(No Model.)

J. B. MORRIS & G. VOLL.
DEVICE FOR ELEVATING AND LOWERING ELECTRIC LAMPS.

UNITED STATES PATENT OFFICE.

JOHN B. MORRIS AND GEORGE VOLL, OF CINCINNATI, OHIO; SAID VOLL ASSIGNOR TO SAID MORRIS.

DEVICE FOR ELEVATING AND LOWERING ELECTRIC LAMPS.

SPECIFICATION forming part of Letters Patent No. 428,401, dated May 20, 1890.

Application filed February 1, 1890. Serial No. 338,933. (No model.)

To all whom it may concern:

Be it known that we, JOHN B. MORRIS and GEORGE VOLL, citizens of the United States of America, and residents of the city of Cincinnati, in the county of Hamilton and State of Ohio, have invented certain new and useful Improvements in Devices for Elevating and Lowering Electrical Lamps, of which the following is a specification.

The various features of our invention and the several advantages resulting from their use, conjointly or otherwise, will be apparent from the following description and claims.

In the accompanying drawings, making a 15 part of this application, and to which reference is hereby made, Figure 1 is a top view of a windlass and its accompanying mechanism embodying our improvements. This figure also illustrates a common means for sus-20 taining our invention—viz., a telegraph-pole and also shows the preferred mode of attaching our improved windlass to said pole. In this figure the upper part of the pole is cut off, so as to the better illustrate the mode of ap-25 plying our improved windlass to said pole. Fig. 2 is a side elevation of the windlass and its accompanying mechanism and of the portion of the pole shown in Fig. 1. Fig. 3 is a vertical central section of the same, taken in 30 the plane of the dotted line 3 3 of Fig. 2, and looking toward that face of the section which faces toward the left in Fig. 2. Fig. 4 is a vertical transverse section taken in the plane of the dotted line 4 4 of Fig. 3, and looking 35 toward the adjacent end of the windlass, and showing in section the axial shaft actuating said windlass, and showing also in section the tooth of the dog, which at will engages the circular rack at the other end of the wind-The dotted lines on this figure indicate the sliding dog, whose tooth engages the rack of the windlass. From this view the supports of the windlass and the poles aforesaid are omitted. Fig. 5 shows an elevation of the ad-45 justable clutch for operating the windlass and of the handle for operating the clutch, and Fig. 6 shows an elevation of the free end of the clutch and of a part of the said handle. Fig. 7 is a view in perspective of the side and 50 rear of the upper portion of the dog, which at

will engages the rack of the windlass.

It is here stated for the benefit of those needing information that the electric light or lamp, known ordinarily as the "arc light," is held aloft at an elevation desirable for the 55 best utilization of the light by a wire rope running over a pulley or equivalent device and extended down to within easy reach of a person standing upon the floor or pavement. This wire is there wound upon a windlass. 60 To lower the lamp the windlass is turned so as to unwind the rope from the windlass, and to elevate the lamp the windlass is turned so as to wind up the rope.

As heretofore constructed, a common pawl 65 was pivoted at one end to a fixed part of the frame, the free end of this pawl engaging a common ratchet on the exterior of the periphery of a wheel or ring attached to the windlass. This old device was very imperfect and 70 defective, as unless protected by an encompassing-box or other defensive inclosure it was insecure from manipulation by persons unauthorized to operate it. Children or thoughtless or mischievous adults in passing 75 would lift the pawl, thereby freeing the windlass therefrom. The weight of the arc lamp pulling on the rope would then cause the unfettered windlass to turn and unwind the said rope. The arc light would at the same 80 time rapidly descend, thereby not only endangering its own integrity, but also putting in jeopardy the lives of passers-by who accidentally might come into such contact with the electrical current passing through the 85 lamp as to form a part of a direct electrical circuit or a powerful induced circuit.

Our invention not only obviates the above disadvantage, but presents other and novel advantages, hereinafter set forth.

A indicates the windlass, having an axial shaft E fixed thereto and extending beyond each end of the windlass. Beyond the rear end of the windlass this shaft is journaled in a bearing piece or arm B, and in front of the front end of the windlass the shaft is there journaled in another bearing or arm B. The shaft E passes through this last-named arm B, and the end portion of the shaft, formed as hereinafter described, projects in front of said arm B. The arms B are suitably supported. They are preferably, as shown, rig-

idly united to a back piece B'. Ordinarily this back piece B' and the arms B are cast

together and are integral.

Where the windlass and its accompanying 5 mechanism is to be supported by a telephone or telegraph post, or, like post B3, circular in cross-section, the rear surface of the piece B' will be concave, as shown, so as to fit the convexity of the post. The back piece B' being 10 placed against the side of the post at a suitable height thereon, it is secured to the post by screws B² B² passing through the back piece and into the post. A screw-hole in the upper part of the back piece B' receives one 15 of these screws B², and a screw-hole in the lower portion of the back piece receives another screw B². It is not necessary, however, that the securing of the back B' to the post B³ be limited to any particular mode. 20 back B' is preferably made sufficiently long to extend up some distance above the windlass and down some distance below the latter, first, for the purpose of giving the back a greater bearing on the post, thereby secur-25 ing the windlass more firmly in position, and, secondly, for the purpose of enabling the screws respectively located in said upper and lower portions of the back piece to be conveniently reached for insertion or withdrawal. The windlass A is a hollow one. At the central portion of each end A2 of said windlass, where the shaft E passes through it, it is preferably provided with an annular flange A^3 , extending from the end A^2 of the wind-35 lass inward toward the opposite end thereof. These flanges A³ afford a larger bearing on the shaft and strengthen the windlass at its point of junction with the shaft. One of these flanges A³ (in the present illustrative instance 40 the forward one) is also at E' perforated radially to the longitudinal axis of the windlass, and this perforation is interiorly provided with a screw-thread and receives a setscrew E^2 engaging the screw-thread of the 45 perforation. The shaft being placed in position in the windlass, as shown more particularly in Fig. 3, the set-screw E² is screwed through the perforation E and into a screwthreaded recess E³ (see Fig. 3) in the shaft.

50 The head of this screw E² is seen in position through opening A⁵ in Fig. 1. The shaft is thus secured in position and the windlass is thereby rigidly connected to the shaft, so that the rotation of the shaft will rotate the wind-55 lass. An annular flange, similar to the flange

Ass. An annular flange, similar to the flange As, is preferably also extended beyond the forward end of the windlass as far as the front face of the adjacent peripherial rim A' of the windlass and gives additional strength

60 to the windlass in the neighborhood of the shaft. The set-screw E² is reached and turned through an opening A⁴ in the peripheral shell of the windlass. This opening A⁴ also performs another function soon to be mentioned.

65 A second opening A⁵ is present in the shell, preferably in about the same vertical plane (when the axis of the windlass is horizontal,

as shown) as the opening A^4 . The opening A^5 is just large enough to allow the passage through it of the wire or other rope or cord F 70 which is to be used on the windlass. The opening A^4 is large enough to allow the knotted end of said rope F to pass through it.

In practice, the proper length of rope, including its knot, to be used having been 75 ascertained, the cord is cut of such length. Its free end next the windlass is now passed into the windlass through the opening A^5 , closely fitting the latter, and is then passed up out of the windlass through the opening 80 A⁴, and drawn out a sufficient extent to enable a knot to be made out of this free end of said rope. The knot being formed on this end of the rope, the latter is pulled upon above the opening A4 and the knot pulled through 85 opening A4 and into the interior of the windlass, and there remains, as it is too large to pass out through the opening A⁵ of the windlass. The rope is thus securely and quickly fastened to the windlass, and at the same 90 time the securing-knot is out of the way and cannot interfere with the coiling of the rope on the windlass or the uncoiling of said rope therefrom. The rope may obviously be quickly untied from the windlass when it (the 95 rope) is uncoiled, and is relieved of the weight of the arc light it ordinarily sustains.

The forward end of the windlass is provided with a circular rack C, having teeth C' and recesses C2, the adjacent teeth being sepa- 100 rated by a recess C2. The number of teeth will preferably vary with the change in the diameter of the windlass. The circles between which those ends of each recess C2 which are nearest to and farthest from the 105 shaft E are located are concentric with the longitudinal axis of shaft E, and the same is true of the circle in which is located that end of each tooth which is nearest the shaft E. This rack, for the sake of compactness and 110 strength, occupies a recess in the front end of the windlass, and the front end A² of the windlass and its annular flanges around the shaft are set back, as shown, while the annular rim A' of the windlass is kept forward, 115 so that its front face is flush with that side or face of each tooth C' which faces toward the front arm B. This rim A' is connected to the peripheral shell of the cylinder or an extension thereof, substantially as shown.

The peripheral shell of the windlass and the rims A' and ends A², annular flanges A³, and rack C are preferably cast in one piece,

and hence are integral.

At the lower portion of the front face of 125 the arm B is an extension or lug B⁴ for enabling the sliding dog D, hereinafter mentioned, to be locked to the arm B. The main part D' of this dog D slides against the front of the arm B, and in the present position of 130 the parts the movement is a vertically reciprocating one. An arm D² of this dog D extends through a vertical slot B⁷ in the arm B, and the rear end of this arm D² at and close

428,401

to the inner face of the arm B carries a tooth D³. This tooth D³ is wider than the slot B⁵—that is to say, extends to the right beyond the right edge of said slot and to the left besond the left edge of said slot. Hence it cannot, when in the position shown, pass through the said slot B⁵; but it slides up and down on the inner face of the arm B when the arm D² slides in slot B⁵, and the main part D' of the dog D slides on the outer face of the arm B. The main part D' of the dog is at its lower end provided with a vertical recess D⁴, located directly over the lug B⁴ of arm B, and of a size to receive said lng B⁴

of a size to receive said lng B⁴.

Below the recess D⁴ and to one side of the vertical plane thereof a lng D⁵ is rigidly secured to and extends forward from the front face of the portion D' of the sliding dog D. The object of this lng D⁵ is to enable the dog to be locked to the arm B. Through this lng is a horizontal opening D⁶, large enough to receive the hasp of the padlock or equivalent lock aforementioned. The recesses C² are substantially of the same width. The tooth D² is of a size to readily slide within any of the recesses C² and to closely fit against the sides of the same, these sides being the sides of the adjacent teeth C'. When the dog is elevated, the tooth has entered one of said recesses

30 and the rotation of the windlass is prevented.

The location of the lug D⁵ on the dog D is

such that when the dog is elevated, its tooth engaging the ratchet, the lug D⁵ is alongside of the lug B⁴ of the arm B and the perforation B⁵ of lug B⁴. The hasp of a padlock difficult to pick being passed through these openings and the padlock being locked, the windlass is securely locked in position and cannot be moved unless the padlock is picked by an experienced locksmith, or the windlass or its accompanying part broken by the blows of a sledge or other heavy instrument. When the padlock is unlocked and removed and the wind-45 lass turned to wind up the cord sufficiently to take the pull or tension of the rope, and

consequently the pressure of the windlass and rack C from the tooth D³ of the dog D, the latter will fall, and the tooth D³, coming out 50 of the recess C², the windlass is then free to rotate and the cord to unwind. When the dog D falls, the lug B⁴ of the arm B comes within the recess D⁴ of the dog D, thereby steadying the latter and also preventing the further 55 descent of the dog. In the main portion D' of the dog is a vertical slot D³ of a width just sufficient to admit the front end portion of the shaft E, and this slot is sufficiently long

to allow the dog D to reciprocate vertically, 60 as far as already described. The shaft thereby aids in steadying the dog in its vertical movement.

In the front end of the shaft E is an axial recess W'. In this end of the shaft are also 65 one or more recesses W². These recesses are preferably of less depth than the recess W', and are located around the recess W'. Two

of said recesses W2 are amply sufficient. A crank-handle H, consisting of shank H', carrying at one end a suitable handle H2 and at 70 the other the clutch portion H³, is of use in connection with the recesses W' W² of the shaft E. The length of the handle H² and eluteh portion H3 are at right angles to the length of the shank and are preferably lo- 75 cated on the opposite sides thereof. clutch portion H³ consists of the central axial projection H⁴ and the wings or lugs H⁵. There are as many lugs H5 as there are recesses W2 of shaft E. Each of these lugs fits any one 80 of the recesses W2 of the shaft E, and the axial projection H⁴ fits the axial recess W' When the windlass is to be rotated, the padlock being unlocked and detached, the clutch portion H3 is fitted to the front or clutch end 85 of the shaft E, the parts H⁴ H⁴ respectively fitting the respective recesses W² and the axial projection H4 entering the axial recess This projection H⁴ holds the positive and negative parts of the clutch in line. The 90 dog being dropped and its tooth being disengaged from the rack C, the windlass, by means of the crank H, is rotated in the desired direction. When the rope is subjected to a tension from the weight of the are light 95 and the windlass is thus urged to rotate, the pressure of the windlass and rack upon the tooth of the dog will check its ready descent until a pressure is applied to the handle of the crank in the direction of winding up the 100 rope on the windlass equal to the tendency exerted by the tension of the rope to turn the windlass in a direction to unwind it. The pressure of the rack C upon the tooth D³ of the dog is thereby relieved, and the dog will 105 fall by its own weight. Thereupon the windlass can be rotated as desired. The dog D is then elevated and thus engages the rack C. The hasp of the padlock is passed through the openings in lugs D^5 and B^4 and the pad- 110 lock locked. The windlass is now securely locked in a stationary position.

It will be observed that our invention is

It will be observed that our invention is compact in construction, simple and effective in operation, secure from manipulation of 115 those not authorized to handle the windlass, and cheap of manufacture. It will also be observed that the parts co-operate in a very simple and novel manner to accomplish a number of valuable functions.

While the various features of our invention are preferably employed together, one or more of them may be employed without the remainder, and in so far as applicable one or more of them may be employed in connection 125 with windlasses other than the one herein specifically set forth.

What we claim as new and of our invention, and desire to secure by Letters Patent, is—

1. The windlass and shaft supported on 130 bearing B B, and circular rack carried by the windlass, and dog D, having a portion D' located at the front side of bearing B, arm D², sliding in slot B⁷ of said bearing and carry-

ing the tooth D³, located at the inside of said bearing B and wider than said slot, and means, substantially as described, for holding the said tooth in engagement with said rack, substantially as and for the purposes specified.

2. The windlass and shaft supported on bearings, and circular rack connected to said windlass, and reciprocating dog upheld by arm B, the tooth of the dog when advanced engaging said rack, the dog carrying lug D⁵, and the arm having lug B⁴ for the reception of the locking bolt or hasp of a lock, substantially as and for the purposes specified.

3. The windlass having circular rack whose teeth point toward the axis of the windlass, a shaft on which said windlass is axially secured, bearings for said shaft, one of which bearings carries dog D, one part of which slides outside of said bearing, the dog having the arm D² located in a slot in said bearing and carrying tooth D³, located at the inner side of said bearing for engagement with said rack, the outer portion D⁵ of the dog being provided with lug D⁴ and recess D⁵, and the bearing B, carrying lug B⁴, substantially as and for the purposes specified.

4. The windlass having circular rack whose teeth point toward the axis of the windlass, a

shaft on which said windlass is axially secured, bearings for said shaft, one of which 30 bearings carries dog D, one part of which slides outside of the said bearing, the arm D², located in a slot in said bearing and carrying tooth D³, located at the inner side of said bearing for engagement with said rack, 35 and means for locking the dog in position, substantially as described, the dog being provided with slot D¹, through which passes the front end of the windlass-shaft, the latter being there formed for engagement with a crank, 40 substantially as and for the purposes specified.

5. The combination of the windlass, shaft thereof, bearings, circular rack, reciprocating dog having slot D⁷, through which passes the said shaft, the dog having recess D⁴ and lug 45 D⁵, and the arm B, having lug B⁴, the shaft at its front end having axial recess W', and recess or recesses W², and the crank having clutch portion H³, having axial extension H⁴, and extension or extensions H⁵, substantially 50 as and for the purposes specified.

JOHN B. MORRIS. GEORGE VOLL.
