BICYCLIC HETEROARYL DERIVATIVES

5 **Field of the invention**

The present invention relates to bicyclic heteroaryl compounds useful as gamma-secretase modulators, their manufacture, pharmaceutical compositions comprising said compounds and their use as medicaments for the therapeutic and/or prophylactic treatment of
10 diseases associated with the deposition of β -amyloid in the brain, such as Alzheimer's disease, cerebral amyloid angiopathy, hereditary cerebral hemorrhage with amyloidosis-Dutch type (HCHWA-D), multi-infarct dementia, dementia pugilistica and Down syndrome.

Background of the invention

15 Alzheimer's disease (AD) is the most common cause of dementia in later life. Pathologically, AD is characterized by the deposition of amyloid in extracellular plaques and intracellular neurofibrillary tangles in the brain. The amyloid plaques are mainly composed of amyloid peptides ($A\beta$ peptides) which originate from the β -Amyloid Precursor Protein (APP) by a series of proteolytic cleavage steps. Several forms of APP have been identified of which the
20 most abundant are proteins of 695, 751 and 770 amino acids length. They all arise from a single gene through differential splicing. The $A\beta$ peptides are derived from the same domain of the APP.

$A\beta$ peptides are produced from APP through the sequential action of two proteolytic
25 enzymes termed β - and γ -secretase. β -Secretase cleaves first in the extracellular domain of APP just outside of the trans-membrane domain (TM) to produce a C-terminal fragment of APP ($CTF\beta$) containing the TM- and cytoplasmatic domain. $CTF\beta$ is the substrate for γ -secretase which cleaves at several adjacent positions within the TM to produce the $A\beta$ peptides and the cytoplasmic fragment. Various proteolytic cleavages mediated by γ -secretase result in $A\beta$
30 peptides of different chain lengths, e.g. $A\beta_{38}$, $A\beta_{40}$ and $A\beta_{42}$. The latter one is regarded to be the more pathogenic amyloid peptide because of its strong tendency to form neurotoxic aggregates. β -Secretase is a typical aspartyl protease.

γ -Secretase is a high molecular weight complex that consists of four essential subunits: presenilin (PS, including PS1 and PS2), nicastrin, anterior pharynx defective 1 (APH-1), and

presenilin enhancer 2 (PEN-2). The atomic structure of human γ -secretase at 3.4 Å resolution has been published (X. Bai, C. Yan, G. Yang, P. Lu, D. Ma, L. Sun, R. Zhou, S. H. W. Scheres, Y. Shi, *Nature*, 525 (2015), 212 – 217). The presenilins are bearing the catalytic site and represent a group of atypical aspartyl proteases which cleave their substrates within the TM and which are themselves polytopic membrane proteins. The other essential components of γ -secretase, nicastrin and the products of the *aph1* and *pen-2* genes are believed to be responsible for substrate recognition and recruitment. Proven substrates for γ -secretase are APP and the proteins of the Notch receptor family, however, γ -secretase has a loose substrate specificity and many further membrane proteins unrelated to APP and Notch have been reported to be cleaved by the γ -secretase in vitro.

The γ -secretase activity is absolutely required for the production of A β peptides. This has been shown both by genetic means, i.e. ablation of the presenilin genes, and by low-molecular weight inhibitory compounds. According to the amyloid cascade hypothesis for AD the production and deposition of A β is the ultimate cause for the disease. Therefore, it is believed that selective and potent inhibition of γ -secretase might be useful for the prevention and treatment of AD.

An alternative mode of treatment is the modulation of the γ -secretase activity which results in a selective reduction of the A β 42 production. This would lead to an increase of shorter A β isoforms, such as A β 38, A β 37 or others, which have no or reduced capability for aggregation and plaque formation, and are not or less neurotoxic. Compounds modulating γ -secretase activity include certain non-steroidal anti-inflammatory drugs (NSAIDs) and related analogues (Weggen et al., *Nature*, 414 (2001) 212-216).

Numerous documents describe the current knowledge on γ -secretase modulation, such as the following publications:

10 Therefore, modulating the γ -secretase activity is a promising therapeutic strategy for the treatment or prevention of diseases associated with the deposition of β -amyloid in the brain, such as Alzheimer's disease, cerebral amyloid angiopathy, hereditary cerebral hemorrhage with amyloidosis-Dutch type (HCHWA-D), multi-infarct dementia, dementia pugilistica and Down syndrome.

15 There is a need for new compounds, formulations, treatments and therapies to treat diseases and disorders associated with the deposition of β -amyloid in the brain. It is, therefore, an object of this invention to provide compounds useful for the treatment or prevention or amelioration of such diseases and disorders with improved therapeutic properties.

Processes of manufacturing

Processes for the manufacture of compounds of formula (I) as described herein are also an object of the present invention.

The preparation of compounds of formula (I) as described herein may be carried out in sequential or convergent synthetic routes. Syntheses of the invention are shown in the following general schemes. The skills required for carrying out the reactions and purifications of the resulting products are known to those skilled in the art. The substituents and indices used in the following description of the processes have the significance given herein before unless indicated to the contrary.

If one of the starting materials, intermediates or compounds of formula (I) contain one or more functional groups which are not stable or are reactive under the reaction conditions of one or more reaction steps, appropriate protecting groups (as described e.g. in "Protective Groups in Organic Chemistry" by T. W. Greene and P. G. M. Wuts, 3rd Ed., 1999, Wiley, New York) can be introduced before the critical step applying methods well known in the

art. Such protecting groups can be removed at a later stage of the synthesis using standard methods described in the literature. Examples of protecting groups are tert-butoxycarbonyl (Boc), 9-fluorenylmethyl carbamate (Fmoc), 2-trimethylsilylethyl carbamate (Teoc), carbobenzyloxy (Cbz) and p-methoxybenzyloxycarbonyl (Moz).

5

If starting materials or intermediates contain stereogenic centers, compounds of formula (I) can be obtained as mixtures of diastereomers or enantiomers, which can be separated by methods well known in the art e.g., chiral HPLC, chiral SFC or chiral crystallization. Racemic compounds can, for example, be separated into their antipodes via diastereomeric salts by crystallization with optically pure acids or by separation of the antipodes by specific chromatographic methods using either a chiral adsorbent or a chiral eluent. It is equally possible to separate starting materials and intermediates containing stereogenic centers to afford diastereomerically/enantiomerically enriched starting materials and intermediates. Using such diastereomerically/enantiomerically enriched starting materials and intermediates in the synthesis of compounds of formula (I) will typically lead to the respective diastereomerically/enantiomerically enriched compounds of formula (I).

10

15

A person skilled in the art will acknowledge that the sequence of reactions may be varied depending on reactivity and nature of the intermediates.

20

In more detail, the compounds of formula (I) can be manufactured by the methods given below, by the methods given in the examples or by analogous methods. Appropriate reaction conditions for the individual reaction steps are known to a person skilled in the art. Also, for reaction conditions described in literature affecting the described reactions see for example: *Comprehensive Organic Transformations: A Guide to Functional Group Preparations, 2nd Edition, Richard C. Larock. John Wiley & Sons, New York, NY. 1999*). It was found convenient to carry out the reactions in the presence or absence of a solvent. There is no particular restriction on the nature of the solvent to be employed, provided that it has no adverse effect on the reaction or the reagents involved and that it can dissolve the reagents, at least to some extent. The described reactions can take place over a wide range of temperatures, and the precise reaction temperature is not critical to the invention. It is convenient to carry out the described reactions in a temperature range between -78 °C to reflux. The time required for the reaction may also vary widely, depending on many factors, notably the reaction temperature and the nature of the reagents. However, a period of from 0.5 hours to several days will usually suffice to yield the

25

30

described intermediates and compounds. The reaction sequence is not limited to the one displayed in the schemes, however, depending on the starting materials and their respective reactivity, the sequence of reaction steps can be freely altered.

- 5 If starting materials or intermediates are not commercially available or their synthesis not described in literature, they can be prepared in analogy to existing procedures for close analogues or as outlined in the experimental section.

10 In one embodiment, compounds of formula (I) as described herein may be prepared by a process comprising reacting a compound **5**

with an amine **6**

wherein Ar, R¹, n and m are as defined herein

- 15 to form said compound of formula (I), and if desired, converting said compound obtained into a pharmaceutically acceptable salt thereof.

20 In one embodiment, the process according to the invention can be carried out in the presence of a catalyst, e.g palladium, optionally in the presence of a ligand, e.g 2-di-tert-butylphosphino-2',4',6'-triisopropylbiphenyl.

In a further embodiment, the process according to the invention can further comprise a step of performing a chiral separation to obtain compounds of formulas (Ia) and (Ib).

- 25 In one embodiment, compounds of formula (I) wherein R¹, n, m and Ar are as described herein and their intermediates may be prepared in analogy to literature procedures and/or depicted for example in schemes 1 and 2 respectively.

Scheme 1

The preparation of compounds of formula (I) may start with the alkylation of 3,5-dibromo-1H-1,2,4-triazole **2** with as electrophile either 2-(2-bromoethoxy)tetrahydropyran (if *m* equal 1) or 2-(3-bromopropoxy)tetrahydropyran (if *m* equal 2) to yield compound **3**. A regioselective halo lithiation with *n*BuLi followed by the addition of an optionally substituted benzaldehyde derivative affords primary alcohol **4**. After deprotection of the primary alcohol **4** with *p*TsOH, an intramolecular etherification may be performed using *p*TsOH at high temperature to yield intermediate **5**. Finally, a Buchwald type coupling with amine **6** in the presence of palladium and a ligand affords the compounds of formula (I). A preparative chiral HPLC may be performed to separate the enantiomers.

Intermediates **6** may be synthesized as depicted for example in scheme 2 and/or in analogy to methods described in literature.

Scheme 2

The coupling of tert-butyl N-[(1S,5R,8S)-3-azabicyclo[3.2.1]octan-8-yl]carbamate **7** (CAS 847862-26-4) with heterocyclic halides of general formula Ar-X can be accomplished under thermal conditions in a solvent such as ethanol or NMP in the presence of a base such as Et₃N or by using displacement reactions under catalytic conditions (like e.g. palladium(0) or copper(II))

catalysis) to provide intermediates **8**. Deprotection with acid, e.g. trifluoroacetic acid affords amine **6**. The heterocyclic halides are either commercially available or well known in the literature so they can be prepared by methods known in the art.

5 In one aspect, the present invention provides a compound of formula (I) as described herein, when manufactured according to any one of the processes described herein.

Pharmaceutical composition and administration

10 Another object of the present invention is a pharmaceutical composition comprising a compound of formula (I) as described herein and a therapeutically inert carrier.

The compounds of formula I and their pharmaceutically acceptable salts can be used as medicaments, in the form of pharmaceutical preparations. The pharmaceutical preparations can
15 be administered internally, such as orally (e.g. in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions), nasally (e.g. in the form of nasal sprays) or rectally (e.g. in the form of suppositories). However, the administration can also be effected parenterally, such as intramuscularly or intravenously (e.g. in the form of injection solutions). The administration can also be effected topically, e.g. transdermal administration, or
20 in form of eye drops or ear drops.

The compounds of formula (I) and their pharmaceutically acceptable salts can be processed with pharmaceutically inert, inorganic or organic carriers for the production of pharmaceutical preparations, such as tablets, coated tablets, dragées, hard gelatin capsules, injection solutions or topical formulations. Lactose, corn starch or derivatives thereof, talc,
25 stearic acids or salts thereof, and the like can be used, for example, as such carriers for tablets, coated tablets, dragées and hard gelatin capsules.

Suitable carriers for soft gelatin capsules are, for example, vegetable oils, waxes, fats, semi-solid substances and liquid polyols and the like. Depending on the nature of the active
30 substance no carriers are, however, usually required in the case of soft gelatin capsules.

Suitable carriers for the production of solutions and syrups are, for example, water, alcohols, polyols, saccharose, glucose, invert sugar, vegetable oil, etc.

Suitable carriers for injection solutions are, for example, water, alcohols, polyols, glycerol, vegetable oils, etc.

Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols, etc.

Suitable carriers for topical ocular formulations are, for example, cyclodextrins, mannitol or many other carriers and excipients known in the art.

5

Moreover, the pharmaceutical preparations can contain preservatives, solubilizers, viscosity increasing substances, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They can also contain still other therapeutically valuable substances.

10

Medicaments containing a compound of formula (I) or a pharmaceutically acceptable salt thereof and a therapeutically inert carrier are also an object of the present invention, as is a process for their production, which comprises bringing one or more compounds of formula (I) and/or pharmaceutically acceptable salts thereof and, if desired, one or more other therapeutically valuable substances into a galenical administration form together with one or more therapeutically inert carriers.

15

The dosage can vary within wide limits and will, of course, have to be adjusted to the individual requirements in each particular case. In general, in the case of oral administration a daily dosage of about 0.1 mg to 20 mg per kg body weight, preferably 0.5 mg to 4 mg per kg body weight (e.g. about 300 mg per person), divided into preferably 1-3 individual doses, which can consist, for example, of the same amounts, should be appropriate. In the case of topical administration, the formulation can contain 0.001% to 15% by weight of medicament and the required dose, which can be between 0.1 and 25 mg, and can be administered either by single dose per day or per week, or by multiple doses (2 to 4) per day, or by multiple doses per week. It will, however, be clear that the upper or lower limit given herein can be exceeded when this is shown to be indicated.

2) Biological examples

15 2.1) Assay procedure: Cellular γ -secretase assay

Human neuroglioma H4 cells overexpressing human APP695 with the Swedish double mutation (K595N/M596L) were plated at 30,000 cells/well/100 μ L in 96-well plates in IMDM containing 10% FCS, 0.2 mg/L Hygromycin B and incubated at 37°C, 5% CO₂.

20 3-4 h post plating, compounds are diluted in media and 50 μ L is added as 1.5-fold concentrate to achieve the final concentration. Compound incubation is performed for 24 h. Final doses typically range from 4 μ M down to 0.0013 μ M in half-log steps resulting in an eight-point dose response curve.

Appropriate controls using vehicle only and reference compound were applied to this assay. The 25 final concentration of Me₂SO was 0.4%.

After incubation at 37°C, 5% CO₂, the supernatant was subjected to quantification of secreted A β 42 by the means of an AlphaLisa assay kit (Human Amyloid beta 1-42 Kit: Cat# AL203C, Perkin Elmer). 20 μ L of the cell culture supernatant was transferred to an assay plate. Then 10 μ L of a mixture of the AlphaLisa coupled capture antibody and the biotinylated detection

antibody was added and incubated for 3h at RT while softly shaking the assay plate. After a further addition of 20 μ L of the Donor beads the assay plate was incubated for 30 min at RT and constant shaking without exposure to direct light. The assay plate was then read on a Paradigm AlphaLisa Reader using the build-in program with excitation at 680 nm and emission at 570 nm.

- 5 The measured signals were then used to calculate IC_{50} values for inhibition of A β 42 secretion by nonlinear regression fit analysis using XLfit 5.3 software (from IDBS company).
