Title: ZONED CATALYST FOR TREATING EXHAUST GAS

Abstract: Provided is a system for treating an exhaust gas comprising a first SCR catalyst zone comprising an iron loaded medium- or large-pore molecular sieve having a first ammonia storage capacity, and a second SCR catalyst zone comprising a copper loaded small-pore molecular sieve having a second ammonia storage capacity, wherein the first SCR catalyst zone is disposed upstream of the second SCR catalyst zone with respect to normal exhaust gas flow through the system and wherein the second ammonia storage capacity is greater than the first ammonia storage capacity. Also provided is a method for using the system to treat exhaust gas.
ZONED CATALYST FOR TREATING EXHAUST GAS

BACKGROUND

Field of Invention:

The present invention relates to a system of zoned catalysts and methods for treating combustion exhaust gas.

Description of Related Art:

Combustion of hydrocarbon-based fuel in engines produces exhaust gas that contains, in large part, relatively benign nitrogen (N₂), water vapor (H₂O), and carbon dioxide (CO₂). But the exhaust gases also contain, in relatively small part, noxious and/or toxic substances, such as carbon monoxide (CO) from incomplete combustion, hydrocarbons (HC) from un-burnt fuel, nitrogen oxides (NOₓ) from excessive combustion temperatures, and particulate matter (mostly soot). To mitigate the environmental impact of flue and exhaust gas released into the atmosphere, it is desirable to eliminate or reduce the amount of the undesirable components, preferably by a process that, in turn, does not generate other noxious or toxic substances.

Typically, exhaust gases from lean burn gas engines have a net oxidizing effect due to the high proportion of oxygen that is provided to ensure adequate combustion of the hydrocarbon fuel. In such gases, one of the most burdensome components to remove is NOₓ, which includes nitric oxide (NO), nitrogen dioxide (NO₂), and nitrous oxide (N₂O). The reduction of NOₓ to N₂ is particularly problematic because the exhaust gas contains enough oxygen to favor oxidative reactions instead of reduction. Notwithstanding, NO can be reduced by a process commonly known as Selective Catalytic Reduction (SCR). An SCR process involves the conversion of NOₓ, in the presence of a catalyst and with the aid of a reducing agent, such as ammonia, into elemental nitrogen (N₂) and water. In an SCR process, a gaseous reductant such as ammonia is added to an exhaust gas stream prior to contacting the exhaust gas with the SCR catalyst. The reductant is absorbed onto the catalyst and the NOₓ reduction reaction takes place as the gases pass through or over the catalyzed substrate. The chemical equation for stoichiometric SCR reactions using ammonia is:

\[
4\text{NO} + 4\text{NH}_3 + \text{O}_2 \rightarrow 4\text{N}_2 + 6\text{H}_2\text{O}
\]

\[
2\text{NO}_2 + 4\text{NH}_3 + \text{O}_2 \rightarrow 3\text{N}_2 + 6\text{H}_2\text{O}
\]

\[
\text{NO} + \text{NO}_2 + 2\text{NH}_3 \rightarrow 2\text{N}_2 + 3\text{H}_2\text{O}
\]

1
Zeolites having an exchanged transition metal are known to be useful as SCR catalysts. Conventional small pore zeolites exchanged with copper are particularly useful in achieving high NO\textsubscript{x} conversion at low temperatures. However, the interaction of NH\textsubscript{3} with NO absorbed onto the transition metal of an exchanged zeolite can lead to an undesirable side reaction that produces N\textsubscript{2}O. This N\textsubscript{2}O is particularly problematic to remove from the exhaust stream. Accordingly, there remains a need for improved methods that result in a high conversion of NO\textsubscript{x} with minimal N\textsubscript{2}O production. The present invention satisfies this need amongst others.

**SUMMARY OF THE INVENTION**

Applicants have found that the combination of at least two SCR catalytic zones, one of which contains an iron loaded molecular sieve and the other of which contains a copper loaded molecular sieve, can substantially reduce the undesirable production of N\textsubscript{2}O while maintaining overall high N\textsubscript{2} selectivity in an SCR reaction, provided that the iron loaded molecular sieve is upstream of the copper loaded molecular sieve and has a lower ammonia storage capacity compared to the copper loaded molecular sieve. For example, high N\textsubscript{2} selectivity and low N\textsubscript{2}O byproduct can be achieved when the iron loaded molecular sieve has an ammonia storage capacity of not more than about 1.5 mmol NH\textsubscript{3} / g catalyst and the copper-loaded molecular sieve has an ammonia storage capacity of at least about 1.2 mmol NH\textsubscript{3} / g catalyst. Preferably, the upstream SCR catalyst zone is free or substantially free of copper and the downstream SCR catalyst zone is free or substantially free of iron.

Accordingly, in one aspect provided is a system for treating an exhaust gas comprising (a) a first SCR catalyst zone comprising an iron loaded medium- or large-pore molecular sieve having a first ammonia storage capacity, and (b) a second SCR catalyst zone comprising a copper loaded small-pore molecular sieve having a second ammonia storage capacity; wherein the first SCR catalyst zone is disposed upstream of the second SCR catalyst zone with respect to normal exhaust gas flow through the system and wherein the second ammonia storage capacity is greater than the first ammonia storage capacity.

In another aspect of the invention, provided is a method for treating an exhaust gas comprising the step of treating a mixture of ammonia and an exhaust gas derived from an internal combustion engine by contacting, in series, the mixture with a first SCR catalyst zone comprising an iron loaded molecular sieve having an ammonia storage capacity of not more than about 1.5 mmol NH\textsubscript{3} / g and a second SCR catalyst zone comprising a copper-loaded molecular sieve having an ammonia storage
capacity of at least about 1.2 mmol NH₃ / g catalyst, provided that iron loaded molecular sieve has a lower ammonia storage capacity relative to the copper-loaded molecular sieve.

DETAILED DESCRIPTION OF PREFERRED EMBODIMENTS OF THE INVENTION

Provided is a system and method for improving environmental air quality, and in particular for treating exhaust gas emissions generated by power plants, gas turbines, lean burn internal combustion engines, and the like. Exhaust gas emissions are improved, at least in part, by reducing NOx concentrations over a broad operational temperature range. The conversion of NOx is accomplished by contacting the exhaust gas with two or more specific NH3-SCR catalysts arranged in zones.

In part, the system comprises two NH3-SCR catalyst zones: a first SCR catalyst zone comprising an iron loaded medium- or large-pore molecular sieve having a first ammonia storage capacity, and a second SCR catalyst zone comprising a copper loaded small-pore molecular sieve having a second ammonia storage capacity; wherein the first SCR catalyst zone is disposed upstream of the second SCR catalyst zone with respect to normal exhaust gas flow through the system and wherein the second ammonia storage capacity is greater than the first ammonia storage capacity. In one example, the iron loaded medium- or large-pore molecular sieve is coated on and/or within the channel walls of the flow-through monolith in a first zone and the copper loaded small-pore molecular sieve is coated on and/or within the channel walls of the flow-through monolith in a second zone, the first zone being upstream of the second zone. In certain embodiments, the first or second zone can be in the form of an extruded catalyst body and the other zone is a coating on the body. In another example, the iron loaded medium- or large-pore molecular sieve is coated on and/or within a wall-flow filter and the copper loaded small-pore molecular sieve is coated on and/or within the channel walls of the flow-through monolith disposed downstream of the filter.

The iron-loaded molecular sieve can have, for example, an ammonia storage capacity of about 1.0 to about 1.5, about 1.0 to about 1.25, about 1.25 to about 1.5, or about 1.35 to about 1.45 mmol NH3/g catalyst.

The copper-loaded molecular sieve can have, for example, an ammonia storage capacity of about 1.2 to about 2.5, about 1.5 to about 2.5, about 1.6 to about 2.0, or about 1.7 to about 1.9 mmol NH3/g catalyst.
Here, the ammonia storage capacity is measured by Thermal Gravimetric Analysis (TGA). More particularly, the ammonia storage capacity is measured via TGA, by first purging water from the catalyst material at high temperatures (e.g., 550 °C), then saturating the catalyst material with NH₃ at 100 °C, follow by inert gas purging the loosely bound NH₃ from the catalyst material for about 10 minutes, and then gradually ramping the temperature to at least 550 °C at a rate of 5 °C per minute. The total weight loss during the ramp corresponds to the ammonia storage capacity of the material.

Turning to Figure 1, shown is an embodiment of the invention in which a flow-through honeycomb substrate (10) has a first catalyst zone (20) and a second catalyst zone (30), wherein the first and second catalyst zones are consecutive and in contact. The terms “first zone” and “second zone”, as used herein, are indicative of the zone’s orientation on the substrate. More specifically, the zones are oriented in series so that under normal operating conditions, the exhaust gas to be treated contacts the first zone prior to contacting the second zone.

The first and second SCR catalyst zones may be arranged consecutively, so that one follows the other in an uninterrupted succession (i.e., there is no catalyst or other exhaust gas treatment operation such as a filter between the first and second SCR catalyst zones). Therefore, in certain embodiments, the first SCR catalyst zone is upstream of the second SCR catalyst zone with respect to normal exhaust gas flow through or over a substrate or series of substrates.

Differences in the catalyst materials of the first and second SCR catalyst zones result in different treatment of the exhaust gas. For example, the first SCR catalyst zone reduces NOₓ with lower selectivity to by-products (including N₂O at low temperature and NOₓ at high temperature), and the second SCR catalyst zone efficiently reduces NOₓ at a higher selectivity relative to the first SCR catalyst zone. The synergistic effect of the combination of the two SCR catalyst zones improves the overall performance of the catalyst compared to single catalyst systems or other zoned arrangements. Preferably, the first and second zones are in contact (i.e., there are no intervening catalytically active layers between the first and second SCR catalyst zones).

In Figure 9, a zoned catalytic substrate (2) is shown wherein the substrate is a honeycomb flow-through monolith (100) having an inlet end (110) and an outlet end (120), relative to the normal direction of exhaust gas flow (1) through the substrate. The substrate has an axial length (190) that extends from the inlet end (110) to the outlet end (120). Figure 10 shows a single cell (200) of a honeycomb substrate having channel walls (110) that define open channels (120) through which exhaust gas can flow.

In general, the channel walls are preferably porous or semi-porous.
Typically, the catalyst of each zone can be a coating on the surface of the walls, a coating that permeates partially or fully into the walls, incorporated directly into the wall as an extruded body, or some combination thereof.

In Figure 1, the first SCR catalyst zone (20) extends from the inlet end (110) to a first end point (29).

Generally, the first end point is positioned about 10 to 90 percent, for example about 80-90 percent, about 10 to 25 percent or about 20 – 30 percent, of the axial length (190).

The second SCR catalyst zone (120) typically extends from the outlet end (120) for a certain distance along axial length (190), for example about 20 to 90 percent, for example about 60 to about 80 percent or about 50 to about 75 percent, of the axial length (190). Preferably, the second SCR catalyst zone extends to at least the first end point so that the first and second SCR catalyst zones are in contact.

The axial length is preferably less than 24 inches, such as about 1 to about 24 inches, about 3 to about 12 inches, or about 3 to about 6 inches.

In Figure 2, the first SCR catalyst zone (20) partially overlaps the second SCR catalyst zone (30).

In Figure 3, the second SCR catalyst zone (30) partially overlaps the first SCR catalyst zone (20).

The overlap is preferably less than 90 percent of the axial length of the substrate, for example about 80 to about 90 percent, less than about 40, about 40 to about 60, about 10 to about 15 percent, or about 10 to about 25 percent. For embodiments in which the second SCR catalyst zone overlaps the first SCR catalyst zone, the overlap can be greater than 50 percent of the axial length, such as 80 – 90 percent. For embodiments in which the first SCR catalyst zone overlaps the second SCR catalyst zone, the overlap is preferably less than 50 percent of the axial length, for example about 10 – 20 percent.

In Figure 4, the first SCR catalyst zone (20) completely overlaps the second SCR catalyst zone (30). For such embodiments, exhaust gas first contacts, and is at least partially treated by, the first SCR catalyst zone. At least a portion of the exhaust gas permeates through the first SCR catalyst zone where it contacts the second SCR catalyst zone and is further treated. A least a portion of the treated exhaust gas permeates back through the first SCR catalyst zone, enters the open channel, and exits the substrate. Figure 4 shows an embodiment in which both the first and second SCR catalyst zones extend the entire axial length of the substrate.

Figure 4A shows an embodiment in which the second SCR catalyst zone extends from the outlet end to less than the full axial length of the substrate and the first SCR catalyst zone extends the entire axial length of the substrate, thus completely overlapping the second SCR catalyst zone.
Figure 5 shows another embodiment of the invention. Here, a third catalyst zone is proximal to, and preferably extends from, the outlet end of the substrate.

The third catalyst zone typically comprises an oxidation catalyst, preferably a catalyst effective to oxidize ammonia.

In general, the catalyst comprises one or more platinum group metals (PGM), such as Pt, Pd, or a combination thereof, preferably on a metal oxide support, such as alumina.

The combination of the second and third catalyst zones in a layered arrangement serves as an ammonia slip catalyst, wherein at least a portion of the excess ammonia not consumed by the upstream SCR reaction passes through the second zone to the third catalyst zone where it is oxidized into H₂O and secondary NOₓ. The H₂O and secondary NOₓ pass back through the second catalyst zone where at least a portion of the secondary NOₓ is reduced to N₂ and H₂O via an SCR-type reaction.

Preferably, the first and second SCR catalyst zones are consecutively arranged so that the first SCR catalyst zone contacts the second SCR catalyst zone.

Typically, the first and second SCR catalyst zones are coated or otherwise incorporated on separate substrates which are arranged in an exhaust gas treatment system so that the first and second SCR catalyst zones are in series and are either in contact or separated by a short distance with no intervening exhaust gas treatment catalyst.

Where two substrates are used, the substrates can be the same or different substrates. For example, the first substrate can be a wall-flow filter and the second substrate can be a flow-through honeycomb or the first and second substrates can be flow-through honeycombs.

When two substrates are used, preferably when the first and second substrates are flow-through honeycombs, the first substrate may have a higher porosity than the second substrate, the first and second substrates can be different compositions or have a different cell density, and/or the first and second substrates can be different lengths.

In Figure 6, the first and second SCR catalyst zones are arranged on separate substrates which are arranged in an exhaust gas treatment system so that the first and second SCR catalyst zones are in series and are adjacent, but are not in direct contact.

The maximum distance between the first and second substrates is preferably less than 2 inches, more preferably less than 1 inch, and preferably there are no intervening substrates, filters, or catalyst materials between the first and second SCR catalyst zones and/or between the first and second substrates.
In Figure 6A, the second substrate further comprises an ammonia oxidation catalyst under-layer (40) that extends from the outlet end of the substrate to a length less than the total length of substrate. The second SCR catalyst zone completely covers the oxidative catalyst and preferably extends the length of the substrate.

The first or second SCR catalyst zone may comprise an extruded catalyst material. The embodiment shown in Figure 7, for example, comprises a first SCR catalyst zone (26) in the form of a coating on and/or within a portion of an extruded catalyst substrate. The extruded catalyst substrate, in turn, comprises the second SCR catalyst zone (16). The first SCR catalyst zone is arranged on the substrate so that it is upstream of the second SCR catalyst zone with respect to the normal flow of exhaust gas (1). The catalytically active substrate in zone (16) comprises a catalytically active material similar to that of the other second SCR catalyst zones described herein.

In Figure 7, the first SCR catalyst zone extends from the inlet end to less than the full length of the substrate.

In Figure 7A, the first SCR catalyst zone (26) completely covers the catalytically active substrate comprising the second SCR catalyst zone.

In Figure 7B, a catalytically active substrate (300), for example, a flow-through honeycomb substrate formed from an extruded catalytic material, is coated with a first SCR catalyst zone (310) and a second SCR catalyst zone (330).

Typically, the first SCR catalyst zone extends from the inlet end (312) to a first end point (314) that is positioned about 10 to 80 percent, for example about 50-80 percent, about 10 to 25 percent, or about 20 – 30 percent, of the axial length (390).

The second SCR catalyst zone typically extends from the outlet end (344) to a second end point (332) that is position about 20 to 80 percent, for example about 20 – 40 percent, about 60 to about 80 percent, or about 50 to about 75 percent, of the axial length (390).

Generally, the first and second SCR catalyst zones are not in direct contact and thus a gap (320) exists between the upstream and the downstream zone. Preferably, this gap does not contain a catalyst layer but instead is directly exposed to the exhaust gas to be treated. The exhaust gas contacts the catalytic body at the gap whereby the exhaust gas is treated, for example to selectively reduce a portion of NO, in the exhaust gas.

The gap, which is defined by the first end point (314) and the second end point (332), is preferably less than 75 percent of the axial length, for example about 40 to about 60, about 10 to about 15 percent, or about 10 to about 25 percent of the axial length (390).
An optional NH₃ oxidation catalyst may be coated on and/or within the substrate (300) in a zone that extends from the outlet end (344) towards the inlet end (312) for a length that is equal to or less than the length of the downstream zone. The optional NH₃ oxidation catalyst is preferably an under-layer that is completely covered by the catalyst composition forming the downstream zone.

The compositions of the catalysts in the upstream zone, the extruded body, and the downstream zone are not particularly limited provided that at least two of the upstream zones, the extruded body, and the downstream zone conform to the first and second zone requirements as defined herein, that is the iron-loaded molecular sieve in the first zone has an ammonia storage capacity of not more than about 1.5 mmol NH₃/g catalyst, the copper-loaded molecular sieve in the second zone has an ammonia storage capacity of at least about 1.2 mmol NH₃/g catalyst, and the copper-loaded molecular sieve has an ammonia storage capacity that is greater than the corresponding ammonia storage capacity of the iron-loaded molecular sieve.

In one example, the upstream zone corresponds to the first zone and the downstream zone corresponds to the second. The extruded catalyst body preferably comprises another type of SCR catalyst, such as vanadium, preferably supported on a metal oxide such as TiO₂, and optionally comprising one or more additional metals such as tungsten.

In another example, the extruded catalyst body corresponds to the first zone and the downstream zone corresponds to the second zone. In this example, the upstream zone can comprise another type of catalyst. In another example, the upstream zone corresponds to the first zone and the extruded body corresponds to the second zone. In this example, this downstream zone can comprise another type of catalyst.

Figure 8 shows another embodiment wherein a first catalytic zone (17) is part of an extruded catalytic body and the second SCR catalyst zone (37) is a coating on and/or within a portion of the extruded catalyst substrate. Again, the first zone is arranged upstream of the second zone with respect to the normal flow of exhaust gas (1) and the catalytically active substrate in zone (17) comprises a catalytically active material similar to that of the other first zones described herein.

The first catalytic zone comprises a first NH₃-SCR catalyst composition. The first NH₃-SCR catalyst comprises an iron-loaded molecular sieve as a catalytically active component, but may include other components, particularly catalytically inactive components such as binders.

As used herein, a “catalytically active” component is one that directly participates in the catalytic reduction of NOₓ and/or oxidization of NH₃ or other nitrogenous-based SCR reductants. By
corollary, a “catalytically inactive” component is one which does not directly participate in the catalytic reduction of NO₂ and/or oxidization of NH₃ or other nitrogenous-based SCR reductants.

Useful molecular sieves are crystalline or quasi-crystalline materials which can be, for example, aluminosilicates (zeolites) or silicoaluminophosphates (SAPOs).

Such molecular sieves are constructed of repeating SiO₄, AlO₄, and optionally PO₄ tetrahedral units linked together, for example in rings, to form frameworks having regular intra-crystalline cavities and channels of molecular dimensions. The specific arrangement of tetrahedral units (ring members) gives rise to the molecular sieve’s framework, and by convention, each unique framework is assigned a unique three-letter code (e.g., “CHA”) by the International Zeolite Association (IZA).

Examples of useful molecular sieve frameworks include large pore frameworks (i.e., having a minimum ring size of 12-members), medium pore frameworks (i.e., having a minimum ring size of 10-members), and small-pore frameworks (i.e., having a minimum ring size of 8-members). Examples of frameworks include BEA, MFI, CHA, AEI, LEV, KFI, MER, RHO, ERI, OFF, FER, and AFX. The molecular sieve can also be an intergrowth of two or more frameworks, such as AEI and CHA. In certain embodiments, the first and/or second zones can independently comprise a blend of two or more molecular sieves. Preferred blends have at least one molecular sieve having a CHA framework, and more preferably a majority of the CHA framework.

Particularly useful molecular sieves are small pore zeolites. As used herein, the term “small pore zeolite” means a zeolite framework having a maximum ring size of eight tetrahedral atoms. Preferably, the primary crystalline phase of the molecular sieve is constructed of one or more small pore frameworks, although other molecular sieve crystalline phases may also be present. Preferably, the primary crystalline phase comprises at least about 90 weight percent, more preferably at least about 95 weight percent, and even more preferably at least about 98 or at least about 99 weight percent small pore molecular sieve framework, based on the total amount of molecular sieve material.

In some examples, the small pore zeolite for use in the present invention have a pore size in at least one dimension of less than 4.3 Å.

The small pore zeolite typically has a framework selected from the group of consisting of: ACO, AEI, AEN, AFN, AFT, AFX, ANA, APC, APD, ATT, CDO, CHA, DDR, DFT, EAB, EDI, EPI, ERI, GIS, GOO, IHW, ITE, ITW, LEV, KFI, MER, MON, NSI, OWE, PAU, PHI, RHO, RTH, SAT, SAV, SIV, THO, TSC, UEI, UFI, VNI, YUG and ZON. Preferred zeolite frameworks are selected from AEI, AFT, AFX, CHA, DDR, ERI, LEV, KFI, RHO, and UEI.
For certain applications, preferred zeolite frameworks are selected from AEI, AFT, and AFX, particularly AEI.

In certain application, a preferred zeolite framework is CHA. In certain applications, an ERI framework is preferred.

Particular zeolites that are useful for the present invention include SSZ-39, Mu-10, SSZ-16, SSZ-13, Sigma-1, ZSM-34, NU-3, ZK-5, and MU-18.

Other useful molecular sieves include SAPO-34 and SAPO-18.

Small pore zeolites are particularly useful in the second NH$_3$-SCR catalyst.

In a preferred embodiment, the second NH$_3$-SCR catalyst comprises an aluminosilicate having a CHA framework (e.g., SSZ-13) loaded with copper and the first NH$_3$-SCR catalyst comprises an iron-loaded large pore zeolite, such as Beta or iron-isomorphous Beta.

Preferred aluminosilicates have a silica-to-alumina ratio (SAR) of about 10 to about 50, for example about 15 to about 30, about 10 to about 15, 15 to about 20, about 20 to about 25, about 15 to about 18, or about 20 to about 30. Preferred SAPOs have an SAR of less than 2, for example about 0.1 to about 1.5 or about 0.5 to about 1.0. The SAR of a molecular sieve may be determined by conventional analysis. This ratio is meant to represent, as closely as possible, the ratio in the rigid atomic framework of the molecular sieve crystal and to exclude silicon or aluminum in the binder or in cationic or other form within the channels. Since it may be difficult to directly measure the SAR of the molecular sieve after it has been combined with a binder material, particularly an alumina binder, the SAR value described herein is expressed in terms of the SAR of the molecular sieve _per se_, i.e., prior to the combination of the zeolite with the other catalyst components.

In another example, the second zone molecular sieve is a SAPO having a SAR of less than 1.

The molecular sieve may include framework metals other than aluminum (i.e., metal-substituted zeolites). As used herein, the term “metal substituted” with respect to a molecular sieve means a molecular sieve framework in which one or more aluminum or silicon framework atoms has been replaced by the substituting metal. In contrast, the term “metal exchanged” means a molecular sieve in which one or more ionic species associated with the zeolite (e.g., H$^+$, NH$_4^+$, Na$^+$, etc.) has been replaced by a metal (e.g., a metal ion or free metal, such as metal oxide), wherein the metal is not incorporated as a molecular sieve framework atom (e.g., T-atom), but instead is incorporated into the molecular pores or on the external surface of the molecular sieve framework. The exchanged metal is a type of “extra-framework metal”, that is a metal that resides within the molecular sieve and/or on at least a portion of the molecular sieve surface, preferably as an ionic species, does not include aluminum, and does not include
atoms constituting the framework of the molecular sieve. The terms “metal-loaded molecular sieve” means a molecular sieve that includes one or more extra-framework metals. As used herein, the terms “aluminosilicate” and “silicoaluminophosphate” are exclusive of metal-substituted molecular sieves.

The iron-loaded or copper-loaded molecular sieves of the present invention comprise the metal disposed on and/or within the molecular sieve material as an extra-framework metal. Preferably, the presence and concentration of the iron or copper facilitates the treatment of exhaust gases, such as exhaust gas from a diesel engine, including processes such as NO\textsubscript{x} reduction, NH\textsubscript{3} oxidation, and NO\textsubscript{x} storage, while also suppressing the formation of N\textsubscript{2}O.

Unless otherwise specified, the amount of iron loaded onto a molecular sieve and the iron concentration in the catalyst is referenced in terms of the iron per total weight of the corresponding molecular sieve, and is thus independent of the amount of catalyst washcoat loading on the substrate or the presence of other materials in the catalyst washcoat. Likewise, the amount of copper loaded onto a molecular sieve and the copper concentration in the catalyst is referenced in terms of the copper per total weight of the corresponding molecular sieve, and is thus independent of the amount of catalyst washcoat loading on the substrate or the presence of other materials in the catalyst washcoat.

The extra-framework copper may be present in the molecular sieve of the second zone at a concentration of about 0.1 to about 10 weight percent (wt\%) based on the total weight of the molecular sieve, for example from about 0.5 wt\% to about 5 wt\%, from about 0.5 to about 1 wt\%, from about 1 to about 5 wt\%, about 2.5 wt\% to about 3.5 wt\%, and about 3 wt\% to about 3.5 wt\%.

The extra-framework iron may be present in the molecular sieve of the first zone at a concentration of about 0.1 to about 10 weight percent (wt\%) based on the total weight of the molecular sieve, for example from about 0.5 wt\% to about 5 wt\%, from about 1 to about 5 wt\%, about 3 wt\% to about 4 wt\%, and about 4 wt\% to about 5 wt\%.

Typically, the first zone has a higher metal loading concentration (based on weight of zeolite) compared to the second zone.

In addition to iron and copper, the molecular sieve can further comprise one or more additional extra-framework metals, provided that the additional extra-framework metal is present in a minority amount (i.e., < 50 mol. %, such as about 1 to 30 mol. %, about 1 – 10 mol. % or about 1 – 5 mol. %) relative to the iron or copper.

The additional extra-framework metal may be any of the recognized catalytically active metals that are used in the catalyst industry to form metal-exchanged molecular sieves, particularly those
metals that are known to be catalytically active for treating exhaust gases derived from a combustion process.

Particularly preferred are metals useful in NOx reduction and storage processes. Examples of such metals include metal nickel, zinc, iron, copper, tungsten, molybdenum, cobalt, titanium, zirconium, manganese, chromium, vanadium, niobium, as well as tin, bismuth, and antimony; platinum group metals, such as ruthenium, rhodium, palladium, indium, platinum, and precious metals such as gold and silver.

Preferred transition metals are base metals, and preferred base metals include those selected from the group consisting of chromium, manganese, iron, copper, cobalt, nickel, and mixtures thereof.

In certain examples of the invention, the iron-loaded or copper-loaded molecular sieves are free of platinum group metals.

In certain examples of the invention, the iron-loaded or copper-loaded molecular sieves are free of alkali and alkaline earth metals.

In certain examples of the invention, the iron-loaded molecular sieve is free of transition metals except iron and the copper-loaded molecular sieve is free of transition metals except copper.

Preferably, the iron and copper is highly dispersed within the molecular sieve crystals, preferably without a high temperature treatment of the metal loaded molecular sieve.

The transition metal loading is preferably fully ion exchanges and/or is preferably less than can be accommodated by the exchange sites of the molecular sieve support.

Preferably, the catalyst is free or substantially free of bulk iron oxide or bulk copper oxide, free or substantially free of species of iron or copper on external molecular sieve crystal surfaces, and/or free or substantially free of iron or copper metal clusters as measured by temperature programmed reduction (TPR) analysis and/or UV-vis analysis.

In one example, a metal-exchanged molecular sieve is created by mixing the molecular sieve, for example an H-form molecular sieve or an NH4-form molecular sieve, into a solution containing soluble precursors of the catalytically active metal(s). The pH of the solution may be adjusted to induce precipitation of the catalytically active metal cations onto or within the molecular sieve structure (but not including the molecular sieve framework. For example, in a preferred embodiment, a molecular sieve material is immersed in a solution containing a metal nitrate or metal acetate for a time sufficient to allow incorporation of the catalytically active metal cations into the molecular sieve structure by ion exchange. Un-exchanged metal ions are precipitated out. Depending on the application, a portion of the un-exchanged ions can remain in the molecular sieve material as free metals. The metal-exchanged
molecular sieve may then be washed, dried, and calcined. The calcined material may include a certain percentage of iron or copper as iron oxide or copper oxide, respectively, residing on the surface of the molecular sieve or within the molecular sieve cavities.

Generally, ion exchange of the catalytic metal cation into or on the molecular sieve may be carried out at room temperature or at a temperature up to about 80°C over a period of about 1 to 24 hours at a pH of about 7. The resulting catalytic molecular sieve material is preferably dried and then calcined at a temperature of at least about 500°C.

The catalyst composition may comprise the combination of iron or copper and at least one alkali or alkaline earth metal, wherein the iron or copper and alkali or alkaline earth metal(s) are disposed on or within the molecular sieve material. The alkali or alkaline earth metal can be selected from sodium, potassium, rubidium, cesium, magnesium, calcium, strontium, barium, or some combination thereof. Preferred alkali or alkaline earth metals include calcium, potassium, and combinations thereof.

Alternatively, the catalyst composition is essentially free of magnesium and/or barium. In certain embodiments, the catalyst is essentially free of any alkali or alkaline earth metal except calcium and potassium. In certain embodiments, the catalyst is essentially free of any alkali or alkaline earth metal except calcium. And in certain other embodiments, the catalyst is essentially free of any alkali or alkaline earth metal except potassium.

As used herein, the term “essentially free” means that the material does not have an appreciable amount of the particular metal. That is, the particular metal is not present in amount that would affect the basic physical and/or chemical properties of the material, particularly with respect to the material’s capacity to selectively reduce or store NOx. In certain embodiments, the molecular sieve material has an alkali content of less than 3 weight percent, more preferably less than 1 weight percent, and even more preferably less than 0.1 weight percent.

The alkali and/or alkaline earth metal (collectively \(A_m\)) may be present in the molecular sieve material in an amount relative to the amount of iron or copper in the molecular sieve. Preferably, the Fe or Cu and \(A_m\) are present, respectively, in a molar ratio of about 15:1 to about 1:1, for example about 10:1 to about 2:1, about 10:1 to about 3:1, or about 6:1 to about 4:1, particularly where \(A_m\) is calcium.

In certain embodiments which include an alkali and/or alkaline earth metal such as calcium, the amount of iron or copper present is less than 2.5 weight percent, for example less than 2 weight percent or less than 1 weight percent, based on the weight of the molecular sieve.

In certain embodiments, the copper loaded molecular sieve of the second zone contains an alkali or alkaline earth metal, particularly calcium, and the iron loaded molecular sieve of the first zone is
essentially free of an alkali or alkaline earth metal. For such embodiments, the relative cumulative amount of iron or copper and alkali and/or alkaline earth metal (A_{M}) present in the molecular sieve material of the second zone is relative to the amount of aluminum in the molecular sieve, namely the framework aluminum. As used herein, the \((T_{M} + A_{M}):\text{Al}\) ratio is based on the relative molar amounts of Transition metal (T_{M}), (e.g., either Cu or Fe) + A_{M} to molar framework Al in the corresponding molecular sieve. In certain embodiments, the molecular sieve of the second zone has a \((T_{M} + A_{M}):\text{Al}\) ratio of not more than about 0.6, particularly where A_{M} is calcium. In certain embodiments, the \((T_{M} + A_{M}):\text{Al}\) ratio is at least 0.3, for example about 0.3 to about 0.6. In such embodiments, the \(T_{M}:\text{Al}\) ratio of the catalyst in the first zone is about 0.1 to about 0.375, provided that the \(T_{M}:\text{Al}\) ratio in the first zone catalyst is less than the \((T_{M} + A_{M}):\text{Al}\) ratio in the second zone catalyst.

In certain embodiments, the relative cumulative amount of iron or copper and alkali and/or alkaline earth metal (A_{M}) is present in the molecular sieve material of the second zone in an amount relative to the amount of aluminum in the molecular sieve, namely the framework aluminum. As used herein, the \((T_{M} + A_{M}):\text{Al}\) ratio is based on the relative molar amounts of T_{M} + A_{M} to molar framework Al in the corresponding molecular sieve. In certain embodiments, the catalyst material has a \((T_{M} + A_{M}):\text{Al}\) ratio of not more than about 0.6. In certain embodiments, the \((T_{M} + A_{M}):\text{Al}\) ratio is not more than 0.5, for example about 0.05 to about 0.5, about 0.1 to about 0.4, or about 0.1 to about 0.2.

The alkali/alkaline earth metal can be added to the molecular sieve via any known technique such as ion exchange, impregnation, isomorphous substitution, etc. The iron or copper and the alkali or alkaline earth metal can be added to the molecular sieve material in any order (e.g., the metal can be exchanged before, after, or concurrently with the alkali or alkaline earth metal), but preferably the alkali or alkaline earth metal is added prior to or concurrently with the iron or copper.

The catalytic articles of the present invention are applicable for heterogeneous catalytic reaction systems (i.e., solid catalyst in contact with a gas reactant). To improve contact surface area, mechanical stability, and/or fluid flow characteristics, the SCR catalysts are disposed on and/or within a substrate such as honeycomb cordierite brick.

In general, one or more of the catalyst compositions is applied to the substrate as a washcoat(s).

Alternatively, one or more of the catalyst compositions is kneaded along with other components such as fillers, binders, and reinforcing agents, into an extrudable paste which is then extruded through a die to form a honeycomb brick.

Certain aspects of the invention provide a catalytic washcoat. The washcoat comprising an iron-loaded or copper-loaded molecular sieve catalyst described herein is preferably a solution, suspension,
or slurry. Suitable coatings include surface coatings, coatings that penetrate a portion of the substrate, coatings that permeate the substrate, or some combination thereof.

A washcoat can also include non-catalytic components, such as fillers, binders, stabilizers, rheology modifiers, and other additives, including one or more of alumina, silica, non-molecular sieve silica alumina, titania, zirconia, ceria. In certain embodiments, the catalyst composition may comprise pore-forming agents such as graphite, cellulose, starch, polyacrylate, and polyethylene, and the like. These additional components do not necessarily catalyze the desired reaction, but instead improve the catalytic material’s effectiveness, for example, by increasing its operating temperature range, increasing contact surface area of the catalyst, increasing adherence of the catalyst to a substrate, etc. In preferred embodiments, the washcoat loading is >0.3 g/in³, such as >1.2 g/in³, >1.5 g/in³, >1.7 g/in³ or >2.00 g/in³, and preferably < 3.5 g/in³, such as < 2.5 g/in³. In certain embodiments, the washcoat is applied to a substrate in a loading of about 0.8 to 1.0 g/in³, 1.0 to 1.5 g/in³, 1.5 to 2.5 g/in³, or 2.5 to 3.5 g/in³.

Preferred substrates, particularly for mobile applications, include flow-through monoliths having a so-called honeycomb geometry that comprise multiple adjacent, parallel channels that are open on both ends and generally extend from the inlet face to the outlet face of the substrate and, typically, result in a high-surface area-to-volume ratio.

For certain applications, the honeycomb flow-through monolith preferably has a high cell density, for example about 600 to 1000 cells per square inch, and/or an average internal wall thickness of about 0.18 – 0.35 mm, preferably about 0.20 – 0.25 mm. For certain other applications, the honeycomb flow-through monolith has a low cell density of about 150 – 600 cells per square inch, such as about 200 – 400 cells per square inch.

Preferably, the honeycomb monoliths are porous. In addition to cordierite, silicon carbide, silicon nitride, ceramic, and metal, other materials that can be used for the substrate include aluminum nitride, silicon nitride, aluminum titanate, α-alumina, mullite, e.g., acicular mullite, pollucite, a thermet such as Al₂OsZFe, Al₂O₃/Ni or B₉CZFe, or composites comprising segments of any two or more thereof. Preferred materials include cordierite, silicon carbide, and alumina titanate.

Preferred filter substrates include diesel particulate filters, and preferred diesel particulate filters for use in mobile applications include wall-flow filters, such as wall-flow ceramic monoliths. Other filter substrates include flow through filters, such as metal or ceramic foam or fibrous filters.

In addition to cordierite, silicon carbide, and ceramic, other materials that can be used for the porous substrate include, but are not limited to, alumina silica, aluminum nitride, silicon nitride,
aluminum titanate, α-alumina, mullite, pollucite, zircon, zirconia, spinel, borides, feldspar, titania, fused silica, borides, ceramic fiber composites, mixtures of any of these, or composites comprising segments of any two or more thereof. Particularly preferred substrate include cordierite, silicon carbide, and aluminum titanate (AT), wherein AT is the predominant crystalline phase.

The porous walls of a wall-flow filter have an inlet side and an outlet side relative to the typical direction of exhaust gas flow through the walls. The inlet side has an inlet surface that is exposed to the channels open to the front of the substrate, and the outlet side has an outlet surface that is exposed to the channels open to the rear of the substrate.

Wall-flow filter substrates for diesel engines typically contain about 100 – 800 cpsi (channels per square inch), for example about 100 to about 400 cpsi, about 200 to about 300 cpsi, or about 500 to about 600 cps. The walls typically have an average wall thickness of about 0.1 to about 1.5 mm, for example about 0.15 to about 0.25 mm, about 0.25 to about 0.35 mm, or about 0.25 to about 0.50 mm.

Wall flow filters for use with the present invention preferably have an efficiency of at least 70%, at least about 75%, at least about 80%, or at least about 90%. In certain embodiments, the efficiency will preferably be from about 75 to about 99%, about 75 to about 90%, about 80 to about 90%, or about 85 to about 95%.

The filter’s useful range of porosity and mean pore size are not particularly limited but are correlated to, or are used to determine, the particle size and viscosity of the catalyst coating. As described herein, the filter substrate’s porosity and mean pore size are determined based on a bare filter (e.g., without a catalyst coating).

In general, the porosity of the substrate is at least about 40%, more preferably at least about 50%, for example about 50 to about 80%, about 50 to about 70 percent, or about 55 to about 65 percent. Porosity may be measure by any suitable means, including mercury porosimetry.

In general, the mean pore size of the substrate is about 8 to about 40 µm, for example about 8 to about 12 µm, about 12 to about 20 µm, or about 15 to about 25 µm. In certain embodiments, at least about 50%, and more preferably at least about 75% of the pores are within these ranges, based on the total pore volume and/or total number of pores. Mean pore size can be determined by any acceptable means, including by mercury porosimetry.

It may be preferable that the filter substrate has a mean pore size of about 12 to about 15 µm and a porosity of about 50 to about 55%.
It may be preferable that the filter substrate has a mean pore size of about 18 to about 20 μm and a porosity of about 55 to about 65%.

The catalyst washcoat of first SCR catalyst zone can be loaded on the inlet side of the filter walls, the outlet side of the filter walls, partially or fully permeate the filter walls, or some combination thereof.

In certain embodiments, the filter is the substrate for the first or second SCR catalyst zone as described herein. For example, a wall flow filter can be used as a substrate for the first zone and a flow-through honeycomb can be used as the substrate for the second zone. In another example, a flow-through honeycomb can be used as the substrate for the first zone and a wall-flow filter can be used as the substrate for the second zone. In such embodiments, the wall flow substrate may further comprise an NH₃ oxidation catalyst to form an ASC zone.

In certain embodiments, the invention is a catalyst article made by a process described herein. In a particular embodiment, the catalyst article is produced by a process that includes the steps of applying the first SCR catalyst composition, preferably as a washcoat, to a substrate as a layer either before or after the second SCR catalyst composition, preferably as a washcoat, has been applied to the substrate.

In certain embodiments, the second SCR catalyst composition is disposed on the substrate as a top layer and another composition, such as an oxidation catalyst, reduction catalyst, scavenging component, or NOx storage component, is disposed on the substrate as a bottom layer.

In general, the production of an extruded solid body containing the first or second SCR catalyst composition involves blending the molecular sieve and the iron (either separately or together as a metal-exchanged molecular sieve), a binder, an optional organic viscosity-enhancing compound into an homogeneous paste which is then added to a binder/matrix component or a precursor thereof and optionally one or more of stabilized ceria, and inorganic fibers. The blend is compacted in a mixing or kneading apparatus or an extruder. The mixtures have organic additives such as binders, pore formers, plasticizers, surfactants, lubricants, dispersants as processing aids to enhance wetting and therefore produce a uniform batch. The resulting plastic material is then molded, in particular using an extrusion press or an extruder including an extrusion die, and the resulting moldings are dried and calcined. The organic additives are "burnt out" during calcinations of the extruded solid body. A metal-promoted zeolite catalyst may also be washcoated or otherwise applied to the extruded solid body as one or more sub-layers that reside on the surface or penetrate wholly or partly into the extruded solid body. Alternatively, a metal-promoted zeolite can be added to the paste prior to extrusion. Preferably, the
iron-loaded or copper-loaded molecular sieve is dispersed throughout, and preferably evenly throughout, the entire extruded catalyst body.

Extruded solid bodies containing metal-promoted zeolites according to the present invention generally comprise a unitary structure in the form of a honeycomb having uniform-sized and parallel channels extending from a first end to a second end thereof. Channel walls defining the channels are porous. Typically, an external "skin" surrounds a plurality of the channels of the extruded solid body. The extruded solid body can be formed from any desired cross section, such as circular, square or oval. Individual channels in the plurality of channels can be square, triangular, hexagonal, circular etc.

The catalytic article described herein can promote the reaction of a nitrogenous reductant, preferably ammonia, with nitrogen oxides to selectively form elemental nitrogen (N₂) and water (H₂O). Examples of such nitrogenous reductants include ammonia and ammonia hydrazine or any suitable ammonia precursor, such as urea ((NH₂)₂CO), ammonium carbonate, ammonium carbamate, ammonium hydrogen carbonate or ammonium formate. The SCR process of the present method can result in a NO (NO and/or NO₂) conversion of at least 75%, preferably at least 80%, and more preferably at least 90% over a broad temperature range (e.g., about 150 – 700 °C, about 200 – 350 °C, about 350 – 550 °C, or about 450 – 550 °C).

Importantly, the use of zoned catalysts according to the present invention generates low amounts of N₂O byproduct compared to conventional SCR catalysts. That is, the SCR process of the present method can result in low N₂O generation based on NO and/or NO₂ at the SCR inlet.

For example, the relative ratio of inlet NO concentration at the SCR catalyst compared to outlet N₂O concentration after the SCR catalyst is greater than about 25, greater than about 30 (for example about 30 to about 40), greater than about 50, greater than about 80, or greater than about 100 over a broad temperature range (e.g., about 150 – 700 °C, about 200 – 350 °C, about 350 – 550 °C, or about 450 – 550 °C). In another example, the relative ratio of inlet NO₂ concentration at the SCR catalyst compared to outlet N₂O concentration after the SCR catalyst is greater than about 50, greater than about 80, or greater than about 100 over a broad temperature range (e.g., about 150 – 700 °C, about 200 – 350 °C, about 350 – 550 °C, or about 450 – 550 °C).

The metal-loaded molecular sieve catalyst described herein can promote the storage or oxidation of ammonia or can be coupled with an oxidation catalyst, such as a platinum and/or palladium supported on alumina, can also promote the oxidation of ammonia and limit the undesirable formation of NOₓ by the oxidation process (i.e., an ammonia slip catalyst (ASC)).
It may be preferable that the catalytic article of the present invention contains an ASC zone at the outlet end of the substrate.

Additionally or alternatively, an ammonia slip catalyst can be disposed on a separate brick downstream of the zoned SCR catalysts. These separate bricks can be adjacent to, and in contact with, each other or separated by a specific distance, provided that they are in fluid communication with each other and provided that the SCR catalyst brick is disposed upstream of the ammonia slip catalyst brick.

Typically, the SCR and/or ASC process is performed at a temperature of at least 100 °C.

In general, the process(es) occur at a temperature from about 150 °C to about 750 °C. In a particular embodiment, the temperature range is from about 175 to about 550 °C. In another embodiment, the temperature range is from 175 to 400 °C. In yet another embodiment, the temperature range is 450 to 900 °C, preferably 500 to 750 °C, 500 to 650 °C, 450 to 550 °C, or 650 to 850 °C.

According to another aspect of the invention, provided is a method for the reduction of NOx compounds and/or oxidation of NH3 in a gas, which comprises contacting the gas with a catalyst described herein for a time sufficient to reduce the level of NOx compounds in the gas. Methods of the present invention may comprise one or more of the following steps: (a) accumulating and/or combusting soot that is in contact with the inlet of a filter; (b) introducing a nitrogenous reducing agent into the exhaust gas stream prior to contacting the SCR catalyst, preferably with no intervening catalytic steps involving the treatment of NOx and the reductant; (c) generating NH3 over a NOx adsorber catalyst or lean NOx trap, and preferably using such NH3 as a reductant in a downstream SCR reaction; (d) contacting the exhaust gas stream with a DOC to oxidize hydrocarbon based soluble organic fraction (SOF) and/or carbon monoxide into CO2, and/or oxidize NO into NO2, which in turn, may be used to oxidize particulate matter in particulate filter; and/or reduce the particulate matter (PM) in the exhaust gas; (e) contacting the exhaust gas with one or more downstream SCR catalyst device(s) (filter or flow-through substrate) in the presence of a reducing agent to reduce the NOx concentration in the exhaust gas; and (f) contacting the exhaust gas with an ammonia slip catalyst, preferably downstream of the SCR catalyst to oxidize most, if not all, of the ammonia prior to emitting the exhaust gas into the atmosphere or passing the exhaust gas through a recirculation loop prior to exhaust gas entering/re-entering the engine.

It may be preferable that all or at least a portion of the nitrogen-based reductant, particularly NH3, for consumption in the SCR process can be supplied by a NOx adsorber catalyst (NAC), a lean NOx trap (LNT), or a NOx storage/reduction catalyst (NSRC), (collectively NAC) disposed upstream of the SCR...
catalyst. In certain embodiments, the NAC is coated on the same flow-through substrate as the zoned SCR catalyst. In such embodiments, the NAC and SCR catalysts are coated in series with the NAC being upstream of the SCR zones.

NAC components useful in the present invention include a catalyst combination of a basic material (such as alkali metal, alkaline earth metal or a rare earth metal, including oxides of alkali metals, oxides of alkaline earth metals, and combinations thereof), and a precious metal (such as platinum), and optionally a reduction catalyst component, such as rhodium. Specific types of basic material useful in the NAC include cesium oxide, potassium oxide, magnesium oxide, sodium oxide, calcium oxide, strontium oxide, barium oxide, and combinations thereof. The precious metal is preferably present at about 10 to about 200 g/ft³, such as 20 to 60 g/ft³. Alternatively, the precious metal of the catalyst is characterized by the average concentration which may be from about 40 to about 100 grams/ft³.

Under certain conditions, during the periodically rich regeneration events, NH₃ may be generated over a NOₓ adsorber catalyst. The SCR catalyst downstream of the NOₓ adsorber catalyst may improve the overall system NOₓ reduction efficiency. In the combined system, the SCR catalyst is capable of storing the released NH₃ from the NAC catalyst during rich regeneration events and utilizes the stored NH₃ to selectively reduce some or all of the NOₓ that slips through the NAC catalyst during the normal lean operation conditions.

In certain aspects, the invention is a system for treating exhaust gas generated by combustion process, such as from an internal combustion engine (whether mobile or stationary), a gas turbine, coal or oil fired power plants, and the like. Such systems include a zoned SCR catalytic article described herein and at least one additional component for treating the exhaust gas, wherein the zoned SCR catalytic article and at least one additional component are designed to function as a coherent unit. The zoned SCR catalytic article and at least one additional component are in fluid communication, optionally by one or more sections of conduit for channeling exhaust gas through the system.

The exhaust gas treatment system can comprise an oxidation catalyst (e.g., a diesel oxidation catalyst (DOC)) for oxidizing nitrogen monoxide in the exhaust gas to nitrogen dioxide can be located upstream of a point of metering the nitrogenous reductant into the exhaust gas.

The oxidation catalyst may be adapted to yield a gas stream entering the SCR zeolite catalyst having a ratio of NO to NOₓ of from about 4:1 to about 1:20 by volume, e.g. at an exhaust gas temperature at oxidation catalyst inlet of 200 °C to 550 °C. The oxidation catalyst can include at least one platinum group metal (or some combination of these), such as platinum, palladium, or rhodium,
preferably coated on a flow-through monolith substrate. Preferably, the at least one platinum group metal is platinum, palladium or a combination of both platinum and palladium.

The platinum group metal can be supported on a high surface area washcoat component such as alumina, a zeolite such as an aluminosilicate zeolite, silica, non-zeolite silica alumina, ceria, zirconia, titania or a mixed or composite oxide containing both ceria and zirconia.

The exhaust gas treatment system can comprise an additional SCR catalyst on a second flow-through monolith or a wall-flow filter, wherein the second flow-through monolith or wall-flow filter containing the additional SCR is positioned upstream or downstream of, and in fluid communication with, the first and second SCR catalyst zones described herein. The additional SCR catalyst is preferably a metal-exchanged zeolite, such as Fe-Beta, Fe-iron-isomorphous Beta, Fe-ZSM5, Fe-CHA, Fe-ZSM-34, Fe-AEI, Cu-Beta, Cu-ZSM5, Cu-CHA, Cu-ZSM-34, or Cu-AEI.

The exhaust gas treatment system can comprise an NAC and/or an external source of nitrogenous reductant (e.g., an ammonia or urea injector) disposed upstream of the catalytic article.

The system can include a controller for the metering the external nitrogenous reductant into the flowing exhaust gas only when it is determined that the SCR catalyst zones are capable of catalyzing \( \text{NO}_x \) reduction at or above a desired efficiency, such as at above 100 °C, above 150 °C or above 175 °C. The metering of the nitrogenous reductant can be arranged such that 60% to 200% of theoretical ammonia is present in exhaust gas entering the SCR catalyst calculated at 1:1 \( \text{NH}_3 / \text{NO} \) and 4:3 \( \text{NH}_3 / \text{NO}_2 \).

The exhaust gas treatment system can comprise a suitable particulate filter, such as a wall-flow filter. Suitable filters include those useful in removing soot from an exhaust gas stream. The filter can be bare and passively regenerated, or can contain a soot combustion catalyst or a hydrolysis catalyst. A filter can be positioned in the exhaust gas treatment system either upstream or downstream of the SCR catalysts. Preferably, the filter is positioned downstream of the DOC if a DOC is present. For embodiments comprising a bare filter (i.e. having no catalyst coating) and an ammonia injector upstream of the zoned SCR catalyst, the injector can be positioned upstream or downstream of the filter provided that it is positioned upstream of the zoned SCR catalyst. For embodiments having a filter containing a hydrolysis catalyst and downstream zoned SCR catalyst, an ammonia injector is preferably positioned upstream of the filter.

Turning to Figure 10, shown is an exhaust gas treatment system comprising an internal combustion engine (501), an exhaust gas treatment system (502), a direction of exhaust gas flow through the system (1), an optional DOC 510 and/or an optional NAC (520), an optional particulate filter.
(570), an optional external source of ammonia and injector 530, a zoned SCR catalyst (540), an optional additional SCR catalyst (550), and an optional ASC (560).

Figure 11A shows an exhaust gas treatment system comprising a passive NOx absorber (PNA) (610) upstream of a wall-flow filter (620) containing the first SCR catalyst zone, which is preferably coated from the outlet side of the filter. The PNA may contain an alkali and/or alkaline earth metals such as barium, strontium, potassium and a metal oxide such as BaO, TiO₂, ZrO₂, CeO₂, and Al₂O₃. Preferably, the PNA contains a PGM, such as rhodium, palladium, platinum, or a combination of metals such as palladium and platinum and also contains a metal oxide such as barium oxide, cerium oxide, or a mixed metal oxide containing cerium or barium and at least one other transition metal. Suitable PGM loadings can be, for example, 1 – 120 g/ft². The individual components of the PNA may be layered or combined into a single washcoat.

The system shown in Figure 11A further comprises a flow through substrate containing the second SCR catalyst zone which is positioned downstream of the filter. The system preferably includes an ammonia slip catalyst as a separate brick downstream of the flow through substrate or on the rear of the flow through substrate, similar to the arrangement shown in Figure 6A. The system may optionally include a source of SCR reductant (620), such as an injector for introducing ammonia or an ammonia precursor into the system.

The wall-flow filter in Figure 11A is preferably proximal to the flow-through substrate, but the distance between the two is not particularly limited. Preferably, there are no intervening catalysts or filters between units (630) and (640) or between (610) and (630). Preferably, there are no intervening catalysts between the second SCR catalyst zone and the ASC. Preferably, there are no intervening exhaust gas treatment catalysts between the engine and the PNA or downstream of the second SCR catalyst zone or ASC.

Another configuration is shown in Figure 11B wherein the PNA and first SCR catalyst zone are coated on a wall-flow filter (635). Here, the PNA is coated from the inlet side of the filter as a washcoat on the wall surface and/or partially permeating the wall and the first SCR catalyst zone is coated from outlet side of the filter as a washcoat on the wall surface and/or partially permeating the wall. The system further comprises a flow through substrate containing the second SCR catalyst zone which is positioned downstream of the filter. The system preferably includes an ammonia slip catalyst on a separate substrate downstream of the first and second SCR catalyst zones or on the rear of the flow through substrate containing the second SCR catalyst zone, similar to the arrangement shown in Figure 6A. A first reductant supply (e.g., an injector) is positioned upstream of the filter and supplies reductant
to the system under conditions that would not lead to oxidation of the reductant by the PNA (e.g., at temperatures less than 400 °C). An optional second reductant supply (e.g., an injector) is positioned between the first SCR catalyst zone and the second SCR catalyst zone and operates either independently of, or in conjunction with the first reductant supply.

The wall-flow filter in Figure 11B is preferably proximal to the flow-through substrate, but the distance between the two is not particularly limited. Preferably, there are no intervening catalysts or filters between units (635) and (640). Preferably, there are no intervening catalysts between the second SCR catalyst zone and the ASC. Preferably, there are no intervening exhaust gas treatment catalysts between the engine and the PNA or downstream of the second SCR catalyst zone or ASC.

The method for treating exhaust gas as described herein can be performed on an exhaust gas derived from a combustion process, such as from an internal combustion engine (whether mobile or stationary), a gas turbine and coal or oil fired power plants. The method may also be used to treat gas from industrial processes such as refining, from refinery heaters and boilers, furnaces, the chemical processing industry, coke ovens, municipal waste plants and incinerators, etc. In a particular embodiment, the method is used for treating exhaust gas from a vehicular lean burn internal combustion engine, such as a diesel engine, a lean-burn gasoline engine or an engine powered by liquid petroleum gas or natural gas.
CLAIMS

What is claimed is:

1. A system for treating an exhaust gas comprising:
   a. a first SCR catalyst zone comprising an iron loaded medium- or large-pore molecular sieve having a first ammonia storage capacity; and
   b. a second SCR catalyst zone comprising a copper loaded small-pore molecular sieve having a second ammonia storage capacity,

wherein the first SCR catalyst zone is disposed upstream of the second SCR catalyst zone with respect to normal exhaust gas flow through the system and wherein the second ammonia storage capacity is greater than the first ammonia storage capacity.

2. The system of claim 1, wherein the first ammonia storage capacity is not more than about 1.5 mmol/g catalyst, and the second ammonia storage capacity is at least about 1.2 mmol/g catalyst.

3. The system of any preceding claim, wherein the system is free of any catalyst disposed between the first and second SCR catalyst zones.

4. The system of any preceding claim, wherein the first SCR catalyst zone is essentially free of copper and the second catalyst zone is essentially free of iron.

5. The system of any preceding claim, wherein the first SCR catalyst zone comprises an iron loaded molecular sieve having a BEA framework.

6. The system of any preceding claim, wherein the second SCR catalyst zone comprises a copper loaded molecular sieve having a framework selected from CHA, AEI, AFX, and AFT.

7. The system of any preceding claim, wherein the molecular sieve of the first SCR catalyst zone and the molecular sieve of the second SCR catalyst zone independently have a silica-to-alumina ratio of about 10 to about 50.
8. The system of any preceding claim, wherein the first and second SCR catalyst zones are coated on a flow-through honeycomb substrate having an inlet end, an outlet end, and an axial length measured from the inlet end to the outlet end, and the first and second SCR catalyst zones are adjacent or at least partially overlapping.

9. The system of claim 1, further comprising an oxidation catalyst zone downstream of the second SCR catalyst zone.

10. The system of claim 9, wherein the second SCR catalyst zone completely overlaps the oxidation catalyst zone.

11. The system of claim 1, wherein the first SCR catalyst zone is on a wall-flow filter having an inlet side and an outlet side, and the second SCR catalyst zone is on a flow-through honeycomb substrate, provided that there are no intervening catalyst between the first SCR catalyst zone and the second SCR catalyst zone.

12. The system of claim 11, further comprising a partial NOx absorber disposed upstream of the first SCR catalyst zone.

13. The system of claim 12, further comprising a first reductant supply for introducing nitrogen-based reductant upstream of the filter and a second reductant supply for introducing nitrogen-based reductant between the filter and the flow-through honeycomb substrate.

14. The system of claim 1, further comprising an ammonia slip catalyst coated on the flow-through substrate downstream of the second SCR catalyst zone.

15. A method for treating an exhaust gas comprising the step of contacting, in series, a mixture of ammonia and exhaust gas derived from an internal combustion engine with (a) a first SCR zone comprising an iron loaded molecular sieve having an ammonia storage capacity of not more than about 1.5 mmol NH₃/g, and (b) a second SCR zone comprising a copper-loaded molecular sieve having an ammonia storage capacity of at least about 1.2 mmol NH₃/g catalyst, provided that iron
loaded molecular sieve has a lower ammonia storage capacity relative to the copper-loaded molecular sieve.
**INTERNATIONAL SEARCH REPORT**

**A. CLASSIFICATION OF SUBJECT MATTER**

INV. B01D53/94 B01J35/00 B01J29/072 B01J29/76 B01J35/04

**ADD.**

According to International Patent Classification (IPC) or to both national classification and IPC

**B. FIELDS SEARCHED**

Minimum documentation searched (classification system followed by classification symbols)

B01D B01J F01N

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

EPO-Internal, WPI Data

**C. DOCUMENTS CONSIDERED TO BE RELEVANT**

INTERNATIONAL SEARCH REPORT

Box No. II Observations where certain claims were found unsearchable (Continuation of Item 2 of first sheet)

This international search report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.: because they relate to subject matter not required to be searched by this Authority, namely:

2. ☐ Claims Nos.: because they relate to parts of the international application that do not comply with the prescribed requirements to such an extent that no meaningful international search can be carried out, specifically:

3. ☐ Claims Nos.: because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

Box No. III Observations where unity of invention is lacking (Continuation of Item 3 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this international search report covers all searchable claims.

2. ☐ As all searchable claims could be searched without effort justifying an additional fees, this Authority did not invite payment of additional fees.

3. ☐ As only some of the required additional search fees were timely paid by the applicant, this international search report covers only those claims for which fees were paid, specifically claims Nos.:

4. ☑ No required additional search fees were timely paid by the applicant. Consequently, this international search report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

   1-14

Remark on Protest
☐ The additional search fees were accompanied by the applicant's protest and, where applicable, the payment of a protest fee.
☐ The additional search fees were accompanied by the applicant's protest but the applicable protest fee was not paid within the time limit specified in the invitation.
☐ No protest accompanied the payment of additional search fees.
This International Searching Authority found multiple (groups of) inventions in this international application, as follows:

1. claims: 1-14
   A system for treating an exhaust gas
     ---

2. claim: 15
   a method for treating an exhaust gas
     ---
