti-Saccharomyces cerevisiae immunoglobulin G" or "ASCA-IgG" includes antibodies of the immunoglobulin G isotype that react specifically with *S. cerevisiae*.

[0326] The determination of whether a sample is positive for ASCA-IgA or ASCA-IgG is made using an antigen specific for ASCA. Such an antigen can be any antigen or mixture of antigens that is bound specifically by ASCA-IgA and/or ASCA-IgG. Although ASCA antibodies were initially characterized by their ability to bind *S. cerevisiae*, those of skill in the art will understand that an antigen that is bound specifically by ASCA can be obtained from *S. cerevisiae* or from a variety of other sources so long as the antigen is capable of binding specifically to ASCA antibodies. Accordingly, exemplary sources of an antigen specific for ASCA, which can be used to determine the levels of ASCA-IgA and/or ASCA-IgG in a sample, include, without limitation, whole killed yeast cells such as *Saccharomyces* or *Candida* cells; yeast cell wall mannans such as phosphopeptidomannan (PPM); oligosaccharides such as oligomannosides; neoglycolipids; anti-ASCA idiotypic antibodies; and the like. Different species and strains of yeast, such as *S. cerevisiae* strain Sul, Su2, CBS 1315, or BM 156, or *Candida albicans* strain VW32, are suitable for use as an antigen specific for ASCA-IgA and/or ASCA-IgG. Purified and synthetic antigens specific for ASCA are also suitable for use in determining the levels of ASCA-IgA and/or ASCA-IgG in a sample. Examples of purified antigens include, without limitation, purified oligosaccharide antigens such as oligomannosides. Examples of synthetic antigens include, without limitation, synthetic oligomannosides such as those described in U.S. Patent Publication No. 20030105060, e.g., D-Man β(1-2) D-Man β(1-2) D-Man β(1-2) D-Man-OR, D-Man α(1-2) D-Man a(1-2) D-Man a(1-2) D-Man-OR, and D-Man a(1-3) D-Man α(1-2) D-Man α(1-2) D-Man-OR, wherein R is a hydrogen atom, a C1 to C20 alkyl, or an optionally labeled connector group.
Preparations of yeast cell wall mannans, e.g., PPM, can be used in determining the levels of ASCA-IgA and/or ASCA-IgG in a sample. Such water-soluble surface antigens can be prepared by any appropriate extraction technique known in the art, including, for example, by autoclaving, or can be obtained commercially (see, e.g., Lindberg et al., Gut, 33:909-913 (1992)). The acid-stable fraction of PPM is also useful in the statistical algorithms of the present invention (Sendi et al., Clin. Diag. Lab. Immunol., 3:219-226 (1996)). An exemplary PPM that is useful in determining ASCA levels in a sample is derived from S. uvarum strain ATCC #38926.

Purified oligosaccharide antigens such as oligomannosides can also be useful in determining the levels of ASCA-IgA and/or ASCA-IgG in a sample. The purified oligomannoside antigens are preferably converted into neoglycolipids as described in, for example, Faille et al., Eur. J. Microbiol. Infect. Dis., 11:438-446 (1992). One skilled in the art understands that the reactivity of such an oligomannoside antigen with ASCA can be optimized by varying the mannosyl chain length (Frosh et al., Proc Natl Acad. Sci. USA, 82:1 194-1 198 (1985)); the anomeric configuration (Fukazawa et al., In "Immunology of Fungal Disease," E. Kurstak (ed.), Marcel Dekker Inc., New York, pp. 37-62 (1989); Nishikawa et al., Microbiol. Immunol., 34:825-840 (1990); Poulain et al., Eur. J. Clin. Microbiol., 23:46-52 (1993); Shibata et al., Arch. Biochem. Biophys., 243:338-348 (1985); Trinel et al., Infect. Immun., 60:3845-3851 (1992)); or the position of the linkage (Kikuchi et al., Planta, 190:525-535 (1993)).

Suitable oligomannosides for use in the methods of the present invention include, without limitation, an oligomannoside having the mannotetraose Man(1-3) Man(1-2) Man. Such an oligomannoside can be purified from PPM as described in, e.g., Faille et al, supra. An exemplary neoglycolipid specific for ASCA can be constructed by releasing the oligomannoside from its respective PPM and subsequently coupling the released oligomannoside to 4-hexadecylaniline or the like.

21. Anti-Microbial Antibodies

The determination of anti-OmpC antibody levels in a sample is also useful in the present invention. As used herein, the term "anti-outer membrane protein C antibody" or "anti-OmpC antibody" includes antibodies directed to a bacterial outer membrane porin as described in, e.g., PCT Patent Publication No. WO 01/89361. The term "outer membrane protein C" or "OmpC" refers to a bacterial porin that is immunoreactive with an anti-OmpC antibody.
The level of anti-OmpC antibody present in a sample from an individual can be
determined using an OmpC protein or a fragment thereof such as an immunoreactive
fragment thereof. Suitable OmpC antigens useful in determining anti-OmpC antibody levels
in a sample include, without limitation, an OmpC protein, an OmpC polypeptide having
substantially the same amino acid sequence as the OmpC protein, or a fragment thereof such
as an immunoreactive fragment thereof. As used herein, an OmpC polypeptide generally
describes polypeptides having an amino acid sequence with greater than about 50% identity,
preferably greater than about 60% identity, more preferably greater than about 70% identity,
still more preferably greater than about 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99%
amino acid sequence identity with an OmpC protein, with the amino acid identity determined
using a sequence alignment program such as CLUSTALW. Such antigens can be prepared,
for example, by purification from enteric bacteria such as *E. coli*, by recombinant expression
of a nucleic acid such as Genbank Accession No. K00541, by synthetic means such as
solution or solid phase peptide synthesis, or by using phage display.

The determination of anti-I2 antibody levels in a sample is also useful in the present
invention. As used herein, the term "anti-I2 antibody" includes antibodies directed to a
microbial antigen sharing homology to bacterial transcriptional regulators as described in,
*e.g.*, U.S. Patent No. 6,309,643. The term "I2" refers to a microbial antigen that is
immunoreactive with an anti-I2 antibody. The microbial I2 protein is a polypeptide of 100
amino acids sharing some similarity weak homology with the predicted protein 4 from *C.
pasteurianum*, Rv3557c from *Mycobacterium tuberculosis*, and a transcriptional regulator
from *Aquifex aeolicus*. The nucleic acid and protein sequences for the I2 protein are
described in, *e.g.*, U.S. Patent No. 6,309,643.

The level of anti-I2 antibody present in a sample from an individual can be
determined using an I2 protein or a fragment thereof such as an immunoreactive fragment
thereof. Suitable I2 antigens useful in determining anti-I2 antibody levels in a sample
include, without limitation, an I2 protein, an I2 polypeptide having substantially the same
amino acid sequence as the I2 protein, or a fragment thereof such as an immunoreactive
fragment thereof. Such I2 polypeptides exhibit greater sequence similarity to the I2 protein
than to the *C. pasteurianum* protein 4 and include isotype variants and homologs thereof. As
used herein, an I2 polypeptide generally describes polypeptides having an amino acid
sequence with greater than about 50% identity, preferably greater than about 60% identity,
more preferably greater than about 70% identity, still more preferably greater than about
80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% amino acid sequence identity with a
naturally-occurring 12 protein, with the amino acid identity determined using a sequence alignment program such as CLUSTALW. Such 12 antigens can be prepared, for example, by purification from microbes, by recombinant expression of a nucleic acid encoding an 12 antigen, by synthetic means such as solution or solid phase peptide synthesis, or by using phage display.

[0334] The determination of anti-flagellin antibody levels in a sample is also useful in the present invention. As used herein, the term "anti-flagellin antibody" includes antibodies directed to a protein component of bacterial flagella as described in, e.g., PCT Patent Publication No. WO 03/053220 and U.S. Patent Publication No. 20040043931. The term "flagellin" refers to a bacterial flagellum protein that is immunoreactive with an anti-flagellin antibody. Microbial flagellins are proteins found in bacterial flagellum that arrange themselves in a hollow cylinder to form the filament.

[0335] The level of anti-flagellin antibody present in a sample from an individual can be determined using a flagellin protein or a fragment thereof such as an immunoreactive fragment thereof. Suitable flagellin antigens useful in determining anti-flagellin antibody levels in a sample include, without limitation, a flagellin protein such as Cbir-1 flagellin, flagellin X, flagellin A, flagellin B, fragments thereof, and combinations thereof, a flagellin polypeptide having substantially the same amino acid sequence as the flagellin protein, or a fragment thereof such as an immunoreactive fragment thereof. As used herein, a flagellin polypeptide generally describes polypeptides having an amino acid sequence with greater than about 50% identity, preferably greater than about 60% identity, more preferably greater than about 70% identity, still more preferably greater than about 80%, 85%, 90%, 95%, 96%, 97%, 98%, or 99% amino acid sequence identity with a naturally-occurring flagellin protein, with the amino acid identity determined using a sequence alignment program such as CLUSTALW. Such flagellin antigens can be prepared, e.g., by purification from bacterium such as Helicobacter Bills, Helicobacter mustelae, Helicobacter pylori, Butyrvibrio fibrisolvens, and bacterium found in the cecum, by recombinant expression of a nucleic acid encoding a flagellin antigen, by synthetic means such as solution or solid phase peptide synthesis, or by using phage display.

22. Mast Cell Markers

[0336] The determination of the presence or level of mast cell markers in a sample is also useful in the present invention. As used herein, the term "mast cell marker" includes any protein or metabolite that is indicative of the presence or increased abundance of mast cells,
or mastocytes. In certain embodiments, these mast cell markers may be present on the cell surface of a mast cell and/or be differentially expressed or present within a mast cell. Mast cells are generally found in connective tissue and harbor large granules containing high levels of histamine and heparin. These cells are believed to be derived from CD34+ bone marrow precursor cells and function in several biological processes including wound healing, defense against pathogens, allergy, and anaphylaxis. Non-limiting examples of mast cell markers include tryptase, histamine, prostaglandin E2 (PGE$_2$), prostaglandin D2 (PGD$_2$), carboxypeptidase A, chymase, CD25, CD34, CD$^{117}$ (c-Kit), LAMP-1 (CD107a), LAMP-2 (CD107b), and the like.

[0337] It has been postulated that inflammatory mast cells proximal to intestinal innervation may contribute to abdominal pain experienced in IBS (Rijnierse A. et al, Pharmacol Ther. (2007)). Consistent with this, increased numbers and activation of mast cells are found at intestinal sites in ISB patients. After being localized to the gastrointestinal tract, mast cells may be stimulated by allergens, microbial products, and/or neurotransmitters, to release a wide variety of bioactive mediators that stimulate the secreto-motor reflexes and increase the perceived sensation of abdominal pain. As such, the presence of increased levels of mast cells or mast cell metabolites in the gastrointestinal tract may be diagnostic of IBS. Thus, in one embodiment, biomarkers associated with mast cell degranulation, such as tryptase, prostaglandin E2, histamine, and histamine metabolites (including 4-imidazoleacetic acid, t-methylhistamine, and t-methyl-4-imidazole acetic acid) are useful for the methods of the present invention. In other embodiments, biomarkers that are differentially released from mast cells, including serotonin, nerve growth factor, vascular endothelial cell growth factor, TNF-a, TNF-\(\gamma\), IL-6, and IL-8 are useful for the methods of the present invention.

[0338] In certain instances, the presence or level of a mast cell marker is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of a mast cell marker is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay.

[0339] In certain embodiments, the mast cell marker may be tryptase, histamine, prostaglandin E2 (PGE$_2$), or a combination thereof. In yet other embodiments, the presence or increased abundance of mast cells may be detected by using an anti-Ki antibody, such as a Ki-MCl or Ki-M1P monoclonal antibody (Hamann K. et al, Br J Dermatol. (1995)), or with
a fluorescent berberine binding assay (Berlin and Enerback, *Int Arch Allergy Appl Immunol.* (1983)).

23. **Gastrointestinal hormones**

[0340] The determination of the presence or level of at least one gastrointestinal hormone in a sample is also useful in the present invention. As used herein, the term "gastrointestinal hormone" includes a chemical or peptide present in the intestinal tract that is released by a cell, which alters the metabolism of a second cell located in the organism. Generally, hormones promote a response in a target cell after binding to a specific receptor located on the surface of the cell. In animals, hormones are commonly transported throughout the body in the bloodstream, however, they may also be translocated by diffusion. In this fashion, endocrine hormone molecules are secreted directly into the bloodstream, while exocrine hormones are secreted directly into a duct, from which they traverse into the bloodstream or alternatively diffuse throughout the body via paracrine signaling. Non-limiting examples of gastrointestinal hormones suitable for use as IBS markers include calcitonin gene-related peptide (CGRP), substance P, nerve growth factor (NGF), neurokinin A, neurokinin B, vasoactive intestinal peptide (VIP), glucagon-like peptide 1 (GLP-1), glucagon-like peptide 2 (GLP-2), motilin, pituitary adenylate cyclase-activating peptide (PACAP), secretin, cholecystokinin, neuropeptide Y, pancreatic polypeptide, peptide YY, enteroglucagon, and glucose-dependent insulinotropic peptide.

[0341] In certain instances, the presence or level of a gut peptide hormone marker is detected at the level of mRNA expression with an assay such as, *e.g.*, a hybridization assay, an amplification-based assay, *e.g.* qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of a peptide hormone marker is detected at the level of protein expression using, *e.g.*, an immunoassay (*e.g.*, ELISA), an immunohistochemical assay, or a mass spectrometry based assay.

24. **Calcitonin gene-related peptide (CGRP)**

[0342] CGRP is a member of the calcitonin family of peptides, which in humans exists in two mature forms, α-CGRP and β-CGRP. α-CGRP is a 37 amino acid peptide: ACDTATCVTHRLAGLLSRSGGVVKNFVPTNVGSKAF-NH2 (SEQ ID NO:1) formed from the alternative splicing of the calcitonin/CGRP gene. β-CGRP is a related 37 amino acid polypeptide ACNTATCVTHRLAGLLSRSGMVKSFSVPTNVGSKAF-NH2 (SEQ ID NO:2) formed from the calcitonin-related polypeptide, beta precursor gene. In certain
instances, CGRP may consist of a calcitonin isoform CGRP preproprotein (NP_00 1029 125), or variant thereof (such as NP_001029124 or NP_001732), CGRP propeptide (CAA34070), or calcitonin-related polypeptide, beta precursor (NP_0007 19).

CGRP is one of the most abundant peptides produced in both peripheral and central neurons (Rosenfeld MG et al, Nature (1983)), and is the most potent peptide vasodilator and can function in the transmission of pain (Brian SD et al, Nature (1985); McCulloch et al, PNAS (1986)). CGRP is thought to play a role in cardiovascular homeostasis and nociception by mediating its effects though a heteromorphic receptor composed of a G protein-coupled receptor called calcitonin receptor-like receptor (CLR) and a receptor activity-modifying protein (RAMP1) (Poyner DR et al, Pharmacol Rev. (2002)).

In certain instances, the presence or level of a CGRP or precursor thereof, is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of a peptide hormone marker is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of a CGRP in a serum, plasma, saliva, or urine sample are available from, e.g., Cayman Chemical Co. (Ann Arbor, MI), Bachem Holding AG/Peninsula Laboratories, LLC (San Carlos, CA), and BioPorto Diagnostics (Denmark).

25. Substance P

Substance P is a peptide of 11 amino acids in length (RPKPQFFGLM-NH₂; SEQ ID NO: 3) that is released by nerve endings in both the central and peripheral nervous systems. Among the numerous biological sites innervated by substance P-releasing neurons are the skin, intestines, stomach, bladder, and cardiovascular system. Substance P is derived from a polypeptide precursor after differential splicing of the preprotachykinin A gene (TAC1; NM_003173). In certain embodiments, substance P or a substance P precursor protein may be useful as a marker of IBS, for example a TAC1 polypeptide (NP_003173; NP_054704; NP_054702; and NP_054703) or transcript thereof.

In certain instances, the presence or level of substance P or precursor thereof, is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of a peptide hormone marker is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an
immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for
determining the presence or level of substance P in a serum, plasma, saliva, or urine sample
are available from, e.g., Cayman Chemical Co. (Ann Arbor, MI), Bachem Holding AG/
Peninsula Laboratories, LLC (San Carlos, CA), and MD Biosciences Inc. (St. Paul, MN).

26. Nerve Growth Factor (NGF)

NGF is a member of the NGF-beta family and is a secreted protein which
homodimerizes and is incorporated into a larger complex. NGF has nerve growth stimulating
activity and the complex is involved in the regulation of growth and the differentiation of
sympathetic and certain sensory neurons, a small secreted protein which induces the
differentiation and survival of particular target neurons. NGF binds to at least two receptors
on the surface of cells which are capable of responding to this growth factor, TrkA and
LNGFR. NGF is a small polypeptide (residues 122-241 of NP_002497) that is derived from
a precursor polypeptide (NP_002497) encoded by the NGF gene (NM_002506). In certain
embodiments, NGF, an NGF precursor polypeptide, or NGF propeptide (residues 19-121 of
NP_002497) may be useful as an IBS marker.

In certain instances, the presence or level of NGF or a precursor thereof, is detected
at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an
amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based
assay. In certain other instances, the presence or level of NGF, a precursor thereof, or a
proprotein thereof, is detected at the level of protein expression using, e.g., an immunoassay
(e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable
ELISA kits for determining the presence or level of NGF in a serum, plasma, saliva, or urine
sample are available from, e.g., Millipore (Billerica, MA), CUSABIO Biotech Co., Ltd.
(Newark, DE), Emelca Biosciences (Belgium), and Signosis, Inc. (Sunnyvale, CA).

27. Neurokinin A

Neurokinin A is a peptide of 10 amino acids in length (HKTDSFVGLM; SEQ ID
NO:4) derived from a polypeptide precursor after differential splicing of the preprotachykinin
A gene (TAC1; NM_003182). The peptide is a member of the tachykinin family of
neuropeptide neurotransmitters. In certain embodiments, neurokinin A or a neurokinin A
precursor protein may be useful as a marker of IBS, for example a TAC1 polypeptide
(NPJ303173 and NP_054703) or transcript thereof.
In certain instances, the presence or level of neurokinin A or precursor thereof, is detected at the level of mRNA expression with an assay such as, *e.g.*, a hybridization assay, an amplification-based assay, *e.g.* qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of neurokinin A is detected at the level of protein expression using, *e.g.*, an immunoassay (*e.g.* ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of neurokinin A in a serum, plasma, saliva, or urine sample are available from, *e.g.*, Abeam (Cambridge, MA), Fitzgerald Industries (North Acton, MA), and RayBiotech, Inc (Norcross, GA).

28. Neurokinin B

Neurokinin B is a peptide of 10 amino acids in length (DMHDFVFGLM-NH$_2$; SEQ ID NO:5) derived from the tachykinin 3 precursor (NP_037383), which is encoded by the tachykinin 3 gene (TAC3; NM_003182). The peptide is a member of the tachykinin family of neuropeptide neurotransmitters. In certain embodiments, neurokinin B or a neurokinin B precursor protein may be useful as a marker of IBS, for example a TAC3 polypeptide (NP_037383) or transcript thereof.

In certain instances, the presence or level of neurokinin B or precursor thereof, is detected at the level of mRNA expression with an assay such as, *e.g.*, a hybridization assay, an amplification-based assay, *e.g.* qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of neurokinin B is detected at the level of protein expression using, *e.g.*, an immunoassay (*e.g.* ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of neurokinin B in a serum, plasma, saliva, or urine sample are available from, *e.g.*, Abeam (Cambridge, MA), Bachem Holding AG/ Peninsula Laboratories, LLC (San Carlos, CA), and RayBiotech, Inc (Norcross, GA).

29. Vasoactive Intestinal Peptide (VIP)

VIP is a 28 amino acid peptide hormone (HSDAVFTDNYTRLRKMAVKKYLNSILN; SEQ ID NO:6) found in the gut, pancreas, and hypothalamus of humans. This peptide induces smooth muscle relaxation, causes inhibition of gastric acids secretion and absorption from the intestinal lumen, and stimulates the secretion of water into pancreatic juice and bile. VIP is derived from a polypeptide precursor after differential splicing of the vasoactive intestinal peptide gene (Entrez GeneID:
In certain embodiments, VIP, a VIP precursor protein (such as NP_919416 or NP_003372), a VIP propeptide, or a transcript encoding a VIP peptide (such as NM_003381 or NM_194435) may be useful as a marker of IBS.

In certain instances, the presence or level of VIP is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of VIP, a precursor thereof, or a propeptide thereof is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of VIP in a serum, plasma, saliva, or urine sample are available from, e.g., Phoenix Pharmaceuticals, Inc. (Burlingame, CA), BioPorto Diagnostics (Denmark), and RayBiotech, Inc (Norcross, GA).

30. **Glucagon-Like Peptide 2 (GLP-2)**

GLP-2 is a 33 amino acid peptide hormone (HADGSFSDEMNTILDNLAARDFINWLIQTKITD; SEQ ID NO:7) that is expressed in the intestines, pancreas, and brain. GLP-2 is known to be co-secreted with GLP-1 into the intestines, where it functions to regulate gastric motility, secretion, sugar transport, and cellular differentiation and proliferation. GLP-2 is derived from proglucagon, a polypeptide precursor encoded by the glucagon gene (CGC; NM_002054). In certain embodiments, GLP-2, a GLP-2 precursor protein (such as NP_002045), a GLP-2 propeptide, or a transcript encoding a GLP-2 peptide (such as NM_002054) may be useful as a marker of IBS.

In certain instances, the presence or level of GLP-2 is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of GLP-2, a precursor thereof, or a propeptide thereof is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of GLP-2 in a serum, plasma, saliva, or urine sample are available from, e.g., RayBiotech, Inc (Norcross, GA), BioSupply UK (England), and BioCat GmbH (Germany).
31. Motilin

[0357] Motilin is a 22 amino acid peptide hormone (FVPIFTYGELQRMQEKERNKGQ; SEQ ID NO:8) that is secreted from endocrine M cells located in the small intestines. Once released, motilin stimulates the production of pepsin and regulates migrating motor complexes, which are responsible for the transportation of indigestible substances through the digestive tract. Motilin is derived from promotilin, a precursor polypeptide encoded by the motilin gene (MLN; Entrez GeneID: 4295). Transcription of the MLN gene undergoes differential splicing into one of two isoforms (NM_002418 and NMJX) 1040109, which result in the translation of two different precursor polypeptides (NPJ302409 and NP_001035198). In certain embodiments, motilin, a motilin precursor polypeptide, a motilin propeptide (such as motilin-associated peptide), or a transcript encoding motilin may be useful as a marker of IBS.

[0358] In certain instances, the presence or level of motilin is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of motilin, a precursor thereof, or a propeptide thereof is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of motilin in a serum, plasma, saliva, or urine sample are available from, e.g., Abeam (Cambridge, MA), CUSABIO Biotech Co., Ltd. (Newark, DE), and Phoenix Biotech (China).

32. Pituitary Adenylate Cyclase-Activating Peptide (PACAP)

[0359] PACAP is a vasoactive neuropeptide (VN) found throughout the nervous system, gastrointestinal tract, and lymphatic system. VNs, such as PACAP and VIP, function as neurotransmitters, neuroregulators, neurotropic stimulators, hormonal regulators, vasodilators, and immune and nociception modulators. PACAP is a precursor protein (NP_001108) encoded by the Adenylate Cyclase Activating Polypeptide 1 (pituitary) gene (ADCYAPI; Entrez GeneID: 1271617). Transcription of the ADCYAPI gene undergoes differential splicing into one of two isoforms (NMJX) 1099733 and NM_001117), which result in the translation of two different precursor polypeptides (NP_0011093203 and NP_001108). The expressed PACAP polypeptide is further processed into various smaller peptides, including two propeptides, PACAP-related peptide (DVAHGILNEAYRKVLDSAGKHLQSLVARVGGSLGGGAGDDAEPLS; SEQ ID
NO:9), pituitary adenylate cyclase-activating polypeptide 38
(HSDGIFTDSYRSYKQMAVKKYLAVALGKRYKQRVKNK; SEQ ID NO: 10), and
pituitary adenylate cyclase-activating polypeptide 27
(HSDGIFTDSYRSYKQMAVKKYLAVALGKRYKQRVKNK; SEQ ID NO: 11). In certain embodiments,
PACAP, a PACAP precursor polypeptide, a PACAP propeptide (such as PACAP-related
peptide, pituitary adenylate cyclase-activating polypeptide 38, and pituitary adenylate
cyclase-activating polypeptide 27), or a transcript encoding PACAP may be useful as a
marker of IBS.

[0360] In certain instances, the presence or level of PACAP is detected at the level of
mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based
assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other
instances, the presence or level of PACAP, a precursor thereof, or a propeptide thereof is
detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an
immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for
determining the presence or level of PACAP in a serum, plasma, saliva, or urine sample are
available from, e.g., Santa Cruz Biotechnology, Inc. (Santa Cruz, CA), US Biological
(Swampscott, MA), and Novus Biologicals (Littleton, CO).

33. Serotonin Metabolites

[0361] The determination of the presence or level of at least one serotonin (5-
hydroxytryptamine; 5-HT) metabolite in a sample is also useful in the present invention. As
used herein, the term "serotonin metabolite" includes serotonin, serotonin biosynthesis
intermediates, and serotonin metabolites. Serotonin is primarily found in the gastrointestinal
tract, where it functions to regulate intestinal movements, and to a lesser extent in the central
nervous systems, where it participates in the regulation of mood, appetite, sleep, muscle
contraction, and various cognitive functions. Serotonin levels are upregulated in the
gastrointestinal tracts of IBS patients. Further, serotonin concentrations are higher in IBS(D)
than IBS(C). However, fluctuations in serotonin levels are not easily measured in plasma due
to the tight regulation of re-uptake into blood platelets by the serotonin transporter (SERT).
As such, in one embodiment provided herein, serotonin metabolites may be detected in
biological samples, such as blood and urine, in order to reflect the concentration of serotonin
in the gut, for the diagnosis of IBS. Non-limiting examples of serotonin metabolites suitable
for use as IBS markers include tryptophan, 5-HT-o-sulfate, serotonin O-sulfate (5-
Hydroxytryptamine O-sulfate; 5-HT-o-sulfate), 5-Hydroxyindoleacetic acid (5-HIAA), 5-HT glucuronide (5-HT-GA), and 5-hydroxytrytophol (5-HTOL).

[0362] In certain instances, the presence or level of a serotonin metabolite is detected with a mass spectrometry based assay, a proton magnetic resonance spectroscopy based assay, a chromatographic assay (e.g., liquid chromatographic assay or HPLC), an immunoassay, (e.g., ELISA), and the like.

34. Enteric Nervous System Serum Metabolites

[0363] The determination of the presence or level of at least one enteric nervous system serum metabolite in a sample is also useful in the present invention. As used herein, the term "enteric nervous system serum metabolite" includes dopamine, norepinephrine, epinephrine, tyrosine, phenylalanine, dopamine, norepinephrine, epinephrine biosynthesis intermediates, and dopamine, norepinephrine, epinephrine metabolites. In one embodiment provided herein, enteric nervous system serum metabolites may be detected in biological samples, such as blood and urine, in order to diagnose, sub-type, or provide a prognosis for IBS. In certain embodiments, an elevated level of tyrosine is associated with or indicative of IBS or associated with an increased likelihood of IBS. In other embodiments, an elevated level of tyrosine is associated with or indicative of IBS-D or IBS-M. In another embodiment, an elevated level of phenylalanine is associated with or indicative of IBS or associated with an increased likelihood of IBS. In other embodiments, an elevated level of phenylalanine is associated with or indicative of IBS-D or IBS-M.

[0364] In certain instances, the presence or level of an enteric nervous system serum metabolite is detected with a mass spectrometry based assay, a proton magnetic resonance spectroscopy based assay, a chromatographic assay (e.g., liquid chromatographic assay or HPLC), an immunoassay, (e.g., ELISA), and the like.

1. Serotonin Pathway Markers

[0365] The determination of the presence or level of at least one serotonin pathway marker in a sample is also useful in the present invention. As used herein, the term "serotonin pathway marker" includes genes, proteins, and enzymes involved in the biosynthesis or metabolism of serotonin, or the regulation of serotonin levels in the gastrointestinal tract.

Non-limiting examples of serotonin pathway markers suitable for use as IBS markers include UDP-glucuronosyltransferase 1-6 (uGT1 A6), serotonin reuptake transporter (SERT),
tryptophan hydroxylase 1 (TPH1), monoamine oxidase A (MAO-A), monoamine oxidase B (MAO-B), and hydroxytryptamine receptor 3A (5-HT3A; 5-HT3R).

1. UDP-glucuronosyltransferase 1-6 (UGT1A6)

[0366] UGT1 A6 is a member of UDP-glucuronosyl/UDP-glucosyltransferase superfamily of membrane-bound enzymes of the ER, which catalyze the glucuronidation of various substrates. The UDP-glucuronosyl/UDP-glucosyltransferase superfamily of enzymes catalyzes the addition of the glycosyl group from a UTP-sugar to a small hydrophobic molecule. Mammalian UDP-glucuronosyltransferases are described in, e.g., Burchell et al., DNA Cell Biol., 10(7):487-94 (1991). These enzymes share a conserved domain of about 50 amino acid residues in their C-terminal region and play a major role in the detoxification and subsequent elimination of xenobiotics such as drugs (e.g., topoisomerase I inhibitors) and carcinogens. It was previously discovered that serotonin is a specific endogenous substrate of UGT1A6 (King C. et al, Arch Biochem Biophys (1999)). UGT1A6, an E.C.2.4.1.17 enzyme, is encoded by the UDP glucuronosyl transferase 1 family, polypeptide A6 gene (UGT1 A6; Entrez GeneID: 54578) and matures from one of two precursor polypeptides (NP_001063 and NP_995584) after alternative splicing of the transcript (NM_001072 and NM_205862). Several alleles exist for the UGT1 A6 gene, including UGT1 A6*1, UGT1A6*2, UGT1A6*3, and UGT1 A6*4 (Nagar S. et al., Pharmacogenetics (2004)). These haplotypes contain various combinations of known UGT1 A6 SNPs, which include rs6759892 (158 T>G), rs1042708 (348 C>A), rs2070959 (680 A>G), rs1 105879 (691 A>G), and rs1042709 (1667 G>C). In certain embodiments, UGT1 A6, a precursor protein thereof, a UGT1 A6 mRNA, or a UGT1 A6 SNP, haplotype, or genotype may be useful as a marker of IBS.

[0367] In certain instances, the presence or level of UGT1 A6 is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of UGT1 A6 or a precursor thereof is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of UGT1 A6 in-a serum, plasma, saliva, or urine sample are available from, e.g., Abnova (Walnut CA) and Santa Cruz Biotechnology, Inc. (Santa Cruz, CA). In yet other instances, a SNP or particular haplotype or genotype of the UGT1 A6 gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.
2. Serotonin-Selective Reuptake Transporter (SERT)

SERT is a member of the monoamine transporter family of membrane-bound receptors that facilitate the transport of monoamine neurotransmitters into and out of cells. The serotonin receptor (SERT) mediates the uptake of serotonin into neurons and platelets, thereby regulating serotonin levels in vivo. Polymorphisms in the SERT gene have previously been associated with various diseases, including sudden infant death syndrome (SIDS), Alzheimer's disease, post-traumatic stress disorder, depression, pulmonary hypertension, myocardial infarction, and IBS (for review, see, Murphy DL et ai, Mol Interv. (2004)). SERT is a 70 kDa transmembrane receptor (NP_001036) encoded by the solute carrier family 6 (neurotransmitter transporter, serotonin), member 4 gene (SLC6A4; Entrez GenID: 6532; NM_001045). Various SNPs have been identified in the SLC6A4 gene, including rs6355 (472 G>C), rs2228673 (908 G>C), rs289 14832 (1578 A>C), rs289 14833 (1698 T>C), rs28914834 (1953 C>G), rs6352 (2120 A>C), and I425V. Furthermore, polymorphisms in the promoter region of the SLC6A4 gene, including an A>G polymorphism (rs25531) and a deletion of 44 base pair polymorphism, which results in the short variant (rs4795541; Heils A et ai, J Neurochem. (1996)), have been described. In certain embodiments SERT, an SLC6A4 mRNA, or an SLC6A4 SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

In certain instances, the presence or level of SERT is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of SERT is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of SERT in a serum, plasma, saliva, or urine sample are available from, e.g., Abgent, Inc. (San Diego, CA), OriGene Technologies (Rockville, MD), and Abeam (Cambridge, MA). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the SLC6A4 gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

3. Tryptophan Hydroxylase 1 (TPH1)

TPH1 is an E.C.I .14.16.4 enzyme that catalyzes the hydroxylation of L-tryptophan to form 5-hydroxytryptophan, an intermediate of serotonin biosynthesis. Two isoforms of
tryptophan hydroxylase (TPH1 and TPH2) are found in the gut and central nervous systems of mammals. TPH1 is the predominant isoform found in the gut and TPH2 is the predominant isoform expressed in the central nervous system. Specifically, TPHs are expressed in several cell lineages, including raphe neurons, pinealocytes, mast cells, mononuclear leukocytes, beta-cells of the islets of Langerhans, and intestinal and pancreatic enterochromaffin cells. TPH1 is a 50 kDa protein (NP_004170) encoded by the tryptophan hydroxylase 1 gene (TPH1; Entrez GeneID: 7166; NM_004179). Several SNPs have been identified in the TPH1 gene, including rs172423 (301+1281 G>A), rs211102 (930+629 A>G), rs10488683 (402+1276 A>G), rs684302 (1117+1840 C>T), rs503964 (723 C>T), rs490895 (789 C>T), rs4 1274350 (820 C>A), rs4 1274348 (929 C>T), and rs56151798 (1095 T>C). Several TPH1 SNPs are associated with psychiatric disorders, including impulsive-aggression measures (New AS et al., Am J Med Genet. (1998)) and schizophrenia (Allen NC et al, Nat Genet. (2008)). In certain embodiments TPH1, a TPH1 mRNA, or a TPH1 SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

[0371] In certain instances, the presence or level of TPH1 is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of TPH1 is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of TPH1 in a serum, plasma, saliva, or urine sample are available from, e.g., Novus Biologicals (Littleton, CO) and Abeam (Cambridge, MA). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the TPH1 gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

4. Monoamine oxidase A (MAO-A)

[0372] MAO-A, an E.C. 1.4.3.4 enzyme, is a member of the enzyme family of flavin-containing amine oxidoreductases. This enzyme, which is localized to the outer mitochondrial membrane, catalyzes the deamination of neuroactive and vasoactive amines, including serotonin, norepinephrine, and epinephrine, with the aid of a FAD cofactor. MAO-A is 59.7 kDa protein (NP_000231) encoded by the monoamine oxidase A gene (MAOA; Entrez GeneID: 4128; NM_000240). Several SNPs have been identified in the MAOA gene, including rs1800464 (566 A>C), rs58524323 (696 G>A), rs1137068 (818 G>T), rs72554632
SNPs have been associated with disorders, including autism spectrum disorder (Yoo HJ et al, Neurosci Res. (2009)), bipolar affective disorder (Lin et al., Behav Brain Funct. (2008)), and Attention-deficit/hyperactivity disorder (Rommelse NN et al., Am J Med Genet B Neuropsychiatr Genet. (2008)). In certain embodiments MAO-A, an MAOA mRNA, or an MAOA SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

[0373] In certain instances, the presence or level of MAOA is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of MAO-A is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of MAO-A in a serum, plasma, saliva, or urine sample are available from, e.g., Novus Biologicals (Littleton, CO), Abeam (Cambridge, MA), and Abnova (Walnut, CA). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the MAOA gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

5. **Monoamine oxidase B (MAO-B)**

[0374] MAO-B, an E.C.I.4.3.4 enzyme, is a member of the enzyme family of flavin-containing amine oxidoreductases. MAO-B shares about 70% sequence identity with MAO-A, and like MAO-A is localized to the outer mitochondrial membrane and catalyzes the deamination of neuroactive and vasoactive amines. MAO-B preferentially deaminates benzylamine, phenylethylamine, and dopamine. Due to the fact that MAO-A deaminates serotonin and epinephrine with higher affinity than MAO-B, MAO-B inhibitors are preferred over MAO-A inhibitors for first-line treatment of depression. MAO-B is 58.8 kDa protein (NP_000889) encoded by the monoamine oxidase B gene (MAOB; Entrez GeneID: 4129; NM_000898). Several SNPs have been identified in the MAO-B gene, including rsl 2010260 (260 G>T), rsl 7856663 (289 G>A), rsl 7852046 (565 OA), rsl 12845783 (767 A>C), rsl 2850496 (775 C>A), rsl 2845773 (777 A>C), rs7879356 (782 A>G), rs 55815323 (1087...
C>T), rs5952696 (1229 A>G), rs6324 (1637 C>T), rs1040399 (NT_079573.3, position 6477166 C>T), and rs6651806 (NTJ379573.3, position 6540731 A/C). Several MAOB SNPs have been associated with disorders, including attention deficit hyperactivity disorder (Li J et al., Am J Med Genet B Neuropsychiatr Genet. (2008) and vulnerability of major depression (Dlugos AM et al., J Neural Transm. (2009)). In certain embodiments MAO-B, an MAOB mRNA, or an MAOB SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

[0375] In certain instances, the presence or level of MAO-B is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of MAO-B is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of MAO-B in a serum, plasma, saliva, or urine sample are available from, e.g., Novus Biologicals (Littleton, CO), Abeam (Cambridge, MA), and Santa Cruz Biotechnology, Inc. (Santa Cruz, CA). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the MAOB gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

6. Hydroxytryptamine Receptor 3A (5-HT3R)

[0376] 5-HT3R is a member of the ligand-gated ion channel receptor superfamily. The 5-HT3R polypeptide is a subunit of the pentameric transmembrane 5-HT₃ receptors, which may consist of homopentameric 5-HT3R or heteropentameric structures containing at least one 5-HT3R subunit. The 5-HT₃ receptor is an ion conducting pore that when bound by serotonin elicits a conformational change resulting in an excitatory response in neurons. It has been recently shown that microRNAs contribute to the regulation of HT3R receptors (Kapeller J et al., Hum Mol Genet. (2008)). The 5-HT3R protein is encoded by the 5-hydroxytryptamine (serotonin) receptor 3A gene (HTR3A; Entrez GeneID: 3359) and is processed by removal of a signal peptide from the precursor polypeptide (NP_000860, NP_001155244, and NP_998786) after alternative splicing of the transcript (NM_000869, NM_001161772, and NM_0213621). Several SNPs have been identified in the HTR3A gene, including rs33940208 (168 C>T), rs72466464 (170 OT), rs72466465 (205 G>A), rs72466467 (705 G>T), rs34327364 (714 G>A), rs4938063 (896 G>A), rs56232120 (969 G>A), rs35815285 (1169

112
G>A), rs12285005 (1198 C>T), rs35592083 (1320 C>T), rs341 11946 (1471 G>A),
rs35944954 (1479 C>T), rs176713 (1515 A>G), rs1 50220 (NT_033899.7, position
17420302 C/T), and rs1 062613 (97 C>T). Several HTR3A SNPs have been associated with
disorders, including treatment-resistant schizophrenia (Ji et al, Neurosci Lett. (2008)) and
autism (Anderson et al, Neurogenetics (2009)). In certain embodiments 5-HT3R, an
HTR3A mRNA, an HTR3A microRNA, or an HTR3A SNP, haplotype, polymorphic variant,
or genotype may be useful as a marker of IBS.

[0377] In certain instances, the presence or level of HTR3A is detected at the level of
mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based
assay, e.g., qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other
instances, the presence or level of 5-HT3R is detected at the level of protein expression using,
e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry
based assay. Suitable ELISA kits for determining the presence or level of 5-HT3R in a
serum, plasma, saliva, or urine sample are available from, e.g., RayBiotech, Inc (Norcross,
GA) and Santa Cruz Biotechnology, Inc. (Santa Cruz, CA). In yet other instances, a SNP,
polymorphism, or particular haplotype or genotype of the HTR3A gene is detected with an
assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-
PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

J. Stress Markers

[0378] The determination of the presence or level of at least one stress marker in a sample
is also useful in the present invention. As used herein, the term "stress marker" includes any
peptide, hormone, metabolite, protein or gene that functions to mediate the central nervous
system's response to stress. These markers include hormones released in response to stress,
metabolites that are differentially produced in response to stress, genes and proteins that are
differentially expressed in response to stress, and cellular receptors that bind stress-dependent
hormones and metabolites. Non-limiting examples of stress markers suitable for use as IBS
markers include corticotrophin-releasing hormone (CRH; CRF), Urocortin (Ucn),
Corticotropin-releasing hormone-binding protein (CRFPB), and Adrenocorticotropic
hormone (ACTH, corticotrophin).

1. Corticotrophin-releasing hormone (CRH; CRF)

CRH is a neuroendocrine hormone involved in the stress response of the central nervous
system. This hormone mediates many of the stress-related peripheral effects and behavioral
responses. CRH has been shown to be involved in stress-induced motility in both the upper and lower gastrointestinal tract. CRH is a 41-amino acid peptide hormone (SEEPPISLDTFHLLREVLEMAARAEQLAQHAHSNKLMEII; SEQ ID NO: 12) that is derived from a precursor polypeptide (corticotrophin releasing hormone precursor; NP_000747) encoded by the corticotropin releasing hormone gene (CRH; Entrez GeneID:1392; NM_000756). Several SNPs have been identified in the CRH gene, including rs1272151(189 OG), rs72556398 (236 G>C), rs3832590 (330 -CGG>CGCCCG), rs6159 (473 A>G), rs28364016 (692 G>C), rs28364017 (NT_008183.18, position 18943997 A/G), and rs28364014 (NT_008183.18, position 18943683 G>C). In certain embodiments CRH, a CRH precursor polypeptide, a CRH propeptide, a CRH mRNA, or a CRH SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

[0379] In certain instances, the presence or level of CRH is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of CRH is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of CRH in a serum, plasma, saliva, or urine sample are available from, e.g., IBL America (Minneapolis, MN) and Abbiotec (San Diego, CA). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the CRH gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

2. **Urocortin 1 (Ucn)**

[0380] Ucn is a peptide hormone and member of the sauvagine/corticotropin-releasing factor/urotensin I family. Urocortin has high affinity for both the CRF-1 and CRF-2 receptors and is a more potent anorectic than CRH. Unlike CRH, which is predominantly produced in the hypothalamus, UCN is produced in the gastrointestinal tract and as such, is more easily detected in plasma than is CRH. UCN is a 40-amino acid peptide hormone (DNPSLSIDLTFTFHLRLTLELARTSQRERAENRIFDVS; SEQ ID NO: 13) that is derived from a precursor polypeptide (urocortin preproprotein; NP_003344) encoded by urocortin gene (UCN; Entrez GeneID:7349; NM_003353). Several SNPs have been identified in the CRH gene, including rs11557508 (NT_022184.14; position 6347221 C/T), rs28364046 (NT_022184.14; position 6346948 A/G), rs35403114 (NT_022184.14; position
6346902 C/T), rs6709781 (NT_022184.14; position 6346798 C/G), rs28364045 (525 C>T),
and rsl 1557507 (NT_022 184.14; position 63461 18 G/T). In certain embodiments UCN, a
UCN precursor polypeptide, a UCN propeptide, a UCN mRNA, or a UCN SNP, haplotype,
polyomorphic variant, or genotype may be useful as a marker of IBS.

In certain instances, the presence or level of UCN is detected at the level of mRNA
expression with an assay such as, e.g., a hybridization assay, an amplification-based assay,
e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other
instances, the presence or level of UCN is detected at the level of protein expression using,
e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry
based assay. Suitable ELISA kits for determining the presence or level of UCN in a serum,
plasma, saliva, or urine sample are available from, e.g., Novus Biologicals (Littleton, CO),
Abeam (Cambridge, MA), and US Biological (Swampscott, MA). In yet other instances, a
SNP, polymorphism, or particular haplotype or genotype of the UCN gene is detected with an
assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-
PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

3. Corticotropin-releasing hormone-binding protein (CRHBP)

[0381] CRHBP binds with high affinity to both CRH and Ucn, preventing CRF receptor
activation and thus modulating the bioactivity and bioavailability of these peptide hormones.
Strikingly, these interactions are mediated by distinct binding surfaces on CRHBP (Huising
et al., J Biol Chem. (2008)). CRHBP is a secreted glycoprotein derived from a precursor
polypeptide (NP_001873) encoded by the corticotropin releasing hormone binding protein
gene (CRHBP; Entrez GeneID:1393; NM_001882). Several SNPs have been identified in
the CRHBP gene, including rsl 133082 (372 C>A), rs1053967 (529 OT), rs34347676 (544
G>A), rs26844303 (547 C>G), rs3792738 (NT_006713.14, position 26842142 A/C),
rs41272246 (NT_006713.14, position 26843420 A/C), and rs2135078 (NT_006713.14,
position 26859826 C/T). Several CRHBP SNPs have been associated with disorders,
including anxiety and alcohol abuse disorders (Enoch MA et al, PLoS One (2008)) and
spontaneous preterm birth (Velez DR et al, PLoS One (2008)). In certain embodiments
CRHBP, a CRHBP mRNA, or a CRHBP SNP, haplotype, polymorphic variant, or genotype
may be useful as a marker of IBS.

In certain instances, the presence or level of CRHBP is detected at the level of mRNA
expression with an assay such as, e.g., a hybridization assay, an amplification-based assay,
e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other
instances, the presence or level of CRHBP is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of CRHBP in a serum, plasma, saliva, or urine sample are available from, e.g., Abgent, Inc. (San Diego, CA), Abbiotec (San Diego, CA), and Alpc (Salem, NH). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the CRHBP gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

4. Cortisol

[0382] Cortisol is a corticosteroid hormone produced in the adrenal gland in response to stress and anxiety. Production of the glucocorticoid is regulated by CRH and the adrenocorticotropic hormone (ACTH). After being released in response to stress or anxiety, Cortisol functions to help restore homeostasis, and affects the levels of multiple metabolites in the body, including insulin, collagen free amino acids in serum, gastric acid secretion, sodium, potassium, water, and copper. In certain instances, the presence or level of Cortisol is detected with a mass spectrometry based assay, a proton magnetic resonance spectroscopy based assay, a chromatographic assay (e.g., liquid chromatographic assay or HPLC), an immunoassay, (e.g., ELISA), a fluorescence resonance energy transfer (FRET) based assay (Yu et al., Assay Drug Dev Technol. (2007)), an enzyme fragment complementation based assay (Kumar A et al, Biosens Bioelectron. (2007)), a fluorimetric assay (Appel D et al, Anal Bioanal Chem. (2005)), and the like.

5. Adrenocorticotropic hormone (ACTH, corticotrophin)

[0383] ACTH is a 39 amino acid tropic hormone (SYSMEHFRWGBKPGKRRPVKVYPNGAESAEAEFPLEF; SEQ ID NO: 14) produced and secreted by the anterior pituitary, which functions to stimulate production and release of thyroid hormone by the thyroid gland. ACTH is commonly produced in response to biological stress and affects the increased production of androgens and Cortisol from the adrenal cortex. ACTH is derived from the mature form of the pro-opiomelanocortin preprotein (NP_000930; NP_001030333) which is translated after alternative splicing of the proopiomelanocortin gene(POMC; Entrez GeneID:5443; NM_000939; NM_001035256). Pro-opiomelanocortin preprotein is heavily processed into 11 potential polypeptides, including NPP (residues 27-102), Melanotropin gamma (residues 77-87), a potential peptide (residues 105-134), corticotrophin (residues 138-176), melanotropin alpha (residues 138-
150), corticotropin-like intermediary peptide (residues 156-176), lipotropin beta (residues 179-267), lipotropin gamma (residues 179-234), melanotropin beta (residues 217-234), beta-endorphin (residues 237-267), and Met-enkephalin (residues 237-241). Several SNPs have been identified in the POMC gene, including rs8 192605 (281 C>T), rs28932470 (421 A>G), rs28932471 (448 C>T), rs28930368 (545 OT), rs35254395 (552insAGCAGCGGC), rs10654394 (560insGCCGCTGCT), rs34650613 (609 C>T), rs8 192606 (657 C>G), rs45463492 (697 G>T), rs2071345 (848 OT), rs28932472 (969 C>G), rs3754860 (NT_022184.14, position 4209187 C/T), rs1009388 (NT_022184.14, position 4207034 C/G), and rs1042571 (NT_022184.14, position 4199820 C/T). Several POMC SNPs have been associated with disorders, including Parkinson's disease (Shadrina M et al, Neurosci Lett. (2006)), obesity (Ahituv N et al, Am J Hum Genet. (2007), and substance dependence (Zhang H et al, Biol Psychiatry (2009)). In certain embodiments ACTH, a POMC mRNA, or a POMC SNP, haplotype, polymorphic variant, or genotype may be useful as a marker of IBS.

In certain instances, the presence or level of POMC is detected at the level of mRNA expression with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, or a mass spectrometry based assay. In certain other instances, the presence or level of ACTH is detected at the level of protein expression using, e.g., an immunoassay (e.g., ELISA), an immunohistochemical assay, or a mass spectrometry based assay. Suitable ELISA kits for determining the presence or level of ACTH in a serum, plasma, saliva, or urine sample are available from, Calbiotech (Spring Valley, CA), GenWay Biotech, Inc. (San Diego, CA), and MD Bioproducts (St. Paul, MN). In yet other instances, a SNP, polymorphism, or particular haplotype or genotype of the POMC gene is detected with an assay such as, e.g., a hybridization assay, an amplification-based assay, e.g. qPCR assay, RT-PCR assay, a single nucleotide sequencing assay, or a mass spectrometry based assay.

K. Other Diagnostic Markers

[0384] The determination of the presence or level of lactoferrin in a sample is also useful in the present invention. In certain instances, the presence or level of lactoferrin is detected at the level of mRNA expression with an assay such as, for example, a hybridization assay or an amplification-based assay. In certain other instances, the presence or level of lactoferrin is detected at the level of protein expression using, for example, an immunoassay (e.g., ELISA) or an immunohistochemical assay. A lactoferrin ELISA kit available from calbiochem (San Diego, CA) can be used to detect human lactoferrin in a plasma, urine, bronchoalveolar
lavage, or cerebrospinal fluid sample. Similarly, an ELISA kit available from U.S. Biological (Swampscott, MA) can be used to determine the level of lactoferrin in a plasma sample. U.S. Patent Publication No. 20040137536 describes an ELISA assay for determining the presence of elevated lactoferrin levels in a stool sample. Likewise, U.S. Patent Publication No. 20040033537 describes an ELISA assay for determining the concentration of endogenous lactoferrin in a stool, mucus, or bile sample. In some embodiments, then presence or level of anti-lactoferrin antibodies can be detected in a sample using, e.g., lactoferrin protein or a fragment thereof.

[0385] The determination of the presence or level of carbohydrate deficient transferrin (CDT) in a sample is also useful in the present invention. CDT is a diagnostic test currently used to detect the presence of heavy alcohol consumption. The test measures the level of carbohydrate deficient transferrin proteins, i.e. transferrin polypeptides modified by zero, one, or two sialic acid chains, generally in a blood, serum, hair, or urine sample. As such, CDT tests are used to identify individuals with alcohol abuse problems or alcoholism. In certain embodiments CDT tests or CDT levels may be useful as a marker of IBS. In certain other instances, the presence or level of CDT is detected by an electrophoretic assay, as sold by Consumer Genetics, Inc. (Sunnyvale, CA) and Sebia electrophoresis (Norcross, GA). In certain other instances, the presence or level of CDT is detected using, e.g., an immunoassay (e.g., ELISA), an isoelectric focusing assay, an immunohistochemical assay, or a mass spectrometry based assay.

[0386] Immunoassays such as ELISA are also particularly useful for determining the presence or level of C-reactive protein (CRP) in a sample. For example, a sandwich colorimetric ELISA assay available from Alpco Diagnostics (Salem, NH) can be used to determine the level of CRP in a serum, plasma, urine, or stool sample. Similarly, an ELISA kit available from Biomeda Corporation (Foster City, CA) can be used to detect CRP levels in a sample. Other methods for determining CRP levels in a sample are described in, e.g., U.S. Patent Nos. 6,838,250 and 6,406,862; and U.S. Patent Publication Nos. 20060024682 and 20060019410.

[0387] In addition, hemoccult, fecal occult blood, is often indicative of gastrointestinal illness and various kits have been developed to monitor gastrointestinal bleeding. For example, Hemoccult SENSA, a Beckman Coulter product, is a diagnostic aid for gastrointestinal bleeding, iron deficiency, peptic ulcers, ulcerative colitis, and, in some instances, in screening for colorectal cancer. This particular assay is based on the oxidation of guaiac by hydrogen peroxide to produce a blue color. A similar colorimetric assay is
commercially available from Helena Laboratories (Beaumont, TX) for the detection of blood in stool samples. Other methods for detecting occult blood in a stool sample by determining the presence or level of hemoglobin or heme activity are described in, e.g., U.S. Patent Nos. 4,277,250, 4,920,045, 5,081,040, and 5,3, 10,684.

[0388] The determination of the presence or level of fibrinogen or a proteolytic product thereof such as a fibrinopeptide in a sample is also useful in the present invention. Fibrinogen is a plasma glycoprotein synthesized in the liver composed of 3 structurally different subunits: alpha (FGA); beta (FGB); and gamma (FGG). Thrombin causes a limited proteolysis of the fibrinogen molecule, during which fibrinopeptides A and B are released from the N-terminal regions of the alpha and beta chains, respectively. Fibrinopeptides A and B, which have been sequenced in many species, may have a physiological role as vasoconstrictors and may aid in local hemostasis during blood clotting. In one embodiment, human fibrinopeptide A comprises the sequence: Ala-Asp-Ser-Gly-Glu-Gly-Asp-Phe-Leu-Ala-Glu-Gly-Gly-Gly-Val-Arg (SEQ ID NO: 15). In another embodiment, human fibrinopeptide B comprises the sequence: Glp-Gly-Val-Asn-Asp-Glu-Gly-Asp-Phe-Phe-Ala-Arg (SEQ ID NO: 16). An ELISA kit available from American Diagnostica Inc. (Stamford, CT) can be used to detect the presence or level of human fibrinopeptide A in plasma or other biological fluids.

[0389] In certain embodiments, the determination of the presence or level of calcitonin gene-related peptide (CGRP) in a sample is useful in the present invention. Calcitonin is a 32-amino acid peptide hormone synthesized by the parafollicular cells of the thyroid. It causes reduction in serum calcium, an effect opposite to that of parathyroid hormone. CGRP is derived, with calcitonin, from the CT/CGRP gene located on chromosome 11. CGRP is a 37-amino acid peptide and is a potent endogenous vasodilator. CGRP is primarily produced in nervous tissue; however, its receptors are expressed throughout the body. An ELISA kit available from Cayman Chemical Co. (Ann Arbor, MI) can be used to detect the presence or level of human CGRP in a variety of samples including plasma, serum, nervous tissue, CSF, and culture media.

[0390] In other embodiments, the determination of the presence or level of an anti-tissue transglutaminase (tTG) antibody in a sample is useful in the present invention. As used herein, the term "anti-tTG antibody" includes any antibody that recognizes tissue transglutaminase (tTG) or a fragment thereof. Transglutaminases are a diverse family of Ca$^{2+}$-dependent enzymes that are ubiquitous and highly conserved across species. Of all the transglutaminases, tTG is the most widely distributed. In certain instances, the anti-tTG
antibody is an anti-tTG IgA antibody, anti-tTG IgG antibody, or mixtures thereof. An ELISA kit available from ScheBo Biotech USA Inc. (Marietta, GA) can be used to detect the presence or level of human anti-tTG IgA antibodies in a blood sample.

[0391] The determination of the presence of polymorphisms in the NOD2/CARD15 gene in a sample is also useful in the present invention. For example, polymorphisms in the NOD2 gene such as a C2107T nucleotide variant that results in a R703W protein variant can be identified in a sample from an individual (see, e.g., U.S. Patent Publication No. 20030190639). In an alternative embodiment, NOD2 mRNA levels can be used as a diagnostic marker of the present invention to aid in classifying IBS.

[0392] The determination of the presence of polymorphisms in the serotonin reuptake transporter (SERT) gene in a sample is also useful in the present invention. For example, polymorphisms in the promoter region of the SERT gene have effects on transcriptional activity, resulting in altered 5-HT reuptake efficiency. It has been shown that a strong genotypic association was observed between the SERT-P deletion/deletion genotype and the IBS phenotype (see, e.g., Yeo Gut, 53:1396-1399 (2004)). In an alternative embodiment, SERT mRNA levels can be used as a diagnostic marker of the present invention to aid in classifying IBS (see, e.g., Gershon, J. Clin. Gastroenterol., 39(5 Suppl.):S 184-193 (2005)).

[0393] In certain aspects, the level of tryptophan hydroxylase-1 mRNA is a diagnostic marker. For example, tryptophan hydroxylase-1 mRNA has been shown to be significantly reduced in IBS (see, e.g., Coats, Gastroenterology, 126:1897-1899 (2004)). In certain other aspects, a lactulose breath test to measure methane, which is indicative of bacterial overgrowth, can be used as a diagnostic marker for IBS.

L. Classification Markers

A variety of classification markers are suitable for use in the methods, systems, and code of the present invention for classifying IBS into a category, form, or clinical subtype such as, for example, IBS-constipation (IBS-C), IBS-diarrhea (IBS-D), IBS-mixed (IBS-M), IBS-alternating (IBS-A), or post-infectious IBS (IBS-PI). Examples of classification markers include, without limitation, any of the diagnostic markers described above (e.g., leptin, serotonin reuptake transporter (SERT), tryptophan hydroxylase-1, 5-hydroxytryptamine (5-HT), tryptase, PGE₂, histamine, and the like), as well as antrum mucosal protein 8, keratin-8, claudin-8, zonulin, corticotropin-releasing hormone receptor-1 (CRHR1), corticotropin-releasing hormone receptor-2 (CRHR2), and the like.

For instance, Examples 1 and 2 below illustrate that measuring β-tryptase levels is particularly useful for distinguishing IBS-C patient samples from IBS-A and IBS-D patient samples. Similarly, Example 1 from US Patent Publication No. 2008/0085524, filed August 14, 2007, which is herein incorporated by reference in its entirety for all purposes, illustrates that measuring leptin levels is particularly useful for distinguishing IBS-C patient samples from IBS-A and IBS-D patient samples. In addition, mucosal SERT and tryptophan hydroxylase-1 expression have been shown to be decreased in IBS-C and IBS-D (see, e.g., Gershon, J. Clin. Gastroenterol., 39(5 Suppl):S184-193 (2005)). Furthermore, IBS-C patients show impaired postprandial 5-HT release, whereas IBS-PI patients have higher peak levels of 5-HT (see, e.g., Dunlop, Clin Gastroenterol Hepatol., 3:349-357 (2005)). Furthermore, as can be seen in Figure 11, serum levels of histamine and PGE₂ is also particularly useful for distinguishing IBS-D patient samples from IBS-A, IBS-C, and healthy control patient samples.

M. Statistical Algorithms

In some aspects, the present invention provides methods, assays, systems, and code for classifying whether a sample is associated with IBS using a statistical algorithm or process to classify the sample as an IBS sample or non-IBS sample. In other aspects, the present invention provides methods, systems, and code for classifying whether a sample is associated with IBS using a first statistical algorithm or process to classify the sample as a non-IBD sample or IBD sample (i.e., IBD rule-out step), followed by a second statistical algorithm or process to classify the non-IBD sample as an IBS sample or non-IBS sample (i.e., IBS rule-in step). Preferably, the statistical algorithms or processes independently comprise one or more learning statistical classifier systems. As described herein, a
combination of learning statistical classifier systems advantageously provides improved sensitivity, specificity, negative predictive value, positive predictive value, and/or overall accuracy for classifying whether a sample is associated with IBS. In a preferred embodiment, the methods, assays, systems, and code provided herein use a combination of at least two statistical algorithms.

[0398] In some embodiments, the first statistical algorithm is a learning statistical classifier system selected from the group consisting of a random forest (RF), classification and regression tree (C&RT), boosted tree, neural network (NN), support vector machine (SVM), general chi-squared automatic interaction detector model, interactive tree, multiadaptive regression spline, machine learning classifier, and combinations thereof. In certain instances, the first statistical algorithm is a single learning statistical classifier system. Preferably, the single learning statistical classifier system comprises a tree-based statistical algorithm such as a RF or C&RT. In certain other instances, the first statistical algorithm is a combination of at least two learning statistical classifier systems, e.g., used in tandem or parallel. As a non-limiting example, a RF can first be used to generate a prediction or probability value based upon the diagnostic marker profile, alone or in combination with a symptom profile, and a NN (e.g., artificial NN) can then be used to classify the sample as a non-IBD sample or IBD sample based upon the prediction or probability value and the same or different diagnostic marker profile or combination of profiles. The hybrid RF/NN learning statistical classifier system of the present invention typically classifies the sample as a non-IBD sample with a sensitivity, specificity, positive predictive value, negative predictive value, and/or overall accuracy of at least about 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%.

[0399] In certain embodiments, the second statistical algorithm comprises any of the learning statistical classifier systems described above. In certain instances, the second statistical algorithm is a single learning statistical classifier system such as, for example, a tree-based statistical algorithm (e.g., RF or C&RT). In certain other instances, the second statistical algorithm is a combination of at least two learning statistical classifier systems, e.g., used in tandem or parallel. As a non-limiting example, a RF can first be used to generate a prediction or probability value based upon the diagnostic marker profile, alone or in combination with a symptom profile, and a NN (e.g., artificial NN) or SVM can then be used to classify the non-IBD sample as a non-IBS sample or IBS sample based upon the prediction or probability value and the same or different diagnostic marker profile or combination of profiles. The hybrid RF/NN or RF/SVM learning statistical classifier system
described herein typically classifies the sample as an IBS sample with a sensitivity, specificity, positive predictive value, negative predictive value, and/or overall accuracy of at least about 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%.

[0400] In some instances, the data obtained from using the learning statistical classifier system or systems can be processed using a processing algorithm. Such a processing algorithm can be selected, for example, from the group consisting of a multilayer perceptron, backpropagation network, and Levenberg-Marquardt algorithm. In other instances, a combination of such processing algorithms can be used, such as in a parallel or serial fashion.

[0401] The term "statistical algorithm" or "statistical process" includes any of a variety of statistical analyses used to determine relationships between variables. In the present invention, the variables are the presence or level of at least one marker of interest and/or the presence or severity of at least one IBS-related symptom. Any number of markers and/or symptoms can be analyzed using a statistical algorithm described herein. For example, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 25, 30, 35, 40, 45, 50, 55, 60, or more biomarkers and/or symptoms can be included in a statistical algorithm. In one embodiment, logistic regression is used. In another embodiment, linear regression is used. In certain instances, the statistical algorithms of the present invention can use a quantile measurement of a particular marker within a given population as a variable. Quantiles are a set of "cut points" that divide a sample of data into groups containing (as far as possible) equal numbers of observations. For example, quartiles are values that divide a sample of data into four groups containing (as far as possible) equal numbers of observations. The lower quartile is the data value a quarter way up through the ordered data set; the upper quartile is the data value a quarter way down through the ordered data set. Quintiles are values that divide a sample of data into five groups containing (as far as possible) equal numbers of observations. The present invention can also include the use of percentile ranges of marker levels (e.g., tertiles, quartile, quintiles, etc.), or their cumulative indices (e.g., quartile sums of marker levels, etc.) as variables in the algorithms (just as with continuous variables).

[0402] Preferably, the statistical algorithms of the present invention comprise one or more learning statistical classifier systems. As used herein, the term "learning statistical classifier system" includes a machine learning algorithmic technique capable of adapting to complex data sets (e.g., panel of markers of interest and/or list of IBS-related symptoms) and making decisions based upon such data sets. In some embodiments, a single learning statistical classifier system such as a classification tree (e.g., random forest) is used. In other
embodiments, a combination of 2, 3, 4, 5, 6, 7, 8, 9, 10, or more learning statistical classifier systems are used, preferably in tandem. Examples of learning statistical classifier systems include, but are not limited to, those using inductive learning (e.g., decision/classification trees such as random forests, classification and regression trees (C&RT), boosted trees, etc.).

Probably Approximately Correct (PAC) learning, connectionist learning (e.g., neural networks (NN), artificial neural networks (ANN), neuro fuzzy networks (NFN), network structures, perceptrons such as multi-layer perceptrons, multi-layer feed-forward networks, applications of neural networks, Bayesian learning in belief networks, etc.), reinforcement learning (e.g., passive learning in a known environment such as naive learning, adaptive dynamic learning, and temporal difference learning, passive learning in an unknown environment, active learning in an unknown environment, learning action-value functions, applications of reinforcement learning, etc.), and genetic algorithms and evolutionary programming. Other learning statistical classifier systems include support vector machines (e.g., Kernel methods), multivariate adaptive regression splines (MARS), Levenberg-Marquardt algorithms, Gauss-Newton algorithms, mixtures of Gaussians, gradient descent algorithms, and learning vector quantization (LVQ).

[0403] Random forests are learning statistical classifier systems that are constructed using an algorithm developed by Leo Breiman and Adele Cutler. Random forests use a large number of individual decision trees and decide the class by choosing the mode (i.e., most frequently occurring) of the classes as determined by the individual trees. Random forest analysis can be performed, e.g., using the RandomForests software available from Salford Systems (San Diego, CA). See, e.g., Breiman, Machine Learning, 45:5-32 (2001); and http://stat-www.berkeley.edu/users/breiman/RandomForests/cc_home.htm, for a description of random forests.

[0404] Classification and regression trees represent a computer intensive alternative to fitting classical regression models and are typically used to determine the best possible model for a categorical or continuous response of interest based upon one or more predictors. Classification and regression tree analysis can be performed, e.g., using the CART software available from Salford Systems or the Statistica data analysis software available from StatSoft, Inc. (Tulsa, OK). A description of classification and regression trees is found, e.g., in Breiman et al. "Classification and Regression Trees," Chapman and Hall, New York (1984); and Steinberg et al, "CART: Tree-Structured Non-Parametric Data Analysis," Salford Systems, San Diego, (1995).

Support vector machines are a set of related supervised learning techniques used for classification and regression and are described, e.g., in Cristianini et al., "An Introduction to Support Vector Machines and Other Kernel-Based Learning Methods," Cambridge University Press (2000). Support vector machine analysis can be performed, e.g., using the SVM light software developed by Thorsten Joachims (Cornell University) or using the LIBSVM software developed by Chih-Chung Chang and Chih-Jen Lin (National Taiwan University).

The learning statistical classifier systems described herein can be trained and tested using a cohort of samples (e.g., serological samples) from healthy individuals, IBS patients, IBD patients, and/or Celiac disease patients. For example, samples from patients diagnosed by a physician, and preferably by a gastroenterologist as having IBD using a biopsy, colonoscopy, or an immunoassay as described in, e.g., U.S. Patent No. 6,218,129, are suitable for use in training and testing the learning statistical classifier systems of the present invention. Samples from patients diagnosed with IBD can also be stratified into Crohn's
disease or ulcerative colitis using an immunoassay as described in, e.g., U.S. Patent Nos. 5,750,355 and 5,830,675. Samples from patients diagnosed with IBS using a published criteria such as the Manning, Rome I, Rome II, or Rome III diagnostic criteria are suitable for use in training and testing the learning statistical classifier systems of the present invention. Samples from healthy individuals can include those that were not identified as IBD and/or IBS samples. One skilled in the art will know of additional techniques and diagnostic criteria for obtaining a cohort of patient samples that can be used in training and testing the learning statistical classifier systems of the present invention.

[0408] As used herein, the term "sensitivity" refers to the probability that a diagnostic method, system, or code of the present invention gives a positive result when the sample is positive, e.g., having IBS. Sensitivity is calculated as the number of true positive results divided by the sum of the true positives and false negatives. Sensitivity essentially is a measure of how well a method, system, or code of the present invention correctly identifies those with IBS from those without the disease. The statistical algorithms can be selected such that the sensitivity of classifying IBS is at least about 60%, and can be, for example, at least about 65%, 70%, 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%. In preferred embodiments, the sensitivity of classifying IBS is at least about 90% when a combination of learning statistical classifier systems is used (see, Example 10 from US Patent Publication No. 2008/0085524, which is incorporated herein by reference in its entirety for all purposes) or at least about 85% when a single learning statistical classifier system is used (see, Example 11 from US Patent Publication No. 2008/0085524, which is incorporated herein by reference in its entirety for all purposes).

[0409] The term "specificity" refers to the probability that a diagnostic method, system, or code of the present invention gives a negative result when the sample is not positive, e.g., not having IBS. Specificity is calculated as the number of true negative results divided by the sum of the true negatives and false positives. Specificity essentially is a measure of how well a method, system, or code of the present invention excludes those who do not have IBS from those who have the disease. The statistical algorithms can be selected such that the specificity of classifying IBS is at least about 70%, for example, at least about 75%, 80%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%. In preferred embodiments, the specificity of classifying IBS is at least about 86% when a combination of learning statistical classifier systems is used (see, Example 10 from US Patent Publication No. 2008/0085524, which is incorporated herein by reference in its entirety for all purposes).
all purposes) or at least about 84% when a single learning statistical classifier system is used
(see, Example 1) from US Patent Publication No. 2008/0085524, which is incorporated
herein by reference in its entirety for all purposes).

[0410] As used herein, the term "negative predictive value" or "NPV" refers to the
probability that an individual identified as not having IBS actually does not have the disease.
Negative predictive value can be calculated as the number of true negatives divided by the
sum of the true negatives and false negatives. Negative predictive value is determined by the
characteristics of the diagnostic method, system, or code as well as the prevalence of the
disease in the population analyzed. The statistical algorithms can be selected such that the
negative predictive value in a population having a disease prevalence is in the range of about
70% to about 99% and can be, for example, at least about 70%, 75%, 76%, 77%, 78%, 79%,
80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%,
96%, 97%, 98%, or 99%. In preferred embodiments, the negative predictive value of
classifying IBS is at least about 87% when a combination of learning statistical classifier
systems is used (see, Example 10 from US Patent Publication No. 2008/0085524, which is
incorporated herein by reference in its entirety for all purposes).

[0411] The term "positive predictive value" or "PPV" refers to the probability that an
individual identified as having IBS actually has the disease. Positive predictive value can be
calculated as the number of true positives divided by the sum of the true positives and false
positives. Positive predictive value is determined by the characteristics of the diagnostic
method, system, or code as well as the prevalence of the disease in the population analyzed.
The statistical algorithms can be selected such that the positive predictive value in a
population having a disease prevalence is in the range of about 80% to about 99% and can be,
for example, at least about 80%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%,
95%, 96%, 97%, 98%, or 99%. In preferred embodiments, the positive predictive value of
classifying IBS is at least about 90% when a combination of learning statistical classifier
systems is used (see, Example 10 from US Patent Publication No. 2008/0085524, which is
incorporated herein by reference in its entirety for all purposes).

[0412] Predictive values, including negative and positive predictive values, are influenced
by the prevalence of the disease in the population analyzed. In the methods, systems, and
code of the present invention, the statistical algorithms can be selected to produce a desired
clinical parameter for a clinical population with a particular IBS prevalence. For example,
learning statistical classifier systems can be selected for an IBS prevalence of up to about 1%,
2%, 3%, 4%, 5%, 6%, 7%, 8%, 9%, 10%, 15%, 20%, 25%, 30%, 35%, 40%, 45%, 50%,

127
55%, 60%, 65%, or 70%, which can be seen, e.g., in a clinician's office such as a gastroenterologist’s office or a general practitioner's office.

[0413] As used herein, the term "overall agreement" or "overall accuracy" refers to the accuracy with which a method, system, or code of the present invention classifies a disease state. Overall accuracy is calculated as the sum of the true positives and true negatives divided by the total number of sample results and is affected by the prevalence of the disease in the population analyzed. For example, the statistical algorithms can be selected such that the overall accuracy in a patient population having a disease prevalence is at least about 60%, and can be, for example, at least about 65%, 70%, 75%, 76%, 77%, 78%, 79%, 80%, 81%, 82%, 83%, 84%, 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99%. In preferred embodiments, the overall accuracy of classifying IBS is at least about 80% when a combination of learning statistical classifier systems is used (see, Example 10 from US Patent Publication No. 2008/0085524, which is incorporated herein by reference in its entirety for all purposes).

N. Disease Classification System

[0414] Figure 13 illustrates a disease classification system (DCS) (200) according to one embodiment of the present invention. As shown therein, a DCS includes a DCS intelligence module (205), such as a computer, having a processor (215) and memory module (210). The intelligence module also includes communication modules (not shown) for transmitting and receiving information over one or more direct connections (e.g., USB, Firewire, or other interface) and one or more network connections (e.g., including a modem or other network interface device). The memory module may include internal memory devices and one or more external memory devices. The intelligence module also includes a display module (225), such as a monitor or printer. In one aspect, the intelligence module receives data such as patient test results from a data acquisition module such as a test system (250), either through a direct connection or over a network (240). For example, the test system may be configured to run multianalyte tests on one or more patient samples (255) and automatically provide the test results to the intelligence module. The data may also be provided to the intelligence module via direct input by a user or it may be downloaded from a portable medium such as a compact disk (CD) or a digital versatile disk (DVD). The test system may be integrated with the intelligence module, directly coupled to the intelligence module, or it may be remotely coupled with the intelligence module over the network. The intelligence module may also communicate data to and from one or more client systems (230) over the
network as is well known. For example, a requesting physician or healthcare provider may obtain and view a report from the intelligence module, which may be resident in a laboratory or hospital, using a client system (230).

[0415] The network can be a LAN (local area network), WAN (wide area network), wireless network, point-to-point network, star network, token ring network, hub network, or other configuration. As the most common type of network in current use is a TCP/IP (Transfer Control Protocol and Internet Protocol) network such as the global internetwork of networks often referred to as the "Internet" with a capital "I," that will be used in many of the examples herein, but it should be understood that the networks that the present invention might use are not so limited, although TCP/IP is the currently preferred protocol.

[0416] Several elements in the system shown in Figure 2 from US Patent Publication No. 2008/0085524 may include conventional, well-known elements that need not be explained in detail here. For example, the intelligence module could be implemented as a desktop personal computer, workstation, mainframe, laptop, etc. Each client system could include a desktop personal computer, workstation, laptop, PDA, cell phone, or any WAP-enabled device or any other computing device capable of interfacing directly or indirectly to the Internet or other network connection. A client system typically runs an HTTP client, e.g., a browsing program, such as Microsoft's Internet Explorer® browser, Netscape's Navigator® browser, Opera's browser, or a WAP-enabled browser in the case of a cell phone, PDA or other wireless device, or the like, allowing a user of the client system to access, process, and view information and pages available to it from the intelligence module over the network. Each client system also typically includes one or more user interface devices, such as a keyboard, a mouse, touch screen, pen or the like, for interacting with a graphical user interface (GUI) provided by the browser on a display (e.g., monitor screen, LCD display, etc.) (235) in conjunction with pages, forms, and other information provided by the intelligence module. As discussed above, the present invention is suitable for use with the Internet, which refers to a specific global internetwork of networks. However, it should be understood that other networks can be used instead of the Internet, such as an intranet, an extranet, a virtual private network (VPN), a non-TCP/IP based network, any LAN or WAN, or the like.

[0417] According to one embodiment, each client system and all of its components are operator configurable using applications, such as a browser, including computer code run using a central processing unit such as an Intel® Pentium® processor or the like. Similarly, the intelligence module and all of its components might be operator configurable using
application(s) including computer code run using a central processing unit (215) such as an Intel Pentium processor or the like, or multiple processor units. Computer code for operating and configuring the intelligence module to process data and test results as described herein is preferably downloaded and stored on a hard disk, but the entire program code, or portions thereof, may also be stored in any other volatile or non-volatile memory medium or device as is well known, such as a ROM or RAM, or provided on any other computer readable medium (260) capable of storing program code, such as a compact disk (CD) medium, digital versatile disk (DVD) medium, a floppy disk, ROM, RAM, and the like.

[0418] The computer code for implementing various aspects and embodiments of the present invention can be implemented in any programming language that can be executed on a computer system such as, for example, in C, C++, C#, HTML, Java, JavaScript, or any other scripting language, such as VBScript. Additionally, the entire program code, or portions thereof, may be embodied as a carrier signal, which may be transmitted and downloaded from a software source (e.g., server) over the Internet, or over any other conventional network connection as is well known (e.g., extranet, VPN, LAN, etc.) using any communication medium and protocols (e.g., TCP/IP, HTTP, HTTPS, Ethernet, etc.) as are well known.

[0419] According to one embodiment, the intelligence module implements a disease classification process for analyzing patient test results and/or questionnaire responses to determine whether a patient sample is associated with IBS. The data may be stored in one or more data tables or other logical data structures in memory (210) or in a separate storage or database system coupled with the intelligence module. One or more statistical processes are typically applied to a data set including test data for a particular patient. For example, the test data might include a diagnostic marker profile, which comprises data indicating the presence or level of at least one marker in a sample from the patient. The test data might also include a symptom profile, which comprises data indicating the presence or severity of at least one symptom associated with IBS that the patient is experiencing or has recently experienced. In one aspect, a statistical process produces a statistically derived decision classifying the patient sample as an IBS sample or non-IBS sample based upon the diagnostic marker profile and/or symptom profile. In another aspect, a first statistical process produces a first statistically derived decision classifying the patient sample as an IBD sample or non-IBD sample based upon the diagnostic marker profile and/or symptom profile. If the patient sample is classified as a non-IBD sample, a second statistical process is applied to the same or a different data set to produce a second statistically derived decision classifying the non-
IBD sample as an IBS sample or non-IBS sample. The first and/or the second statistically derived decision may be displayed on a display device associated with or coupled to the intelligence module, or the decision(s) may be provided to and displayed at a separate system, e.g., a client system (230). The displayed results allow a physician to make a reasoned diagnosis or prognosis.

O. Therapy and Therapeutic Monitoring

[0420] Once a sample from an individual has been classified as an IBS sample, the methods, systems, and code of the present invention can further comprise administering to the individual a therapeutically effective amount of a drug useful for treating one or more symptoms associated with IBS (i.e., an IBS drug). For therapeutic applications, the IBS drug can be administered alone or co-administered in combination with one or more additional IBS drugs and/or one or more drugs that reduce the side-effects associated with the IBS drug.

[0421] IBS drugs can be administered with a suitable pharmaceutical excipient as necessary and can be carried out via any of the accepted modes of administration. Thus, administration can be, for example, intravenous, topical, subcutaneous, transcutaneous, transdermal, intramuscular, oral, buccal, sublingual, gingival, palatal, intra-joint, parenteral, intra-arteriole, intradermal, intraventricular, intracranial, intraperitoneal, intranasal, rectal, vaginal, or by inhalation. By "co-administer" it is meant that an IBS drug is administered at the same time, just prior to, or just after the administration of a second drug (e.g., another IBS drug, a drug useful for reducing the side-effects of the IBS drug, etc.).

[0422] A therapeutically effective amount of an IBS drug may be administered repeatedly, e.g., at least 2, 3, 4, 5, 6, 7, 8, or more times, or the dose may be administered by continuous infusion. The dose may take the form of solid, semi-solid, lyophilized powder, or liquid dosage forms, such as, for example, tablets, pills, pellets, capsules, powders, solutions, suspensions, emulsions, suppositories, retention enemas, creams, ointments, lotions, gels, aerosols, foams, or the like, preferably in unit dosage forms suitable for simple administration of precise dosages.

[0423] As used herein, the term "unit dosage form" refers to physically discrete units suitable as unitary dosages for human subjects and other mammals, each unit containing a predetermined quantity of an IBS drug calculated to produce the desired onset, tolerability, and/or therapeutic effects, in association with a suitable pharmaceutical excipient (e.g., an ampoule). In addition, more concentrated dosage forms may be prepared, from which the more dilute unit dosage forms may then be produced. The more concentrated dosage forms
thus will contain substantially more than, e.g., at least 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, or more times the amount of the IBS drug.

[0424] Methods for preparing such dosage forms are known to those skilled in the art (see, e.g., REMINGTON'S PHARMACEUTICAL SCIENCES, 18TH ED., Mack Publishing Co., Easton, PA (1990)). The dosage forms typically include a conventional pharmaceutical carrier or excipient and may additionally include other medicinal agents, carriers, adjuvants, diluents, tissue permeation enhancers, solubilizers, and the like. Appropriate excipients can be tailored to the particular dosage form and route of administration by methods well known in the art (see, e.g., REMINGTON'S PHARMACEUTICAL SCIENCES, supra).

[0425] Examples of suitable excipients include, but are not limited to, lactose, dextrose, sucrose, sorbitol, mannitol, starches, gum acacia, calcium phosphate, alginates, tragacanth, gelatin, calcium silicate, microcrystalline cellulose, polyvinylpyrrolidone, cellulose, water, saline, syrup, methylcellulose, ethylcellulose, hydroxypropylmethylcellulose, and polyacrylic acids such as Carbopol, e.g., Carbopol 941, Carbopol 980, Carbopol 981, etc. The dosage forms can additionally include lubricating agents such as talc, magnesium stearate, and mineral oil; wetting agents; emulsifying agents; suspending agents; preserving agents such as methyl-, ethyl-, and propyl-hydroxy-benzoates (i.e., the parabens); pH adjusting agents such as inorganic and organic acids and bases; sweetening agents; and flavoring agents. The dosage forms may also comprise biodegradable polymer beads, dextran, and cyclodextrin inclusion complexes.

[0426] For oral administration, the therapeutically effective dose can be in the form of tablets, capsules, emulsions, suspensions, solutions, syrups, sprays, lozenges, powders, and sustained-release formulations. Suitable excipients for oral administration include pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, talc, cellulose, glucose, gelatin, sucrose, magnesium carbonate, and the like.

[0427] In some embodiments, the therapeutically effective dose takes the form of a pill, tablet, or capsule, and thus, the dosage form can contain, along with an IBS drug, any of the following: a diluent such as lactose, sucrose, dicalcium phosphate, and the like; a disintegrant such as starch or derivatives thereof; a lubricant such as magnesium stearate and the like; and a binder such a starch, gum acacia, polyvinylpyrrolidone, gelatin, cellulose and derivatives thereof. An IBS drug can also be formulated into a suppository disposed, for example, in a polyethylene glycol (PEG) carrier.
[0428] Liquid dosage forms can be prepared by dissolving or dispersing an IBS drug and optionally one or more pharmaceutically acceptable adjuvants in a carrier such as, for example, aqueous saline (e.g., 0.9% w/v sodium chloride), aqueous dextrose, glycerol, ethanol, and the like, to form a solution or suspension, e.g., for oral, topical, or intravenous administration. An IBS drug can also be formulated into a retention enema.

[0429] For topical administration, the therapeutically effective dose can be in the form of emulsions, lotions, gels, foams, creams, jellies, solutions, suspensions, ointments, and transdermal patches. For administration by inhalation, an IBS drug can be delivered as a dry powder or in liquid form via a nebulizer. For parenteral administration, the therapeutically effective dose can be in the form of sterile injectable solutions and sterile packaged powders. Preferably, injectable solutions are formulated at a pH of from about 4.5 to about 7.5.

[0430] The therapeutically effective dose can also be provided in a lyophilized form. Such dosage forms may include a buffer, e.g., bicarbonate, for reconstitution prior to administration, or the buffer may be included in the lyophilized dosage form for reconstitution with, e.g., water. The lyophilized dosage form may further comprise a suitable vasoconstrictor, e.g., epinephrine. The lyophilized dosage form can be provided in a syringe, optionally packaged in combination with the buffer for reconstitution, such that the reconstituted dosage form can be immediately administered to an individual.

[0431] In therapeutic use for the treatment of IBS, an IBS drug can be administered at the initial dosage of from about 0.001 mg/kg to about 1000 mg/kg daily. A daily dose range of from about 0.01 mg/kg to about 500 mg/kg, from about 0.1 mg/kg to about 200 mg/kg, from about 1 mg/kg to about 100 mg/kg, or from about 10 mg/kg to about 50 mg/kg, can be used. The dosages, however, may be varied depending upon the requirements of the individual, the severity of IBS symptoms, and the IBS drug being employed. For example, dosages can be empirically determined considering the severity of IBS symptoms in an individual classified as having IBS according to the methods described herein. The dose administered to an individual, in the context of the present invention, should be sufficient to affect a beneficial therapeutic response in the individual over time. The size of the dose can also be determined by the existence, nature, and extent of any adverse side-effects that accompany the administration of a particular IBS drug in an individual. Determination of the proper dosage for a particular situation is within the skill of the practitioner. Generally, treatment is initiated with smaller dosages which are less than the optimum dose of the IBS drug. Thereafter, the dosage is increased by small increments until the optimum effect under
circumstances is reached. For convenience, the total daily dosage may be divided and administered in portions during the day, if desired.

[0432] As used herein, the term "IBS drug" includes all pharmaceutically acceptable forms of a drug that is useful for treating one or more symptoms associated with IBS. For example, the IBS drug can be in a racemic or isomeric mixture, a solid complex bound to an ion exchange resin, or the like. In addition, the IBS drug can be in a solvated form. The term "IBS drug" is also intended to include all pharmaceutically acceptable salts, derivatives, and analogs of the IBS drug being described, as well as combinations thereof. For example, the pharmaceutically acceptable salts of an IBS drug include, without limitation, the tartrate, succinate, tartarate, bitartrate, dihydrochloride, salicylate, hemisuccinate, citrate, maleate, hydrochloride, carbamate, sulfate, nitrate, and benzoate salt forms thereof, as well as combinations thereof and the like. Any form of an IBS drug is suitable for use in the methods of the present invention, e.g., a pharmaceutically acceptable salt of an IBS drug, a free base of an IBS drug, or a mixture thereof.

[0433] Suitable drugs that are useful for treating one or more symptoms associated with IBS include, but are not limited to, serotonergic agents, antidepressants, chloride channel activators, chloride channel blockers, guanylate cyclase agonists, antibiotics, opioids, neurokinin antagonists, antispasmodic or anticholinergic agents, belladonna alkaloids, barbiturates, glucagon-like peptide-1 (GLP-1) analogs, corticotropin releasing factor (CRF) antagonists, probiotics, free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof. Other IBS drugs include bulking agents, dopamine antagonists, carminatives, tranquilizers, dextofisopam, phenytoin, timolol, and diltiazem.

[0434] Serotonergic agents are useful for the treatment of IBS symptoms such as constipation, diarrhea, and/or alternating constipation and diarrhea. Non-limiting examples of serotonergic agents are described in Cash et al., Aliment. Pharmacol. Ther., 22:1047-1060 (2005), and include 5-HT₃ receptor agonists (e.g., MKC-733, etc.), 5-HT₄ receptor agonists (e.g., tegaserod (Zelnorm™), prucalopride, AGI-001, etc.), 5-HT₃ receptor antagonists (e.g., alosetron (Lotronex®), cilansetron, ondansetron, granisetron, dolasetron, ramosetron, palonosetron, E-3620, DDP-225, DDP-733, etc.), mixed 5-HT₃ receptor antagonists/5-HT₄ receptor agonists (e.g., cisapride, mosapride, renzapride, etc.), free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof. Additionally, amino acids like glutamine and glutamic acid which
regulate intestinal permeability by affecting neuronal or glial cell signaling can be administered to treat patients with IBS.

[0435] Antidepressants such as selective serotonin reuptake inhibitor (SSRI) or tricyclic antidepressants are particularly useful for the treatment of IBS symptoms such as abdominal pain, constipation, and/or diarrhea. Non-limiting examples of SSRI antidepressants include citalopram, fluvoxamine, paroxetine, fluoxetine, sertraline, free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof. Examples of tricyclic antidepressants include, but are not limited to, desipramine, nortriptyline, protriptyline, amitriptyline, clomipramine, doxepin, imipramine, trimipramine, maprotiline, amoxapine, clomipramine, free bases thereof, pharmaceutically acceptable salts thereof, derivatives thereof, analogs thereof, and combinations thereof.

[0436] Chloride channel activators are useful for the treatment of IBS symptoms such as constipation. A non-limiting example of a chloride channel activator is lubiprostone (Amitiza™), a free base thereof, a pharmaceutically acceptable salt thereof, a derivative thereof, or an analog thereof. In addition, chloride channel blockers such as crofelemer are useful for the treatment of IBS symptoms such as diarrhea. Guanylate cyclase agonists such as MD-1 100 are useful for the treatment of constipation associated with IBS (see, e.g., Bryant et al., Gastroenterol., 128:A-257 (2005)). Antibiotics such as neomycin can also be suitable for use in treating constipation associated with IBS (see, e.g., Park et al., Gastroenterol., 128:A-258 (2005)). Non-absorbable antibiotics like rifaximin (Xifaxan™) are suitable to treat small bowel bacterial overgrowth and/or constipation associated with IBS (see, e.g., Sharara et al., Am. J. Gastroenterol., 101:326-333 (2006)).

[0437] Opioids such as kappa opioids (e.g., asimadoline) may be useful for treating pain and/or constipation associated with IBS. Neurokinin (NK) antagonists such as talnetant, saredutant, and other NK2 and/or NK3 antagonists may be useful for treating IBS symptoms such as oversensitivity of the muscles in the colon, constipation, and/or diarrhea. Antispasmodic or anticholinergic agents such as dicyclomine may be useful for treating IBS symptoms such as spasms in the muscles of the gut and bladder. Other antispasmodic or anticholinergic agents such as belladonna alkaloids (e.g., atropine, scopolamine, hyoscyamine, etc.) can be used in combination with barbiturates such as phenobarbital to reduce bowel spasms associated with IBS. GLP-1 analogs such as GTP-010 may be useful for treating IBS symptoms such as constipation. CRF antagonists such as astressin and probiotics such as VSL#3® may be useful for treating one or more IBS symptoms. One
skilled in the art will know of additional IBS drugs currently in use or in development that are suitable for treating one or more symptoms associated with IBS.

[0438] An individual can also be monitored at periodic time intervals to assess the efficacy of a certain therapeutic regimen once a sample from the individual has been classified as an IBS sample. For example, the levels of certain markers change based on the therapeutic effect of a treatment such as a drug. The patient is monitored to assess response and understand the effects of certain drugs or treatments in an individualized approach. Additionally, patients may not respond to a drug, but the markers may change, suggesting that these patients belong to a special population (not responsive) that can be identified by their marker levels. These patients can be discontinued on their current therapy and alternative treatments prescribed.

IV. Examples

[0439] The following examples are offered to illustrate, but not to limit, the claimed invention.

Example 1. A Tryptase ELISA for Predicting IBS.

[0441] This example describes a sensitive ELISA for detecting the presence or level of mast cell β-tryptase. See also, Figures 1-7.

[0442] Background: Mast cells play an important role in the pathogenesis of irritable bowel syndrome (IBS). Increased mast cell infiltration and activation in distal gut segments are associated with symptom onset and severity of IBS. Mast cells have been implicated in the elevated response of visceral afferent nerves to mucosal stimulus in IBS patients. Measurement of mast cell markers can have important implication in clinical diagnosis of IBS. However this effort was hindered due to lack of sensitive assays.

[0443] Methods: Here we report the development and validation of a highly sensitive two-side ELISA assay to measure tryptase level in human serum samples (detection limit 0.019 ng/ml). The assay is precise, robust, and reproducible. Serum tryptase concentration in healthy controls and IBS patients was measured using this assay.

[0444] Results: The average serum tryptase level in healthy controls was 9.32±2.1 ng/ml (n=156). IBS-D and IBS-A patients showed significant higher serum tryptase concentration
(12.71 ng/ml (n=209) for IBS-D and 1.94 ng/ml (n=57) for IBS-A, p<0.01); while the average tryptase level is 9.34 ng/ml (n=18) for IBS-C, which has no significant difference from healthy controls for IBS-C.

**Conclusion:** This is the first biomarker developed so far that differentiates IBS-D and IBS-A patients from IBS-C patients and healthy controls. Combining serum tryptase level with other Prometheus IBS biomarkers, we were able to improve the accuracy of diagnosing IBS-D and IBS-A patients.

**An ELISA assay was developed for the determination of serum mast cell β-tryptase level using rabbit anti-tryptase as capture antibody and alkaline phosphatase conjugated G3 as detecting antibody. Luminescent substrate CPSD (disodium 3-(4-methoxyspiro[1,2-dioxetane-3,2'-(5'-chloro)tricyclo[3.3.1 .13,7]decan]-4-yl)phenyl phosphate), was used to enhance the assay sensitivity. Linear dose-response curve was observed over the standard range of 1-1000 ng/ml for β-tryptase in buffer with 5% BSA and 10% normal human serum. The low limit of the assay was 0.019 ng/ml, the intra-assay and inter-assay coefficients of variation were below 15% at 1 ng/ml and 1000 ng/ml tryptase concentrations. The recovery of known amounts of purified tryptase added to serum was 88%. The immunoassay was utilized to examine serum levels of tryptase from healthy controls, IBS-C and IBS-D patients. Average serum tryptase level in healthy control was 7.0±2.1 ng/ml (n=13). The average tryptase level in IBS-C and IBS-D were 9.6 ng/ml (n=16) and 12.7 (n=209) respectively. Using the cutoff value of 11.4 ng/ml (average +2SD), the assay specificity for GI healthy control was 82% (n=156), the assay sensitivity for IBS-C and IBS-D were 21.5% and 24.9% respectively. Combine with symptoms of the patient and other markers for IBS, serum tryptase levels may help differentiate IBS-D from other types of irritable bowel syndrome.

**Example 2. Evaluation of the Diagnostic Utility of Serum Tryptase Levels in IBS.**

**Background:** Mast cells play an important role in the pathogenesis of irritable bowel syndrome (IBS). Increased mast cell infiltration and activation in distal gut segments are associated with symptom onset and severity of IBS. Mast cells have been implicated in the elevated response of visceral afferent nerves to mucosal stimulus in IBS patients. Measurement of mast cell markers can have important implications in clinical diagnosis of IBS. However, this effort was hindered due to lack of sensitive assays.

**Methods:** Here we report the development and validation of a highly sensitive two-site ELISA assay to measure tryptase level in human serum samples (detection limit
0.019ng/ml). The assay is precise, robust, and reproducible. Serum tryptase concentrations in healthy controls and IBS patients was measured using this assay.

[0449] Results: The average serum tryptase level in healthy controls was 7.1±2.5 ng/ml. IBS-D and IBS-A patients showed higher serum tryptase concentrations (10.3±8.7ng/ml for IBS-D and 12.1±10.7ng/ml for IBS-A) than the healthy control subjects, while the average tryptase level was 9.6±9.4 ng/ml for IBS-C. There was a statistical difference of serum tryptase levels between the IBS-C and IBS-D groups (p<0.01).

[0450] Conclusion: Serum tryptase concentration is the first biomarker developed so far that differentiates IBS-D from IBS-C patients. Serum tryptase levels can be combined with other IBS biomarkers to improve the accuracy of diagnosing IBS.

[0451] Figure 8 shows the dose-dependent responses of human tryptase in the tryptase ELISA described herein. Protocol: A 96-well microtiter plate was coated with 100ml of 2mg/ml of anti-human tryptase antibody in sodium carbonate (pH 9.6) at 4°C overnight. After washing with PBST, the plate was incubated with 300 ml/well of blocking/assay buffer (5% BSA in PBS) at room temperature (RT) for 30 minutes with gentle agitation. After washing, 100 ml/well of serially diluted (1:8 in assay buffer) human tryptase were added to the plate. After incubating at RT for another 2 hours, the plate was washed, and then incubated with 100 ml of AP-conjugated anti-human tryptase at an optimized dilution in assay buffer. The plate was incubated for 2 hours with gentle agitation and then washed. 100ml of Tropix CSPD substrate was added to each well and incubated in the dark for 30 minutes before reading the luminescence with a luminescence plate reader. The Relative Luminescent Unit (RLU) and the tryptase concentration was plotted with the Prism Graphpad Program. Tryptase detection range = 0.01-9-5000ng/ml. EC50 = 65 ng/ml. Recovery was 81.5% with 20ng spiked in normal pooled serum.

[0452] Figure 9 shows the optimization of the tryptase ELISA described herein. Figure 10 shows tryptase levels in serum from healthy controls (n=139) and from subjects with IBS (n=378). Tryptase levels were measured by ELISA in serum samples diluted 10 times with assay buffer. IBS patients are also shown according to its subtypes: IBS-D (n=206): diarrhea predominant; IBS-C (n=16): constipation predominant; IBS-A (n=56): alternating symptoms. Each value is the average of duplicate determinations. Solid lines are the median value from each group. The cutoff value of 12ng/ml was calculated from healthy subjects with median plus 2SD (dotted line). *p<0.0001 vs healthy subjects; **p<0.0001 vs IBS-D;
Mann Whitney U test. Table 2 provides a summary of tryptase levels in IBS Subtypes and healthy subjects (cutoff = 12.0ng/ml).

Table 2. Tryptase levels (ng/ml) in IBS Subtypes and healthy subjects (cutoff = 12.0ng/ml).

Figure 11 shows the increased serum level of histamine and PGE₂ in IBS patients vs healthy controls. PGE₂ was measured in 50 µl of serum by ELISA using a kit from Cayman. Histamine was measured in 10 µl of serum using an Immunotech EIA kit. The samples were tested in duplicate. The solid line is the median of each group. As such, in certain aspects, IBS-D may be diagnosed or distinguished from other clinical subtypes of IBS by detecting a higher level of PGE₂ relative to healthy control, IBS-A, and/or IBS-C samples or standards.

In certain other aspects, IBS-D or IBS-A may be diagnosed or distinguished from IBS-C by detecting a higher level of histamine relative to healthy control and/or IBS-C samples or standards.

Conclusions: (1) A sandwich ELISA method was developed that can measure serum tryptase level with high sensitivity, accuracy, and precision. The assay has a high degree of reproducibility and is suitable for routine testing of a large number of human sera. (2) Using this ELISA, we found significant differences in serum tryptase levels between healthy controls and IBS patients. Among the IBS patients, IBS-D and IBS-A patients had statistically higher tryptase levels compared to IBS-C patients. (3) Additional mast cell markers, histamine and PGE₂, were also found to be aberrant in IBS patient serum samples.

Combining these markers with tryptase resulted in improved diagnostic accuracy of IBS.

Example 3. Questionnaire for Identifying the Presence or Severity of Symptoms Associated with IBS.

This example illustrates a questionnaire that is useful for identifying the presence or severity of one or more IBS-related symptoms in an individual. The questionnaire can be completed by the individual at the clinic or physician's office, or can be brought home and
submitted when the individual returns to the clinic or physician's office, e.g., to have his or her blood drawn.

[0456] In some embodiments, the questionnaire comprises a first section containing a set of questions asking the individual to provide answers regarding the presence or severity of one or more symptoms associated with IBS. The questionnaire generally includes questions directed to identifying the presence, severity, frequency, and/or duration of IBS-related symptoms such as chest pain, chest discomfort, heartburn, uncomfortable fullness after having a regular-sized meal, inability to finish a regular-sized meal, abdominal pain, abdominal discomfort, constipation, diarrhea, bloating, and/or abdominal distension.

[0457] In certain instances, the first section of the questionnaire includes all or a subset of the questions from a questionnaire developed by the Rome Foundation Board based on the Rome III criteria, available at http://www.romecriteria.org/questionnaires/. For example, the questionnaire can include all or a subset of the 93 questions set forth on pages 920-936 of the Rome III Diagnostic Questionnaire for the Adult Functional GI Disorders (Appendix C), available at http://www.romecriteria.org/pdfs/AdultFunctGIQ.pdf. Preferably, the first section of the questionnaire contains 16 of the 93 questions set forth in the Rome III Diagnostic Questionnaire (see, Table 3). Alternatively, the first section of the questionnaire can contain a subset (e.g., 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, or 15) of the 16 questions shown in Table 3. As a non-limiting example, the following 10 questions set forth in Table 3 can be included in the questionnaire: Question Nos. 2, 3, 5, 6, 9, 10, 11, 13, 15, and 16. One skilled in the art will appreciate that the first section of the questionnaire can comprise questions similar to the questions shown in Table 3 regarding pain, discomfort, and/or changes in stool consistency.

Table 3. Exemplary first section of a questionnaire for identifying the presence or severity of IBS-related symptoms.

[0458] In other embodiments, the questionnaire comprises a second section containing a set of questions asking the individual to provide answers regarding the presence or severity of negative thoughts or feelings associated with having IBS-related pain or discomfort. For example, the questionnaire can include questions directed to identifying the presence,
severity, frequency, and/or duration of anxiety, fear, nervousness, concern, apprehension, worry, stress, depression, hopelessness, despair, pessimism, doubt, and/or negativity when the individual is experiencing pain or discomfort associated with one or more symptoms of IBS.

[0459] In certain instances, the second section of the questionnaire includes all or a subset of the questions from a questionnaire described in Sullivan et al., The Pain Catastrophizing Scale: Development and Validation, Psychol. Assess., 7:524-532 (1995). For example, the questionnaire can include a set of questions to be answered by an individual according to a Pain Catastrophizing Scale (PCS), which indicates the degree to which the individual has certain negative thoughts and feelings when experiencing pain: 0 = not at all; 1 = to a slight degree; 2 = to a moderate degree; 3 = to a great degree; 4 = all the time. The second section of the questionnaire can contain 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, or more questions or statements related to identifying the presence or severity of negative thoughts or feelings associated with having IBS-related pain or discomfort. As a non-limiting example, an individual can be asked to rate the degree to which he or she has one or more of the following thoughts and feelings when experiencing pain: "I worry all the time about whether the pain will end"; "I feel I can't stand it anymore"; "I become afraid that the pain will get worse"; "I anxiously want the pain to go away"; and "I keep thinking about how much it hurts." One skilled in the art will understand that the questionnaire can comprise similar questions regarding negative thoughts or feelings associated with having IBS-related pain or discomfort.

[0460] In some embodiments, the questionnaire includes only questions from the first section of the questionnaire or a subset thereof (see, e.g., Table 3). In other embodiments, the questionnaire includes only questions from the second section of the questionnaire or a subset thereof.

[0461] Upon completion of the questionnaire by the individual, the numbers corresponding to the answers to each question can be summed and the resulting value can be combined with the analysis of one or more diagnostic markers in a sample from the individual and processed using the statistical algorithms described herein to increase the accuracy of predicting IBS.

[0462] Alternatively, a "Yes" or "No" answer from the individual to the following question: "Are you currently experiencing any symptoms?" can be combined with the analysis of one or more of the biomarkers described herein and processed using a single
statistical algorithm or a combination of statistical algorithms to increase the accuracy of predicting IBS.

[0463] The present example describes the first blood-based biomarker test for Irritable Bowel Syndrome (IBS). This test can aid clinicians in the diagnosis of IBS. The IBS Diagnostic described below was validated using well-characterized IBS samples collected from recognized IBS experts and GI clinics. The samples were either Rome II or Rome III positive and the patients had a diagnosis of IBS for greater than one year. The test has a sensitivity of 50%, specificity of 88% with an overall accuracy of 70%.

[0464] The total cohort used to develop the present assay consisted of 1,721 serum samples. The validation cohort used consisted of 516 serum samples, of which 50% were diagnosed with IBS according to Rome II or Rome III criteria; 36% were Non-IBS disease controls; and 14% were normal healthy controls. The sensitivity of the assay is 50% and the specificity is 88%. When ruling in IBS, wherein the physician has determined that there is about a 75% probability of disease in the patient, 94% of the positive test results are true positives, while 38% of the negative test results are true negatives. When ruling out IBS, wherein the physician has determined that there is about a 25% probability of disease in the patient, 86% of the negative test results are true negatives, while 61% of the positive test results are true positives.

[0465] The assay involves the quantitative analysis of bio-markers combined with a two learning statistical classifier system consisting of a random forest classifier and a neural network classifier.

[0466] The specimen requirements for the assay consist of the physician obtaining 2.0 ml of separated serum in, for example, an SST tube. For best results, the sample should be centrifuges and refrigerates within 2 hours of collection. When samples need to be shipped prior to assay detection, the samples should be refrigerated or frozen. For best results, the samples should be stored, prior to use, for no more than 7 days at 4°C or 30 days if frozen.

[0467] Briefly, enzyme-linked immunosorbent assays (ELISAs) are performed with antibodies specific for the IBS biomarkers ASCA-IgA, CBir1, ANCA, and tTG. Additionally, chemiluminescent assays are performed for the IBS biomarkers BDNF, NGAL,
TWEAK, GRO-α, IL-1β, and TIMP-1. Reference values for the normal range of these markers in healthy subjects are provided in Table 4.

**Table 4.** Reference values for the markers detected in the IBS assay.

Example 5. Identification of Novel Metabolites in Serum of Patients with Irritable Bowel Syndrome.

[0469] 5-Hydroxytryptamine is converted from tryptophan catalyzed by tryptophan dehydrogenase. Over 95% of 5-HT in the body is released from the enterohromaffin cells of the gastrointestinal tract. 5-HT acts through various receptor subtypes located on submucosal and myenteric neurons of the enteric nerve system is known to play a key role in the normal functioning of the GI tract. Abnormal level of 5-HT is associated with pathogenesis of irritable bowel syndrome.

[0470] 5-HT (Hydroxytryptamines) plays an important role in GI motility, secretion, and sensation. Serotonergic therapies act on 5-HT receptors effectively ameliorate symptoms that IBS patients experience. Study 5-HT metabolites may lead to identification of biologically relevant biomarkers that can be used for accurate diagnosis of IBS.

[0471] Serum metabolites were investigated in samples from 12 IBS-C, 24 IBS-DJ4 IBS-M patients and 38 healthy subjects using high performance liquid chromatography (HPLC). We developed and optimized a high throughput HPLC method using a Diphenyl column which enabled us to separate over 20 peaks in IBS and healthy control samples. Plasma, serum and urine samples from the same subjects were compared for levels of 5-HT and its metabolites.

[0472] Briefly, serum samples were collected in SST tubes according to the approved IRB (Prometheus 08IBS04 protocol). 300 ul of human serum was deproteinated with 60 ul of isopropanol and 360 ul of acetonitrile. The mixture was then centrifuged at 2000 x g for 15 minutes. The supernatant containing metabolites was transferred to a second tube and concentrated using a Speed Vac Plus (model SCI 10A). The dry pellet was reconstituted with 160 ul of water, of which 100 ul is injected into the HPLC system (Agilant 1200).
Liquid chromatography was performed using an Agilent 1200 HPLC system consisting of a quaternary pump, an autosampler, a DAD and a FLD. Chromatographic separation was performed on a Varian Pursuit Diphenyl 5 \( \mu \)m 4.6 x 150 mm column, protected by a Metaguard Pursuit XR 10 \( \mu \)m C18 guard column, as well as, a SunFire 5 \( \mu \)m 4.6 x 20 mm C18 guard column. For the first 20 minutes of the analysis a gradient from 100% buffer A to 100% buffer B was employed. After 55 minutes, the mobile phase was changed from 100% buffer B to 100% buffer A over 1 minute. Buffer A was then kept at 100% for 10 minutes in preparation for the next injection. Mobile phase A consisted of a 10 mM sodium acetate buffer, pH 4 using glacial acetic acid. Mobile phase B is the same as buffer A but with 12% methanol. 5-HT, as well as other indoles, were detected using the FLD set at an excitation of 225 and emission of 342. Tryptophan and Kynurenine are detected with the UV set at the wavelengths of, respectively, 278 and 360.

Measurements were carried out at 25°C at Eox = 0.65 V. The calibration curves are linear through the range of 10-200 pg/mL. Method validation was performed according to internationally accepted criteria. Blood was collected from healthy controls and IBS subjects.

Upon analysis, several known analytes were identified, such as tryptophan and 5-HT and its metabolites, 5-HT-O-S and Kynurenine, as well as several novel metabolites with retention time at 7.5 minute, 13.5 minute, 52 minute by fluorescent detector and at 20 minute by UV detector, respectively. Representative chromatograms from this analysis are shown in Figure 14. The level of each biomarker is shown in Figure 15.

As can be seen in Table 6, the serum 5-HT concentrations in all three IBS subtypes were lower than those of healthy controls after normalized by internal standards, a median AUC of 94.5 for healthy subjects, 66.85, 48.3, and 46.25 for IBS-C, IBS-D, and IBS-M respectively. The area under curve for the peaks at 7.5 min and 13.5 were higher in all three IBS subgroups after normalized by 5-HT. IBS-D patients had higher level of 20 min UV peaks compared to IBS-C, IBS-M, and healthy volunteers. These findings suggest serum metabolites may serve as biomarkers for diagnosis of IBS. The predictive power of the serum metabolites is illustrated in Figure 16.

Example 6. Effect of inflammatory cytokine treatment on 5-HT metabolism and mast cell activation in human blood cells.

[0477] Irritable bowel syndrome is a multi-factorial functional GI disorder. Inflammatory stimulation in local gut mucosa has been implicated as a trigger for IBS disease onset. Serotonin dysregulation, mast cell activation and stress response all contribute to pathogenesis of the disease. The present example provides a study of the interactions of those pathways in inflammatory cytokine treated blood samples from healthy volunteers. Changes in 5-HT metabolism and plasma level of mast cell and stress markers were measured. It was found that inflammatory stimulation alter tryptophan and 5-HT metabolism. Similarly, plasma kynurenine and 5-HT-O-S level were up-regulated by TNF-a treatment. IL-1β stimulation resulted in increase level of PGE₂, which is a marker of mast cell activation. Quantification of 5-HT biosynthesis enzyme (TPH-1) and metabolic enzyme (MAO) led to finding of change in transcript of those enzymes by cytokines. Understanding of the interactions between those pathways help us to identify biology relevant biomarkers to assist clinical diagnosis.

[0478] Irritable bowel syndrome is a heterogenous disorder. There is increasing evidence for involvement of the immune system in its pathogenesis. Gastrointestinal infection may serve as a triggering factor for onset of symptoms. IBS is often described as a "brain-get disorder". Alterations in gastrointestinal motility and secretion may underlie irregularities in bowel habits that may be mediated by dysregulation of serotonin signaling system. Activated
mast cells in proximity to colonic nerves correlated with abnormal pain in patients with IBS. Mast cells are well known for capable of releasing and producing a variety of inflammatory mediators upon activation. It remains unclear how those pathways communicate with each other and whether the interactions behave the same in IBS patients as in healthy subjects.

[0479] Blood samples were collected and treated as follows. Fresh human blood samples from healthy volunteers were collected into heparin tubes. The samples were aliquoted into seven 15 ml colloquial tubes and treated with inflammatory cytokines, TNF-a, IL-1β, TIMP1, NGAL, 2-Plex (BDNF and TWEAK), 5-Plex (Gro-a, ASCA, ANCA, tTG, CBir1) for 2 day at 37°C in cell culture incubator. In order to measure the levels of metabolites in the samples, chemicals from 300 µ of treated plasma samples were extracted by isopropanol and acetonitrile. Metabolites were separated by HPLC using a diphenol column (Aligant system). The machine was run at a gradient of 0-12% methanol for 20 minutes, followed by an isocratic run at 12% methanol for 55 minutes. 5-HT and other indoles are detected using the FLD set at an excitation of 225 and emission of 342. Tryptophan and Kynurenine were detected with the UV set at the wavelengths of 278 and 360 respectively. Representative chromatograms from this analysis are shown in Figure 17. As seen in Figure 18 and Table 7, TNF-a treatment of blood samples significantly stimulated tryptophan and 5-HT metabolism, resulting in elevated kynurenin and 5-HT-O-S production.

[0480] MAO, TPH1, and SERT expression profiling: 2.4 ml of each treated blood sample was added into Paxigen tubes, total RNA was prepared according to manufacture's protocol. 200ng of total RNA was reversely transcribed into cDNA, 200ng of cDNA was used for quantification subsequently by qPCR reaction (ABI 7000 systems).

[0481] Measurement of immune markers: Mast cell markers, 5-HT, and Urocortin (Ucn) were measured by ELISA. Tryptase and Ucn were measured using assays developed by Prometheus. PGE₂, histamine, and 5-HT were measured using the commercial assays. As
seen in Table 8 and Figure 19, Ucn levels were significantly elevated in response to TNF-a, TIMP1, and NGAL treatment. As seen in Table 9 and Figure 20, the mast cell marker PGE$_2$ was significantly elevated in response to IL-1$\beta$ treatment.

The present example demonstrates that TNF-a treatment leads to increase release of tryptophan metabolites, kynurenin, and 5-HT metabolite, 5-HT-O-S in healthy human blood cells. This alteration in tryptophan and 5-HT metabolism may be due to change in 5-HT MAO and TPH1 expression in blood cells induced by cytokine treatment. Furthermore, it was found that the level of the mast cell marker PGE$_2$ was significantly increased upon IL-1$\beta$ treatment of fresh whole blood. Further studies of cytokine response in IBS patient blood cells may shed some light on the mechanistic interaction in the pathways contributing the IBS pathogenesis.
Example 7. Discovery of tyrosine, phenylalanine and serotonin as useful metabolite biomarkers for the identification of IBS and subtypes thereof.

[0483] Serotonin (5-Hydroxy-tryptamine, 5-HT) plays an important role in gastrointestinal (GI) motility, secretion and sensation. A 5-HT3 receptor antagonist, Alosetron, was approved for the management of severe diarrhea-predominant female irritable bowel syndrome (IBS) patients and a 5-HT4 receptor agonist, Tegaserod, was approved for the management of constipation-predominant IBS patients. Due to the prominent role 5-HT plays in IBS, analysis of 5-HT and its metabolites in serum may lead to the identification of biologically relevant biomarkers that can be used for accurate diagnosis of IBS. For this purpose, high performance liquid chromatography (HPLC) has been employed to analyze serum metabolites from IBS patients and healthy control (HC) subjects, looking for novel biomarkers. Indeed, several potential biomarkers were discovered, which exhibited different concentrations in IBS patients versus HC subjects. In order to identify those novel biomarkers, a large scale extraction and HPLC purification of pooled human serum samples was performed to isolate those markers and used mass spectrometric analysis to establish their chemical structures. One of the marker was identified to be 5-HT itself, while two of the other isolated markers were identified to be tyrosine and phenylalanine and the identity of those marker peaks in the analytical HPLC were subsequently confirmed by spiking synthetic tyrosine and phenylalanine into human serum samples. Serum level of 5-HT was found to be higher in HC subjects compared to IBS patients, whereas IBS patient subtypes have varied levels of tyrosine and phenylalanine. Measurement of tyrosine and phenylalanine levels is relevant to IBS diagnosis since these two amino acids are precursors for the biosynthesis of dopamine, norepinephrine and epinephrine, which are important regulators of the enteric nervous system.

[0484] While the etiology of IBS remains obscure, there is a body of evidence suggesting several pathophysiological pathways that are dysregulated in IBS, including serotonin (5-HT) biosynthesis and metabolism, mast cell infiltration, visceral hypersensitivity, stress response and bacteria infection (post infectious IBS). Of these, the 5-HT system plays a significant role in GI physiology and pathophysiology and several 5-HT receptor agonists and antagonists are either approved or under clinical development for the management of IBS. For this reason, identification of 5-HT and its metabolites as potential biomarkers in IBS patient serum samples may facilitate an accurate diagnosis of IBS and provide a better treatment. Towards this goal, a high performance liquid chromatography (HPLC) method
has been developed to identify potential biomarkers in serum samples from IBS patients and healthy control (HC) subjects.

[0485] Preparation of Serum Samples for HPLC Analysis: IBS patient serum samples were collected in SST tubes according to an IRB approved protocol and healthy control serum samples were obtained from volunteers. To prepare a serum sample for HPLC analysis, 300 µL of serum was deproteinized by vortexing with 60 µL of isopropanol and 360 µL of acetonitrile in an Eppendorf tube and the mixture centrifuged at 2000Xg for 15 min. The supernatant containing the serum metabolites was transferred to a second Eppendorf tube and the solvent evaporated using a Speed Vac Plus concentration (model SCI 10A). The dry pellet is reconstituted in 160 µL of water, of which 100 µL is injected into the HPLC system for analysis.

[0486] Analytical HPLC Procedure: The HPLC system employed for the analysis is an Agilent model 1200 HPLC system, consisting of a binary pump, an autosampler, a DAD detector and a FLD detector. Separation of the metabolites was performed on a 4.6x150 mm, 5 µm, Varian Pursuit Diphenyl column, protected by a 10 µm, C18 Metaguard Pursuit XR guard column as well as a 4.6x20 mm, 5 µm, C18 Sun Fire guard column connected in series. Mobile phase A consisted of a 10 mM sodium acetate solution, buffered to pH 4.0 with glacial acetic acid and mobile phase B was 12% methanol by volume in mobile phase A. The HPLC analysis was carried out at room temperature by using a gradient that changed from 100% mobile phase A to 100% mobile phase B in 20 min at a flow-rate of 1 mL/min and then stayed at 100% mobile phase B for 35 min. At 55 min, the mobile phase was changed from 100% B to 100% A in 1 min and maintained at 100% A for the next 10 min in preparation for the next analysis. 5-HT as well as other indole-containing molecules were detected by using the FLD detector set at an excitation wave-length of 225 nm and emission wave-length of 342 nm. Kynurenine and other metabolites were detected by using the DAD detector with the UV wave-length set at 278 and 360 nm, respectively.

[0487] Large Scale Isolation and Identification of the Metabolites: To establish the chemical structure of the biomarker peaks identified in the HPLC analysis, a large scale purification of a pooled serum sample was performed by 3D BioOptima and the structure of the isolated metabolite markers was determined by mass spectrometry.

[0488] Figure 22 shows the representative chromatograms obtained from the HPLC analysis of a serum sample from an IBS patient (Figure 22, panels a, b and c) and a healthy control subject (panels d, e and f). The peaks in panels a and d were detected by UV...
absorbance at 278 nm, while the peaks in panels b and e were detected by UV absorbance at 360 nm. The peaks in panels c and f were monitored by fluorescence detection. As seen in Figure 22, three prominent peaks (denoted in boxes), eluting at 7.5, 13.5 and 17.2 minutes showed a difference in peak area between the IBS and HC serum samples. Difference in peak area between IBS and HC serum samples was also noted at other eluted peaks but they were not as prominent. Due to the significant difference in the 7.5, 13.5 and 17.2 minute peak areas between IBS and HC subjects, all of the collected serum samples were evaluated by the HPLC method. Figure 23 shows the statistical distribution of the three peak levels in the serum samples obtained from the IBS-C, IBS-D, IBS-M and HC subjects. As seen in Figure 23, serum levels of the 17.2 minute peak were found to be higher in HC subjects compared to IBS patients, whereas IBS patient subtypes have varied levels in the 7.5 and 13.5 minute peaks. The peak eluting at 17.2 minute was readily identified as 5-HT by co-elution with a spiked in 5-HT standard in the HPLC analysis but the identity of the 7.5 and 13.5 minute peaks was not known. In order to establish the chemical structure of the these two peaks, a large scale purification of a pooled serum sample was performed to isolate the compounds present in these two peaks and determine their structure by mass spectrometry. Figure 24 shows the structure elucidation of the 7.5 minute peak by mass spectrometry to establish its identity as the amino acid tyrosine and Figure 25 shows the structure elucidation of the 13.5 minute peak by mass spectrometry to establish its identity as the amino acid phenylalanine. Figure 26 shows the HPLC analysis results from the spiking of standard D-tyrosine to the serum samples to generate a linear dose-dependent response curve and Figure 27 shows the HPLC analysis results from the spiking of standard L-phenylalanine to the serum samples to generate a linear dose-dependent response curve.

[0489] In this study, an HPLC method has been developed to analyze the metabolites present in serum samples obtained from IBS patients and healthy control subjects, looking for potential biomarkers for the diagnosis of IBS. Three prominent markers were discovered, which corresponded to tyrosine, phenylalanine and serotonin. Serum levels of serotonin was found to be higher in healthy control subjects compared to IBS patients, whereas IBS patient subtypes have varied levels of tyrosine and phenylalanine. Measurement of tyrosine and phenylalanine levels, in addition to serotonin level, is relevant to IBS diagnosis since these two amino acids are precursors for the biosynthesis of dopamine, norepinephrine and epinephrine, which are important regulators of the enteric nervous system.
Example 8. TNFa treatment results in increased release of the tryptophan metabolite, kynurenin, and the 5-HT metabolite, 5-HT-0-S03H. IL-1β treatment increases PGE₂ and TNFa and TIMP1 treatment elevates uroctin levels in whole blood cells.

Irritable bowel syndrome (IBS) is a multi-factorial functional gastrointestinal (GI) disorder. Inflammatory stimulation in local gut mucosa has been implicated as one trigger for IBS disease onset. Pathways involved with serotonin (5-HT) dysregulation, mast cell activation and stress response all contributed to the pathogenesis of the disease. In an attempt to find biomarkers for the diagnosis of IBS, the interplay of these pathways has been studied in inflammatory cytokine treated whole blood samples from healthy volunteers. Changes in 5-HT metabolism and levels of mast cell activation and stress response markers were determined. Inflammatory cytokine stimulation was found to alter tryptophan and 5-HT metabolism. Plasma kynurenine and 5-HT-0-S03H levels were up-regulated by TNFa treatment. IL-1β stimulation resulted in increased level of PGE₂, which is a marker for mast cell activation. Measurement of 5-HT biosynthesis enzyme (TPH1) and metabolism enzyme (MAO) mRNAs levels indicated that the transcripts of these enzymes were affected by cytokine treatment. Thus, understanding the interactions between these pathways could help us to identify biological relevant markers to assist the clinical diagnosis of IBS.

Blood Sample Collection and Treatment: Fresh human blood samples from healthy volunteers were collected into heparin tubes. The collected samples were aliquoted into seven 15mL Colloquial tubes and treated with inflammatory cytokines, TNF-a, IL-1β, TIMP1 (tissue inhibitor of metalloproteinases-1), NGAL (neutrophil gelatinase-associated lipocalin) for 2 day at 37°C in a cell culture incubator.

Measurement of Metabolites: The product from each 300 µL of treated plasma sample was extracted with isopropanol and acetonitrile and the extract analyzed by using a diphenyl column on an Agilent HPLC system. Separation of the metabolites was performed with a linear gradient from 0-12% methanol in 10 mM sodium acetate buffer, pH 4.0, for 20 min, followed by an isocratic run at 12% methanol in the same buffer for 35 minutes. Indole metabolites and 5-HT were detected using the FLD detector set at an excitation wave length of 225 nm and emission wave length of 342 nm. Tryptophan and Kynurenine were detected with the UV set at wave lengths of 278 nm and 360 nm, respectively.

MAO, TPH1 and SERT Expression Profiling: Aliquots of 2.4 mL from each of the treated blood samples were added into PAXgen tubes and total RNA was prepared according
to manufacturer's protocol. Aliquots of 200 ng total RNA were reversely transcribed into cDNA and 200 ng of the resulting cDNA was used for quantification by qPCR reaction (ABI 7000 systems).

[0494] Measurement of Immune Markers: Tryptase and Ucn (urocortin) were measured using assays developed by Prometheus. PGE$_2$, histamine, and 5-HT were measured using the commercially available ELISA assays.

[0495] Figure 28 shows the 5-HT pathway and its participation in the pathophysiology of IBS. A 5-HT3 receptor antagonist, Lotronex, was approved for the management of severe diarrhea-predominant female IBS patients because it blocks the activation of the 5-HT3 receptors that results in stimulation of gut secretion, propulsion and pain. Table 10 shows the effects of cytokine treatment on the levels of the 5-HT pathway metabolites in whole blood cells while Figure 29 shows the effects of cytokine treatment on the transcript levels of 5-HT pathway metabolic enzymes in whole blood cells. As seen in Table 10, TNFα treatment greatly increased the relative levels of the metabolites kynurenine and 5-HT-0-S03H, indicating that this cytokine stimulated tryptophan and 5-HT metabolism, which resulted in the increase of kynurenine and 5-HT-0-S03H synthesis. No distinct effects on 5-HT pathway metabolites were noted by treatment with IL-1β and TIMPl.

[0496] By contrast, TNFα treatment of whole blood cells inhibited the transcript of MAO but not TPH1, whereas IL-1β treatment greatly increased the transcript level of TPH1 but not that of MAO (see, Figure 29). TIMPl treatment also slightly increased the transcript level of TPH1 but inhibited the transcript level of MAO whereas NGAL treatment did not seem to have much effect on these two transcripts. The transcript level of SERT was not detectable in any of the treated cells. Table 11 and Figure 30 show the levels of mast cell activation markers produced by cytokine treatment of whole blood cells. Treatment with IL-1β greatly increase the level of the marker PGE$_2$, whereas no distinct changes in other markers levels were noted by treatment with NGAL, TIMPl and TNFα. Figure 31 shows the level of the stress response marker urocortin (Ucn) produced by cytokine treatment of whole blood cells. Urocortin level was greatly elevated by treatment with TNFα, TIMPl and NGAL but not by IL-1β. Figure 19 shows a diagram illustrating the interplay between leukocytes, enterochromaffin cells, mast cells and platelets in the gastrointestinal system mediated by some of the markers determined herein.

This example demonstrates that TNFa treatment resulted in increased release of the tryptophan metabolite, kynurenin, and the 5-HT metabolite, 5-HT-O-SO\(_3\)H, in healthy human whole blood cells. Without being bound by theory, the alteration seen in tryptophan and 5-HT metabolism could be caused by changes in the expression of the enzymes MAO and TPH1 in blood cells induced by the cytokine treatment.

As seen in Figure 30, the level of the mast cell activation marker PGE\(_2\) was greatly increased upon IL-1β treatment of whole blood cells. Furthermore, as shown in Figure 31, TNFa and TIMP1 treatment also greatly elevated the level of the stress response marker urocortin in whole blood cells. Further studies of the responses in cytokine treatment of IBS patient blood cells may shed some light on the mechanistic interaction in the pathways that contribute to the pathogenesis of IBS.

References:

Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, one of skill in the art will appreciate that certain changes and modifications may be practiced within the scope of the appended claims. In addition, each reference provided herein is incorporated by reference in its entirety to the same extent as if each reference was individually incorporated by reference.
WHAT IS CLAIMED IS:

1. A method for aiding in the diagnosis of irritable bowel syndrome (IBS) in a subject, said method comprising:
   (a) contacting a blood or serum sample from the subject with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety; and
   (b) determining the level of said complex, thereby determining the level or concentration of the IBS marker present in the sample,
   wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, uroctin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.

2. The method of claim 1, wherein the method further comprises:
   (c) comparing the level or concentration of the IBS marker present in the sample to a control level or concentration, wherein a difference in the level or concentration of the IBS marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

3. The method of claim 2, wherein the control level or concentration is the level or concentration of the IBS marker present in a blood or serum sample from a healthy subject.

4. The method of claim 3, wherein an increased level or concentration of the IBS marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

5. The method of claim 3, wherein the same or a reduced level or concentration of the IBS marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.
6. The method of claim 2, wherein the control level or concentration is the level or concentration of the IBS marker present in a blood or serum sample from a subject with IBS.

7. The method of claim 6, wherein the same or an increased level or concentration of the IBS marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject having IBS.

8. The method of claim 6, wherein a reduced level or concentration of the IBS marker present in the sample relative to the control level or concentration is indicative of an increased likelihood of said subject not having IBS.

9. The method according to any one of claims 1 to 8, wherein the IBS marker is carbohydrate deficient transferrin.

10. The method according to any one of claims 1 to 8, wherein the IBS marker is urocortin.

11. The method according to any one of claims 1 to 8, wherein the IBS marker is corticotrophin-releasing hormone-binding protein.

12. The method according to any one of claims 1 to 8, wherein the IBS marker is Cortisol.

13. The method according to any one of claims 1 to 8, wherein the IBS marker is adrenocorticotropic hormone.

14. The method according to any one of claims 1 to 8, wherein the IBS marker is substance P.

15. The method according to any one of claims 1 to 8, wherein the IBS marker is nerve growth factor.

16. The method according to any one of claims 1 to 8, wherein the IBS marker is neurokinin A.

17. The method according to any one of claims 1 to 8, wherein the IBS marker is neurokinin B.
18. The method according to any one of claims 1 to 8, wherein the IBS marker is vasoactive intestinal peptide.

19. The method according to any one of claims 1 to 8, wherein the IBS marker is glucagon-like peptide 2.

20. The method according to any one of claims 1 to 8, wherein the IBS marker is motilin.

21. The method according to any one of claims 1 to 8, wherein the IBS marker is pituitary adenylate cyclase-activating peptide.

22. The method according to any one of claims 1 to 8, wherein the IBS marker is serotonin.

23. The method according to any one of claims 1 to 8, wherein the IBS marker is tryptophan.

24. The method according to any one of claims 1 to 8, wherein the IBS marker is serotonin O-sulfate.

25. The method according to any one of claims 1 to 8, wherein the IBS marker is 5-hydroxyindoleacetic acid.

26. The method according to any one of claims 1 to 8, wherein the IBS marker is 5-HT glucuronide.

27. The method according to any one of claims 1 to 8, wherein the IBS marker is tyrosine.

28. The method according to any one of claims 1 to 8, wherein the IBS marker is phenylalanine.

29. The method according to any one of claims 1 to 8, wherein the IBS marker is UDP-glucuronosyltransferase 1-6.

30. The method according to any one of claims 1 to 8, wherein the IBS marker is serotonin reuptake transporter.
31. The method according to any one of claims 1 to 8, wherein the IBS marker is tryptophan hydroxylase 1.

32. The method according to any one of claims 1 to 8, wherein the IBS marker is monoamine oxidase A.

33. The method according to any one of claims 1 to 8, wherein the IBS marker is monoamine oxidase B.

34. The method according to any one of claims 1 to 8, wherein the IBS marker is hydroxytryptamine (serotonin) receptor 3A.

35. The method according to any one of the preceding claims, wherein the subject is suspected of having IBS.

36. The method according to any one of the preceding claims, wherein the binding moiety comprises an antibody.

37. The method of claim 36, wherein the method is an enzyme-linked immunosorbent assay (ELISA).

38. The method of claim 37, wherein the ELISA is a sandwich ELISA.

39. The method according to any one of the preceding claims, wherein the method further comprises determining the level or concentration of at least one additional biomarker in a biological sample from the subject, the biomarker selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.

40. The method according to any one of the preceding claims, wherein the method further comprises:
(d) determining a symptom profile for the subject, wherein said symptom profile is determined by identifying the presence or severity of at least one symptom in said subject; and
(e) diagnosing the subject as having IBS or not having IBS using an algorithm based upon the level of an IBS biomarker and the symptom profile.

41. The method of claim 40, wherein said at least one symptom is selected from the group consisting of chest pain, chest discomfort, heartburn, uncomfortable fullness after having a regular-sized meal, inability to finish a regular-sized meal, abdominal pain, abdominal discomfort, constipation, diarrhea, bloating, abdominal distension, negative thoughts or feelings associated with having pain or discomfort, and a combination thereof.

42. The method of claim 40, wherein the presence or severity of said at least one symptom is identified using a questionnaire.

43. The method according to any one of the preceeding claims, wherein the method comprises the use of an algorithm based upon the level of an IBS biomarker.

44. The method of claim 43, wherein the algorithm is further based upon the system profile.

45. The method of claim 43 or 44, wherein said statistical algorithm comprises a learning statistical classifier system.

46. The method of claim 45, wherein said statistical algorithm comprises a combination of at least two learning statistical classifier systems.

47. The method of claim 46, wherein the combination of at least two learning statistical classifier systems comprises a random forest classifier and a neural network classifier.

48. The method according to any one of the preceeding claims, wherein the method further comprises providing a probability that the subject has IBS.

49. The method according to any one of the preceeding claims, wherein the method further comprises classifying a diagnosis of IBS as IBS-constipation (IBS-C), IBS-diarrhea (IBS-D), IBS-mixed (IBS-M), IBS-alternating (IBS-A), or post-infectious IBS (IBS-PI).
50. The method according to any one of claims 40 to 49, wherein said method further comprises diagnosing the subject not having IBS as having IBD, as not having IBD, or as being a healthy subject.

51. A method for monitoring the progression or regression of irritable bowel syndrome (IBS) in a subject, the method comprising:
   (a) contacting a first blood or serum sample taken from the subject at a first time with an IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety;
   (b) determining the level of said complex, thereby determining the level of the IBS marker present in the first sample;
   (c) contacting a second blood or serum sample taken from the subject at a second time with the IBS marker binding moiety under conditions suitable to transform the IBS marker present in the sample into a complex comprising the IBS marker and the IBS marker binding moiety;
   (d) determining the level of said complex, thereby determining the level of the IBS marker present in the second sample; and
   (e) comparing the level of the IBS marker present in the first sample to the level of the IBS marker present in the second sample,
   wherein a higher level of the IBS marker in the second sample relative to the first sample is indicative of the progression of IBS in the subject and a lower level of the IBS marker in the second sample relative to the first sample is indicative of the regression of IBS in the subject, and
   wherein the IBS marker is selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.

52. The method according to claim 51, wherein the IBS marker is carbohydrate deficient transferrin.
53. The method according to claim 51, wherein the IBS marker is urocortin.

54. The method according to claim 51, wherein the IBS marker is corticotrophin-releasing hormone-binding protein.

55. The method according to claim 51, wherein the IBS marker is Cortisol.

56. The method according to claim 51, wherein the IBS marker is adrenocorticotropic hormone.

57. The method according to claim 51, wherein the IBS marker is substance P.

58. The method according to claim 51, wherein the IBS marker is nerve growth factor.

59. The method according to claim 51, wherein the IBS marker is neurokinin A.

60. The method according to claim 51, wherein the IBS marker is neurokinin B.

61. The method according to claim 51, wherein the IBS marker is vasoactive intestinal peptide.

62. The method according to claim 51, wherein the IBS marker is glucagon-like peptide 2.

63. The method according to claim 51, wherein the IBS marker is motilin.

64. The method according to claim 51, wherein the IBS marker is pituitary adenylate cyclase-activating peptide.

65. The method according to claim 51, wherein the IBS marker is serotonin.

66. The method according to claim 51, wherein the IBS marker is tryptophan.
67. The method according to claim 51, wherein the IBS marker is serotonin O-sulfate.

68. The method according to claim 51, wherein the IBS marker is 5-hydroxyindoleacetic acid.

69. The method according to claim 51, wherein the IBS marker is 5-HT glucuronide.

70. The method according to claim 51, wherein the IBS marker is tyrosine.

71. The method according to claim 51, wherein the IBS marker is phenylalanine.

72. The method according to claim 51, wherein the IBS marker is UDP-glucuronosyltransferase 1-6.

73. The method according to claim 51, wherein the IBS marker is serotonin reuptake transporter.

74. The method according to claim 51, wherein the IBS marker is tryptophan hydroxylase 1.

75. The method according to claim 51, wherein the IBS marker is monoamine oxidase A.

76. The method according to claim 51, wherein the IBS marker is monoamine oxidase B.

77. The method according to claim 51, wherein the IBS marker is hydroxytryptamine (serotonin) receptor 3A.

78. The method according to any one of claims 51 to 77, wherein the binding moiety comprises an antibody.

79. The method of claim 78, wherein the method is an enzyme-linked immunosorbent assay (ELISA).

80. The method of claim 79, wherein the ELISA is a sandwich ELISA.
81. The method of claim according to any one of claims 51 to 80, wherein the method further comprises determining the level of at least one additional biomarker in a biological sample from the subject, the biomarker selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E₂ (PGE₂), and a combination thereof.

82. The method of claim 51, wherein the method further comprises determining a symptom profile for the subject, wherein said symptom profile is determined by identifying the presence or severity of at least one symptom in said subject.

83. The method of claim 82, wherein said at least one symptom is selected from the group consisting of chest pain, chest discomfort, heartburn, uncomfortable fullness after having a regular-sized meal, inability to finish a regular-sized meal, abdominal pain, abdominal discomfort, constipation, diarrhea, bloating, abdominal distension, negative thoughts or feelings associated with having pain or discomfort, and a combination thereof.

84. The method according to any one of claims 51 to 83, wherein the method comprises the use of an algorithm based upon the level of an IBS biomarker.

85. The method of claim 84, wherein the algorithm is further based upon the system profile.

86. The method of claim 84 or 85, wherein said algorithm comprises a statistical algorithm.

87. The method of claim 86, wherein said statistical algorithm comprises a learning statistical classifier system.

88. The method of claim 87, wherein said statistical algorithm comprises a combination of at least two learning statistical classifier systems.
89. The method of claim 88, wherein the combination of at least two learning statistical classifier systems comprises a random forest classifier and a neural network classifier.

90. The method according to any one of claims 51 to 89, wherein the method comprises monitoring drug efficacy in a subject receiving a drug useful for treating irritable bowel syndrome (IBS).

91. A computer-readable medium comprising code for controlling one or more processors to classify whether a serum or blood sample from an subject is associated with irritable bowel syndrome (IBS), said code comprising:

instructions to apply a statistical process to a data set comprising a diagnostic marker profile to produce a statistically derived decision classifying said sample as an IBS sample or non-IBS sample based upon said diagnostic marker profile,

wherein said diagnostic marker profile indicates the level of at least one diagnostic IBS marker selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A.

92. The computer-readable medium of claim 91, wherein the IBS marker is carbohydrate deficient transferrin.

93. The computer-readable medium of claim 91, wherein the IBS marker is urocortin.

94. The computer-readable medium of claim 91, wherein the IBS marker is corticotrophin-releasing hormone-binding protein.

95. The computer-readable medium of claim 91, wherein the IBS marker is Cortisol.
96. The computer-readable medium of claim 91, wherein the IBS marker is adrenocorticotropic hormone.

97. The computer-readable medium of claim 91, wherein the IBS marker is substance P.

98. The computer-readable medium of claim 91, wherein the IBS marker is nerve growth factor.

99. The computer-readable medium of claim 91, wherein the IBS marker is neurokinin A.

100. The computer-readable medium of claim 91, wherein the IBS marker is neurokinin B.

101. The computer-readable medium of claim 91, wherein the IBS marker is vasoactive intestinal peptide.

102. The computer-readable medium of claim 91, wherein the IBS marker is glucagon-like peptide 2.

103. The computer-readable medium of claim 91, wherein the IBS marker is motilin.

104. The computer-readable medium of claim 91, wherein the IBS marker is pituitary adenylate cyclase-activating peptide.

105. The computer-readable medium of claim 91, wherein the IBS marker is serotonin.

106. The computer-readable medium of claim 91, wherein the IBS marker is tryptophan.

107. The computer-readable medium of claim 91, wherein the IBS marker is serotonin O-sulfate.

108. The computer-readable medium of claim 91, wherein the IBS marker is 5-hydroxyindoleacetic acid.
109. The computer-readable medium of claim 91, wherein the IBS marker is 5-HT glucuronide.

10. The computer-readable medium of claim 91, wherein the IBS marker is tyrosine.

111. The computer-readable medium of claim 91, wherein the IBS marker is phenylalanine.

112. The computer-readable medium of claim 91, wherein the IBS marker is UDP-glucuronosyltransferase 1-6.

113. The computer-readable medium of claim 91, wherein the IBS marker is serotonin reuptake transporter.

114. The computer-readable medium of claim 91, wherein the IBS marker is tryptophan hydroxylase 1.

115. The computer-readable medium of claim 91, wherein the IBS marker is monoamine oxidase A.

116. The computer-readable medium of claim 91, wherein the IBS marker is monoamine oxidase B.

117. The computer-readable medium of claim 91, wherein the IBS marker is hydroxytryptamine (serotonin) receptor 3A.

118. The computer-readable medium according to any one of claims 91 to 117, wherein the diagnostic marker profile indicates the level of at least one additional diagnostic marker in a biological sample from the subject selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBir1), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E$_2$ (PGE$_2$), and a combination thereof.
19. The computer-readable medium according to any one of claims 9 to 18, wherein said computer-readable medium comprises instructions to apply a statistical process to a data set comprising said diagnostic marker profile in combination with a symptom profile which indicates the presence or severity of at least one symptom in said subject to produce a statistically derived decision classifying said sample as an IBS sample or non-IBS sample based upon said diagnostic marker profile and said symptom profile.

20. The computer-readable medium of claim 19, wherein said statistical process comprises a single learning statistical classifier system.

21. The computer-readable medium of claim 20, wherein said statistical process comprises a combination of at least two learning statistical classifier systems.

22. The computer-readable medium of claim 21, wherein the combination of at least two learning statistical classifier systems comprises a random forest classifier and a neural network classifier.

23. A system for classifying whether a serum or blood sample from a subject is associated with irritable bowel syndrome (IBS), said system comprising:

(a) a data acquisition module configured to produce a data set comprising a diagnostic marker profile, wherein said diagnostic marker profile indicates the presence or level of at least one diagnostic IBS marker selected from the group consisting of carbohydrate deficient transferrin, urocortin, corticotrophin-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, vasoactive intestinal peptide, glucagon-like peptide 2, motilin, pituitary adenylate cyclase-activating peptide, serotonin, tryptophan, serotonin O-sulfate, 5-hydroxyindoleacetic acid, 5-HT glucuronide, tyrosine, phenylalanine, UDP-glucuronosyltransferase 1-6, serotonin reuptake transporter, tryptophan hydroxylase 1, monoamine oxidase A, monoamine oxidase B, and hydroxytryptamine (serotonin) receptor 3A;

(b) a data processing module configured to process the data set by applying a statistical process to the data set to produce a statistically derived decision classifying said sample as an IBS sample or non-IBS sample based upon said diagnostic marker profile; and

(c) a display module configured to display the statistically derived decision.

24. The system of claim 23, wherein the IBS marker is carbohydrate deficient transferrin.
125. The system of claim 123, wherein the IBS marker is urocortin.

126. The system of claim 123, wherein the IBS marker is corticotropin
releasing hormone-binding protein.

127. The system of claim 123, wherein the IBS marker is Cortisol.

128. The system of claim 123, wherein the IBS marker is
adrenocorticotropic hormone.

129. The system of claim 123, wherein the IBS marker is substance P.

130. The system of claim 123, wherein the IBS marker is nerve growth
factor.

131. The system of claim 123, wherein the IBS marker is neurokinin A.

132. The system of claim 123, wherein the IBS marker is neurokinin B.

133. The system of claim 123, wherein the IBS marker is vasoactive
intestinal peptide.

134. The system of claim 123, wherein the IBS marker is glucagon-like
peptide 2.

135. The system of claim 123, wherein the IBS marker is motilin.

136. The system of claim 123, wherein the IBS marker is pituitary adenylate
cyclase-activating peptide.

137. The system of claim 123, wherein the IBS marker is serotonin.

138. The system of claim 123, wherein the IBS marker is tryptophan.

139. The system of claim 123, wherein the IBS marker is serotonin O-
sulfate.

140. The system of claim 123, wherein the IBS marker is 5-
hydroxyindoleacetic acid.

141. The system of claim 123, wherein the IBS marker is 5-HT glucuronide.
142. The system of claim 123, wherein the IBS marker is tyrosine.

143. The system of claim 123, wherein the IBS marker is phenylalanine.

144. The system of claim 123, wherein the IBS marker is UDP-glucuronosyltransferase 1-6.

145. The system of claim 123, wherein the IBS marker is serotonin reuptake transporter.

146. The system of claim 123, wherein the IBS marker is tryptophan hydroxylase 1.

147. The system of claim 123, wherein the IBS marker is monoamine oxidase A.

148. The system of claim 123, wherein the IBS marker is monoamine oxidase B.

149. The system of claim 123, wherein the IBS marker is hydroxytryptamine (serotonin) receptor 3A.

150. The system according to any one of claims 123 to 149, wherein the diagnostic marker profile indicates the level of at least one additional diagnostic marker in a biological sample from the subject selected from the group consisting of Brain-Derived Neurotropic Factor (BDNF), Neutrophil Gelatinase-Associated Lipocalin (NGAL), TNF-related Weak Inducer of Apoptosis (TWEAK), Growth-Related Oncogene Alpha (GRO-a), Interleukin-1 Beta (IL-1β), Tissue Inhibitor of Metalloproteinase-1 (TIMP-1), Anti-Saccharomyces cerevisiae Antibody (ASCA-IgA), Anti-CBir-1 Antibody (CBirl), Anti-Human Neutrophil Cytoplasmic Antibody (ANCA), Anti-Human Tissue Transglutaminase IgA (tTG), histamine, β-tryptase, prostaglandin E2 (PGE2), and a combination thereof.

151. The system according to any one of claims 123 to 150, wherein said data processing module comprises instructions to apply a statistical process to a data set comprising said diagnostic marker profile in combination with a symptom profile which indicates the presence or severity of at least one symptom in said subject to produce a statistically derived decision classifying said sample as an IBS sample or non-IBS sample based upon said diagnostic marker profile and said symptom profile.
152. The system of claim 151, wherein said statistical process comprises a single learning statistical classifier system.

153. The system of claim 152, wherein said statistical process comprises a combination of at least two learning statistical classifier systems.

154. The system of claim 153, wherein the combination of at least two learning statistical classifier systems comprises a random forest classifier and a neural network classifier.

**INTERNATIONAL SEARCH REPORT**

**INTERNATIONAL CLASSIFICATION OF SUBJECT MATTER**

- IPC(8) - C12Q 1/68 (201 1.01)
- USPC - 435/6

According to International Patent Classification (IPC) or to both national classification and IPC

**FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

- IPC(8): C12Q 1/68 (201 1.01)
- USPC: 435/6

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

- IPC(8): G01 N 33/53, 33/00, 33/48 (201 0.01)
- USPC: 435/7.1,7.24,7.92,7.94;

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

- PubWEST, PGPB, USPT, EPAB, JPAB, Thomson Innovation, GoogleScholar

- Irritable bowel syndrome (IBS), carbohydrate, deficient transterrin, urocortin, c-releasing hormone-binding protein, Cortisol, adrenocorticotropic hormone, substance P, nerve growth factor, neurokinin A, neurokinin B, computer, learning statistical classifier

**III** Further documents are listed in the continuation of Box C. ❌

- Special categories of cited documents:
  - "A" document defining the general state of the art which is not considered to be of particular relevance
  - "E" earlier application or patent but published on or after the international filing date
  - "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
  - "O" document referring to an oral disclosure, use, exhibition or other means
  - "P" document published prior to the international filing date but later than the priority date claimed
  - "I" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
  - "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
  - "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
  - "K" document member of the same patent family

**Date of the actual completion of the international search**
