ABSTRACT
Water-dispersible or water-soluble polymers, particularly those of the family of compounds comprising the poloxamers or the polyesters or amphiphilic agents (emulsifiers), and also lipophilic materials are dispersed by melting the components at suitable temperatures with admixture of pharmaceutically active substances by mechanical procedures, i.e. a lipophilic dispers phase is distributed in a hydrophilic continuous polymer phase to form a stable dispersion. By controlled cooling, curing, and storage followed by high-pressure molding at defined temperatures and operating pressures there are produced, in addition to other types of shaped bodies, dispersed polymeric fatty sticks distinguished by particularly good fracture strength, flexibility, and variable time-specific dimensional stability.
SHAPED BODY AND METHOD FOR PRODUCTION OF SAID BODY

[0001] The invention relates to a shaped body for medicinal use in body cavities and/or wound cavities in humans or animals according to the generic clauses of claims 1, 4, 7, 9, and 10 and also to a method of producing said shaped bodies according to the generic clauses of claims 23 and 28 and to a method of using the same as defined in claims 29 and claim 30.

[0002] Pharmaceutical or medical sticks (shaped bodies) are an old pharmaceutical dosage form, usually obtained by casting and curing suitable pharmaceutical auxiliary materials in appropriate casting molds. A frequently used special form of medical sticks comprises suppositories for anal or rectal administration, these usually being produced on the basis of triglycerides. Since triglycerides (fats) tend to become brittle, it is hardly possible to use these materials for making sticks of lasting non-breakability having a diameter of less than 4 mm and lengths of more than 20 mm.

[0003] In order to counteract this, it might be possible to use pure blends of plastics material and active agent and to extrude them to produce sticks of any diameter. Such sticks would indeed have adequate fracture strength and high elasticity and would thus have the desired material characteristics, but they would suffer from serious drawbacks with regard to their compatibility in physiological compartments, since plastics materials are degradable only to a small extent or not at all. If on the other hand the carrier degrades too quickly, the desired compartment will not, in most cases, be supplied with the necessary medicinal substance to an adequate extent, which may spoil the wound healing effect.

[0004] These handicaps are counteracted in Patent Application EP-A 1,064,514 by adding polyethylene glycols acting as amphiphilic agents. Despite the resulting increased elasticity of the shaped body formed, it is not possible to disperseably stabilize large concentrations, by weight, of lipids or fatty acids in the shaped body and thus to vary the release rate of various polar pharmaceutically active substances over a wide range.

[0005] It is an object of the present invention to avoid these and other prior art drawbacks and to provide shaped bodies for medical administration in body cavities and/or wound cavities in humans or animals, which shaped bodies show high elasticity and a high fracture strength and release the active substances or combinations of active substances present therein at a constant rate over a quite long period of time.

[0006] The main features of the invention are declared in the characterizing clauses of claims 1, 4, 7, 9, and 10 and in the characterizing clauses of claims 23 and 28, and in claims 29 and 30. Embodiments are the subject of claims 2 to 3, from 5 to 6, 8, from 11 to 22, and from 24 to 27.

[0007] A shaped body for medical administration in body cavities and/or wound cavities in humans or animals, comprising at least one amphiphilic continuous phase, for example, a water-dispersible polymer, and at least one lipophilic component as disperse phase and also comprising at least one pharmaceutically effective water-soluble or insoluble material, is characterized, as defined in claim 1 according to the present invention, in that the continuous phase is a biologically neutral oligomer, for example, a copolymer, of a polyester. By this means the shaped body is imparted with exceptionally high elasticity and fracture strength, which is particularly important for its introduction into a body cavity or wound cavity. This also ensures stabilization of relatively high concentrations, by weight, of the lipophilic disperses phase. The shaped body is capable of residing in the desired compartment for many hours and of releasing its content of (pharmaceutically) active substances (in retarded manner) to the environment over a long period of time. The curative action is exceptional good. The use of a biologically neutral oligopolymer ensures that no undesirable reciprocal effects occur with the environment.

[0008] According to claim 2, the continuous phase is an ether-like block oligopolymer having at least two consecutively linked sets of blocks of various alkoxyl groups, for example, a block copolymer. This class of substances having the general empirical formula

\[
\text{R}^1\text{O} = [(\text{CHR})_{1-a}-\text{O}]_a-[(\text{CHR})_{b}-\text{O}]_b-[(\text{CHR})_{c}-\text{O}]_c= \text{OR}^2,
\]

in which \(k\), \(m\) \(\geqslant\) 50 and \(L\) \(\geqslant\) 20 and also \(a, b,\) and \(c=1\) to 6, where \(a, b,\) and in which \(R^1\), \(R^2\) = alkyl, aryl and \(R^2\) = methyl, and having the poloxamer-typical formula

\[
\text{HO}-\overbrace{\text{CH}_{2}-\text{CH}_{2}-\text{O}}_{a}-\overbrace{\text{CH}_{2}-\text{CH}_{2}-\text{O}}_{b}-\overbrace{\text{CH}_{2}-\text{CH}_{2}-\text{O}}_{c}=\text{H},
\]

in which \(a=2\) to 130 and \(b=15\) to 67, is distinguished by the fact that lipophilic materials such as beeswax or triglycerides can be mixed therewith in high concentrations of up to 50 wt % to give homogeneous dispersions without the shaped body losing the elasticity or fracture strength necessary for its introduction into the cavity, which is of particular significance for the present invention. The block copolymer can, as defined in claim 3, be a poloxamer, for example, poloxamer 124, poloxamer 188, poloxamer 237, poloxamer 338, or poloxamer 407.

[0009] In the embodiment defined in claim 4, for which independent protection is claimed, the invention provides that the continuous phase is a biologically neutral polyester. The latter, depending on its structure, is more or less readily hydrolytically cleavable, which also applies to polyanhydrides and polyamide ester to various extents. It is preferred to use biodegradable copolymeric or oligopolymeric structures, and use may also be made of block copolymers and block oligopolymeric forms. These molecules are on account of their heterogeneous periodic structure particularly suitable for the production of shaped bodies containing active substance, since specific selection of these polymers can precisely adjust the rate of degradation thereof and thus that of the shaped body in the tissue compartment. In this way it is easy to achieve uniform release of active substance into the organism over a specific period of time. Another advantage consists in that the monomers forming in the tissue compartment as a result of degradation can be metabolized by the body.

[0010] According to claim 5, the continuous phase is a thermoplastic polyester, for example, a polycarbonate, a poly(lactic acid) in the D, L, or DL form, a polycarbonate, or a poly(carboxylate), a polyglycolide, a polyethylene carbonate, a polylacticacid, or a polyhydroxybutyrate, or a polyhydroxyvalerate. Claim 6 provides, on the other hand, the use of an oligopolymer or a block oligopolymer composed of at least two different monomers, for example, a copolymer or a block copolymer.

[0011] In another independent embodiment of the invention as defined in claim 7, the continuous phase comprises at
least one biologically neutral, non-ionic or neutrally charged emulsifier. Here again, there are obtained shaped bodies which despite large lipophilic contents have a high degree of elasticity and fracture strength. Biologically acceptable, neutrally charged or non-ionic emulsifiers, i.e. detergents, such as CHAPS, Tween®, or Span® can be used in the continuous phase as amphiphilic components, which is particularly advantageous when the shaped body is not an oral administration form. They form association colloids in which otherwise very difficultly stabilizable pharmaceutically active species can be very easily introduced.

[0012] It is expedient to use emulsifiers having a high CMC, e.g., octyl glucoside or dodecyl maltoside, since such surfactants avoid excessive foam formation and, in particular, avoid cell lysis at the site of action. According to claim 8, the CMC should be, say, greater than 6.

[0013] If very long residence times of the shaped body in the desired compartment are required or if the pharmaceutically active substance is required to be released extremely slowly from the shaped body, the continuous phase comprises, according to the invention as defined in the independent claim 9, a biologically neutral polyanhydride, polyester amide, or polyamide or comprises an oligopolymer or copolymer containing oligomeric or polymeric D-amino acid regions. The decisive factor here is the use of chemically and mechanically more stable amphiphilic polymers in the formulation. Particularly suitable are polyamides or polypeptides and polyester amides comprising D-amino acids. Oligopolymeric or block oligopolymeric structures of the aforementioned molecule families are likewise admirably suitable, but in such cases the amide-binding portion must be increased.

[0014] In the case of the preparation of shaped bodies in the form of tablets or sticks, claim 10 provides that the continuous phase is a macrogol (homopolyether), for example, PEG 1000, PEG 1500, PEG 2000, or PEG 4000, which in one embodiment is associated with low-molecular macrogols, for example, PEG 400 or PEG 200. This makes it possible to achieve very homogeneous distribution of the pharmaceutically active substance during dispersion, and it has been found to be particularly practical to dissolve the pharmaceutically active substance in low-molecular macrogols before adding it to the dispersion.

[0015] In an advantageous development of the invention, as defined in claim 11, the continuous phase is composed of copolymers of said polymer types or emulsifiers/polymer mixtures. This is particularly useful when, on the one hand, an active species is required to be introduced into the shaped body in a finely dispersed form in the interior of micelles only and, on the other hand, a slow release thereof to the environment is required. Furthermore, numerous other possible variations are feasible, particularly regarding the residence times of the shaped body in the cavity and also with reference to the release of the active substances or combinations of active substances to the environment.

[0016] The feature defined in claim 12 also serves this end, in which the composition of lipophilic component is between 25 and 50 wt% and preferably between 40 and 50 wt%, and the proportion of the continuous phase is from 40 to 70 wt% and preferably between 48 and 52 wt%. Thus the composition of lipophilic phase, which usually contains the pharmaceutically active substances, is relatively large compared with the continuous phase. Wound healing is optimally assisted by the retarded release of active substance. Nevertheless the shaped body possesses adequate dimensional stability, for which reason it does not break when introduced into the cavity.

[0017] In the embodiment defined in claim 13, the lipophilic component used is a wax, particularly an ester of a long-chain fatty acid with a long-chain fatty alcohol, for example, ointment beeswax EuAB 98 or bleached beeswax EuAB 98, or the lipophilic component used is a fatty alcohol or a mixture of fatty alcohols, for example, stearyl alcohol or cetyl/stearyl alcohol.

[0018] According to claim 14 the lipophilic component can be a triglyceride mixture, for example, a high-melting suppository composition having a melting point above 40°C. Alternatively, as defined in claim 15, the lipophilic component used is a long-chain hydrocarbon mixture, for example, a higher-melting paraffin composition having a melting point above 40°C. Also suitable are ozocesteres (hard paraffins) or mixtures of pharmaceutically useful fatty alcohols (cetyl/stearyl alcohols) as the retarding dispers matrix, which serve for delayed release of the active substances added to the shaped body at the site of action. In order to fix very non-polar active substances, use is made of mixtures of long-chain hydrocarbons, to great advantage.

[0019] The group of possible active substances and/or combinations of active substances, for example, pharmaceutical materials having anti-infective, antimicrobial, fungistatic or fungicidal, virustatic or virucidal action alone or together with steroidal antiphlogistics, local anesthetic agents, or anesthetic agents, from which a selection may be made, is disclosed in claims 16 to 20. The concentration of active substances or combination of active substances should not exceed 10 wt%. The active substance present can be an antibiotic agent, e.g., benzyl penicillin procaine or gentamicin, an antiseptic agent, an antymycotic agent, and/or a virustatic agent, e.g., Aciclovir®. Alternatively, use can be made of a glucocorticoid, e.g., a hydrocortisol, its esters, a betamethason, its esters or a triacemolone acetone. A particularly good curative action is achieved when PVP iodine is incorporated as an active substance. Depending on the field of application, use may also be made of metronidazol. In addition, higher doses are conceivable in individual cases.

[0020] The geometry of the shaped bodies of the invention can, according to claim 21, be characterized in that the stick has a cylindrical conical or barrel-like shape. For example, the shaped body can have a cylindrical corpus of from 2 to 10 mm in diameter and from 40 to 100 mm in length in order to be suitable for administration in wound cavities and body cavities in humans and animals. Furthermore the shaped body as defined in claim 22 can have the shape of a suppository or torpedo or be in the form of a tablet. Another possibility is the production thereof in suppository form (suppository or torpedo form or the like) or vaginal globulin form (vaginal tablets). Other shapes are realizable, depending alone on their end use.

[0021] The patent also relates to a process for the production of the shaped bodies of the invention according to the independent claim 23. This is characterized in that at least one hydrophilic continuous phase, for example, a water-soluble or water-dispersible polymer (e.g., polyethers or polysteres of various molecular weights and compositions or emulsifiers of various molecular weights), is melted with at least one lipophilic component (e.g., waxes, triglycerides, or the like) acting as disperse phase, to form a melt, to which at least one active substance or a combination of active substances is added and the whole is mechanically dispersed under con-
stant temperature conditions to form a composition. This is poured into a receptacle, vessel or the like, where it is cooled and stored for a specific period of time at constant temperature. The composition thus obtained is then heated to just below its softening point, plasticized by pressure or shearing, and compressed to a predefined shaped body, during which operation the operating pressure is not less than 50 bar, i.e. for example at least 100 bar and the operating temperature is below the softening point of the composition. According to claim 24 there is added to a molten, low-molecular polymer the active substance or active substances or a combination of active substances, to which end this premix is dispersed and added to the melt, this having a favorable effect on the overall procedure.

It is important that the composition is cooled at a constant temperature gradient of at least 5° C/h, as defined in claim 25. This prevents flocculation or crystallization of the individual components, which would make the shaped body brittle.

Experimentally, the composition as defined in claim 26 is compressed at a constant temperature and under a specific operating pressure to form dispersed solid shaped bodies, for which purpose preferably an extruder is used, by means of which the composition is compressed, as defined in claim 27, to produce extrudates of from 2 to 10 mm in diameter, which are then cut into lengths of from 40 to 100 mm.

The cylindrical shaped bodies produced by the process of the invention (sticks, styls medicinals) have, compared with those produced by simple melting and subsequent pouring into casting molds, exceptionally high elasticity and fracture strength.

A significant development of the invention is defined in claim 28, for which independent protection is claimed. According to said claim, a process for the production of compressed shaped bodies having a high content of low-melting hydrophobic components, or a process for the production of flowable or pourable pelletizatable mixtures exhibiting a high content of low-melting hydrophobic components, is characterized in that small beads of a cooled melt are compressed, small spheres are pulverized and compressed, or a cooled powder is filled into capsules.

A pharmaceutical preparation is characterized, as defined in claim 29, by a solid dispersed fat in a polymer dispersion or a fat in a detergent dispersion.

Yet another object of the present invention is, finally, the use of dispersed solid shaped bodies containing active substances as pharmaceuticals in the teats of agricultural working animals, for example, milk-producing cows.

Other features, details, and advantages of the invention may be gathered from the wording of the claims and from the following description of working examples.

A shaped body of the invention possesses an amphiphilic continuous phase, for example, a biologically neutral oligomer of a polyester, a lipophilic component as the dispers phase, for example, an official beeswax EUAB 98 or bleached beeswax EUAB 98, and a water-soluble or fat-soluble active substance such as PVP iodine. The continuous phase and the lipophilic dispers phase dispersed therein form a dispersed "fat-in-polymer system", which can release the medically active substances dissolved therein to the environment at a retarded rate.

The shaped bodies are preferably sticks having diameters of from 2 to 19 mm, preferably from 2 to 10 mm, and lengths of from 40 to 100 mm, these sticks being characterized by high elasticity and bending strength by reason of their novel composition. They are used as pharmaceuticals for the treatment of diseases and injuries. In particular, they can be readily introduced into wound cavities, where the dissolved active substances are released.

The rate at which the active substance is released depends on the amount of lipophilic phase in the shaped body. It decreases as the amount of usable lipophilic phase increases. Heteropolymers and block heteropolymers (eg, copolymers) in a concentration of up to 70 wt % (advantageously from 48 to 52 wt %) as the continuous phase allow the introduction of lipophilic disperse phase in concentrations of up to 50 wt %. Under specific conditions, still higher percentages of the lipophilic phase are suitable to be used. Important representatives of these heteropolymeric alkoxamers are the polyesters poloxamer 124, poloxamer 188, poloxamer 237, poloxamer 338, and poloxamer 407. It is generally also possible to use ether-like polymers having a molecular weight of from 300 g/mol to 30,000 g/mol for the formulation.

Moreover, the release rate of the active substance is governed by the dwell time of the shaped body and the decomposition thereof in the designated compartment, i.e. by the polymer selected for the continuous phase and its mechanical and chemical stability. Polymers which are labile in a physiological environment are degraded either by surface erosion or by hydrolytic cleavage over a period of time dependent on the polymer composition to form monomers which can be metabolized by the organism. The use of hydrolytically cleavable polymers allows for the control of the release rate of the pharmaceutically active substance to be governed not only by the dwell time of the shaped body in the organism or by the concentration of the disperse phase, but also by the stability of the shaped body. Degradable biologically acceptable polymers, poly(vinyl alcohol), poly(vinyl acetate), or poly(vinylpyrrolidone) in multilayer forms, or, for example, the combination of D-lactides and L-lactides, offer manifold possibilities of controlling the release kinetics of active species. Furthermore the biodegradable copolymers poly(dioxanone-co-e-caprolactone), poly(lactide-co-glycolide), poly(glycolide-co-trimethylene carbonate), poly(hydroxybutyrate-co-hydroxyvalerate), poly(trimethylene carbonate-co-e-caprolactone), poly(DL-lactide-co-e-caprolactone), poly(glycolide-co-e-caprolactone), or the terpolymer poly(glycolide-co-trimethylene carbonate-co-p-dioxanone) are, for example, very suitable for this field of activity.

If a very slow release of the pharmaceutical is desired and/or if it is desired that only very slow or no degradation of the shaped body takes place in the organism due to fusion or decomposition, the concentration of the disperse phase must be very high and the polymer used should be relatively resistant to hydrolysis. In addition to polymers, use is preferably made of polypeptides and polymeric structures in which D-amino acid regions linked by peptide bonds are present.

If it is desired to make a shaped body from aggregates of active substances or poorly solubilizable and emulsifiable pharmaceutical substances, in finely divided form, it is convenient to use, as the continuous phase, neutrally charged or non-ionic, biologically harmless detergents. It is advantageous to select representatives having a CMC greater than 6, as otherwise excessive foaming in the tissue compartment and lysis of cells may occur. For example, N-octylglucoside, dodecyl maltoside, or CTAPS may be used.
Especially when producing tablets and sticks, it is particularly advantageous to use polyethylene glycols. If PEG 1000, PEG 1500, PEG 2000, and PEG 4000 and furthermore PEG 200 or PEG 400 are used to form the continuous phase, the resulting dispersions can, after maturing, be processed, not only directly to compression moldings but also to small spherules or a powder. The powder can be placed in capsules or compressed to tablets. The beads can also be used to form a tablet having, however, a different type of fine distribution. PEG 200 and PEG 400, moreover, have the advantage that they can be used as low-molecular polyethylene glycols for wetting or dissolving the active species. This is carried out, where necessary, prior to the actual dispersing process.

The medical action of the shaped body of the invention may be described as follows:

Topical administration (for example, for wound disinfection, care of bite wounds, administration in the teats of milk-providing working animals and the like) of anti-infective agents, chemotherapeutics, antimicrobial, fungicidal, or virucidal pharmaceutically active substances by way of the shaped body, achieves a bacteriostatic or bactericidal, virucidal or fungicidal action at or in the desired compartment, i.e. the body cavity or wound cavity, which action is characterized by a high, uniform local concentration of active substance over a defined period of time (retarded liberation of active substance) and at the same time low systemic absorption of active substances.

The addition of steroidal antiphlogistic active substances (antiphlogistics) has a decongesting and anti-adhesive action. The addition of suitable analgesics or local anesthetics relieves wound pain.

The shaped body retarded, inter alia, by the lipophilic disperse phase remains at the site of action for hours and thus keeps the lumen of the compartment concerned open, which is of considerable advantage particularly when administering to teats. Adhesion of the tissue concerned is reliably avoided. There is a reduction of the secondary swelling occurring with an injury. The water-soluble or water-dispersible polymers used in the shaped body (predominantly polyethylenes and polyesters, alternatively emulsifiers and polyamides) are also secretion-absorbing and thus unfold an adjuvant antimicrobial action. In addition, they assist proliferation and thus accelerate wound healing.

Possible compositions of the shaped body are as follows:

The individual steps of the manufacturing process of the invention can be described as follows:

1. The selected water-soluble or water-dispersible polymers or surfactants are melted together with the lipophilic component (eg, official beeswaxes, fatty alcohols, triglycerides), the processing temperature being governed by the melting points of the components used.
2. The pharmaceutically active substance(s) can be optionally dissolved or dispersed in a low-molecular macrogol (eg, PEG 200/400) or in alcohols conventionally used for pharmaceutical purposes; and then added to the melt or directly dispersed in the melt.
3. The pharmaceutically active substances used can be any of the pharmaceutically active substances which are suitable for administration in body cavities or wound cavities. Preference is given to the following groups of active agents: antibiotics, antiseptics, anti-inflammatory, virustatics (anti-infective agents, chemotherapeutics), antiphlogistics, particularly glucocorticoids and anesthetic agents or local anesthetics, which can be added individually or in combination with each other in amounts or concentrations known to the person skilled in the art.

Particularly preferred antibiotics are penicillins, particularly benzyl penicillin procaine and gentamycin and their chemical derivatives, the preferred antiseptic agent being PVP iodine. The preferred glucocorticoids employed are hydrocortisone and its esters, betamethasone and its esters, dexamethasone and its esters, and triamcinolone (triamcinolone acetonide) and its esters. The preferred anti-inflammatory and antiprotozoal agent used is metronidazol, and the preferred virustatic agent used is Aciclovir®.

3. The mixtures of 1. and 2. are, if necessary, combined and mechanically dispersed, during which process the temperature should not fall below the melting temperature of the polymers used.
4. The dispersion melt is poured into a temperature-controlled vessel (e.g., a cylinder) and cooled to 15° C. under time control and then left to mature or cure for at least 4 hours at 15° C.

5. Following this period of cool storage, the dispersed solid composition thus obtained and containing active substance, is hydraulically extruded (extended) by means of a temperature-controlled high-pressure extruder at operating temperatures which must be from ca 5° to 10° C. below the softening point of the mixture used, to form shaped bodies via various nozzles or attached molds, the operating pressure being 100 bar.

[0045] In one embodiment, the manufacturing process is modified for the production of tablets and capsules. To this end, the pressure-loaded dispersion is converted by compression molding at a temperature below its softening point through a breaker plate to form small spherules. These are sifted and then compressed to tablets or ground to a powder with cooling. The latter is compressed to tablets or filled into capsules

[0046] By combining physiologically acceptable polymers or emulsifiers with various conventional pharmaceutically acceptable fats, waxes, and fatty alcohols in a dispersed solid system, the drawbacks of the prior art, particularly the limits imposed by use of only polymers or fats or waxes may be overcome. Hitherto possible maximum concentrations of the lipophilic component are pushed up to higher values by the use of copolymers and block copolymers or their oligomeric variants, and this considerably influences the release rate of the active species. The solid fat-in-polymer dispersions or polymer-in-fat dispersions of the invention exhibit the material characteristics necessary for handling and administration and are at the same time a retarded pharmaceutical dosage form for administration in wound cavities and body cavities. The sticks show good physiological compatibility and degradability.

[0047] The process steps of the invention and their order of execution guarantee high and stable dispersity of the medical sticks, i.e. the degree of interdispersion of the materials and the interfacial affinity of the materials used toward each other is exceptionally high compared with conventional shaped bodies. The medical sticks form a homogeneous solid dispersion exhibiting all of the required properties.

[0048] The invention is not restricted to any of the embodiments described above but can be modified in diverse ways. For example, instead of a fat-in-polymer system, use may be made of a reverse system, i.e. a polymer-in-fat system. Furthermore non-lamellar phases and inverted systems comprising lipids, surfactants, or phospholipids can be used.

[0049] It is seen that water-soluble or water-dispersible polymers, particularly those of the family of compounds comprising the polyethers, polyesters, polyamides and/or detergents, and also lipophilic materials can readily form a dispersion by melting the components at suitable temperatures and admixing pharmaceutically active substances by mechanical procedures, i.e. a lipophilic dispers phase is distributed in a hydrophilic polymer phase as the continuous phase, to form a stable dispersion. By controlled cooling, curing, and storage followed by high-pressure molding or worm extrusion at defined temperatures and operating pressures, it is possible to produce, in addition to other types of shaped bodies, dispersed polymeric fatty sticks distinguished by particularly good fracture strength and flexibility. When used for medicinal purposes, such sticks have the advantage that the polymers and hydrophobic materials used for production (waxes, fatty alcohols, triglycerides etc.) are physiologically and toxicologically acceptable and any desired pharmaceutically active substances are suitable to be incorporated.

[0050] The combination of water-dispersible polymers with hydrophobic substances has the great advantage of delayed degradation of the dimensionally stable sticks in the desired physiological compartment, due to the lipophilic dispers phase matrix, which can only be slowly dissolved by endogenic liquids and secretions. This is accompanied by delayed but uniform release of active substance in the desired compartment, which ensures that there is an adequate therapeutic active level of pharmaceutically active substances over prolonged periods of time. Furthermore the slowly degrading stick corpus (shaped body) can maintain an injured body lumen, which is thus protected from undesirable adhesion.

[0051] All of the features and advantages, including structural details, spatial arrangements, and process steps, disclosed in the claims and description can be essential to the invention both independently and in a great variety of combinations.

1. Shaped body for medical administration in body cavities and/or wound cavities in humans or animals, comprising at least one amphiphilic continuous phase, for example, a water-dispersible polymer, and at least one lipophilic component as dispers phase, and also comprising at least one pharmaceutically effective water-soluble or fat-soluble material, the continuous phase being a biologically neutral oligomer of a polyether, for example, a copolymer, wherein
   a) the continuous phase is a poloxamer, for example, poloxamer 124, poloxamer 188, poloxamer 237, poloxamer 338, or poloxamer 407,
   b) the proportion of continuous phase is at least 40 wt % and the proportion of disperser phase is up to 50 wt %,
   c) the continuous phase, the disperser phase and the pharmaceutically effective material being shaped as a dispersed solid composition following defined maturing or storage at constant temperature with liquefaction under compression
   d) the shaped body having a diameter of down to 2 mm and a length of up to 100 mm.

2. Shaped body as defined in claim 1, wherein the lipophilic component is a wax, particularly an ester of a long-chain fatty acid with a long-chain fatty alcohol, for example, officinal beeswax EUAB 98 or bleached beeswax EUAB 98, or that the lipophilic component is a fatty alcohol or a mixture of fatty alcohols, for example, stearyl alcohol or cetyl/stearyl alcohol.

3. Shaped body as defined in claim 1, wherein the lipophilic component is a triglyceride mixture, for example, higher-melting suppository compositions having a melting point above 40° C.

4. Shaped body as defined in claim 1, wherein the lipophilic component is a long-chain hydrocarbon mixture, for example, higher-melting paraffin compositions having a melting point above 40° C.

5. Shaped body as defined in claim 1, wherein the proportion of active substance or combination of active substances does not exceed 10 wt %.

6. Shaped body as defined in claim 1, wherein the active substance present is an antibiotic agent, e.g., benzyl penicillin procaine or gentamycin, an antiseptic agent, an antimycotic agent, and/or a virustatic agent, e.g., Aciclovir®.
7. Shaped body as defined in claim 1, wherein the active substance present is a glucocorticoid, e.g., a hydrocortisol, an ester thereof, a betamethason, an ester thereof or a triamcinolone acetonide.
8. Shaped body as defined in claim 1, wherein the active substance present is PVP iodine.
9. Shaped body as defined in claim 1, wherein the active substance present is metronidazol.
10. Shaped body as defined in claim 1, wherein the shaped body is a cylindrical or a conical or barrel-shaped stick.
11-15. (canceled)
16. Pharmaceutical preparation, characterized by a dispersed solid fat-in-polymer dispersion or fat-in-detergent dispersion as defined in at least claim 1.
17. (canceled)
18. The shaped body of claim 1, wherein the at least one amphiphilic continuous phase is a water-dispersible polymer.
19. The shaped body of claim 1, wherein the poloxamer is poloxamer 124, poloxamer 188, poloxamer 237, poloxamer 338, or poloxamer 407.
20. The shaped body of claim 2, wherein the wax is an ester of a long-chain fatty acid with a long-chain fatty alcohol or the lipophilic component is a fatty alcohol or a mixture of fatty alcohols.
21. The shaped body of claim 20, wherein the ester of a long-chain fatty acid with a long-chain fatty alcohol is officinal beeswax EUAB 98 or bleached beeswax EUAB 98.
22. The shaped body of claim 20, wherein the fatty alcohol is stearyl alcohol or cetyl/stearyl alcohol.
23. The shaped body of claim 3, wherein the triglyceride mixture is a suppository composition having a melting point above 40°C.
24. The shaped body of claim 4, wherein the long-chain hydrocarbon mixture is a higher-melting paraffin compositions having a melting point above 40°C.
25. The shaped body as defined in claim 1, wherein the proportion of the lipophilic component is between 25 and 50 wt %, and the proportion of the continuous phase is from 40 to 70 wt %.
26. The shaped body of claim 25, wherein the proportion of the lipophilic component is between 40 and 50 wt %, and the proportion of the continuous phase is from 48 to 52 wt %.
27. The shaped body of claim 25, wherein the proportion of the lipophilic component is between 25 and 50 wt %, and the proportion of the continuous phase is from 48 to 52 wt %.
28. The shaped body as defined in claim 1, wherein the shaped body has the shape of a suppository or torpedo, or is in the form of a tablet.
29. The shaped body of claim 6, wherein the antibiotic agent is a benzyl penicillin procaine or gentamycin.
30. The shaped body of claim 7, wherein the virustatic agent is Aciclovir®.
31. The shaped body of claim 7, wherein the active substance is a hydrocortisol.
