It has been surprisingly been found that the compounds of general formula I are positive allosteric modulators (PAMs) of metabotropic glutamate receptor 4 (mGluR4).

Metabotropic glutamate receptor 4 is a protein that in humans is encoded by the *GRM4* gene.

Together with GRM6, GRM7 and GRM8 it belongs to group III of the Metabotropic glutamate receptor family, and is negatively coupled to adenylate cyclase via activation of the

Pop/02.05.2016

Gai/o protein. It is expressed primarily on presynaptic terminals, functioning as an autoreceptor or heteroreceptor and its activation leads to decreases in transmitter release from presynaptic terminals. mGluR4 is currently receiving much attention based primarily upon its unique distribution and the recent evidence that activation of this receptor plays key modulatory role in many CNS and non-CNS pathways (*Celanire S, Campo B, Expert Opinion in Drug Discovery, 2012*)

The similarity in the ligand binding domains of group III mGluRs creates a challenge for identifying selective orthosteric agonists of this receptor, although some progress has been made in this area. However, targeting positive allosteric modulators (PAMs) rather than orthosteric agonists provides a broader opportunity to identify molecules that are exclusively selective between mGluRs.

mGluR4 PAM is emerging as a promising target for the treatment of motor (and non motor) symptoms as well as a disease-modifying agent in Parkinson's disease through a non-dopaminergic approach.

Parkinson's disease is a progressive neurodegenerative disease that results in the loss of dopaminergic neurons in the substantia nigra (SN). One consequence of the depletion of dopamine in this disease is a series of movement disorders, including bradykinesia, akinesia, tremor, gait disorders and problems with balance. These motor disturbances form the hallmark of PD, although there are many other non-motor symptoms that are associated with the disease. Early in the course of the disease, PD symptoms are effectively treated by dopamine replacement or augmentation, with the use of dopamine D2 receptor agonists, levodopa or monoamine oxidase B inhibitors. However, as the disease progresses these agents become less effective in controlling motor symptoms. Additionally, their use is limited by the emergence of adverse effects including dopamine agonist-induced dyskinesias. Consequently, there remains a need for new approaches to the treatment of PD that improve the effectiveness of the control of motor symptoms.

Activation of metabotropic glutamate receptor 4 (mGluR4) has been proposed as a potential therapeutic approach to Parkinson's disease. A member of the group III mGluRs, mGluR4 is predominantly a presynaptic glutamate receptor that is expressed in several key locations in the basal ganglia circuits that control movement. Activation of mGluR4 with group

III-preferring agonists decreases inhibitory and excitatory post synaptic potentials, presumably by decreasing the release of GABA and glutamate respectively.

The search for novel drugs that relieve motor symptoms of Parkinsonism whilst attenuating the ongoing degeneration of nigrostriatal neurons is of particular interest. Orthosteric mGluR4 agonist L-AP4 has demonstrated neuroprotective effects in a 6-OHDA rodent model of PD and first positive allosteric modulator (-)-PHCCC reduced nigrostriatal degeneration in mice treated with 1-Methyl-4-Phenyl-1,2,3,6-Tetrahydropyridine (MPTP). Those studies provide preclinical evidence suggesting that mGluR4 activators constitute a strong approach not only for symptomatic treatments of PD, but also potentially as disease modifiers.

The neuroprotective effect of selective mGluR4 agonists was also described in *Neuroreport*, 19(4), 475-8, 2008, *Proc.Natl. Acad. Sci, USA*, 100(23), 13668-73, 2003 and *J.Neurosci.* 26(27), 7222-9, 2006 and *Mol. Pharmacol.* 74(5), 1345-58, 2008..

Anxiety disorders are among the most prevalent psychiatric disorders in the world, and are co-morbid with Parkinson's disease (*Prediger R, et al. Neuropharmacology* 2012;62:115-24). Excessive glutamatergic neurotransmission is one important feature of anxiety pathophysiology. Based on presynaptic localization of mGluR4 in brain areas involved in anxiety and mood disorders, and dampening excessive brain excitability, the mGluR4 activators may represent a new generation of anxiolytic therapeutics (*Eur. J. Pharmacol.*, 498(1-3), 153-6, 2004).

Addex has reported in 2010 that ADX88178 was active in two preclinical rodent models of anxiety: the marble burying test in mice and EPM in mice and rats. ADX88178 also displayed an anxiolytic-like profile in the rat EPM test after oral dosing.

mGluR4 modulators were also shown to exert anti-depressive actions (*Neuropharmacology*, 46(2), 151-9, 2004).

In addition, mGluR4 were also shown to be involved in glucagon secretion inhibition (*Diabetes*, 53(4), 998-1006, 2004). Therefore, orthosteric or positive allosteric modulators of mGluR4 have potential for the treatment of type 2 diabetes through its hypoglycemic effect.

Moreover, mGluR4 was shown to be expressed in prostate cancer cell-line (*Anticancer Res.* 29(1), 371-7, 2009) or colorectal carcinoma (*Cli. Cancer Research*, 11(9)3288-95, 2005). mGluR4 modulators may therefore have also potential role for the treatment of cancers.

Other proposed effects of mGluR4 PAM's can be expected for the treatment of emesis, obsessive compulsive disorder and autism.

Compounds of formula I are distinguished by having valuable therapeutic properties. They can be used in the treatment or prevention of disorders, relating to allosteric modulators for the mGluR4 receptor.

The most preferred indications for compounds which are allosteric modulators for the mGluR4 receptor are Parkinson's disease, anxiety, emesis, obsessive compulsive disorder, autism, neuroprotection, cancer, depression and type 2 diabetes.

The present invention relates to compounds of formula I and to their pharmaceutically acceptable salts, to these compounds as pharmaceutically active substances, to the processes for their production as well as to the use in the treatment or prevention of disorders, relating to allosteric modulators for the mGluR4 receptor, such as Parkinson's disease, anxiety, emesis, obsessive compulsive disorder, anorexia, autism, neuroprotection, cancer, depression and diabetes type 2 and to pharmaceutical compositions containing the compounds of formula I..

A further object of the present invention is a method for the treatment or prophylaxis of Parkinson's disease, anxiety, emesis, obsessive compulsive disorder, autism, neuroprotection, cancer, depression and type 2 diabetes, which method comprises administering an effective amount of a compound of formula I to a mammal in need.

Furthermore, the invention includes all racemic mixtures, all their corresponding enantiomers and/or optical isomers.

The preparation of compounds of formula I of the present invention may be carried out in sequential or convergent synthetic routes. Syntheses of the compounds of the invention are shown in the following scheme 1. The skills required for carrying out the reaction and purification of the resulting products are known to those skilled in the art. The substituents and

indices used in the following description of the processes have the significance given herein before.

The compounds of formula I can be manufactured by the methods given below, by the methods given in the examples or by analogous methods. Appropriate reaction conditions for the individual reaction steps are known to a person skilled in the art. The reaction sequence is not limited to the one displayed in the schemes, however, depending on the starting materials and their respective reactivity the sequence of reaction steps can be freely altered. Starting materials are either commercially available or can be prepared by methods analogous to the methods given below, by methods described in references cited in the description or in the examples, or by methods known in the art.

The present compounds of formula I and their pharmaceutically acceptable salts may be prepared by methods, known in the art, for example by the process variant described below, which process comprises

- a) reacting a compound of formula IV

with a compound of formula XLR^2 , wherein X is halogen,

to a compound of formula I

and, if desired, converting the compounds obtained into pharmaceutically acceptable acid addition salts.

The preparation of compounds of formula I is further described in more detail in schemes 1 and 2 and in the examples 1 – 112.

Scheme 1

A substituted pyrimidine-2,6-dione compound of general formula **I** can be obtained for example by Sonogashira coupling of an appropriately substituted aniline or aminopyridine **1** with a phenyl-acetylene **2** to yield the desired ethynyl compounds of formula **II**. Reacting ethynyl compounds of formula **II** with an appropriately substituted aminoester or aminoacid of formula **III** with phosgene or a phosgene equivalent such as triphosgene or carbonyldiimidazole (CDI) in presence or absence of a base such as triethylamine in a solvent such as toluene or dioxane forms the desired ethynyl-phenyl, ethynyl-pyridyl or ethynyl-pyrimidinyl substituted imidazolidine-2,4-dione compounds of general formula **IV** (scheme 1). The two steps involving reaction of intermediates **II** and **III** to form a urea derivative which then reacts with the ester group to form the pyrimidine dione of formula **IV** can be conducted in a one pot two step reaction or the two steps can be performed sequentially in normal or reverse order (amide formation followed by urea formation) depending on the starting materials available.

Introduction of the L-R² substituent can also be realized at various points in the synthetic sequence via functionalization of the corresponding intermediates **III** or **IV**.

The R⁴ substituent can also be introduced by reacting a compound of formula **I** with trimethylsilylacetylene followed by a second Sonogashira reaction in presence of fluoride with an aryl iodide or bromide R⁴-X to yield the corresponding R⁴ substituted acetylene derivative **II**.

Generally speaking, the sequence of steps used to synthesize the compounds of formula **I** can also be further modified in certain cases. It is also possible to separate the racemic mixtures of compounds of formula **I**, **III** or **IV** on a chiral stationary phase in order to yield the corresponding optically pure enantiomers. The intermediate of formula **IV** can also be synthesized for example using the following method (scheme 2):

Scheme 2

An appropriately substituted epoxide (**1**) is ring-opened under basic or acidic conditions with an alcohol (**2**) which has a protecting group moiety attached such as allyl- or cinnamyl-alcohol. The secondary alcohol formed (**3**) is oxidized to the corresponding ketone **4** which is then transformed to the corresponding α,β -unsaturated ester **5** using Wittig or Wittig-Horner conditions. The ester is then treated with ammonia to yield the Michael-addition product **6** which is cyclized using the same conditions mentioned before to yield compound **8**. The urea nitrogen is then alkylated using a suitable protected bromoethylamino-derivative to yield the alkylated compound **9**. Deprotection of the alcohol followed by oxidation to the carboxylic acid leads to cyclised product (**10**) which is deprotected to yield intermediate **V** which can then be further transformed to form compounds of formula **I**.

Biological Assay and Data:**Determination of EC₅₀ values using a Ca²⁺ mobilization in vitro assay on recombinant human mGlu4 expressed in HEK293 cells:**

A monoclonal HEK-293 cell line stably transfected with a cDNA encoding for the human mGlu4 receptor was generated; for the work with mGlu4 Positive Allosteric Modulators (PAMs), a cell line with low receptor expression levels and low constitutive receptor activity was selected to allow the differentiation of agonistic versus PAM activity. Cells were cultured according to standard protocols (Freshney, 2000) in Dulbecco's Modified Eagle Medium with high glucose supplemented with 1 mM glutamine, 10% (vol/vol) heat-inactivated bovine calf serum, Penicillin/Streptomycin, 50 µg/ml hygromycin and 15 µg/ml blasticidin (all cell culture reagents and antibiotics from Invitrogen, Basel, Switzerland).

About 24 hrs before an experiment, 5×10^4 cells/well were seeded in poly-D-lysine coated, black/clear-bottomed 96-well plates. The cells were loaded with 2.5 µM Fluo-4AM in loading buffer (1xHBSS, 20 mM HEPES) for 1 hr at 37°C and washed five times with loading buffer. The cells were transferred into a Functional Drug Screening System 7000 (Hamamatsu, Paris, France), and 11 half logarithmic serial dilutions of test compound at 37°C were added and the cells were incubated for 10-30 min. with on-line recording of fluorescence. Following this pre-incubation step, the agonist (2S)-2-amino-4-phosphonobutanoic acid (L-AP4) was added to the cells at a concentration corresponding to EC₂₀ with on-line recording of fluorescence; in order to account for day-to-day variations in the responsiveness of cells, the EC₂₀ of L-AP4 was determined immediately ahead of each experiment by recording of a full dose-response curve of L-AP4.

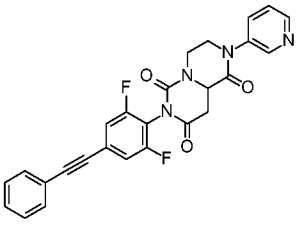

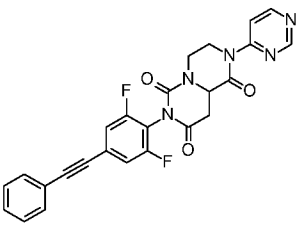

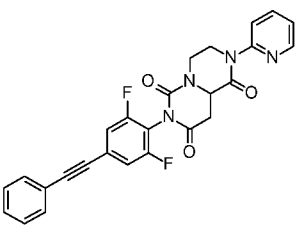

Responses were measured as peak increase in fluorescence minus basal (i.e. fluorescence without addition of L-AP4), normalized to the maximal stimulatory effect obtained with saturating concentrations of L-AP4. Graphs were plotted with the % maximal stimulatory using XLfit, a curve fitting program that iteratively plots the data using Levenburg Marquardt algorithm. The single site competition analysis equation used was $y = A + ((B-A)/(1+((x/C)^D)))$, where y is the % maximal stimulatory effect, A is the minimum y, B is the maximum y, C is the EC₅₀, x is the log₁₀ of the concentration of the competing compound and D is the slope of the curve (the Hill Coefficient). From these curves the EC₅₀ (drug concentration at which 50% of the maximal receptor activation was achieved), the Hill coefficient as well as the maximal response in % of

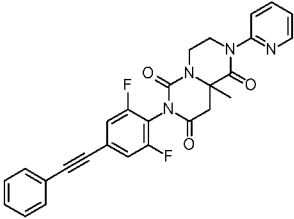

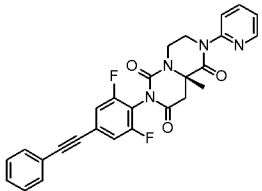

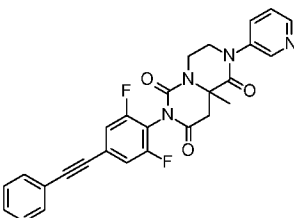

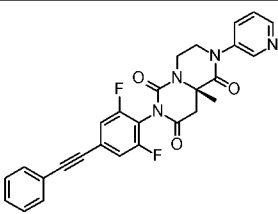

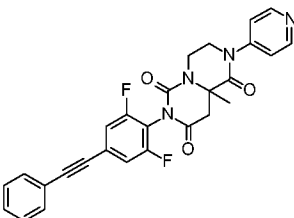

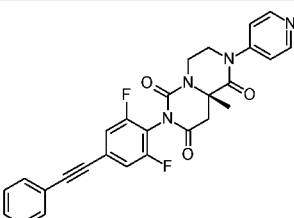

the maximal stimulatory effect obtained with saturating concentrations of L-AP4 were calculated (see Fig. 1).

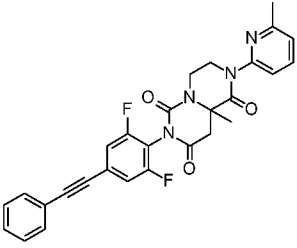

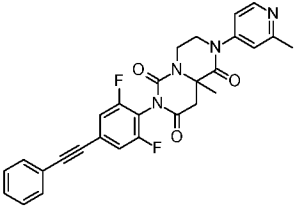

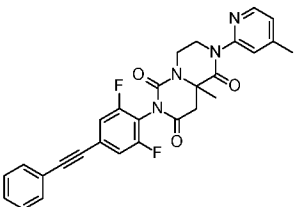

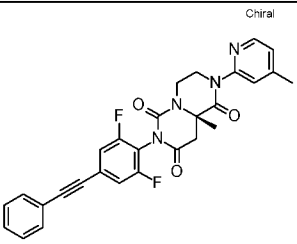

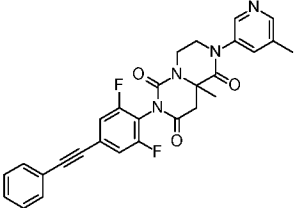

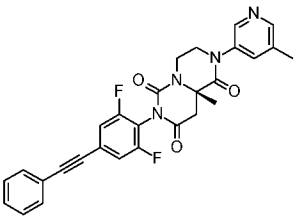

Positive signals obtained during the pre-incubation with the PAM test compounds (i.e. before application of an EC₂₀ concentration of L-AP4) were indicative of an agonistic activity, the absence of such signals were demonstrating the lack of agonistic activities. A depression of the signal observed after addition of the EC₂₀ concentration of L-AP4 was indicative of an inhibitory activity of the test compound.

The compounds of formula (I) and pharmaceutically acceptable salts thereof can be used as medicaments, e.g. in the form of pharmaceutical preparations. The pharmaceutical preparations can be administered orally, e.g. in the form of tablets, coated tablets, dragées, hard and soft gelatine capsules, solutions, emulsions or suspensions. However, the administration can also be effected rectally, e.g. in the form of suppositories, or parenterally, e.g. in the form of injection solutions.

The compounds of formula (I) and pharmaceutically acceptable salts thereof can be processed with pharmaceutically inert, inorganic or organic carriers for the production of pharmaceutical preparations. Lactose, corn starch or derivatives thereof, talc, stearic acid or its salts and the like can be used, for example, as such carriers for tablets, coated tablets, dragées and hard gelatin capsules. Suitable carriers for soft gelatin capsules are, for example, vegetable

oils, waxes, fats, semi-solid and liquid polyols and the like; depending on the nature of the active substance no carriers are, however, usually required in the case of soft gelatin capsules. Suitable carriers for the production of solutions and syrups are, for example, water, polyols, sucrose, invert sugar, glucose and the like. Adjuvants, such as alcohols, polyols, glycerol, vegetable oils and the like, can be used for aqueous injection solutions of water-soluble salts of compounds of formula (I), but as a rule are not necessary. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

In addition, the pharmaceutical preparations can contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They can also contain still other therapeutically valuable substances.

As mentioned earlier, medicaments containing a compound of formula (I) or pharmaceutically acceptable salts thereof and a therapeutically inert excipient are also an object of the present invention, as is a process for the production of such medicaments which comprises bringing one or more compounds of formula I or pharmaceutically acceptable salts thereof and, if desired, one or more other therapeutically valuable substances into a galenical dosage form together with one or more therapeutically inert carriers.

As further mentioned earlier, the use of the compounds of formula (I) for the preparation of medicaments useful in the prevention and/or the treatment of the above recited diseases is also an object of the present invention.

The dosage can vary within wide limits and will, of course, be fitted to the individual requirements in each particular case. In general, the effective dosage for oral or parenteral administration is between 0.01-20 mg/kg/day, with a dosage of 0.1-10 mg/ kg/day being preferred for all of the indications described. The daily dosage for an adult human being weighing 70 kg accordingly lies between 0.7-1400 mg per day, preferably between 7 and 700 mg per day.

Step 1: 2,6-Difluoro-4-phenylethynyl-phenylamine

Bis-(triphenylphosphine)-palladium(II)dichloride (826 mg, 1.18 mmol, 0.02 equiv.) was dissolved in 100 ml THF. 2,6-Difluoro-4-iodoaniline (15 g, 58.8 mmol) and phenylacetylene (7.2 g, 7.8 ml, 70.6 mmol, 1.2 equiv.) were added at room temperature. Triethylamine (29.8 g, 41 ml, 0.29 mol, 5 equiv.), triphenylphosphine (617 mg, 2.35 mmol, 0.04 equiv.) and copper(I)iodide (112 mg, 0.58 mmol, 0.01 equiv.) were added and the mixture was stirred for 1 hour at 60°C. The reaction mixture was cooled and extracted with saturated NaHCO₃ solution and two times with ethyl acetate. The organic layers were washed three times with water, dried over sodium sulfate and evaporated to dryness. The crude product was purified by flash chromatography on a

silica gel column eluting with an ethyl acetate:heptane gradient 0:100 to 40:60. The desired 2,6-difluoro-4-phenylethynyl-phenylamine (12.6 g, 93 % yield) was obtained as a yellow solid, MS: $m/e = 230.1$ ($M+H^+$).

In a 6 ml closed vessel were introduced 2,6-Difluoro-4-phenylethynyl-phenylamine (*Example 1, step 1*) (100 mg, 0.44 mmol), and toluene (2.5 ml). Carbonyl diimidazole (149 mg, 0.92 mmol, 2.1 equiv.) was added at room temperature. The mixture was stirred for 40 min at 115 °C. To the mixture ethyl 2-(3-oxopiperazin-2-yl)acetate [Abelman & al., Tetrahedron Lett. 44,1823 (2003)] (81 mg, 0.44 mmol, 1.0 equiv.) were added and stirred for 16 hours at 115 °C. The reaction mixture was cooled, concentrated in vacuo and loaded directly onto a silica gel column. The crude product was purified by flash chromatography eluting with a 10:90 to 100:0 ethyl acetate:heptane gradient. The title compound (50 mg, 29 % yield) was obtained as a light yellow solid, MS: $m/e = 396.1$ ($M+H^+$).

Cs_2CO_3 (115 mg, 0.354 mmol, 2.0 equiv.), 3-bromopyridine (31 mg, 0.195 mmol, 1.1 equiv.), palladium (II) acetate (8.0 mg, 0.035 mmol, 0.2 equiv.) and 4,5-bis(diphenylphosphino)-9,9-dimethylxanthene [Xantphos®] (30.7 mg, 0.053 mmol, 0.3 equiv.) were added at room temperature. The mixture was stirred for 4 hours at 110°C. The reaction mixture was evaporated and loaded directly onto a silica gel column. The crude product was purified by flash chromatography eluting with an ethyl acetate:heptane 0:100 to 100:0 gradient.
