ABSTRACT

The invention is directed to a promoter, designated MuB, sequences which hybridize to same and functional fragments thereof. The regulatory element of the invention provide improved expression in plants of operably linked nucleotide sequences. Expression vectors with the regulatory element is the subject of the invention, which may further include an operably linked nucleotide sequence. The invention is further directed to transformed plant tissue including the nucleotide sequence and to transformed plants and seeds thereof. The regulatory element is useful for driving gene or antisense expression or the like for the purpose of imparting agronomically useful traits such as, but not limited to, increase in yield, disease resistance, insect resistance, herbicide tolerance, drought tolerance and salt tolerance in plants.

The expression of a heterologous nucleotide sequence in a plant cell is impacted by regulatory nucleic acids. Promoters and terminators are two types of regulatory elements that impact expression of such operably linked sequences. Promoters are vital molecular tools that have been applied widely in plant biotechnology to control the expression of introduced genes. A promoter is a nucleic acid sequence to which RNA polymerase must bind if it is to transcribe the linked gene into messenger RNA and ultimately produce protein. A promoter may affect a structural gene operationally associated with the promoter in different ways. For example, it may enhance or repress expression of an associated structural gene, subject that gene to developmental regulation, or contribute to the tissue-specific regulation of that gene. There are different types of promoters used dependent upon the function desired. Constitutive promoters provide for expression throughout all tissues of the plant, where tissue preferred promoters will express at a higher rate in a (or a few) select tissue of the plant. Inducible promoters are those which induce the regulatory effect of the promoter in response to a stimulus, which can be, for example, chemical, temperature, stress, wounding or other stimuli. The linked nucleotide sequence can perform any of a wide variety of functions desired, whether it is repressing or initiating expression of a trait or protein of interest, providing for overexpression, modifying metabolic and developmental pathways within the plant tissue, or the like.

Several promoters of plant and plant pathogen (bacterial and viral) origin have been used to direct transgene expression in plants. Prominent examples include the French bean beta-phaseolin promoter (Busot et al., 1989), the maize intron enhancer promoter of Agrobacterium tumefaciens (Leung et al., 1991), and the 3SS promoter of cauliflower mosaic virus (Guilley et al., 1982). These and several other promoters in widespread use in plants were originally developed and utilized in dicot species. Despite the desire to identify constitutive promoters capable of driving a relatively high level of gene expression in most tissues of the plant, there remain few to choose from and there is an ongoing need to identify promoters for use in expressing linked sequences.

All references cited herein are incorporated herein by reference.

SUMMARY OF THE INVENTION

A promoter designated MuB has been identified, and function as a promoter demonstrated. The invention is further directed to sequences which hybridize to one another highly stringent circumstances and functional fragments. In an embodiment, the regulatory element is used to regulate high level, constitutive expression of linked nucleotide sequences.

DESCRIPTION OF THE DRAWINGS

FIG. 1 shows the promoter sequence of the invention, SEQ ID NO: 1. The putative TATA box is underlined.

FIG. 2 shows the nucleotide sequence, including all 351 base pairs of the MuB promoter, and the source of each homologous sequence from which a given segment is mostly comprised. The source and GenBank accession is as follows: A: MuA U.S. Pat. No. 6,222,096 (SEQ ID NO: 2); B: AB000835 (SEQ ID NO: 3); C: Y08502 (SEQ ID NO: 4); D: U09376 (SEQ ID NO: 5); E: AB005247 (SEQ ID NO: 6); F: AF028711 (SEQ ID NO: 7); G: ACO0252 (SEQ ID NO: 8); H: D12522 (SEQ ID NO: 9); I: AB012243 (SEQ ID NO: 10); J: AL022347 (SEQ ID NO: 11).

FIG. 3 shows the homology between the MuB and the CaMV 3SS promoter sequences (SEQ ID NO: 12) over a 351 bp overlap.

FIG. 4 shows the homology between the MuB and the MuA promoter sequences (SEQ ID NO: 13) over a 352 bp overlap.

DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention is directed to a promoter, designated MuB, providing constitutive expression of an operably linked sequence. The construction of this promoter provides a general method for the discovery of novel sequences with utility as promoters. The present invention is also directed to DNA molecules including said promoter, such as a DNA construct comprising the promoter operably linked to one or more genes or antisense DNA. The invention is further directed to transformed plant tissue including the DNA molecule and to transformed plants and seeds thereof. The promoter is useful for driving gene or antisense expression for the purpose of imparting agronomically useful traits such as, but not limited to, increased yield, disease resistance, insect resistance, herbicide tolerance, drought tolerance and salt tolerance in plants. Nucleotide sequences are described herein that regulate transcription with high constitutive expression in plant cells.

A recombinant host may be any prokaryotic or eukaryotic cell that contains either a cloning vector or an expression vector. This term also includes those prokaryotic or eukaryotic cells that have been genetically engineered to contain the cloned gene(s) in the chromosome or genome of the host cell. The promoter is, in an embodiment, particularly useful for the expression of gene sequences in plants. It can be used in any plant species, including a dicotyledonous plant, such as, by way of example but not limitation, tobacco, tomato, potato, soybean, cotton, canola, sunflower or alfalfa. Alternatively, the plant may be a monocotyledonous plant, by way of example but not limitation, maize, wheat, rye, rice, oat, barley, turfgrass, sorghum, millet or sugarcane.

The nucleotide sequences of the invention can be used to isolate corresponding sequences from other organisms, particularly other plants, or to synthesize synthetic sequences. In this manner, methods such as polymerase chain reaction (PCR), hybridization, synthetic gene construction and the like can be used to identify or generate such sequences based on their sequence homology to the sequences set forth herein. Sequences identified, isolated or constructed based on their sequence identity to the whole of or any portion of the promoter sequences set forth are encompassed by the present invention. Synthesis of sequences suitably employed in the present invention can be effected by means of mutually priming long oligonucleotides. See for example, Wosnick et al. (1987). In a PCR approach, oligonucleotide primers can be designed for use in PCR reactions to amplify corresponding DNA sequences from cDNA or genomic DNA extracted from any plant of interest. Methods for designing PCR primers and PCR cloning are generally known in the art and are disclosed.
(Sambrook et al., 1989; Innis et al., 1990; Innis et al., 1995; Innis et al., 1999). Moreover, current techniques which employ the PCR reaction permit the synthesis of genes as large as 1.8 kilobases in length. See Adang et al. (1993) and Bambot et al. (1993). Known methods of PCR include, but are not limited to, methods using paired primers, nested primers, degenerate primers, gene-specific primers, vector-specific primers, partially-mismatched primers, and the like. In addition, genes can readily be synthesized by conventional automated techniques.

For example, probes for hybridization can be made by labeling synthetic oligonucleotides based on the DNA sequences of the invention. Methods for preparation of probes for hybridization and for construction of cDNA and genomic libraries are generally known in the art and are disclosed (Sambrook et al., 1989).

For example, the promoter sequence disclosed herein, or one or more portions thereof, may be used as a probe capable of specifically hybridizing to corresponding sequences. To achieve specific hybridization under a variety of conditions, such probes include sequences that are unique among the sequences to be screened and are preferably at least about 10 nucleotides in length, and more preferably at least about 20 nucleotides in length. Such sequences may alternatively be used to amplify corresponding sequences from a chosen plant by PCR. This technique may be used to isolate sequences from a desired plant or as a diagnostic assay to determine the presence of sequences in a plant. Hybridization techniques include hybridization screening of DNA libraries plated as either plaques or colonies (Sambrook et al., 1989).

Hybridization of such sequences may be carried out under stringent conditions. By “stringent conditions” or “stringent hybridization conditions” is intended conditions under which a probe will hybridize to its target sequence to a detectably greater degree than to other sequences (e.g., at least 2-fold over background). Stringent conditions are sequence-dependent and will be different in different circumstances. By controlling the stringency of the hybridization and/or washing conditions, target sequences that are 100% complementary to the probe can be identified (homologous probing). Alternatively, stringency conditions can be adjusted to allow some mismatching in sequences so that lower degrees of similarity are detected (heterologous probing). Generally, a probe is less than about 1000 nucleotides in length, preferably less than 500 nucleotides in length.

Typically, stringent conditions will be those in which the salt concentration is less than about 1.5 M Na+ ion, typically about 0.1 to 1.0 M Na+ ion concentration (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30°C. for short probes (e.g., 10 to 50 nucleotides) and at least about 60°C. for long probes (e.g., greater than 50 nucleotides). Stringent conditions may also be achieved with the addition of destabilizing agents such as formamide. Exemplary low stringency conditions include hybridization with a buffer solution of 30 to 35% formamide, 1M NaCl, 1% SDS (sodium dodecyl sulfate) at 37°C, and a wash in 1x to 2x SSC (20xSSC=0.1 M NaCl/0.1 M trisodium citrate) at 50 to 55°C. Exemplary moderate stringency conditions include hybridization in 40 to 45% formamide, 1.0 M NaCl, 1% SDS at 37°C, and a wash in 0.5x to 1x SSC at 55 to 60°C. Exemplary high stringency conditions include hybridization in 50% formamide, 1.0 M NaCl, 0.1% SDS at 37°C, and a wash in 0.1x SSC at 60 to 65°C.

In general, sequences that correspond to the nucleotide sequences of the present invention and hybridize to the nucleotide sequence disclosed herein will be at least 50% homologous, 70% homologous, and even 85%, 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% homologous or more with the disclosed sequence. That is, the sequence similarity between probe and target may range, sharing at least about 50%, about 70%, and even about 85% or more sequence similarity.

Specificity is also the function of post-hybridization washes, the critical factors being the ionic strength and temperature of the final wash solution. For DNA-DNA hybrids, the Tm can be approximated from the equation Tm=81.5 °C+16.6 (logM)+0.41 (%GC)-0.61( %form. )-500/L, where M is the molarity of monovalent cations, %GC is the percentage of guanosine and cytosine nucleotides in the DNA, % form. is the percentage of formamide in the hybridization solution, and L is the length of the hybrid in base pairs (Meinkoth and Wahl, 1984). The Tm is the temperature (under defined ionic strength and pH1) at which 50% of a complementary target sequence hybridizes to a perfectly matched probe. Tm is reduced by about 1°C for each 1% of mismatching; thus, Tm, hybridization, and/or wash conditions can be adjusted for sequences of the desired identity to hybridize. For example, if sequences with 90% identity are sought, the Tm can be decreased to 10°C. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (Tm) for the specific sequence and its complement at a defined ionic strength and pH. However, severely stringent conditions can utilize a hybridization and/or wash at 1, 2, 3, or 4°C lower than the thermal melting point (Tm); moderately stringent conditions can utilize a hybridization and/or wash at 6, 7, 8, 9, or 10°C lower than the thermal melting point (Tm); low stringency conditions can utilize a hybridization and/or wash at 20°C lower than the thermal melting point (Tm). Using the equation, hybridization and wash conditions, and desired Tm, those of ordinary skill will understand that variations in the stringency of hybridization and/or wash solutions are inherently desired. If the desired degree of mismatching results in a Tm of less than 45°C. (aqueous solution) or 32° C. (formamide solution), it is preferred to increase the SSC concentration so that a higher temperature can be used. An extensive guide to the hybridization of nucleic acids is found (1997) Ausubel et al, Short Protocols in Molecular Biology, page 2-40, Third Ed. (1997) and Sambrook et al. (1989).

Thus, isolated sequences that have regulatory element activity and which hybridize under stringent conditions to the promoter sequences disclosed herein, or to fragments thereof, are encompassed by the present invention.

The following terms are used to describe the sequence relationships between two or more nucleic acids or polynucleotides: (a) “reference sequence”, (b) “comparison window”, (c) “sequence identity” and (d) “percentage of sequence identity.”
(a) As used herein, “reference sequence” is a defined sequence used as a basis for sequence comparison. A reference sequence may be a subset or the entirety of a specified sequence, for example, as a segment of a full-length promoter sequence, or the complete promoter sequence.

(b) As used herein, “comparison window” makes reference to a contiguous and specified segment of a polynucleotide sequence, wherein the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. Generally, the comparison window is at least 20 contiguous nucleotides in length, and optionally can be 30, 40, 50, 100, or longer. Those of skill in the art understand that to accurately reflect the similarity to a reference sequence due to inclusion of gaps in the polynucleotide sequence a gap penalty is typically introduced and is subtracted from the number of matches.

Methods of alignment of sequences for comparison are well known in the art. Thus, the determination of percent identity between any two sequences can be accomplished using a mathematical algorithm. Preferred, non-limiting examples of such mathematical algorithms are the algorithm of Myers and Miller (1988), the local homology algorithm of Smith and Waterman (1981), the homology alignment algorithm of Needleman and Wunsch (1970), the search-for-similarity-method of Pearson and Lipman (1988) and the algorithm of Karlin and Altschul (1990), modified as in Karlin and Altschul (1993).

Computer implementations of these mathematical algorithms can be utilized for comparison of sequences to determine sequence identity. Such implementations include, but are not limited to: CLUSTAL in the PCGene program (available from Intellicogenetics, Mountain View, Calif., USA); the ALIGN program (Version 2.0) and GAP, BESTFIT, BLAST, FASTA, and TFASTA in the Wisconsin Genetics Software Package, Version 8 (available from Genetics Computer Group (GCG), 575 Science Drive, Madison, Wis., USA). Alignments using these programs can be performed using the default parameters. The CLUSTAL program is well described by Higgins and Sharp (1988), Higgins and Sharp (1989), Corpet (1988), Huang et al. (1992) and Pearson (1994). The ALIGN program is based on the algorithm of Myers and Miller (1988). The BLAST programs of Altschul et al. (1990) are based on the algorithm of Karlin and Altschul (1990). To obtain gapped alignments for comparison purposes, Gapped BLAST (in BLAST 2.0) can be utilized as described in Altschul et al. (1997). Alternatively, PSI-BLAST (in BLAST 2.0) can be used to perform an iterated search that detects distant relationships between molecules, see Altschul et al. (1997). When utilizing BLAST, Gapped BLAST or PSI-BLAST, the default parameters of the respective programs (e.g. BLASTN for nucleotide sequences, BLASTX for proteins) can be used, see the World Wide Web site ncbi.nlm.nih.gov. Alignment may also be performed manually by inspection.

For purposes of the present invention, comparison of nucleotide sequences for determination of percent sequence identity to the promoter sequences disclosed herein is preferably made using the BlastN program (version 1.4.7 or later) with its default parameters or any equivalent program. By “equivalent program” is intended any sequence comparison program that, for any two sequences in question, generates an identical or similar alignment of nucleotide matches and percent sequence identity when compared to the corresponding alignment generated by the preferred program.

(c) As used herein, “sequence identity” or “identity” in the context of two nucleic acid sequences makes reference to the residues in the two sequences that are the same when aligned for maximum correspondence over a specified comparison window.

(d) As used herein, “percentage of sequence identity” means the value determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. The percentage is calculated by determining the number of positions at which the identical nucleic acid base occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison, and multiplying the result by 100 to yield the percentage of sequence identity.

Identity to the sequence of the present invention would mean a polynucleotide sequence having at least 65% sequence identity, more preferably at least 70% sequence identity, more preferably at least 75% sequence identity, more preferably at least 80% identity, more preferably at least 85% 86%, 87%, 88%, 89%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99% sequence identity.

In accordance with one embodiment, a novel promoter is constructed by the following steps. The sequence of a known or newly discovered promoter is compared with known nucleic acid sequences, such as sequences in genomic databases. In one embodiment, this comparison is made in the GenBank database using a program such as FASTA (Genetics Computer Group, Madison, Wis.). Additional suitable databases and comparison programs are known to a person of skill in the art. Segments of sequence similar to the query sequence, i.e., the known or newly discovered promoter, are identified and selected. Segments are considered similar if they have between 60% and 100% sequence identity over the segment being examined. These segments can be 20-100 bases in length, although smaller or longer segments can also be selected. The selected sequences are aligned in linear order according to the sequence of the promoter being modified. The resultant promoter is a hybrid promoter comprised of sequences similar to but different from the original promoter. The short segments that make up the synthetic hybrid promoter may be parts of promoters or regulatory regions from other genes. The synthetic hybrid promoter is then constructed and empirically tested in a test expression system to determine its quantitative and qualitative characteristics. If the synthetic hybrid promoter has maintained or improved activity, it may be used directly. If the synthetic hybrid promoter has a lower activity, the sequence of the synthetic hybrid promoter is further modified by replacing some of the bases to generate a new hybrid promoter. The new hybrid promoter is again constructed and tested to determine if it has the desired maintained or improved activity. This procedure can be performed as often as necessary to derive the final hybrid promoter having the desired activity.

The invention is further to “functional variants” of the regulatory sequence disclosed. Functional variants include, for example, regulatory sequences of the invention having one or more nucleotide substitutions, deletions or
insertions and wherein the variant retains promoter activity, particularly the ability to drive expression preferentially to the embryo of a plant. Functional variants can be created by any of a number of methods available to one skilled in the art, such as by site-directed mutagenesis, induced mutation, identified as allelic variants, cleaving through use of restriction enzymes, or the like. Activity can likewise be measured by any variety of techniques, including measurement of reporter activity as is described at U.S. Pat. No. 6,844,484, Northern blot analysis, or similar techniques. The `484 patent describes the identification of functional variants of different promoters.

[0030] The invention further encompasses a “functional fragment,” that is, a regulatory sequence fragment formed by one or more deletions from a larger regulatory element. For example, the 5' portion of a promoter up to the TATA box near the transcription start site can be deleted without abolishing promoter activity, as described by Opsihi-Sorteberg, H-G, et al., 2004. Such fragments should retain promoter activity, particularly the ability to drive expression of operably linked nucleotide sequences. Activity can be measured by Northern blot analysis, reporter activity measurements when using transcriptional fusions, and the like. See, for example, Sambrook et al. (1989). Functional fragments can be obtained by use of restriction enzymes to cleave the naturally occurring regulatory element nucleotide sequences disclosed herein; by synthesizing a nucleotide sequence from the naturally occurring DNA sequence; or can be obtained through the use of PCR technology. See particularly, Mullis et al. (1987) and Erlich, ed. (1989).

[0031] For example, a routine way to remove part of a DNA sequence is to use an exonuclease in combination with DNA amplification to produce unidirectional nested deletions of double stranded DNA clones. A commercial kit for this purpose is sold under the trade name Exo-Size™ (New England Biolabs, Beverly, Mass.). Briefly, this procedure entails incubating exonuclease III with DNA to progressively remove nucleotides in the 3' to 5' direction at 5' overhangs, blunt ends or nicks in the DNA template. However, exonuclease III is unable to remove nucleotides at 3', 4-base overhangs. Timed digests of a clone with this enzyme produces unidirectional nested deletions.

[0032] By “promoter” is meant a regulatory element of DNA capable of regulating the transcription of a sequence linked thereto. It usually comprises a TATA box capable of directing RNA polymerase II to initiate RNA synthesis at the appropriate transcription initiation site for a particular coding sequence. The promoter is the minimal sequence sufficient to direct transcription in a desired manner. The term “regulatory element” is also used to refer to the sequence capable of “regulatory element activity,” that is, initiating transcription in a desired manner. Therefore the invention is directed to the regulatory element described herein including those sequences which hybridize to same and have identity to same, as indicated, and fragments and variants of same which have regulatory activity.

[0033] The promoter of the invention may also be used in conjunction with another promoter. In one embodiment, the plant selection marker and the nucleotide sequence of interest can be both functionally linked to the same promoter. In another embodiment, the plant selection marker and the nucleotide sequence of interest can be functionally linked to different promoters. In yet third and fourth embodiments, the expression vector can contain two or more nucleotide sequences of interest that can be linked to the same promoter or different promoters. For example, the promoter described here can be used to drive the gene of interest and the selectable marker, or a different promoter used for one or the other. These other promoter elements can be those that are constitutive or sufficient to render promoter-dependent gene expression controllable as being cell-type specific, tissue-specific or time or developmental stage specific, or being inducible by external signals or agents. Such elements may be located in the 5' or 3' regions of the gene. Although the additional promoter may be the endogenous promoter of a structural gene of interest, the promoter can also be a foreign regulatory sequence. Promoter elements employed to control expression of product proteins and the selection gene can be any plant-compatible promoters. These can be plant gene promoters, such as, for example, the ubiquitin promoter (European patent application no. 0 342 926); the promoter for the small subunit of ribulose-1,5-bis-phosphate carboxylase (Rubisco) (Coruzzi et al., 1984; Brolge et al., 1984); or promoters from the tumor-inducing plasmids from Agrobacterium tumefaciens, such as the nopaline synthase, octopine synthase and mannopine synthase promoters (Velten and Schell, 1985) that have plant activity; or viral promoters such as the cauliflower mosaic virus CaMV) 19S and 35S promoters (Guilley et al., 1982; Odell et al., 1985), the figwort mosaic virus F1 promoter (Malet et al., 1997) or the coat protein promoter of TMV (Grzeliak et al., 2000).

[0034] The range of available plant compatible promoters includes tissue specific and inducible promoters. An inducible regulatory element is one that is capable of directly or indirectly activating transcription of one or more DNA sequences or genes in response to an inducer. In the absence of an inducer the DNA sequences or genes will not be transcribed. Typically the protein factor that binds specifically to an inducible regulatory element to activate transcription is present in an inactive form which is then directly or indirectly converted to the active form by the inducer. The inducer can be a chemical agent such as a protein, metabolite, growth regulator, herbicide or phenolic compound or a physiological stress imposed directly by heat, cold, salt, or toxic elements or indirectly through the action of a pathogen or disease agent such as a virus. A plant cell containing an inducible regulatory element may be exposed to an inducer by externally applying the inducer to the cell or plant such as by spraying, watering, heating or similar methods. Any inducible promoter can be used in the instant invention. See Ward et al. (1993). Exemplary inducible promoters include ecodysone receptor promoters, U.S. Pat. No. 6,504,082; promoters from the ACE1 system which responds to copper (Mett et al. (1993)); In2-1 and In2-2 gene from maize which respond to benzenesulfonyl-mide herbicide safeners (U.S. Pat. No. 5,364,780); the maize GST promoter, which is activated by hydrophobic electrophilic compounds that are used as pre-emergent herbicides; and the tobacco PR-1a promoter, which is activated by salicylic acid. Other chemical-regulated promoters of interest include steroid-responsive promoters (see, for example, the glucocorticoid-inducible promoter in Schena et al. (1991) and McNellis et al. (1998)) and tetracycline-inducible and tetracycline-repressible promoters (see, for example, Gatz et al. (1991), and U.S. Pat. Nos. 5,814,618 and 5,789,156). Alternatively, plant promoters such as heat shock promoters for example soybean hsp 17.5-E (Gurley et al., 1986); or ethanold-inducible promoters (Caddick et al., 1998) may be
for a review of illustrative plant promoters suitably employed in
the present invention.

Tissue-preferred promoters can be utilized to target
enhanced transcription and/or expression within a particular
plant tissue. Promoters may express in the tissue of interest,
along with expression in other plant tissue, may express
strongly in the tissue of interest and to a much lesser degree
than other tissue, or may express highly preferably in the
tissue of interest. Tissue-preferred promoters include, for
example, those described in Yamamoto et al. (1997); Kawamata
et al. (1997); Hansen et al. (1997); Russell et al.
(1997); Rinehart et al. (1996); Van Camp et al. (1996);
Canevascini et al. (1996); Yamamoto et al. (1994); Lam
(1994); Orozco et al. (1993); and Matsusaka et al. (1993).

A promoter can additionally comprise other recogni-
tion sequences generally positioned upstream or 5' to the
TATA box, referred to as upstream promoter elements, which
influence the transcription initiation rate. Using the promoter
sequences disclosed here, it is possible to isolate and identify
further regulatory elements in the 5' region upstream from the
particular promoter region identified. Thus the promoter
region disclosed is generally further defined by comprising
upstream regulatory elements such as those responsible for
high level and temporal expression of the coding sequence,
enhancers and the like. In the same manner, the promoter
elements which enable low to high level expression can be
identified, isolated, and used with other core promoters to
confirm embryo-preferred expression. By core promoter is
meant the sequence sometimes referred to as the TATA box
(or similar sequence) which is common to promoters in most
genes encoding proteins. Thus the upstream promoter of
MaB promoter can optionally be used in conjunction with
its own or core promoters from other sources.

The promoter of the invention may be combined with
any number of other components to be introduced into
the plant, including combined with a nucleotide sequence
of interest to be expressed in the plant. The "nucleotide
sequence of interest" refers to a nucleotide sequence that encodes for
a desired polypeptide or protein but also may refer to nucleo-
tide sequences that do not constitute an entire gene, and
which do not necessarily encode a polypeptide or protein.
For example, when used in a homologous recombination process,
the promoter may be placed in a construct with a sequence
that targets an area of the chromosome in the plant but may
do not encode a protein. Use of antisense versions of a nucleic
acid sequence is another example where use of a sequence
may not result in an encoded protein. If desired, the nucleo-
tide sequence of interest can be optimized for plant transla-
tion by optimizing the codons used for plants and the
sequence around the translational start site for plants.
Sequences resulting in potential mRNA instability can also
be avoided.

In general, the methods available for construction of recombinant
genes, optionally comprising various modifications
for improved expression, can differ in detail. However,
conventionally employed methods include PCR amplifi-
tion, or the designing and synthesis of overlapping, comple-
mentary synthetic oligonucleotides, which are annealed and
ligated together to yield a gene with convenient restriction
sites for cloning, or subcloning from another already cloned
source, or cloning from a library. The methods involved are
standard methods for a molecular biologist (Sambrook et al.,
1989). An expression vector is a DNA molecule comprising a
gene or antisense DNA that is expressed in a host cell. Typi-
cally, gene expression is placed under the control of certain
regulatory elements, including constitutive or inducible pro-
moters, tissue-specific regulatory elements, and enhancers.

One skilled in the art readily appreciates that the
promoter can be used with any of a variety of nucleotide
sequences comprising the nucleotide sequence of interest to
be expressed in plants. In referring to an operably linked
nucleotide sequence is intended a functional linkage between
a promoter and another sequence where the promoter initiates
and mediates transcription of the nucleotide sequence. For
example, the nucleotide sequence of interest may encode a
protein that is useful for industrial or pharmaceutical
purposes or the like, or to impact the plant itself, such as through
expression of a protein that provides disease resistance, insect
resistance, herbicide resistance, or impacts agronomic traits
as well as grain quality traits. DNA sequences native to plants
as well as non-native DNA sequences can be transformed into
plants and used to modulate levels of native or non-native
proteins. One or more of such sequences and/or expression
cassettes may be transformed into a plant cell (in referring to
a plant cell, it is intended to include cells without plant mem-
branes, such as protoplasts).

Such nucleotide sequences include, but are not lim-
ited to, those examples provided below:

1. Genes That Confer Resistance to Pests or Disease

(A) Plant Disease Resistance Genes. Plant defenses
are often activated by specific interaction between the product
of a disease resistance gene (R) in the plant and the product
of a corresponding avirulence gene (Avr) in the pathogen.
A plant variety can be transformed with cloned resistance gene
to engineer plants that are resistant to specific pathogen
strains. Examples of such genes include, the tomato CI-9
gene for resistance to Cladosporium fulvum (Jones et al.,
1994), tomato Pto gene, which encodes a protein kinase, for
resistance to Pseudomonas syringae pv. tomato (Martin et al.,
1993), and Arabidopsis RRS2 gene for resistance to
Pseudomonas syringae (Mindrinos et al., 1994).

(B) A Bacillus thuringiensis protein, a derivative
thereof or a synthetic polypeptide modeled thereon, such as,
a nucleotide sequence of a Bt δ-endotoxin gene (Geiser et al.,
1986). Moreover, DNA molecules encoding δ-endotoxin
genesis can be purchased from American Type Culture
Collection (Rockville, Md.), under ATCC accession numbers.
40098, 67136, 31995 and 31998.

(C) A lectin, such as, nucleotide sequences of sev-
eral Clivia miniata mannose-binding lectin genes (Van
Damme et al., 1994).

(D) A vitamin binding protein, such as avidin and
avidin homologs which are useful as larvicides against insect
pests. See U.S. Pat. No. 5,659,026.

(E) An enzyme inhibitor, e.g., a protease inhibitor
or an amylase inhibitor. Examples of such genes include, a rice
glycoalkaline protease inhibitor (Abe et al., 1987), a tobacco
protease inhibitor I (Huib et al., 1993), and an α-amylase
inhibitor Sumitani et al., 1993).

(F) An insect-specific hormone or pheromone
such as an ecdysteroid and juvenile hormone a variant thereof,
a mimetic based thereon, or an antagonist or agonist thereof,
such as, baculovirus expression of cloned juvenile hormone
esterase, an inhibitor of juvenile hormone (Hammock et al.,
1990).
An insect-specific peptide or neuropeptide which, upon expression, disrupts the physiology of the affected pest. Examples of such genes include, an insect diuretic hormone receptor (Regan, 1994), an allstatin identified in *Diptera punctata* (Pratt, 1989), insect-specific, paralytic neurotoxins (U.S. Pat. No. 5,266,361).

An insect-specific venom produced in nature by a snake, a wasp, etc., such as, a scorpion insectotoxic peptide (Pang, 1992).

An enzyme responsible for a hyperaccumulation of monoterpene, a sesquiterpene, a steroid, hydroxamic acid, a phenylpropanoid derivative or another non-protein molecule with insecticidal activity.

An enzyme involved in the modification, including the post-translational modification, of a biologically active molecule; for example, glycolytic enzyme, a proteolytic enzyme, a lipolytic enzyme, a nuclease, a cyclase, a transaminase, an esterase, a hydrolyase, a phosphatase, a kinase, a phosphorylase, a polymerase, an elastase, a chitinase and a glucanase, whether natural or synthetic. Examples of such genes include, a callas gene (PCT published application WO95/02197), chitinase-encoding sequences (which can be obtained, for example, from the ATCC under accession numbers 3996637 and 67152), tobacco hawkworm chitinase (Kramer et al., 1993) and parsley ubi-6 polyubiquitin gene (Kawalleck et al., 1993).

A molecule that stimulates signal transduction. Examples of such molecules include, nucleotide sequences for mung bean calmodulin cDNA clones (Botella et al., 1994) and a nucleotide sequence of a maize calmodulin cDNA clone (Griess et al., 1994).

A hydrophobic moment peptide. See U.S. Pat. Nos. 5,659,026 and 5,607,914, the latter teaches synthetic antimicrobial peptides that confer disease resistance.

A membrane permease, a channel former or a channel blocker, such as, a cecropin-β lytic peptide analog (Jaynes et al., 1993) which renders transgenic tobacco plants resistant to *Pseudomonas solanacearum*.

A viral-invasive protein or a complex toxin derived there from. For example, the accumulation of viral coat proteins in transformed plant cells imparts resistance to viral infection and/or disease development affected by the virus and resistance to the coat protein gene is derived as well as by related viruses. Coat protein-mediated resistance has been conferred upon transformed plants against alfalfa mosaic virus, cucumber mosaic virus, tobacco streak virus, potato virus X, potato virus Y, tobacco etch virus, tobacco rattle virus and tobacco mosaic virus. See, for example, Beachy et al. (1990).

An insect-specific antibody or an immunotoxin derived there from. Thus, an antibody targeted to a critical metabolic function in the insect gut would inactive an affected enzyme, killing the insect. For example, Taylor et al. (1994) shows enzymatic inactivation in transgenic tobacco via production of single-chain antibody fragments.

A virus-specific antibody. See, for example, Tavladonaki et al. (1993), which shows that transgenic plants expressing recombinant antibody genes are protected from virus attack.

A developmental-arrestive protein produced in nature by a pathogen or a parasite. Thus, fungal endo α-1,4-D polygalacturonases facilitate fungal colonization and plant nutrient release by solubilizing plant cell wall homo-α-1,4-D-galacturonase (Lamb et al., 1992). The cloning and characterization of a gene which encodes a bean endopolygalacturonase-inhibiting protein is described by Toubart et al. (1992).

A developmental-arrestive protein produced in nature by a plant, such as, the barley ribosome-inactivating gene has an increased resistance to fungal disease (Longemann et al., 1992).

2. Genes That Confer Resistance to a Herbicide

A herbicide that inhibits the growing point or meristem, such as, a miazidazolinone or a sulfonylurea. Exemplary genes in this category code for mutant ALS (Lee et al., 1988) and AHAS enzyme (Miki et al., 1990).

Glyphosate (resistance imparted by mutant EPSP synthase and aroA genes, respectively) and other phosphono compounds such as glufosinate (PAT and bar genes), and pyridino or phenoxy propionic acids and cyclohexone (ACCCase inhibitor encoding genes). See, for example, U.S. Pat. No. 4,940,835, which discloses the nucleotide sequence of a form of EPSP which can confer glyphosate resistance. A DNA molecule encoding a mutant aroA gene can be obtained under ATCC accession number 39256, and the nucleotide sequence of the mutant gene is disclosed in U.S. Pat. No. 4,769,061. European patent application No. 0 333 033 and U.S. Pat. No. 4,975,374 disclose nucleotide sequences of glutamine synthetase genes which confer resistance to herbicides such as 1-phosphinothricin. The nucleotide sequence of a phosphinothricin acetyltransferase gene is provided in European application No. 0 242 246. De Greef et al. (1989) describes the production of transgenic plants that express chimeric bar genes coding for phosphinothricin acetyl transferase activity. Exemplary of genes conferring resistance to phenoxy propionic acids and cyclohexones, such as sethoxydim and haloxyfop, are the Accl-S1, Accl-S2 and Accl-S3 genes described by Marshall et al. (1992).

A herbicide that inhibits photosynthesis, such as a triazine (psbA and gs+ genes) and a benzoinitrile (nitrate gene). Prizibilla et al. (1991) describes the use of plasmids encoding mutant psbA genes to transform *Chlamydomonas*. Nucleotide sequences for nitrate genes are disclosed in U.S. Pat. No. 4,810,648, and DNA molecules containing these genes are available under ATCC accession numbers 53435, 67441 and 67442. Cloning and expression of DNA coding for a glutathione S-transferase is described by Hayes et al. (1992).

3. Genes That Confer or Contribute to a Value-Added Trait

Modified fatty acid metabolism, for example, by transforming maize or *Brassica* with an antisense gene or stearoyl-ACP desaturase to increase stearic acid content of the plant (Knutzon et al., 1992).

Decreased phytate content

(1) Introduction of a phytase-encoding gene would enhance breakdown of phytate, adding more free phosphate to the transformed plant, such as the *Aspergillus niger* phytase gene (Hartingsveldt et al., 1993).

(2) A gene could be introduced that reduces phytate content. In maize, this, for example, could be accomplished by cloning and then reintroducing DNA associated with the single allele which is responsible for maize mutants characterized by low levels of phytic acid (Raboy et al., 1990).

Modified carbohydrate composition affected, for example, by transforming plants with a gene coding for an
enzyme that alters the branching pattern of starch. Examples of such enzymes include, Streptococcus mucus fructosyltransferase gene (Shiroza et al., 1988), Bacillus subtilis levansucrase gene (Steinmetz et al., 1985), Bacillus licheniformis α-amylase (Pen et al., 1992), tomato invertase genes (Elliot et al., 1993), barley amylase gene (Sogaard et al., 1993), and maize endosperm starch branching enzyme II (Fisher et al., 1993).

The nucleotide sequence of interest can also be a nucleotide sequence used to target an area of the plant genome through homologous recombination. The promoter may be placed in a construct with such sequence, which sequence will not necessarily encode a protein. The sequence recombines in the genome and the promoter may be placed at the desired site targeted by the sequences to regulate the desired endogenous nucleotide sequence.

Further, the promoter can be used to drive mRNA that can be used for a silencing system, such as antisense, and in that instance, no protein is produced. Nellen et al. (1993); Alexander et al. (1988). Means of increasing or inhibiting a protein are well known to one skilled in the art and, by way of example, may include, transgenic expression, antisense suppression, use of hairpin formations, co-suppression methods including but not limited to: RNA interference, gene activation or suppression using transcription factors and/or repressors, mutagenesis including transposon tagging, directed and site-specific mutagenesis, chromosome engineering and, homologous recombination. In the case of use with homol-

A terminator region may also be included in the vector. Convenient termination regions are available from the Ti-plasmid of A. tumefaciens, such as the octopine synthase (MacDonald et al., 1991) and nopaline synthase termination regions. Examples of various other terminators include the pin I terminator from the protease inhibitor II gene from potato (An et al., 1989). See also, Guerineau et al. (1991); Proudfoot (1991); Sanfacon et al. (1991); Mogen et al. (1990); Manroe et al. (1990); Ballas et al. (1989); and Joshi et al. (1987).

In one embodiment, the expression vector also contains a nucleotide sequence encoding a selectable or score-
able marker that is operably or functionally linked to a pro-

Where appropriate, the nucleotide sequence(s) may be optimized for increased expression in the transformed plant. That is, the genes can be synthesized using plant-preferred codons for improved expression. See, for example, Campbell and Gowri (1990) for a discussion of host-preferred codon usage. Methods are available in the art for synthesizing plant-preferred genes. See, for example, U.S. Pat. Nos. 5,380, 831, 5,436,391, and Murray et al. (1989). Additional sequence modifications are known to enhance gene expression in a plant. These include elimination of sequences encoding spurious polyadenylation signals, exon-intron splice site signals, transposon-like repeats, and other such well-characterized sequences that may be deleterious to gene expression. The G-C content of the sequence may be adjusted to levels average for a given cellular host, as calculated by reference to known genes expressed in the host cell. When possible, the sequence is modified to avoid predicted hairpin secondary mRNA structures.

In preparing the nucleotide construct, the various nucleotide sequence fragments can be manipulated, so as to provide for the nucleotide sequences in the proper orientation and, as appropriate, in the proper reading frame. Toward this end, adapters or linkers can be employed to join the nucleotide sequence fragments or other manipulations may be involved to provide for convenient restriction sites, removal of superfluous nucleotide sequences, removal of restriction sites, or the like. For this purpose, in vitro mutagenesis, primer repair, restriction, annealing, resubstitutions, e.g., transitions and transversions, may be involved.
Methods for introducing expression vectors into plant tissue available to one skilled in the art are varied and will depend on the plant selected. Procedures for transforming a wide variety of plant species are well known and described throughout the literature. See, for example, Miki and McHugh (2004); Klein et al. (1992); and Weising et al. (1988). For example, the DNA construct may be introduced into the genomic DNA of the plant cell using techniques such as microprojectile-mediated delivery (Klein et al. 1992), electroporation (Fromm et al., 1985), polyethylene glycol (PEG) precipitation (Mathur and Koncz, 1998), direct gene transfer (WO 85/01856 and EP-A-275 069), and in vitro protoplast transformation (U.S. Pat. No. 4,684,611), and microinjection of plant cell protoplasts or embryogenic callus (Crossway, 1985). Agrobacterium transformation methods of Ishida et al. (1996) and also described in U.S. Pat. No. 5,591,616 are yet another option. Co-cultivation of plant tissue with Agrobacterium tumefaciens is a variation, where the DNA constructs are placed into a binary vector system (Ishida et al., 1996). The virulence functions of the Agrobacterium tumefaciens host will direct the insertion of the construct into the plant cell DNA when the cell is infected by the bacteria. See, for example, Fraley et al. (1983). Agrobacterium is primarily used in dicots, but monocots including maize can be transformed by Agrobacterium. See, for example, U.S. Pat. No. 5,550,318. In one of many variations on the method, Agrobacterium infection of corn can be used with heat shocking of immature embryos (Wilson et al. U.S. Pat. No. 6,420,630) or with antibiotic selection of Type II callus (Wilson et al., U.S. Pat. No. 6,919,494).

Rice transformation is described by Hiei et al. (1994) and Lee et al. (1991). Standard methods for transformation of canola are described by Moloney et al. (1989). Corn transformation is described by Fromm et al. (1990) and Gordon-Kamm et al. (1990). Wheat can be transformed by techniques similar to those used for transforming corn or rice. Sorghum transformation is described by Casaa et al. (1993) and barley transformation is described by Tan and Lemieux (1994). Soybean transformation is described in a number of publications, including U.S. Pat. No. 5,015,580.

In one preferred method, use of aerosol beam technology for introduction of nucleotide sequences into cells is employed. Aerosol beam technology employs the jet expansion of an inert gas as it passes from a region of higher gas pressure to a region of lower gas pressure through a small orifice. The expanding gas accelerates aerosol droplets containing the molecules to be introduced into a cell or tissue. Aerosol droplets produced are typically less than 0.1 micron in diameter at the point of impact with the target cells. DNA carried in aerosol droplets of this small size penetrates cells only because of the speeds attained by the aerosol droplets. Speeds achieved by the aerosol beam method of the invention are supersonic and can reach 2000 meters/second. In a preferred embodiment, the process includes (I) culturing a source of cells, (II) optionally, pretreating cells to yield tissue with increased capacity for uptake and integration by aerosol beam technology, (III) transforming said tissue with an exogenous nucleotide sequence by the aerosol beam method of the invention, (IV) optionally, identifying or selecting for transformed tissue, (V) optionally regenerating transgenic plants from the transformed cells or tissue, and (VI) optionally, producing progeny of said transgenic plants. This process is described in detail at Held et al., U.S. Pat. Nos. 6,809,232, 7,067,716; and 7,026,286 (these references, as all cited references, are incorporated herein by reference).

In accordance with the present invention, a transgenic plant can be produced that contains an introduced Mu3 promoter. It can be combined with any one of the components set forth above.

In a further embodiment, plant breeding can be used to introduce the nucleotide sequences into other plants once transformation has occurred. This can be accomplished by any means known in the art for breeding plants such as, for example, cross pollination of the transgenic plants that are described above with other plants, and selection for plants from subsequent generations which contain the nucleic acid and/or express the amino acid sequence or trait. The plant breeding methods used herein are well known to one skilled in the art. For a discussion of plant breeding techniques, see Poehlman and Sleper (1995). Many crop plants useful in this method are bred through techniques that take advantage of the plant's method of pollination. A plant is self-pollinating if pollen from one flower is transferred to the same or another flower of the same plant. A plant is cross-pollinating if the pollen comes from a flower on a different plant. For example, in Brassica, the plant is normally self-sterile and can only be cross-pollinated unless, through discovery of a mutant or through genetic intervention, self-compatibility is obtained. In self-pollinating species, such as rice, oats, wheat, barley, peas, beans, soybeans, tobacco and cotton, the male and female plants are anatomically juxtaposed. During natural pollination, the male reproductive organs of a given flower pollinate the female reproductive organs of the same flower. Maize plants (Zea mays L.) can be bred by both self-pollination and cross-pollination techniques. Maize has male flowers, located on the tassel, and female flowers, located on the ear, on the same plant. It can self or cross-pollinate.

Pollination can be by any means, including but not limited to hand, wind or insect pollination, or mechanical contact between the male fertile and male sterile plant. For production of hybrid seeds on a commercial scale in most plant species pollination by wind or by insects is preferred. Stricter control of the pollination process can be achieved by using a variety of methods to make one plant pool male sterile, and the other the male fertile pollen donor. This can be accomplished by hand detasseling, cytoplasmic male sterility, or control of male sterility through a variety of methods well known to the skilled breeder. Examples of more sophisticated male sterility systems include those described by Brar et al., U.S. Pat. Nos. 4,654,465 and 4,727,219 and Albertsen et al., U.S. Pat. Nos. 5,859,341 and 6,013,859.

Backcrossing methods may be used to introduce the gene into the plants. This technique has been used for decades to introduce traits into a plant. An example of a description of this and other plant breeding methodologies that are well known can be found in references such as Poehlman et al. (1995). In a typical backcross protocol, the original variety of interest (recurrent parent) is crossed to a second variety (non-recurrent parent) that carries the single gene of interest to be transferred. The resulting progeny from this cross are then crossed again to the recurrent parent and the process is repeated until a plant is obtained wherein essentially all of the desired morphological and physiological characteristics of the recurrent parent are recovered in the converted plant, in addition to the single transferred gene from the nonrecurrent parent.

**EXAMPLES**

The present invention is described by reference to the following Examples, which are offered by way of illus-
iration and are not intended to limit the invention in any manner. Standard techniques well known in the art or the techniques specifically described below were utilized. In these Examples, corn is used for illustrative purposes only. Other plant species are also transformed with the DNA constructs of the present invention using techniques well known in the art.

Example 1

Construction of Plasmids used in Corn Transient Assays

A promoter sequence, designated Arabidopsis homolog to the CaMV 35S, was designed with around 80% homology to the CaMV 35S promoter (Fig. 1) and segments with homology to sequences from Arabidopsis as shown in FIG. 2. A: MuA U.S. Pat. No. 6,222,096 (SEQ ID NO: 2); B: AB000835 (SEQ ID NO: 3); C: Y08502 (SEQ ID NO: 4); D: U09376 (SEQ ID NO: 5); E: AB005247 (SEQ ID NO: 6); F: AF028711 (SEQ ID NO: 7); G: ACO02521 (SEQ ID NO: 8); H: D12522 (SEQ ID NO: 9); I: E1012243 (SEQ ID NO: 10); J: AL022347 (SEQ ID NO: 11). The sequence was not randomly derived but based on homologies found in the database at the time of design. Three hundred fifty one bases of the CaMV 35S promoter were compared to plant DNA sequences, mainly from Arabidopsis, in the database GenBank using the FASTA program. Regions of homologies were then manually aligned using the CaMV 35S promoter as the template. A few bases within segments and in regions linking segments were changed to match the CaMV 35S sequence so that the homology would remain around 80%. The composition of the MuB promoter with the CaMV 35S promoter is shown in FIG. 3. Homology to the MuA promoter of U.S. Pat. No. 6,222,096 was about 70%. The composition of the MuB promoter with the MuA promoter is shown in FIG. 4. The sequence was synthesized by the Molecular Biology Group at The Midland Certified Reagent Company, Midland, Tex. with EcoRI and SacI compatible overhangs on the 5' and 3' ends, respectively.

Plasmid 350096 was constructed by removing a root preferential promoter with an EcoRI and SacI double digestion from the plasmid p2MO096 of U.S. Pat. No. 5,633,363 and replacing it with a CaMV 3SS promoter from pSLJ4k1 which had compatible EcoRI/SacI cohesive ends. Plasmid pSLJ4k1 was obtained from the Sainsbury Laboratory at the John Innes Center, England. Plasmid 350096 consisted of a 1.3 kb CAMV 35S promoter, 0.5 kb intervening sequence six (IV6) from corn alcohol dehydrogenase, 1.8 kb GUS reporter gene, 0.25 kb nopaline synthase 3' end (nos) in a pUC18 backbone.

The CaMV 35S promoter in p350096 was replaced with the synthesized Arabidopsis homolog. The plasmid p350096 was digested with EcoRI and SacI, then dephosphorylated to prevent self-ligation. The homolog was directionally ligated into the EcoRI and SacI sites to produce pY0096.

Example 2

Transient Assays in Corn Callus

Tissue preparation: Type II callus of Stine elite inbred 963 was used as target tissue for transient assays. The Type II callus, initiated from immature embryos on N6AMOD medium (Table 1), was maintained as a stock culture on DN62 medium (Table 1). Tissue was transferred every ten days. For transient assays tissue was taken from these cultures (usually 4 to 5 days after subculture) and spread on a Whatman No 4 filter disk on DN620SM medium (Table 1) up to one day prior to bombardment with the particle inflow gun.

DNA Delivery: A particle inflow gun (PIG) as described by Finer et al. (1992) and Vain et al. (1993) was used to deliver the DNA. In brief, 50 mg of tungsten particles (M10 from Sylvania Chemicals/Metals, Towanda, Pa) were sterilized for 15 minutes in 95% ethanol in a 1.5 ml microfuge tube. Particles were rinsed 3 times in sterile distilled water by repeated vortexing, centrifugation and resuspension in 0.5 ml water. Particle suspensions were made for each experiment. Plasmid DNA was coated onto the particles by mixing 25 ul of tungsten particle suspension (2.5 mg), 5 ul of DNA (5 μg), 25 ul of 2.5 M CaCl2sub.2, and 10 ul of 100 mM spermidine (free base). After allowing the particles to settle for a few minutes while on ice, 50 ul of supernatant was removed. Two ul of the remaining particle suspension was pipetted onto the center of the screen of a syringe filter unit. The syringe filter unit was reassembled and screwed into the Luer-lok needle adaptor within the chamber. The target tissue in a petri plate was placed about 15 cm below the syringe filter unit. A vacuum of approximately 28 in Hg was applied and the particles were discharged when helium (80 psi) was released following activation of the solenoid by the timer relay.

1N6 salts - Sigma Plant Culture Catalogue ref. C 1416.
2N6 vitamins: 2 mg/l glycine, 0.5 mg/l nicotinic acid, 0.5 mg/l pyridoxine HCl, 1 mg/l thiamine HCl (Chu, 1978).

After bombardment, callus was incubated at 25°C. in the dark for 16-24 hours on the same medium used for bombardment. Then, transient GUS expression was evaluated by incubating the tissue in 0.5 mg/ml X-gluc (Gold Biotechnology, Inc. St. Louis, Mo.) in 0.1M sodium phosphate buffer PH 7.0 and 0.1% Triton-X-100 at 57degree. C. for 4-16 h after which the number and intensity of blue foci were evaluated under a stereo microscope at approximately 10x magnification. Tissue was transformed with either p350096, or pMuB0096. Tissue transformed with p350096 or pMuB0096 had similar levels of transient expression. Tissue transformed with pY0096 was found to have lower levels of transient expression.

Example 3

Construction of Plasmids Used in the Transformation of Corn

The bar gene in pBARGUS (Fromm et al., 1990) was used to replace the GUS gene in pMuB0096 using the
BamHI and PstI sites. Briefly, pBARGUS was digested with BamHI and PstI and the 800 bp fragment containing the bar gene was isolated. The plasmid pMutB0096 was digested with BamHI and PstI and the ends were dephosphorylated. The 800 bp fragment containing the bar gene was ligated to the digested, dephosphorylated pMutB0096 to produce the plasmid pMutBBar.

[0090] The MutBBar expression cassette was removed from pMutBBar by digestion with EcoRI and HindIII and cloned into pSB11 (obtained from Japan Tobacco) after digestion with EcoRI and HindIII and dephosphorylation, resulting in the plasmid pSB11MutBar. Plasmid pSB11MutBar was combined with pSH1 (obtained from Japan Tobacco) via homologous recombination and mobilized into Agrobacterium LBA 4404 via triparental mating according to U.S. Pat. No. 5,591,616 resulting in pSBMutBar. This plasmid in LBA 4404 was used in the transformation of corn.

Example 4
Transformation of Corn

[0091] Agrobacterium-mediated DNA delivery was used to produce stable corn transformants carrying Mut driving the bar gene. Agrobacterium LBA 4404 harboring pSB11MutBar recombined with pSH1 (Example 3) was taken from glycerol stocks and streaked out on YP medium (5 g/l yeast extract, 10 g/l peptone, 5 g/l NaCl, 15 g/l agar and pH 6.8) supplemented with 50 mg/l spectinomycin and grown for one or two days at 28 degree C.

[0092] Immature embryos of Stine elite inbred 963 were aseptically removed from kernels of plants grown in a grow room (15 h photoperiod; 28° day and 25° night). Embryos were harvested 10 to 11 days after pollination when they were between 1 mm and 2 mm in length and then placed in 2 ml of Lsinf medium (Table 2) in an Eppendorf tube. The mixture was then stirred with a vortex mixer (Vortex Genie 2) at full speed for 5 seconds, the Lsinf removed, replaced with fresh medium and then stirred again. All medium was then removed from the tube using a Pasteur pipette. Bacteria were collected with a platinum loop (enough to coat the wire of the loop) and thoroughly suspended in 1 ml of Lsinf-AS medium (Table 2) using a Pasteur pipette. The bacterial suspension was then introduced into the tube containing the embryos and the mixture stirred with a vortex mixer at full speed for 30 seconds. After this the embryos were allowed to stand for five minutes and were then transferred to the surface of LsAS medium (Table 2) solidified with agar, care being taken to remove any accompanying liquid. Embryos were immediately oriented so that the scutellar surface was uppermost.

Example 5

Transformation of Soybean

[0095] The plasmid pMuBGUS35N was transformed into soybean using aerosol beam technology as described in U.S. Pat. No. 6,809,232. The plasmid pMuBGUS35N contained two expression cassettes: 1) MuB promoter linked to the GUS gene with a NOS terminator and 2) 3SS promoter linked to an NPTII gene with an OCS terminator. The NPTII expression cassette facilitated the selection of transformed callus on media supplemented with 300 mg/l kanamycin.

[0096] Embryogenic soybean callus was transferred after a culture passage of about 28 to 30 days from stock culture medium (B1-30 3C05M5y 50 mg/l phytic acid—Table 5) to the center of a target plate containing the same medium. Embryogenic soybean callus can survive being held in a vacuum for at least 10 minutes. After one to three days' growth on the target plate, the soybean embryogenic callus is exposed to an aerosol beam of pMuBGUS35N (the MuB promoter driving the GUS gene). After beaming the tissue is spread out on a fresh plate (to minimize the risk of contamination) of the same medium.

*Variations of media referred to in Table 5 were tested, e.g., B1-30 3C05M5y, which was made by adding 3% coconut water and 5 g/ml myo-inositol to B1-30. Other variations included: B1-30 3C05M5y0.25 PAO SK which contained B1-30 basal medium plus 3% coconut water, 5 g/ml myo-inositol, 0.25 g/ml phytic acid, and 0.5 g/ml additional K$_2$HPO$_4$ and ½ B5G which contained all ingredients of B5G medium at half strength.

[0097] Briefly, the treatment of target tissue with the aerosol beam apparatus was performed as follows: 1) place petri dish with tissue on the stage and close vacuum chamber; 2) start the vacuum pump; 3) start the syringe pump; 4) set the nebulizing gas pressure; 5) set the entrainment gas pressure, and by this time the correct vacuum in the chamber is reached; and 6) start the movement of the stage and let the system run for the time needed to complete the run. After the run is completed, shut down the stage, vacuum, syringe pump, nebulizing gas, entrainment gas, and remove target tissue from the chamber.

[0098] The aerosol was produced by a microflow nebulizer such as the HEN from J.E. Meinhart Associates Inc., or the MCN100 style M4 nebulizer from Cetec Technologies Inc. (Liu and Montus, 1994; Tan, et al., 1992). The nebulizing gas was high purity compressed-helium which was regulated with an ACCU-1ROL gas regulator—876x model RS-7-4 and filtered through an Arrow F300-02 IT filter. When HEN and the MCN100 microflow nebulizers were used, the nebulizing pressure was preferably 20-30 psi but worked within the range from about 10 psi to about 40 psi. The entrainment gas filled the entrainment tube and entrained the aerosol droplets in a straight line. Unfiltered, high purity compressed helium was used as the entrainment gas and was regulated by an Arrow R262 regulator to produce slight positive pressure as measured by a Gilnoel model 65 mm gauge. The entrainment housing contained a nucleospot to reduce electrostatic charges and was maintained at a temperature of about 42º C. to about 55º C., and most preferably about 55º C. This reduced coalescing of the aerosol droplets and was controlled by two Omega CN9000 series temperature controllers. The sample flow rate to the nebulizer was controlled by a Harvard 11 infusion only syringe pump. The flow rate was 1 to 1200 µl/min using a sterile Becton Dickinson 1 cc plastic syringe with a 0.2 micron filter attached. The sample contained 10 mM Tris buffer (pH 7.0) or a carbohydrate molecule (for example 1 µl sucrose) and the molecules to be delivered.

[0099] Approximately one day after treating the soybean callus with the aerosol beam apparatus, transient expression was evaluated by histochemical analysis. Embryogenic callus was incubated in the presence of the substrate X-gluc (Gold Biotechnology, Inc.) at a concentration of 0.5 mg/ml in 0.1 M sodium phosphate buffer pH 7.0 and 0.1% Triton-x-100 at 37º C. After 1-4 hours blue spots appeared indicating GUS expression.

[0100] Plants were regenerated as described in U.S. Pat. No. 6,809,232 and assayed for GUS activity, as described supra. Strong GUS activity was observed in leaves, roots and stem.

[0101] Thus MuB is a functional promoter with the characteristics of a constitutive promoter and useful in the genetic engineering of plants.

[0102] It will be appreciated that the methods and compositions of the instant invention can be incorporated in the form of a variety of embodiments, only a few of which are disclosed herein. It will be apparent to the artisan that other embodiments exist and do not depart from the spirit of the invention. Thus, the described embodiments are illustrative and should not be construed as restrictive.

What is claimed is:

1. A isolated regulatory element comprising a nucleic acid molecule selected from the group consisting of:
   (a) the nucleotide sequence of SEQ ID NO: 1;
   (b) a sequence having more than 80% identity to SEQ ID NO: 1;
   (c) a sequence which hybridizes to SEQ ID NO: 1 under highly stringent conditions of a wash of 50% formamide, 1.0 M NaCl, 0.1% SDS at 37°C, and a wash in 0.1 x SSC at 60°C, wherein the sequence exhibits regulatory element activity; and
   (d) a sequence comprising a functional fragment of the nucleotide sequence set forth in SEQ ID NO: 1, wherein the fragment exhibits regulatory element activity.

2. An expression vector comprising a regulatory element selected from the group consisting of:
   (a) the nucleotide sequence of SEQ ID NO: 1;
   (b) a sequence having more than 80% identity to SEQ ID NO: 1;
   (c) a nucleotide sequence which hybridizes to SEQ ID NO: 1 under highly stringent conditions of a wash of 50% formamide, 1.0 M NaCl, 0.1% SDS at 37°C, and a wash in 0.1 x SSC at 60°C, wherein the sequence exhibits regulatory element activity; and
   (d) a sequence comprising a functional fragment of the nucleotide sequence set forth in SEQ ID NO: 1, wherein the fragment exhibits regulatory element activity.

3. The expression vector of claim 2 further comprising a second nucleotide sequence operably linked to the regulatory element, the second nucleotide sequence capable of conferring a selected agronomic trait to a plant.

4. The vector of claim 2 wherein the agronomic trait is selected from the group consisting of herbicide resistance, insect resistance, disease resistance, drought tolerance, salt tolerance and increased yield.

5. A plant comprising the expression vector of claim 2.

6. A plant cell comprising the expression vector of claim 2.

7. A method of producing a transformed plant cell, the method comprising transforming a plant cell with the nucleotide sequence of claim 1.
