(54) Title: POWERED DISPENSING DEVICES FOR THE DELIVERY OF EVAPORABLE MATERIALS

(57) Abstract: A powered dispensing device for the provision of an evaporable liquid to an atmosphere comprises a reservoir containing evaporable material, a wick extending from said reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, and a blower or fan, which, when operating, induces a flow of air containing evaporable material from the headspace into the atmosphere. The device is particularly suited for the dispensing of evaporable materials, such as fragrances, odour masking agents, insecticides and medicaments into the atmosphere.

## POWERED DISPENSING DEVICES FOR THE DELIVERY OF EVAPORABLE MATERIALS

The present invention relates to dispensing devices, especially powered dispensing devices,  
5 useful for the delivery of a volatile or evaporable material to an ambient environment.

Various devices useful for the delivery into an ambient environment, such as a room or interior of a vehicle, of evaporable materials, such as fragrances, odour masking agents, insecticides and medicaments, are known to the art. Typically, such a device includes a  
10 reservoir containing an evaporable material, which reservoir has a neck through which protrudes a wick. The wick transports the liquid by means of capillary action from the reservoir to the ambient environment, into which the liquid evaporates or volatilizes. Such devices are simple, cheap and generally effective. In certain embodiments, they are supplied as part of a larger apparatus, which may provide an external feature for static diffusion  
15 systems or it may include a means of diffusing the volatile liquid. Examples of the latter include a heat source, which may surround at least part of the wick, and which, when heated, induces more rapid volatilization of the liquid, or a fan that causes more rapid volatilization of the liquid into the ambient environment.

20 While such devices have proved useful, they are not free from shortcomings. For example, when a delivery device relies upon a heating element to facilitate the evaporation of a volatile material, the material released is typically driven only by convection currents of the rising hot air released from the device, and the dissemination of the volatile material is dependent on their speed of movement alone. Where such devices are powered by mains electricity, the  
25 location of the devices is generally limited to the power outlets available, and the release of the evaporable material thus tends to be largely limited to the vicinity of these outlets. In addition, the operating temperatures of such devices are often high, sometimes between about 65°C and about 140°C, and this can not only degrade chemical materials (evaporable materials, materials of construction of the devices) but may also pose a potential hazard to  
30 small children and pets coming into contact with the delivery device.

Battery-powered devices are known to the art, but these are often complicated to manufacture, requiring the assembly of a relatively large number of elements. Such devices usually deliver

their fragrance material from a reservoir, said reservoir often taking the form of a porous or absorbent patch, sponge, or gauze, which is placed at the exhaust face of a fan. In operation, such devices typically draw air through the fan, and the exiting air is forced through the reservoir, thereby forcing the release of the vaporizable material to the ambient environment.

5 While such prior art devices may be in some ways effective, the positioning of the reservoir often acts to impede flow of the air being exhausted from the fan. At the same time, the use of an absorbent patch, sponge, or gauze tends to allow the undesirable release of a larger quantity of the vaporizable material earlier in its service life.

10 Accordingly, there is a need in the art for improved devices useful for the delivery of evaporable materials.

The present invention provides a powered dispensing device adapted to dispense an evaporable material into an atmosphere, comprising a reservoir containing evaporable  
15 material, a wick extending from said reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, and a blower or fan, which, when operating, induces a flow of air to pass through the headspace, and convey evaporable material into the atmosphere.

20 In one aspect, the present invention provides a powered dispensing device comprising a reservoir containing evaporable material, a wick extending from said reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, a blower, which when operating, induces a flow of air containing evaporable material from the headspace, through said blower, and out through a manifold, characterized in that the blower  
25 receives said flow air containing evaporable material in a direction that is generally perpendicular to the air-containing evaporable material exhausted from the blower.

In a second aspect of the present invention, there is provided a powered dispensing device comprising a reservoir containing an evaporable material, a wick extending from said  
30 reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, and a blower, which, when operating, induces the flow of air containing evaporable material from the headspace, through said blower and out through a manifold characterized in that the rotational axis of the blower is perpendicular to the axis of the wick,

the blower receives said air containing evaporable material in a first direction which is generally perpendicular to the air containing evaporable material, which is exhausted from the blower in a second direction and into a manifold.

- 5 In a third aspect of the present invention, there is provided a powered dispensing device comprising a reservoir containing an evaporable material, a wick extending from said reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, and a fan, which, when operating, induces a flow of air from the ambient environment in a direction parallel to that of the air drawn into the fan, through the headspace,  
10 and out through a manifold to the atmosphere.

The invention further provides a method of providing an evaporable material to an atmosphere by providing a headspace that is provided with evaporable material from a wick that communicates with a reservoir of evaporable material and causing a flow of air to pass  
15 through this headspace such that it is conveyed into the atmosphere.

Provided that the device is arranged so that the embodiments hereinabove described are possible, the size, shape and construction materials of the device are not narrowly critical and a wide variety of possibilities exist. Plastics materials are preferable, as they are cheap, easily  
20 formed into complex shapes, and can be attractively coloured. Naturally they must be chosen such that they can withstand any exposure to any solvent in the evaporable liquid. Any other suitable material, such as metals and ceramics, may also be used.

The wick that is used in the dispensing devices according to the present invention to transport  
25 the evaporable material from the reservoir to the headspace by means of capillary action may be formed of any suitable material. Such materials include those based on natural or synthetic fibers, woven or non-woven fabrics, cords, rods or other articles, porous media such as those based on celluloses such as cardboard-based and paper-based wicks, graphite and carbonaceous wicks, as well as porous synthetic polymers and porous ceramic materials.  
30 Examples of commercially-available materials useful for the manufacture of suitable wicks include porous synthetic polymers from Porex Corp., (Fairburn, GA, USA) and Micropore Plastics Inc. (Stone Mountain, GA) as well as porous ceramics available from Rauschert GmbH & Co.-KG (Germany).

In the preferred embodiments of the powered dispensing device according to the invention, a blower is used, rather than a conventional fan. Blowers can be distinguished from fans by the fact that they deliver air in a direction that is perpendicular to the blower axis, usually at a relatively low air-flow rate, but such blowers are capable of operating against a higher  
5 pressure. Fans deliver air in an overall direction which is parallel to the fan blade axis typically at a relatively high air flow rate, but are usually capable of operating only against lower pressures. In each case, the blower axis, or the fan blade axis, is defined as the rotational axis of the motor or of the shaft supporting the respective blower or fan blades. A fan may be used in some embodiments of the invention, but those using a blower are  
10 preferred. Suitable blowers and fans of a sufficiently small size are now readily and cheaply available from the industries that supply such devices to the computer industry.

By "manifold" is meant a component, which, when attached to the device, defines a chamber having at least one opening leading to the atmosphere. It is preferable that the manifold have a  
15 plurality of openings, and the use of the term "opening" herein refers to both singular and plural. The nature and location of this opening is not narrowly critical and can be arranged to suit any suitable application. The opening can be a simple opening in an otherwise closed manifold, or it can be a tube extending from the manifold. The opening may also be variable in direction. For example, it may pivot about one or more axes, so that it can be pointed in any  
20 desired direction. The manifold may be equipped with means for partially or completely closing the opening, so that the emission of evaporable material can be regulated. The manifold is arranged on the device, so that the fan or blower blows air containing evaporable material into the manifold and hence into the atmosphere. The manifold may be merely a chamber with an opening, or it may comprise at least one internal baffle that directs the air  
25 containing evaporable material entering the manifold in a desired direction.

The evaporable material, which may be used in the dispensing devices taught herein, may be any volatile or evaporable material, but is preferably one or more liquids which have a cosmetic effect such as a fragancing or odour masking effect such as may be based on one or  
30 more essential oils, or volatile liquids which have an insecticidal effect or a medical effect.

By way of non-limiting example, useful essential oils include one or more of: anethole 20/21 natural, aniseed oil china star, aniseed oil globe brand, balsam (Peru), basil oil (India), black pepper oil, black pepper oleoresin 40/20, Bois de Rose (Brazil) FOB, borneol flakes (China),

camphor oil, canaga oil (Java), cardamom oil, cassia oil (China), cedarwood oil (China), cinnamon bark oil, cinnamon leaf oil, citronella oil, clove bud oil, clove leaf, coriander (Russia), coumarin (China), cyclamen aldehyde, diphenyl oxide, ethyl vanillin, eucalyptol, eucalyptus oil, eucalyptus citriodora, fennel oil, geranium oil, ginger oil, ginger oleoresin  
5 (India), white grapefruit oil, guaiacwood oil, gurjun balsam, heliotropin, isobornyl acetate, isolongifolene, juniper berry oil, L-methyl acetate, lavender oil, lemon oil, lemongrass oil, lime oil, litsea cubeba oil, longifolene, menthol, methyl cedryl ketone, methyl chavicol, methyl salicylate, musk ambrette, musk ketone, musk xylol, nutmeg oil, orange oil, patchouli oil, peppermint oil, phenyl ethyl alcohol, pimento berry oil, pimento leaf oil, rosalin,  
10 sandalwood oil, sandenol, sage oil, clary sage, sassafras oil, spearmint oil, spike lavender, tagetes, tea tree oil, vanilin, vetyver oil (Java), wintergreen.

These and other suitable materials which may be useful in the volatile liquid may be commercially obtained from a variety of suppliers including: Givaudan Corp. (Teaneck, NJ);  
15 Berje Inc. (Bloomfield, NJ); BBA Aroma Chemical Div. of Union Camp Corp. (Wayne, NJ); Firmenich Inc. (Plainsboro NJ); Quest International Fragrances Inc. (Mt. Olive Township, NJ); Robertet Fragrances Inc. (Oakland, NJ), or from other suppliers not necessarily listed herein.

20 The volatile liquids may be provided in the form of neat compositions, or may be provides as aqueous mixtures, organic mixtures or aqueous-organic mixtures which include of one or more volatile or evaporable materials.

The invention is now further described with reference to the accompanying drawings, which  
25 depict preferred embodiments of the invention and which are not limiting in any way on the scope thereof.

Figure 1 depicts a longitudinal part-cross-sectional view of a preferred powered dispensing device according to the invention.

30

Figure 2 depicts an exploded view of the powered dispensing device according to Figure 1.

Figure 3 depicts a transverse cross-section along the line XX' of the embodiment of Figure 1.

Figure 4 depicts a longitudinal part-cross-section of another embodiment of the invention.

Figure 5A depicts a transverse cross-section along the line YY' of Figure 4.

5 Figure 5B depicts an alternative embodiment of Figure 5A.

Figure 6 depicts a longitudinal part-cross-sectional view of a third embodiment of the invention.

10 In the following description of the embodiment of Figure 1, reference should also be made to Figure 2, in which some of the features may be more clearly seen. A powered dispensing device, generally indicated as 100, comprises a reservoir 105 containing evaporable liquid 110. The reservoir has a neck 130, through which is inserted a wick 115, such that the lower end of the wick 135 is immersed in the liquid 110 and the upper end 120 protrudes from the  
15 neck. The wick is held in place in the neck by an insert 125 that fits tightly into the neck and is a close fit around the wick.

The reservoir and wick fit into a body portion generally indicated as 150. The body portion has the form of a flat plate 155 having an upper surface 160 and a lower surface 165, with  
20 reference to the reservoir in its normal operating position, from which lower surface 165 depend two concentric annular skirts, an outer skirt 170 and an inner skirt 180. The inner skirt is equipped with screw threads 186 on its inner surface, which screw threads are adapted to mate with corresponding screw threads 106 on the neck 130 of the reservoir, such that the reservoir can be screwed into the body portion and such that the upper end of the wick 120 is  
25 in an headspace defined by the plate 155 and the inner skirt 180. The plate 150 has an orifice 190, positioned above the upper end 120 of the wick.

The outer skirt 170 is dimensioned so that its diameter exceeds that of the reservoir 105, and so that it extends lower than the neck 130 and part-way down the body of the reservoir 105,  
30 concealing part of the reservoir but allowing for easy unscrewing when necessary.

Both skirts comprise a plurality of openings that allow air to reach the wick 120. These are 172 in outer skirt 170 and 182 in inner skirt 180.

On the upper surface 160 of the plate 150 is mounted a manifold assembly generally indicated as 200 (shown unsectioned in Figures 1, 4 and 6)). This comprises a cover 205 having a sidewall 210, the sidewall having a plurality of openings 215. Also mounted on this upper surface and within the manifold is a blower 300 (shown schematically in outline in Figures 1, 4 and 6). This is typically of the type used to cool laptop computers, having a series of vanes, which rotates in a horizontal plane with respect to the normal orientation of the device when in use. It is powered by mains electricity, which is supplied by means of a conventional plug 400 of the type that can be inserted into the wall socket. The electricity supply is additionally supplied with the necessary electrical circuitry that allows the device to function, for example a transformer or rectifier. Other possibilities include timers, optical switches, mechanical switches, light and sound sensors, proximity sensors, thermocouples, proximity sensors, sound sensors, thermocouples, "X-10" circuitry that responds to a control signal passed along electrical circuit of a building or a vehicle. These are all generally indicated as 500

15 In operation, evaporable material 110 is drawn via capillary action up the wick 115 to the upper end 120, after which it evaporates into the headspace of the body portion 150, and also possibly into the region between the inner skirt 180 and the outer skirt 170 of the body portion 150 and possibly even into the ambient environment. Once the blower 300 is energized, the blower receives air containing evaporable material in a first direction, here in a direction parallel to its rotational axis via the orifice 190, this air entering through openings 172 in outer skirt 170 and openings 182 in inner skirt 180. Thereafter, the air containing evaporable material is exhausted from the blower 300 in a second direction that is generally perpendicular to the first direction, in this case, in a plane approximately parallel to the plane of rotation of the blower 300. This is made possible by the presence of one or more peripheral openings present within the blower 300. Thereafter, the air containing evaporable material leaves the manifold assembly 200 via the openings 215. The flow of air through the powered dispensing device 100 is depicted by the small arrows labeled "a".

The exploded view of Figure 2 shows the various components of the embodiment of Figure 1.

30 The plurality of openings 172 in the outer skirt 170 may be seen. Similarly, the inner skirt 180 also includes a number of openings 182 which permit the passage of air from the interior of the body part 150, and into the proximity of the upper end 120 of the wick when the powered dispensing device 100 is assembled.

The blower 300 consists of a housing 302 surrounding a series of vanes 310 mounted on a hub 304 and driven by a motor. The housing 302 comprises at least one open sidewall portion 320 that permits the passage of air therethrough when the blower 300 operates (it is possible to have more than one open sidewall portion). When the manifold assembly 200 is placed on  
5 the plate 150 over the blower 300, the top surface 220 of the manifold assembly 200 covers the blower 300 so that air exiting the blower 300 passes out only through the open sidewall portion 320.

The embodiment shown in Figure 2 additionally comprises a sliding cover 500, essentially a  
10 flat, hollow cylinder open at one end and comprising a sidewall 510, an end portion 515, and in the sidewall a plurality of openings 505. The sliding cover 500 is dimensioned to fit tightly and rotatably over the manifold assembly 200. In use, the sliding cover 500 may be rotated so as to cover or uncover one or more of the openings 215 of the manifold assembly 200.

15 In the cross-section view Figure 3, the interior of the manifold may be seen, looking down on the blower from above. Depicted is the blower 300 having one open sidewall 320. The blower 300 comprises an intake port 312 generally visible as a circle within which is seen the hub 304 and vanes 310. Depending from the top surface 220 of the manifold assembly 200 are baffles 250 and 255. Baffle 250 has the form of two arcuate sections joined at one end to  
20 form in plan a broad arrowhead, the point of the arrow 252 being directed towards and located centrally to the open sidewall 320 of the blower. As can be seen by the arrows labeled "a" which are intended to indicate the direction of airflow within the manifold assembly 200, air exiting the blower 300 via the open sidewall 320 impacts upon the baffle 250 and is directed to opposite sides of the manifold assembly 200, and along opposite sides of the blower 300.  
25 This directed air, which contains evaporable material, may then exit the manifold assembly 200 through one or more of the openings 215. The second baffle 255 is positioned within the manifold assembly 200 in a position diametrically opposite to that of the first baffle 250. This baffle 255 has, in plan, a generally triangular cross section, and it is intended to direct the air containing evaporable material within the interior of the manifold assembly 200 to one or  
30 more openings 215, and thus into the ambient environment. It is naturally possible to vary the number and shape of baffles; such modifications are well within the skill of the art.

The embodiment of Figure 4 is essentially the same as that of Figure 1, but the blower 300 is mounted underneath the plate 150 and adjacent to it, but outside the outer skirt 170 and orientated such that the axis of rotation is perpendicular to that of the longitudinal axis of the wick. The reservoir is fitted to the inner skirt 180 by means of a snap-fit attachment means,  
5 formed of corresponding elements 107 and 186 in the neck 130 and skirt 180 respectively.

In this case, the central orifice 190 of Figure 1 is replaced by an orifice 195 in the plate 150 (see also Figures 5A, 5B for its shape and location), corresponding with an open sidewall portion in the blower housing, of the type depicted in Figure 2. In operation, the blower draws  
10 air containing evaporable material from the headspace surrounding the upper end of the wick 120, through orifices in the inner and outer skirts and blows it through orifice 195 into the manifold assembly 200. The air containing the evaporable material passes into the blower in a first direction generally parallel to the rotational axis of the blower 300, and exits the blower in a second direction generally perpendicular to the rotational axis of the blower 300.  
15 Thereafter, the air containing the evaporable material exits the manifold through one or more of the openings 215 and into the ambient environment, in the direction of the arrows a. The manifold assembly may be equipped with one or more baffles, to assist in distributing the air.

Figures 5A and 5B depict two possible alternative baffle arrangements within the manifold of  
20 an embodiment according to Figure 4. Figure 5A shows an interior with a series of baffles, 272, 274, 275, 277, 278. Baffle 272 is generally straight and is generally perpendicular to the orifice 195. The paired baffles 274, 275 are approximately one-half as long as baffle 272, and are angled with respect thereto but do not contact baffle 272. While the offset angle from baffle 272 may vary, here it is depicted to be approximately 30 degrees from the baffle 272.  
25 In a similar manner, paired baffles 277 and 278 are also shorter, again about one-half of the length of baffle 272 and are angled with respect thereto but do not contact baffle 272. Again, while the offset angles may vary, the offset angle between each of baffles 277 and 278 from baffle 272 is approximately 45 degrees. In operation, the baffles 272, 274, 275, 277, 278 deflect the flow of air containing the evaporable substance which enters the manifold  
30 assembly 2000 via the orifice 195 (shown in dotted outline), past the baffles and then through one or more of the openings 215.

In Figure 5B, there is a series of baffles, 280, 282, 284, and 286. Each of the baffles is arcuate, and they extend from the orifice 195 towards the sidewall 210. In operation, the baffles 280, 282, 284, and 286 deflect the flow of air containing the evaporable substance which enters into the manifold assembly 2000 via the orifice 195, past these baffles and  
5 thereafter through one or more of the openings 215 and into the ambient environment.

In Figure 6 is depicted an apparatus that is similar in configuration to that of Figure 1. The difference here is that the apparatus uses a fan 300 designed to blow air in a direction parallel to the axis of rotation, rather than a blower, this fan being installed in the space between the  
10 inner and outer skirts and is mounted with its rotational axis perpendicular to the longitudinal axis of the wick, in the manner of the blower of Figure 2. This fan draws in air through openings 172 in the outer skirt 170 and exhausts it in the same general direction as the incoming air, through orifices 182 in the inner skirt 180 to the upper end of the wick 120 and the headspace surrounding it. The air containing evaporable material from the headspace  
15 leaves the headspace through orifice 190 positioned above the upper end of the wick 120 and enters the manifold assembly 200, exiting therefrom into the atmosphere through the openings 215 in the manifold, along the directions indicated by the arrows a. The manifold may be equipped internally with baffles of the type shown in Figures 3, 5A and 5B.

20 The embodiments hereinabove described are given by way of example only and the skilled person will readily be able to envisage many variations that fall within the scope of this invention. Some examples:

- The device need not be powered by mains electricity, but by alternative, self-contained  
25 energy sources, for example, solar cells or batteries. The modifications to include such possibilities are straightforward.
- The fans in the embodiments shown are adapted to suck air containing evaporable material from a headspace around a wick and blow it into a manifold. The fan can be easily rearranged to suck in air from the atmosphere and blow it into the headspace  
30 and thence into the manifold.
- The manifold orifices may be replaced by a sealed manifold lacking internal baffles, but from which lead tubes, which emit air containing evaporable material. These tubes

may be of the same or different lengths and they may be made decorative, for example, by providing the ends thereof with artificial flower petals.

- Another possibility is to replace the manifold orifices with a single vent, whose direction of exhaust may be varied, for example, by making it able to be swiveled through 360°, or by making its angle adjustable in a plane perpendicular to the plate 150, or by making it universally adjustable, for example, an “eyeball” vent.

## Claims:

1. A powered dispensing device adapted to dispense an evaporable material into an atmosphere, comprising a reservoir containing evaporable material, a wick extending from  
5 said reservoir and providing said evaporable material to a headspace surrounding an exposed end of the wick, and a blower or fan, which, when operating, induces a flow of air to pass through the headspace, and convey evaporable material into the atmosphere.
2. A device according to claim 1, wherein the device comprises a blower, which is so  
10 arranged such that, in operation, it induces a flow of air containing evaporable material from the headspace to pass through the blower, and out into the atmosphere through a manifold having at least one vent exiting to the atmosphere, the blower receiving said flow air containing evaporable material in a direction that is generally perpendicular to the air containing evaporable material exhausted from the blower.  
15
3. A device according to claim 1, in which the rotational axis of the blower is perpendicular to the longitudinal axis of the wick, the blower being arranged such that it receives air containing evaporable material from the headspace in a first direction that is generally perpendicular to a second direction in which the air containing evaporable material  
20 is exhausted from the blower into a manifold having at least one vent exiting to the atmosphere and thence into the atmosphere.
4. A device according to claim 1, in which the device comprises a fan that induces a flow of air from the ambient environment in a direction parallel to that of the air drawn into the  
25 fan, through the headspace, and out into the atmosphere through a manifold having at least one vent exiting to the atmosphere.
5. A device according to any one of claims 2-4, in which the manifold comprises at least one baffle, adapted to assist in the dissemination of the air containing evaporable material into  
30 the atmosphere.
6. A method of providing an evaporable material to an atmosphere by providing a headspace that is provided with evaporable material from a wick that communicates with a

reservoir of evaporable material and causing a flow of air to pass through this headspace such that the air containing evaporable material is conveyed into the atmosphere.

7. A method according to claim 6, in which the flow of air is caused by a blower and the  
5 blower receives a flow of air containing evaporable material in a direction that is generally perpendicular to the air containing evaporable material exhausted from the blower.
