(54) Title: ADAPTIVE BITRATE MANAGEMENT FOR STREAMING MEDIA OVER PACKET NETWORKS

Fig. 3

(57) Abstract: A method including receiving a receiver report from a terminal; estimating one or more network conditions of a media network based at least in part on the receiver report; determining an optimal session bitrate based on the estimated one or more network conditions; and providing media data to the terminal based on the optimal session bitrate.
ADAPTIVE BITRATE MANAGEMENT FOR STREAMING MEDIA OVER PACKET NETWORKS

Cross Reference to Related Patents

[001] This application claims the benefit of U.S. Provisional Application No. 60/948,917, filed July 10, 2007, "Adaptive Bitrate Management for Streaming Media over Packet Networks," which is incorporated herein by reference.

Background Information

[002] Rate control is essential for media streaming over packet networks. The challenge in delivering bandwidth-intensive content like multimedia over capacity-limited, shared links is to quickly respond to changes in network conditions by adjusting the bitrate and the media encoding scheme to optimize the viewing and listening experience of the user. In particular, when transferring a fixed bitrate over a connection that cannot provide the necessary throughput, several undesirable effects arise. For example, a network buffer may overflow resulting in packet loss causing garbled video or audio playback, or a media player buffer may underflow resulting in playback stall. Standard bodies have recommended protocols to address these issues. Internet Engineering Task Force (IETF), in RFC 3550, specifies RTCP as the fundamental building block to implement bit rate/packet rate control in streaming media. Several extensions to RTCP, suited for high capacity networks, follow this original recommendation.

[003] Even with these recommended protocols, delivering a multimedia session over wireless networks can be particularly challenging, due in part to the following:
- Sudden Adjustment of nominal transmission rate: Due to interference, fading, etc, 3+G networks negotiate physical layer parameters on the fly. Nominal transmission bitrates can change by a factor of 10;

- Packet Loss: caused by either link transmission errors or by network congestion;

- Reduction of Effective bandwidth: The wireless link is a shared resource at Layer 2, with MAC (Media Access Control) mechanism and scheduling. This means that an increased load presented by other wireless terminals in the same sector can reduce the effective bandwidth or capacity that a terminal will see; and

- Limited Capacity: Available capacity is typically a fraction to that obtained in traditional wireline internet access technologies, where currently capacity is not an issue. Fixed internet media sessions can typically offer to the network loads between 250 and 400 kbps. Despite the fact that current 3G cellular networks can sustain throughputs of 500kbps and above, the total bitrate budget for a wireless multimedia session is typically kept under 150 kbps to ensure scalability.

[004] For wireless mobile devices, providing a good experience in streaming media sessions is particularly difficult, due to

- Infrequent and incomplete network state information. The typical wireless media player support RTCP receiver report as defined in RFC 3550, and the report generation frequency is fixed. As a result, the network state information obtained at the sender end is limited and sporadic. In its Packet
Streaming Service specification, 3GPP recommends several extensions to the basic IETF RTCP Receiver Report (i.e. RTCP Extended Reports, or XR). Unfortunately, very few handsets implement these enhancements;

- Different media streams are handled separately. Despite the fact that they are both transmitted over the same network link, audio and video streams are handled separately by RTCP. Both RTCP reports provide state information about the same network, therefore a joint analysis; and
- Low bitrates available: The bitrate budget for a wireless multimedia session is generally very low (under 150kbps). The adjustment of audio and video bitrates can have large perceptual impact on the session, and the total available network bitrate, even for 3G networks, can fall well below acceptable quantities. With these issues, to wireless networks and wireless mobile devices it has been difficult to set up a consistent streaming media session.

**BRIEF DESCRIPTION OF THE DRAWINGS**

[005] FIG. 1 is a block diagram of an exemplary system.

[006] FIG. 2 is a block diagram illustrating an embodiment of the exemplary system of FIG. 1.

[007] FIG. 3 is a functional diagram illustrating an exemplary communication flow in the exemplary system of FIG. 2.

[008] FIG. 4 is a flowchart representing an exemplary method for processing an RTCP packet.
[009] FIG. 5 is a flowchart representing an exemplary method for processing optimal session bitrate data.

DETAILED DESCRIPTION OF DRAWINGS

[010] Reference will now be made in detail to the exemplary embodiments consistent with the invention, the examples of which are illustrated in the accompanying drawings. Wherever possible, the same reference numbers will be used throughout the drawings to refer to the same or like parts.

[011] Adjusting the bitrate of streaming media sessions according to instantaneous network capacity can be a critical function required to deliver streaming media over wireless packet networks. Adaptive bitrate management is a comprehensive framework and method that enables the delivery of self-adjusting streaming sessions to media players, for example, such as standard 3GPP-compliant media players. Adaptive bitrate management includes, among other things, an adaptive bitrate controller and a variable bitrate encoder, both of which allow the adaptive bitrate management the ability to implement joint session bitrate management for audio, video and/or other streams simultaneously.

[012] FIG. 1 is a block diagram of an exemplary system. Exemplary system 100 can be any type of system that transmits data packets over a network. For example, the exemplary system can include a mobile terminal accessing streaming media data from content servers through the Internet. The exemplary system can include, among other things, a terminal 102, a gateway 104, one or more networks 106, 110, an adaptive bitrate manager 108, and one or more content servers 112-114.
Terminal 102 is a hardware component including software applications that allow terminal 102 to communicate and receive packets corresponding to streaming media. Terminal 102 provides a display and one or more software applications, such as a media player, for displaying streaming media to a user of terminal 102. Further, terminal 102 has the capability of requesting and receiving data packets, such as data packets of streaming media, from the Internet. For example, terminal 102 can send request data to content servers 112-114 for a particular file or object data of a web page by its URL, and the content server of the web page can query the object data in a database and send the corresponding response data to terminal 102. In some embodiments, response data may be routed through adaptive bitrate manager 108.

While terminal 102 can be a wired terminal, some embodiments of the invention may prefer using a mobile terminal because mobile terminals are more likely to be in networks that would benefit more from an adaptive bitrate manager. The network connection tends to be less stable as compared to wired network connection due to, for example, the changing position of the mobile terminal where data rate transmissions between the mobile terminal and the network can fluctuate, in some cases quite dramatically.

Gateway 104 is a device that converts formatted data provided in one type of network to a particular format required for another type of network. Gateway 106, for example, may be a server, a router, a firewall server, a host, or a proxy server. Gateway 104 has the ability to transform the signals received from terminal 102 into a signal that network 106 can understand and vice versa. Gateway 104 may be capable
of processing audio, video, and T.120 transmissions alone or in any combination, and is capable of full duplex media translations.

[016] Networks 106 and 110 can include any combination of wide area networks (WANs), local area networks (LANs), or wireless networks suitable for packet-type communications, such as Internet communications. Further, networks 106 and 110 can include buffers for storing packets prior to transmitting them to their intended destination.

[017] Adaptive bitrate manager 108 is a server that provides communication between gateway 104 and content servers 112-114. Adaptive bitrate manager 108 can optimize performance by adjusting a streaming media bitrate according to the connection, i.e., media network, between adaptive bitrate manager 108 and terminal 102. Adaptive bitrate manager 108 can include optimization techniques, further described below.

[018] Content servers 112-114 are servers that receive the request data from terminal 102, process the request data accordingly, and return the response data back to terminal 102 through, in some embodiments, adaptive bitrate manager 108. For example, content servers 112-114 can be a web server, an enterprise server, or any other type of server. Content servers 112-114 can be a computer or a computer program responsible for accepting requests (e.g., HTTP, RTSP, or other protocols that can initiate a media session) from terminal 102 and serving terminal 102 with streaming media.

[019] FIG. 2 is a block diagram illustrating an embodiment of the exemplary system of FIG. 1. Terminal 102 may include, among other things, a media player 202
and a buffer 204. Adaptive bitrate manager 108 can include, among other things, an adaptive bitrate controller 210, a buffer 212, a variable bitrate encoder 214, and a Real-time Transport Protocol (RTP) packetization 216.

[020] Media player 202 is computer software for playing multimedia files (such as streaming media) including video and/or audio media files. Such popular examples of media player 202 can include Microsoft Windows Media Player, Apple Quicktime Player, and RealOne Player. In some embodiments, media player 202 decompresses the streaming video or audio using a codec and plays it back on a display of terminal 102. Media player 202 can be used as a stand alone application or embedded in a web page to create a video application interacting with HTML content. Further, media player 202 can communicate with adaptive bitrate manager 108 by sending RTCP receiver reports.

[021] Buffer 204 (also known as terminal buffer 204) is a software program and/or a hardware device that temporarily stores multimedia packets before providing the multimedia packets to media player 202. In some embodiments, buffer 204 receives the multimedia packets from adaptive bitrate manager 108 via network 106. These packets can be configured based on the real-time transport protocol (RTP). In some embodiments, buffer 204 receives the multimedia packets from a device other than adaptive bitrate manager 108. Once buffer 204 receives multimedia packets, it can provide the stored multimedia packets to media player 202. While FIG. 2 illustrates that terminal buffer 204 and media player 202 are separate components, one of ordinary skill the art will appreciate that terminal buffer 204 can be a part of media player 202. Further, while FIG. 2 illustrates only a single buffer, one of ordinary skill the
art will appreciate that multiple buffers can exist, for example, one or more buffers for audio media packets and one or more buffers for video media packets.

[022] Adaptive bitrate controller 210 of adaptive bitrate manager 108 is a software program and/or hardware device that periodically receives RTCP receiver reports from terminal 102 and provides an optimal session bitrate to be used during the next period for encoding multimedia data to be sent to terminal 102. In some embodiments, adaptive bitrate controller 210 includes a buffer for storing the current and previous RTCP receiver reports. To compute the optimal session bitrate, adaptive bitrate controller 210 uses one or more network state estimators for estimating the state of the streaming media network and computing the optimal session bitrate to be used in the next RTCP interval. For example, these network state estimators can estimate a media time in transit (MTT), a bitrate received at terminal 102, a round trip time estimate (RTTE), and a packet loss count. Adaptive bitrate controller 210 can use the history and statistics of the estimator to implement different control algorithms to compute the optimal session bitrate. Further, adaptive bitrate controller 210 may update the optimal session bitrate by determining the stability of the streaming media network. This can be done by checking the newly computed estimators for compliance to one or more stability criterion. Using the estimations and the stability criterion, adaptive bitrate controller 210 can determine whether to adjust the outgoing bitrate or keep the current outgoing bitrate unchanged for the next period. After this determination, adaptive bitrate controller 210 provides the optimal session bitrate value to variable bitrate encoder 214.

[023] Buffer 212 of adaptive bitrate manager 108 is a software program and/or a hardware device that temporarily stores media data before providing the media data to
variable bitrate encoder 214. In some embodiments, buffer 212 receives the media
data from one or more content servers 112-114 via network 110. In some
embodiments, buffer 212 receives the media data from a device other than content
servers 112-114.

[024] Variable bitrate encoder 214 of adaptive bitrate manager 108 is a software
program and/or hardware device that receives optimal session bitrate data from
adaptive bitrate controller 210 and provides, to RTP packetization 216, audio and/or
video data that are encoded at a bitrate matching the optimal session bitrate provided
by adaptive bitrate controller 210. Variable bitrate encoder can include, among other
things, a bitrate splitter 220, an audio encoder 222, a video encoder 224, and, for some
embodiments, a frame dropper 226.

[025] Bitrate splitter 220 is a software program and/or a hardware device that
receives the optimal session bitrate data from adaptive bitrate controller 210 and
allocates optimal bitrates to be used when encoding the audio and video media data
during the next interval. The allocation is such that the summation of bitrates for all
tracks, when combined, can be substantially equal to the optimal session bitrate
specified by adaptive bitrate controller 210. For example, this allocation could be based
on a predetermined allocation, user preference, optimal performance data, privileging
one type of data over the other, the amount of audio and video data to be provided,
and/or any combination of the above. For example, bitrate splitter 220 may privilege
audio quality in a way that if a reduced bitrate is specified, bitrate splitter 220 will reduce
the video bitrate first and postpone reducing the audio bitrate as much as possible.
[026] Audio encoder 222 and video encoder 224 are software programs and/or hardware devices that receive their respective bitrate allocation from bitrate splitter 220 and provide outgoing media data encoded to match the bitrate of their respective bitrate allocation for the next RTCP interval. Both audio encoder 222 and video encoder 224 receive their respective media data from buffer 212 and output this media data according to its respective bitrate allocation from bitrate splitter 220. After the bitrate has been determined for both audio and video, it is the responsibility of each encoder to deliver maximum quality in the corresponding media track. For example, audio encoder 222 can generate variable bitrates by adjusting spectral quantization and cutoff frequency. Further, video encoder 224 can generate variable bitrates, for example, by adjusting Discrete Cosine Transform (DCT) coefficient quantization or by introducing frame dropping. This frame dropping can be executed, when needed, by frame dropper 226.

[027] Frame dropper 226 is a software program and/or a hardware device that can be triggered when the desired bitrate is less than a quality threshold. This threshold can be codec dependent, and represents the bitrate value below which the use of coarser quantization leads to intolerable artifacts in the image. Frame dropper 226 can dynamically determine a frame dropping rate based on the desired video bitrate and the bitrate being generated by video encoder 224. To compensate inherent bitrate fluctuations in the video bitrate at the output of the encoder, frame dropper 226 can dynamically update the dropping rate by using a sliding window covering the byte size history of recently encoded frames.
[028] RTP packetization 216 is a software program and/or a hardware device that receives the audio and video media data from audio encoder 222 and video encoder 224 and translates this data into a packet format. RTP defines a standardized packet format for delivering audio and video over the Internet. Besides carrying the audio and media data, these packets can include, among other things, a payload-type identifier for identifying the type of content, a packet sequence number, time stamping for allowing synchronization and jitter calculations, and delivery monitoring data. This type of data can later assist adaptive bitrate controller 210 in determining the quality of service provided by the network when adaptive bitrate controller 210 receives a corresponding RTCP receiver report from terminal 102. Upon translating this data into a packet format, RTP packetization 216 transmits the data through network buffer 230 of network 106 to terminal buffer 204 of terminal 102. In addition adaptive bitrate manager 108 saves the history of sent RTP packets in the audio and video tracks. This history data can include, among other things, the time that each packet is sent, the sequence number, and the size of each RTP packet.

[029] FIG. 3 is a functional diagram illustrating an exemplary communication flow in the system of FIG. 2. It is assumed for purposes of explaining this exemplary embodiment that terminal 102 has already received at least some of the media data of the requested media data package. Further, it is assumed that the media data package includes both audio and video media data. After receiving packets, media player 202 transmits (302) an RTCP receiver report to adaptive bitrate manager 108.

[030] RTCP is a protocol for providing quality control information for an RTP flow, such as the transmission provided by RTP packetization 216 of adaptive bitrate
manager 108. More specifically, RTCP partners with RTP packetization 216 of adaptive bitrate manager 108 in the delivery and packaging of multimedia data. In some embodiments, media player 202 periodically transmits the RTCP receiver report. RTCP receiver report can provide feedback on the quality of service being provided by RTP packetization 216. While RTP/RTCP is used as an exemplary embodiment to explain the adaptive bitrate control method, one of ordinary skill could appreciate that this adaptive bitrate control method is applicable to any protocol that fulfills the functions of media transport with sequencing and timing information and media transport feedback with information about received packets (covering sequencing, timing, loss rate, etc.)

[031] Further, in some embodiments, the receiver report can be a single report having both audio and video report data or it can be separated into multiple reports (such as in the RTCP case), for example, such as a receiver report for audio report data and a another receiver report for video report data. The receiver report data can include, among other things, data regarding the sequence number of the most recently received RTP packet at terminal 102, the timestamp of the last packet received by terminal 102 reported in the RTCP receiver report, the number of bits sent from this report, a round trip time, and a number of packets lost.

[032] After receiving the receiver report, adaptive bitrate controller 210 can estimate the state of the network for determining whether to update the session bitrate for the next period. Adaptive bitrate controller 210 can save the newly received receiver report in a cumulative history and record the time at which the packet was received. To estimate the state of the network, adaptive bitrate controller 210 can combine data from the received RTCP receiver report, the previously received RTCP receiver reports
stored by the adaptive bitrate manager 108, and the history of sent RTP packets stored by adaptive bitrate manager 108. Adaptive bitrate controller can estimate the following exemplary data by using network state estimators:

- Media Time in Transit (MTT), computed as the difference between the timestamp of the most recently sent RTP packet and the timestamp of the last RTP packet received by the player reported in RTCP receiver report;
- Bitrate received, computed as the bits received between the current and previously received RTCP receiver reports, divided by the time elapsed between these two receiver reports. The bits received between receiver reports are computed by cross referencing sequence numbers in the receiver report with the history of bytes sent stored at adaptive bitrate manager 108;
- Round Trip Time Estimate (RTTE) can be obtained by averaging a number of the lower MTT values stored at the adaptive bitrate manager 108. For example, RTTE could be calculated by averaging the lowest 3 MTT values out of all stored MTT values for that streaming media network. Further, adaptive bitrate manager 108 can calculate the RTTE from data within an RTCP sender report. While these exemplary embodiments are illustrated, any method can be used to estimate a round trip time for the streaming media network; and
- Packet Loss count, captured directly from RTCP receiver report.

Adaptive bitrate controller 210 can use these estimates to implement several different control algorithms. For example, the Streaming Media stability criterion can be used to compute the session bitrate for the next RTCP interval.
[033] Adaptive bitrate controller 210 uses the stability criterion to determine the stability of the streaming media network. While any number of algorithms can be used to determine the stability, one exemplary embodiment compares the estimated MTT with the RTTE. If the MTT and the RTTE remain close, adaptive bitrate controller 210 can determine that the streaming media network can properly support the current bitrate. Further, by comparing the bitrate received with the current bitrate session, adaptive bitrate controller 210 can determine that the network can cope with the load imposed by adaptive bitrate manager 108.

[034] Adaptive bitrate controller 210 uses the estimations and the stability criterion to implement control algorithms for discovering the network capacity and adjusting the session bitrate accordingly. Adaptive bitrate controller 210 can define the variations of the control algorithms to operate in two different modes: (1) acquisition mode and (2) normal mode. While two modes have been illustrated in this exemplary embodiment, one of ordinary skill in the art will appreciate that multiple modes of operation can be defined.

[035] In the normal mode, adaptive bitrate controller 210 operates in the steady state condition, indicating that the network is either maintaining or incrementally increasing the effective capacity seen by the system. In some embodiments, while operating in normal mode, the control algorithms can increase the session bitrate while the MTT is not increasing and the bitrate received remains close to the current session bitrate.

[036] Adaptive bitrate controller 210 generally triggers the acquisition mode when it detects high packet loss, a sudden increase in the MTT, and/or a value of the
MTT higher than a threshold (MTT threshold), which can be a fixed value or can be obtained dynamically for an adaptive control mechanism. Once triggered, acquisition mode sets the optimal session bitrate to a value, such as the bitrate received or a fraction of the received bitrate. Because the bitrate received can be the best estimation of the actual bitrate that the network can support at that particular point in time, adaptive bitrate manager 108 should quickly return back to a stable condition. In some embodiments, the new session bitrate is simply set to be a fraction of the current session bitrate.

[037] In this embodiment, while only terminal 102 is illustrated for communicating with adaptive bitrate manager 108, one of ordinary skill in the art will appreciate that multiple terminals can communicate with adaptive bitrate manager 108, where each of the terminals can be located in substantially different network environments. Such environments can vary significantly, as different underlying wireless technologies and fixed network topologies can be used. Therefore, for some embodiments, it may be desirable to discover characteristics of the network environment beforehand so that key parameters in the framework are adjusted automatically. For example, adaptive bitrate controller 210 could set the MTT threshold at the beginning of the multimedia session to a value correlated to the RTTE. In this way, the system can attempt to follow the general stability criterion provided by adaptive bitrate controller 210. As indicated above, this stability criterion could be based on, independent of the network environment (a priori unknown), the comparison between the MTT and the RTTE, which is largely advantageous given that the actual network infrastructure type can rarely be determined a priori. In some embodiments, the optimal
session bitrate can be updated by determining the difference between the MTT and the RTTE and adjusting the session bitrate according to the difference. For example, the larger the difference, the greater adjustment from the current session bitrate to an optimal session bitrate. In some embodiments, the MTT used for this determination can be based on the one or more historical values of MTT.

[038] Using the control algorithms to compute a session bitrate update as described above, adaptive bitrate controller 210 determines an optimal session bitrate for transmitting media data to terminal 102. Adaptive bitrate controller 210 provides (304) the optimal session bitrate data to bitrate splitter 220 of variable bitrate encoder 214. Upon receiving the optimal session bitrate data, bitrate splitter 220 allocates the optimal session bitrate between the audio and video streams. For example, this allocation could be based on a predetermined allocation, a user preference optimal performance data, privileging one type of data over the other, the amount of audio and video data to be provided, and/or any combination of the above. For example, bitrate splitter 220 may privilege audio quality in a way that if a reduced bitrate is specified, bitrate splitter 220 reduces the video bitrate first and postpones reducing the audio bitrate as much as possible.

[039] After splitting the optimal session bitrate into an optimal audio bitrate and an optimal video bitrate, bitrate splitter provides (306) the optimal audio bitrate to audio encoder 222 and provides (308) the optimal video bitrate to video encoder 224. Upon receiving their respective bitrate, both audio encoder 222 and video encoder 224 receive their respective media data from buffer 212 and output their respective audio media data and video media data according to the respective bitrate allocation from
bitrate splitter 220. After the bitrate has been determined for both audio and video, it is
the responsibility of each encoder to deliver maximum quality in the corresponding
media track by maintaining the requested bitrate until the next RTCP interval. For
example, audio encoder 222 can generate variable bitrates by adjusting quantization
and cutoff frequency. Further, video encoder 224 can generate variable bitrates, for
example, by adjusting Discrete Cosine Transform (DCT) coefficient quantization or by
introducing frame dropping. This frame dropping can be executed, when needed, by
frame dropper 226. In some embodiments, the encoding parameters of the encoders
are not modified until they receive optimal bitrate data from bitrate splitter 220, which
would be provided in a subsequent RTCP interval, because the encoders 222, 224 are
slave devices to bitrate splitter 220.

[040] In some embodiments, where frame dropping is preferred, video encoder
224 can provide (310) the video media data to frame dropper 226 when the optimal
session bitrate is less than a quality threshold. This threshold can be codec dependent,
and represents the bitrate value below which the use of coarser quantization leads to
intolerable artifacts in the image. When frame dropping is triggered, frame dropper 226
can dynamically determine a frame dropping rate based on the desired video bitrate and
the bitrate being generated by video encoder 224. To compensate inherent bitrate
fluctuations in the video bitrate at the output of video encoder 224, frame dropper 226
can dynamically update the dropping rate by using a sliding window covering the byte
size history of recently encoded frames. Frame dropper 226 can drop the frames
accordingly to deliver the optimal session bitrate. In addition, in some embodiments,
video encoder 224 can utilize the network state estimator of adaptive bitrate controller
210 to encode video in a more resilient manner. In some embodiments, packet loss information can be used in conjunction with the MTT by video encoder 224 to determine if a Group of Picture (GOP) value should be reduced, increasing the number of I-Frames per second sent in the video stream. In some embodiment, if frame dropping is not needed, video encoder 224 can simply provide the video media data to RTP packetization 216. Audio encoder 222 and, for this embodiment, frame dropper 226 provide (312, 314) the audio media data and the video media data, respectively, to RTP packetization 216.

[041] Upon receiving the audio media data and the video media data, RTP packetization 216 translates this data into a packet format. RTP defines a standardized packet format for delivering audio and video over the Internet. Upon translating this data into a packet format, RTP packetization 216 transmits (316) the audio and video media packets to network buffer 230 of network 106. While only one transmission is shown, one of ordinary skill in the art will appreciate that transmission 316 can include separate transmission for one or more audio media packets and another for one or more video media packets. Furthermore, one of ordinary skill in the art will appreciate that network 106 can include multiple networks, each having their own one or more buffers. Besides carrying the audio and media data, these packets can include, among other things, a payload-type identifier, a packet sequence number, a timestamp, and delivery monitoring data. This type of data can later assist adaptive bitrate controller 210 in determining the quality of service provided by the network when adaptive bitrate controller 210 receives the RTCP receiver report from terminal 102. Moreover, adaptive
bitrate manager 108 can also store a history of sent RTP packets so that it can later adjust the bitrate accordingly.

[042] Upon receiving the packets, network buffer 230 of network 106 can store the packets until it is the packets turn to be provided to terminal 102. While only buffer 230 is illustrated, one of ordinary skill in the art will appreciate that one or more separate buffers can exist for each of the audio media packets and the video media packets. When it is the packets turn, network buffer 230 transmits (318) the packets to terminal buffer 204.

[043] Upon receiving the packets, terminal buffer 204 of terminal 102 can store the packets until it is the packets turn to be provided to media player 202. While only buffer 230 is illustrated, one of ordinary skill in the art will appreciate that one or more separate buffers can exist for each of the audio media packets and the video media packets. When it is the packets turn, buffer 204 provides (320) the packets to media player 202. In turn, media player 202 can extract the relevant data out of packets and provide this data to adaptive bitrate manager 108 in a subsequent RTCP receiver report.

[044] **FIG. 4** is a flowchart representing an exemplary method for processing an RTCP packet. Referring to **FIG. 4**, it will be readily appreciated by one of ordinary skill in the art that the illustrated procedure can be altered to delete steps or further include additional steps. It is assumed for this exemplary method that RTCP packet includes data concerning both audio and video media data. While both types exists, one of ordinary skill in the art will appreciate that RTCP data can include either audio or video data. After initial start step 400, an adaptive bitrate manager obtains (402) RTCP data,
which can include one or more RTCP receiver reports. This RTCP data can correlate to the quality and quantity of audio and video media packets received at a media player of a terminal. The RTCP data can include, among other things, a sequence number of a last packet received by the terminal, a timestamp corresponding to such packet, a number of bits sent, a round trip time, and number of packets lost during a transmission from the adaptive bitrate manager to the terminal. RTCP data can be obtained by receiving an RTCP report from the terminal and by cross-correlating the contents of the last received RTCP packet with the history of RTP packets stored at the adaptive bitrate manager.

[045] After receiving RTCP data, the adaptive bitrate manager estimates (404) network conditions of a streaming media network. To estimate the state of the network, the adaptive bitrate manager can combine data from the received RTCP data from step 402 and previously received RTCP data stored by the adaptive bitrate manager. Adaptive bitrate controller can estimate an MTT, a bitrate received, an RTTE, and a packet loss. The adaptive bitrate manager can use these estimates to implement several different control algorithms.

[046] After estimating the network conditions, the adaptive bitrate manager applies (406) stability criterion to determine the stability of the streaming media network. If needed, the stability criterion can assist in adjusting the bitrate for attempting to stabilize the streaming media network, e.g., such as avoiding buffer overflows in the network and underflows at the terminal. While any number of algorithms can be used to determine the stability criterion, one exemplary embodiment compares the estimated MTT with the estimated RTTE, both of which are estimated in step 404. If the MTT and
the RTTE remain close, the adaptive bitrate manager can use this comparison to
determine that the streaming media network can properly support the current bitrate.
Further, by comparing the bitrate received with the current bitrate session, the adaptive
bitrate manager can determine that the streaming media network can cope with the
load.

[047] After establishing the stability criterion, the adaptive bitrate manager
determines (408) whether the network is stable with respect to the current bitstream
based on estimation step 404 and/or stability criterion establishment step 406. If the
network is stable, the adaptive bitrate manager operates (410) in a steady state
condition by either maintaining or incrementally increasing the current bitrate. In some
embodiments, the optimal session bitrate can be computed by determining the
difference between the MTT and the RTTE and adjusting the session bitrate according
to the difference. For example, if the current session bitrate is less than a set target
session bitrate, the adaptive bitrate manager can incrementally increase the optimal
session bitrate if the values of the MTT and the RTTE are comparable. Then, the
adaptive bitrate manager provides (416) an optimal session bitrate for transmitting
media data to a terminal. After providing step 416, the method can proceed to end 418.

[048] If determining that the network is not stable, the adaptive bitrate manager
adjusts (412) the bitrate so that adaptive bitrate manager can reach a stable condition.
For example, in some embodiments, the adaptive bitrate manager can use the
estimated bitrate received from step 404 because, in some embodiments, the bitrate
received can be the best estimation of the actual bitrate that the network can support at
that particular point in time. Then, the adaptive bitrate manager provides (416) the
optimal session bitrate for transmitting media data to the terminal. After providing step 416, the method can proceed to end 418.

[049] FIG. 5 is a flowchart representing an exemplary method for processing optimal session bitrate data. Referring to FIG. 5, it will be readily appreciated by one of ordinary skill in the art that the illustrated procedure can be altered to delete steps or further include additional steps. It is assumed for this exemplary method that both audio and video media data exists. While both types exists, one of ordinary skill in the art will appreciate that either audio or video data can exist. After initial start step 500, an adaptive bitrate manager obtains (502) optimal session bitrate data for transmitting media data to a terminal.

[050] Upon receiving the optimal session bitrate data, the adaptive bitrate manager allocates (504) the optimal session bitrate between audio and video streams to produce an optimal audio bitrate and an optimal video bitrate. For example, this allocation could be based on a predetermined allocation, user preference, optimal performance data, privileging one type of data over the other, the amount of audio and video data to be provided, and/or any combination of the above. For example, the adaptive bitrate manager may privilege audio quality in a way that if a reduced bitrate is specified, the adaptive bitrate manager can reduce the video bitrate first and postpone reducing the audio bitrate as much as possible.

[051] Adaptive bitrate manager obtains (506) audio and video media data. In some embodiments, obtaining step 506 can occur prior to allocating step 504 or obtaining step 502. After allocating step 504 and obtaining step 506, the adaptive
bitrate manager encodes (508) the audio and video media data according to their respective allocated bitrate specified at step 504.

[052] After encoding the audio and video streams according to the allocated bitrate, the adaptive bitrate manager provides (510) the encoded audio and video media data for transmitting to the terminal. In some embodiments, an RTP packetization receives the encoded audio and video media data and translates this data into a packet format. RTP defines a standardized packet format for delivering audio and video over the Internet. Upon translating this data into a packet format, the RTP packetization can then transmit the audio and video media packets to the terminal. After providing the encoded audio and video media data, the method can proceed to end 512.

[053] The methods disclosed herein may be implemented as a computer program product, i.e., a computer program tangibly embodied in an information carrier, e.g., in a machine readable storage device or in a propagated signal, for execution by, or to control the operation of, data processing apparatus, e.g., a programmable processor, a computer, or multiple computers. A computer program can be written in any form of programming language, including compiled or interpreted languages, and it can be deployed in any form, including as a stand alone program or as a module, component, subroutine, or other unit suitable for use in a computing environment. A computer program can be deployed to be executed on one computer or on multiple computers at one site or distributed across multiple sites and interconnected by a communication network.

[054] In the preceding specification, the invention has been described with reference to specific exemplary embodiments. It will however, be evident that various
modifications and changes may be made without departing from the broader spirit and scope of the invention as set forth in the claims that follow. The specification and drawings are accordingly to be regarded as illustrative rather than restrictive. Other embodiments of the invention may be apparent to those skilled in the art from consideration of the specification and practice of the invention disclosed herein.
WHAT IS CLAIMED IS:

1. A method comprising:
   receiving a receiver report from a terminal;
   estimating one or more network conditions of a media network based at least in part on the receiver report;
   determining an optimal session bitrate based on the estimated one or more network conditions; and
   providing media data to the terminal according to the optimal session bitrate.

2. The method of claim 1, wherein determining the optimal session bitrate further comprises:
   establishing stability criterion based on the estimated one or more network conditions;
   determining the stability of the media network; and
   providing the optimal session bitrate based on the stability determination.

3. The method of claim 2, wherein establishing stability criterion further comprises comparing a media time in transit and a round trip time estimate for assisting with the stability determination.

4. The method of claim 2, wherein establishing stability criterion further comprises comparing a bitrate received with a current bitrate session.

5. The method of claim 2, further comprising maintaining or incrementally increasing a current bitrate when the stability of the media network is considered normal.
6. The method of claim 2, further comprising adjusting a current bitrate when the stability of the network is \textit{not} normal.

7. The method of claim 1, further comprising allocating the optimal session bitrate between audio media data and video media data to produce an optimal audio bitrate and an optimal video bitrate; and encoding audio and video media data according to the optimal audio bitrate and the optimal video bitrate.

8. The method of claim 7, wherein providing media data to the terminal includes providing the encoded audio media data and the encoded video media data based on the optimal audio bitrate and the optimal video bitrate.

9. A method comprising:

   receiving a receiver report from a terminal;

   estimating one or more network conditions of a media network based at least in part on the receiver report;

   determining the stability of the media network based on the estimations;

   controlling a bitrate based on the determination; and

   providing the bitrate to an encoder for transmitting media data according to the provided bitrate.

10. The method of claim 9, wherein determining the stability of the media network is based on establishing stability criterion.

11. The method of claim 10, wherein establishing stability criterion further comprises comparing a media time in transit and a round trip time estimate for assisting with the stability determination.
12. The method of claim 10, wherein establishing stability criterion further comprises comparing a bitrate received with a current bitrate session.

13. The method of claim 9, wherein controlling the bitrate includes maintaining or incrementally increasing a current bitrate when the stability of the media network is considered normal.

14. The method of claim 9, wherein controlling the bitrate includes adjusting a current bitrate when the stability of the network is considered not normal.

15. A method comprising:

   receiving an optimal session bitrate;

   allocating the optimal session bitrate between audio and video media to produce an optimal audio bitrate and an optimal video bitrate;

   encoding audio and video media data according to the optimal audio bitrate and the optimal video bitrate; and

   providing the encoded audio and video data for transmittal to a terminal.

16. The method of claim 15, further comprising dropping frames of the encoded video data.

17. The method of claim 15, wherein allocating the optimal session bitrate between audio and video media is based on privileging either the audio media or the video media over the other.

18. A system comprising:

   a terminal, having a media player, configured to provide a receiver report;

   an adaptive bitrate manager configured to receive the receiver report, estimate one or more network conditions based at least in part on the receiver report, determine
an optimal session bitrate based on the estimated one or more network conditions, and
provide media data to the terminal based on the optimal session bitrate.

19. The system of claim 18, wherein the adaptive bitrate manager further
comprises an adaptive bitrate controller for receiving the receiver report and calculating
an optimal session bitrate.

20. The system of claim 19, wherein the adaptive bitrate manager further
comprises an encoder for obtaining the optimal session bitrate, allocating the optimal
session bitrate between audio and video media to produce an optimal audio bitrate and
an optimal video bitrate, encoding audio and video data according to the optimal audio
bitrate and the optimal video bitrate, and providing the encoded audio and video data for
transmittal to the terminal.

21. A computer readable storage medium storing instruction that, when
executed by a computer, cause the computer to perform a method for processing a
receiver report, the method comprising:

   receiving the receiver report from a terminal;

   estimating one or more network conditions of a media network based at least in
   part on the receiver report;

   determining the stability of the media network based on the estimations;

   controlling a bitrate based on the determination; and

   providing the bitrate to an encoder for transmitting media data according to the
   provided bitrate.
22. A computer readable storage medium storing instruction that, when executed by a computer, cause the computer to perform a method for processing an optimal session bitrate, the method comprising:

receiving the optimal session bitrate;

allocating the optimal session bitrate between audio and video media to produce an optimal audio bitrate and an optimal video bitrate;

encoding audio and video media data according to the optimal audio bitrate and the optimal video bitrate; and

providing the encoded audio and video data for transmittal to a terminal.

23. A terminal comprising:

a buffer that receives media data packets transmitted by an adaptive bitrate manager over a media network; and

a media player that receives media data packets and provides a receiver report to the adaptive bitrate manager, which receives the receiver report, estimates one or more network conditions of the media network based at least in part on the receiver report, determines an optimal session bitrate based on the estimated one or more network conditions, and provides media data to the buffer according to the optimal session bitrate.
