# CROSS-REFERENCE TO RELATED APPLICATIONS

[0001] This application is a Continuation of application Ser. No. 10/534,414, which is the US National Stage application of PCT/JP2003/014986, filed Nov. 25, 2003, which claims priority from Japanese patent application 2002-342399, filed Nov. 26, 2002. The entire contents of each of the aforementioned applications are incorporated herein by reference.

#### FIELD OF THE INVENTION

**[0002]** The present invention relates to novel isoindoline derivatives. The derivatives of the invention are useful for manufacturing pharmaceutical compositions, especially anesthetics.

#### **RELATED ART**

[0003] Many compounds having isoindoline structure have been reported to have effects on central nerves system. Most of those reports aimed for developing tranquilizers, antispasmodics or anxiolytics (Japanese Patent Application Laid Open Nos. 47-12322 and 58-189163). Heretofore, no isoindoline derivative having anesthetic property has been reported.

[0004] As for agents affecting on the CNS, especially intravenous anesthetics, rapid induction and recovery from anesthesia are desired. In order to prepare an injectable dosage form, the anesthetic compounds are also desired to be watersoluble. However, clinically used anesthetic compounds, for example propofol (2,6-diisopropylphenol), are slightly water-soluble and thus, the clinically used intravenous anesthetics are provided in the form of emulsion with soy-oil, glycerin and purified egg phospholipid. Due to the formulation, the clinical intravenous products have side effects such as venous pain during injection and lipid deposition as well as high susceptibility to microbial infection.

[0005] Heretofore, no CNS active agent that is enough soluble or miscible in water as well as induces no or little side effect has been reported.

# SUMMARY OF THE INVENTION

[0006] One object of the present invention is to provide a water-soluble or water-miscible novel compound useful for manufacturing an anesthetic, especially intravenous anesthetic.

[0063] The compound of the invention is useful for anesthesia by inducing sedation in mammal.

[0064] The three components of anesthesia are sedation (unconsciousness), analgesia (blocking receipt and transmittance of pain sensation) and muscular relaxation (blocking unwanted body move or harmful reflex response). Upon clinical anesthesia, compounds having respective activities are used in combination upon anesthesia based on the necessity. The isoindoline derivatives of the present invention have excellent sedative properties on mammalian such as human beings and therefore, effectively used as an anesthetic for mammal

[0065] The compound of the present invention has a wider safety margin than commercially available intravenous anesthetics such as propofol or thiopental sodium as well as rapid introduction and recovery from anesthesia.

[0072] The anesthetic composition of the invention may contain other pharmacologically active ingredients, as far as they are not contrary to the objects of the present invention. [0073] The anesthetic composition of the invention can be administrated intravenously to induce general anesthesia. The composition is effective for induction and maintenance anesthesia state upon surgical operation as well as postoperative sedation control, and for sedation control in a ventilated patient undergoing intensive treatment. The anesthetic composition of the invention may be used in any stage of anesthesia in combination of a suitable analgesic and/or muscular relaxant if desired.

[0074] The anesthetic effective amount of the compound (I) or a salt thereof is not limited and may vary depending on the age, sex, body weight and physical condition of the subject to be treated, desired depth or retention time of anesthesia and the like. For induction of anesthesia, typically about 0.1-10 mg/kg, preferably 1.0-5.0 mg/kg bolus of the compound of the present invention is administrated intravenously. 5,6-dimethyl-3-hexyl-2-(3-pyridyl)isoindolin-1-one (10-a) 5,6-dimethyl-3-hexyl-3-hydroxy-2-(3-pyridyl)-isoindolin-1-one

[0130] Metal magnesium (0.14 g, 5.6 mmol) and 1-bromohexane (0.78 ml, 5.6 mmol) were stirred with heating at 65° C. in anhydrous tetrahydrofuran (24 ml) under an argon atmosphere for 2 hrs, and 5,6-dimethyl-2-(3-pyridyl)isoindolin-1, 3-dione (0.40 g, 1.6 mmol) was added thereto, followed by stirring at 25° C. for 15 minutes. The reaction solution was poured into saturated aqueous NH<sub>4</sub>Cl solution, and extracted with ethyl acetate. The organic layer was concentrated under reduced pressure, and the residue was purified by silica gel chromatography (chloroform:acetone=5:1) to give 0.23 g of 5,6-dimethyl-3-hexyl-3-hydroxy-2-(3-pyridyl)isoindolin-1-one.

**[0190]** As shown in table 10, the 50% lethal dose ( $\mathrm{LD_{50}}$ ) of the test compound is much higher than the  $\mathrm{HD_{50}}$ , which is an indicator of the anesthetic action, and the highest  $\mathrm{LD_{50}}$  among the test compounds was more than 120 mg/kg (i.v.). This means that the anesthetic composition of the invention has a very wide safety margin. Propofol and thiopental sodium, most popular anesthetics, have significantly narrower safety margins.

**[0191]** Anesthesia induction time, the time from the complete injection of the compound  $(2 \times HD_{50})$  to loss of righting reflex, and after wake-up recovery time, the time from righting reflex was back to normal to the animal started to move spontaneously were determined. The results are shown in Table 11.
