UNITED STATES PATENT OFFICE.

CHARLES M. CHILDS, OF KANSAS CITY, MISSOURI.

ADJUSTABLE DESK.

SPECIFICATION forming part of Letters Patent No. 493,480, dated March 14, 1893.

Application filed October 20, 1892. Serial No. 449,423. (No model.)

To all whom it may concern:

Be it known that I, CHARLES M. CHILDS, of Kansas City, Jackson county, Missouri, have invented certain new and useful Improve-
5 ments in Adjustable Desks, of which the following is a full, clear, and exact description, reference being had to the accompanying drawings, forming a part hereof.

My invention relates to an improvement in
10 folding desks or arm rests, and my object is to produce an arm rest or desk, designed especially to be secured to a vertical wall or partition and near a telephone, comprising a cylindrical casing, containing a roll of paper held
15 flat upon a board or table by an adjustable board; the board or table, being adapted to be folded up against the wall when not in use.

Another object is to provide an arm rest and paper holder for use in corridors of post
20 offices, banks, and other public and private buildings where such devices are useful, and where the accommodations or space is so limited that it is inconvenient for tables to be used.

25 A further object of my invention is to provide an arm rest or desk, that is inexpensive and durable in construction, and which is easily secured in position.

To the above purposes, my invention consists in certain peculiar and novel features of
30 construction and arrangement, as will be hereinafter specified and claimed.

In order that my invention may be fully understood, I will proceed to describe it with
35 reference to the accompanying drawings, in which,—

Figure 1. is a perspective view of the desk or arm rest secured in operative position against a wall or partition, and showing a
40 board or table in its vertical and inoperative position in dotted lines. Fig. 2. is a vertical longitudinal sectional view taken on the line 2—2 of Fig. 1. Fig. 3. is a detail view showing a portion of the rear side of the cylindrical casing, and showing the pivotal connection thereof.

45 In the drawings,—1 represents a wall or partition of a room or corridor of a building, to which are secured in horizontal alignment
50 the vertically arranged and opposite support-

ing castings 2, by means of screws 3 or other suitable means, which pass through the feet 4 of the castings, and into the wall or partition. The cylindrical casing 5, comprises a cylindrical body portion, composed of segmental
55 and elongated plates 6 and 7, and the end plates 8—8, which are rigidly attached to and connected by the segmental plate 6. The rear or inner longitudinal edge of the plate 7 is adjacent to the rear or inner edge of the
60 plate 6, and the plate 7 is further provided at its rear or inner edge with the laterally and horizontally projecting trunnions or pins 9—9, which pivotally engage recesses or apertures 10—10 in the periphery of the circular heads
65 11—11 of the end plates 8—8. The end plates further consist each of an extension arm 12 projecting forward a suitable distance, which are parallel to each other, and are in the same plane, preferably, with their respective
70 circular heads 11—11, and have secured between the board or plate 14, by means of screws 13 or other suitable means, passing through said arms and into the edges of the board or plate. The rear end of the board or
75 plate is formed with a beveled or segmental edge 15, arranged concentrically with the axis of the circular heads 11—11.

Secured by the screws 17 to the under side of the board 14, and projecting slightly be-
80 yond the lower and forward edge, when the board is down, of the beveled surface, and a suitable distance from each other, are plates or lugs 16, which normally engage the elongated and corresponding apertures or slots 18
85 of the free end of the segmental plate 7. The circular heads of the end plates 8—8 are further provided with the segmental slots 10^a, arranged concentrically to the axis thereof, and which engage the longitudinally aligned
90 guide pins 2^a, projecting from the inner or adjacent faces of the brackets 2.

A roll of paper 20, is inclosed within the casing 5, and the outer end projects through the space or slot 19, formed between the outer
95 end or edge of the plate 6 and the rear or beveled end of the plate 14, and is carried along the top or upper surface of the said board or plate, and under the flat side of the adjustable bar 21, which is semicircular in cross
100

section and extends transversely of the upper surface of the said board or plate and near the outer end thereof. The bar is further provided near its outer ends with the screws or
 5 projections 22, which extend downwardly through vertical apertures in the board, and have heads or enlargements at their lower ends. The lower end of the perforations through which the screws or projections pass are en-
 10 larged at 23, for the reception of a spiral spring 24, which surround each screw or projection and bears at its opposite ends against the head of the screw and the annular shoulder 25 surrounding the screw, and formed in the
 15 under side of the board 14. A metal strip 26 is secured transversely of and to the forward edge of the board to prevent any defacement thereof. This arm rest or desk, as will be under-
 20 stood, rests normally in the position shown in dotted lines in Fig. 1 of the drawings, and when it is desired to use the desk or arm rest it is simply pulled down to the position shown in full lines in Fig. 1, and the projecting end
 25 of the roll of paper written upon if desired, the end of the paper projecting beyond the forward edge of the adjustable bar is then pulled forward the desired distance, and the forward edge of the flat surface of said ad-
 30 justable bar forms a guide by which to tear the paper written upon from the roller, as will be understood.

To place the roll of paper in, or to remove it from the cylindrical casing, compress slightly the outer or forward longitudinal
 35 edge of the plate 7 until the apertures are disengaged from the lugs or plates secured to the board, and then allow the segmental plate 7 to pivotally open. Insert or remove the roll of paper, and again compress the outer or for-
 40 ward longitudinal edge of the pivotal segment plate 7 and close the same, until the apertures register with, and are engaged by the projecting ends of the lugs or plates secured to the board.

45 Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. A folding desk or arm rest, comprising a cylindrical casing, a board or plate secured to and projecting from said casing, and verti-
 50 cally arranged and stationary guide and supporting castings pivotally connected to said cylindrical casing at each end thereof, substantially as described.

55 2. A folding desk or arm rest, comprising vertically arranged supporting castings secured to the wall in any suitable manner a suitable distance apart, a cylindrical casing located and revoluble vertically between said
 60 supporting castings, inclosing end plates pivotally connected to the supporting castings, and a connecting plate segmental in cross section connected at each end to said inclosing plates, and a second connecting plate segmen-
 65 tal in cross section, having its longitudinal edges adjacent to the longitudinal edges of

the first connecting plate and provided at its rear and inner longitudinal edge with later-ally extending and horizontal pivot pins en-
 70 gaging recesses or apertures in the periphery of the inclosing plates, and having elongated apertures or slots near its forward longitu-
 75 dinal edge adapted to engage locking lugs or plates secured to the board or plate carried by the cylindrical casing, substantially as de-
 80 scribed.

3. In a folding desk or arm rest, a cylindri-
 85 cal casing open at each end, and carrying an extension board or table, and plates adapted to close the ends of said cylindrical casing and
 90 to inclose the outer edges of the board or table, substantially as described.

4. In a folding desk or arm rest, a cylindri-
 95 cal casing having segmental and elongated slots in its opposite ends, concentric with the axis of the cylinder and end supporting cast-
 100 ings, secured to the wall, and guide pins projecting from the inner face of the end sup-
 105 porting castings, and adapted to engage the slots in each end of the cylindrical casing, sub-
 110 stantially as described.

5. A cylindrical casing, comprising segmen-
 115 tal and elongated plates, and a board or table having its rear edge beveled and arranged concentrically to the axis of the cylinder formed
 120 by segmental plates, and lugs or plates secured to the board and adapted to engage ap-
 125 ertures in the lower segmental plate near each end thereof, substantially as described.

6. In a folding desk or arm rest, a cylindri-
 130 cal casing, formed of two segmental and elongated plates permanently adjacent at their rear or inner longitudinal edges, an end plate,
 135 comprising a circular enlargement adapted to fit against the segmental ends of the plates forming the cylinder, and provided each with
 140 an outstanding arm parallel to each other, substantially as described.

7. In a folding desk or arm rest, a cylindri-
 145 cal casing, formed of two segmental and elongated plates having their rear or inner longi-
 150 tudinal edges adjacent to each other, and end plates, comprising a circular enlargement adapted to fit against the segmental ends of the plates forming the cylinder, and provided
 155 each with an outstanding arm parallel with each other, and having a board or plate secured between said parallel arms and having
 160 its rear edge beveled concentrically to the axis of the cylindrical casing, substantially as de-
 165 scribed.

8. In a folding desk or arm rest, a cylindri-
 170 cal casing comprising end plates having extension arms projecting therefrom, a segmen-
 175 tal plate connecting said end closing plates, and a second segmental plate hinged at its rear or inner edge between said end plates,
 180 and having slots or openings in its forward edge, a board carried between the extension arms of the end plates, and having locking
 185 lugs or plates at its rear edge adapted to engage normally the slots or openings in the for-

ward edge of the segmental plate, and openings or perforations also provided in the said board, and a vertically adjustable transversely extending bar, having screws or projections depending from the underside and engaging the perforations of the board, and springs interposed between the underside of the board and the headed end of the screw or projection, and adapted to hold the bar firmly upon

the upper side of the board, substantially as is set forth.

In testimony whereof I affix my signature in the presence of two witnesses.

CHARLES M. CHILDS.
