Title: ELECTROLYZER AND MEMBRANES

Abstract: An electrochemical device converts CO₂ into various products such as CO, HCO⁻, H₂CO₃, H₂CO₂, CH₃OH, CH₃CO₂⁻, CH₃CO₂⁻, CH₃CH₂OH, CH₃COOH, CH₃CH₂OH, CH₃CHOH, CO₂, CO₂, H₂CO₂, CH₂COOH, CH₃CO₂⁻, CH₂COOH, and CH₂COOH. The device is made up of an anode, a cathode, and a Helper Membrane. In some embodiments, the device can also contain a catalytically active element. In some embodiments, the device is able to achieve a faradaic efficiency above 50% and CO₂ conversion current density over 20 mA/cm² at a cell voltage of 3.0 V. In some embodiments, the Helper Membrane comprises a polymer containing an imidazolium ligand, a pyridinium ligand, or a phosphonium ligand.
ELECTROLYZER AND MEMBRANES

Statement of Government Interest

[0001] This invention was made, at least in part, with U.S. government support under ARPA-E Contract No. DE-AR-0000345 and the Department of Energy under Contract No. DE-SC0004453. The government has certain rights in the invention.

Cross-Reference to Related Application(s)

Field of the Invention

[0003] The field of the invention is electrochemistry. The devices and systems described involve the electrochemical conversion of carbon dioxide into useful products, the electrolysis of water, fuel cells and electrochemical water purification.

Background of the Invention

[0004] There is a desire to decrease carbon dioxide (CO2) emissions from industrial facilities and power plants as a way of reducing global warming and protecting the environment. One solution, known as carbon sequestration, involves the capture and storage of CO2. Often the CO2 is simply buried. It would be beneficial if instead of simply burying or storing the CO2, it could be converted into another product and put to a beneficial use.

[0005] Over the years, a number of electrochemical processes have been suggested for the conversion of CO2 into useful products. Some of these processes and their related catalysts are discussed in U.S. Patent Nos. 3,959,094; 4,240,882; 4,349,464; 4,523,981; 4,545,872; 4,595,465; 4,608,132; 4,608,133; 4,609,440; 4,609,441; 4,609,451; 4,620,906; 4,668,349; 4,673,473; 4,711,708; 4,756,807; 4,818,353; 5,064,733; 5,284,563; 5,382,332; 5,457,079; 5,709,789; 5,928,806; 5,952,540; 6,024,855; 6,660,680; 6,664,207; 6,987,134; 7,157,404; 7,378,561; 7,479,570; U.S. Patent App. Pub. No. 2008/0223727; Hori, Y., "Electrochemical CO2 reduction on metal electrodes", Modern Aspects of Electrochemistry 42 (2008), pages 89-189; Gattrell, M. et al. "A review of the aqueous electrochemical reduction of CO2 to hydrocarbons at copper", Journal of Electroanalytical Chemistry 594 (2006), pages 1-19; and DuBois, D., Encyclopedia of Electrochemistry, 7a, Springer (2006), pages 202-
Processes utilizing electrochemical cells for chemical conversions have been known for years. Generally a electrochemical cell contains an anode, a cathode and an electrolyte. Catalysts can be placed on the anode, the cathode, and/or in the electrolyte to promote the desired chemical reactions. During operation, reactants or a solution containing reactants are fed into the cell. Voltage is then applied between the anode and the cathode, to promote the desired electrochemical reaction.

When an electrochemical cell is used as a CO2 conversion system, a reactant comprising CO2, carbonate or bicarbonate is fed into the cell. A voltage is applied to the cell, and the CO2 reacts to form new chemical compounds.

Several different cell designs have been used for CO2 conversion. Most of the early work used liquid electrolytes between the anode and cathode while later scientific papers discussed using solid electrolytes.

U.S. Patent Nos. 4,523,981; 4,545,872; and 4,620,906 disclose the use of a solid polymer electrolyte membrane, typically a cation exchange membrane, wherein the anode and cathode are separated by the cation exchange membrane. More recent examples of this technique include U.S. Patent Nos. 7,704,369; 8,277,631; 8,313,634; 8,313,634; 8,313,634; 8,313,634; 8,313,634; 8,414,758; 8,500,987; 8,500,987; 8,500,987; 8,524,066; 8,562,811; 8,568,581; 8,592,633; 8,658,016; 8,663,447; 8,721,866; and 8,696,883. In these patents, a liquid electrolyte is used in contact with a cathode.

free cathode in a cation exchange membrane style CO2 electrolyzer although it fails to teach a liquid free cathode. Instead, a liquid solution is fed into the cathode in the experiments discussed in PRAKASH.

[0011] In a liquid free cathode electrolyzer no bulk liquids are in direct contact with the cathode during electrolysis, however there can be a thin liquid film on or in the cathode. In addition the occasional wash or rehydration of the cathode with liquids may occur. Advantages of using a liquid free cathode included better CO2 mass transfer and reduced parasitic resistance.

[0012] Dewolf, D., et al. "The electrochemical reduction of CO2 to CH4 and C2H4 at Cu/Nafion electrodes (solid polymer electrolyte structures)" *Catalysis Letters* 1 (1988), pages 73-80 ("DEWOLF"), discloses the use of a liquid free cathode in a cation exchange membrane electrolyzer: an electrolyzer with a cation-conducting polymer electrolyte membrane separating the anode from the cathode. DEWOLF reports an observed maximum faradaic efficiency (the fraction of the electrons applied to the cell that participate in reactions producing carbon containing products) of 19% for CO2 conversion into useful products and a small steady state current of 1 mA/cm².

[0013] Various attempts have been made to develop a dry cell to be used in a CO2 conversion system, as indicated in Table 1 below. However, a system in which the faradaic efficiency in a constant voltage experiment is greater than 32% has not been achieved. Furthermore, the reported rates of CO2 conversion current (calculated as the product of the faradaic efficiency for CO2 conversion and the current in the cell after 30 minutes of operation) have been less than 5 mA/cm²: too small for practical uses.

[0014] There are a few reports that claim higher conversion efficiencies. In
particular, Shironita, S., et al., "Feasibility investigation of methanol generation by CO2 reduction using Pt/C-based membrane electrode assembly for a reversible fuel cell", *J. Power Sources* 228 (2013), pages 68-74 ("SHIRONITA I"), and Shironita, S., et al., "Methanol generation by CO2 reduction at a Pt-Ru/C electrocatalyst using a membrane electrode assembly", *J. Power Sources* 240 (2013), pages 404-410 ("SHIRONITA II"), reported "coulombic efficiencies" up to 70%. However, coulombic efficiency is different from faradaic efficiency. A system can have a high coulombic efficiency for the production of species adsorbed on the electrocatalyst, but may only observe a small faradaic efficiency (0.03% in SHIRONITA I and SHIRONITA II) for products that leave the catalyst layer. This phenomena is adequately explained in Rosen, B.A., et al., "In Situ Spectroscopic Examination of a Low Overpotential Pathway for Carbon Dioxide Conversion to Carbon Monoxide", *J. Phys. Chem. C*, 116 (2012), pages 15307-15312, which found that when CO2 is reduced to adsorbed CO during CO2 conversion by cyclic voltammetry, most of the CO does not leave the electrolyzer.

[0015] Recently, U.S. Patent Application Publication No. US2012/0171583 (the '583 publication) disclosed a cation exchange membrane design that could be run with a liquid free cathode. The application states that a "system may provide selectivity of methanol as part of the organic product mixture, with a 30% to 95% faradaic yield for carbon dioxide to methanol, with the remainder evolving hydrogen." However, the application does not provide data demonstrating a 30% to 95% faradaic yield. Furthermore, in trying to repeat the experiment, a steady state faradaic efficiency near zero during room temperature electrolysis was observed. These results are further laid out in Comparison Example 1 below.
In conclusion, faradaic efficiencies of less than 30% are not practical. What is needed is a process that has a faradaic efficiency of at least 50%, preferably over 80%. Furthermore, a device with a low CO2 conversion current is impractical. What is needed is a device with a CO2 conversion current of at least 25 mA/cm².

**Summary of the Invention**

The low faradaic efficiencies and conversion currents seen in current CO2 electrolyzers with liquid free cathodes can be overcome by an anion exchange membrane electrolyzer with an anode and cathode separated by a Helper Membrane. Helper Membranes can increase the faradaic efficiency of the cell. They can also allow product formation at lower voltages than without the Helper Membrane.

In at least some embodiments the Helper Membrane can include an imidazolium, pyridinium, or phosphonium ligand.

A membrane can be classified as a Helper Membrane if it meets the following test:

1. A cathode is prepared as follows:
   a. A silver ink is made by mixing 30 mg of silver nanoparticles (20-40 nm, 45509, Alfa Aesar, Ward Hill,
MA) with 0.1 ml deionized water (18.2 Mohm, EMD Millipore, Billerica, MA) and 0.2 ml isopropanol (3032-16, Macron Fine Chemicals, Avantor Performance Materials, Center Valley, PA). The mixture is then sonicated for 1 minute.

b. The silver nanoparticle ink is hand painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power Inc., New Castle, DE) covering an area of 2.5 cm x 2.5 cm.

2. An anode is prepared as follows:
   a. RuO2 ink is made by mixing 15 mg of RuO2 (11804, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm Millipore), 0.2 ml isopropanol (3032-16, Macron) and 0.1 ml of 5% Nafion solution (1100EW, DuPont, Wilmington, DE)
   b. The RuO2 ink is hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm.

3. A 50-300 micrometer thick membrane of a "test" material is made by conventional means such as casting or extrusion.

4. The membrane is sandwiched between the anode and the cathode with the silver and ruthenium oxide catalysts facing the membrane.

5. The whole assembly is mounted in Fuel Cell Technologies (Albuquerque, NM) 5 cm² fuel cell hardware with serpentine flow fields.

6. CO2 humidified at 50°C is fed into the cathode at a rate of 5 seem, 3.0 V is applied to the cell, and the output composition is
analyzed after the cell has been running for 30 minutes at room temperature.

7. Selectivity is calculated as follows:

\[
\text{Selectivity} = \frac{\text{(CO Production rate)}}{\text{(CO production rate} + \text{H}_2\text{production rate)}}
\]

where the CO and H₂ production rates are measured in standard cubic centimeters per minute (seem) leaving the electrolyzer.

[0021] If Selectivity is greater than 50%, and the CO₂ conversion current at 3.0 V is 20 mA/cm² or more, the membrane containing the material is a Helper Membrane, for which:

\[
(\text{CO}_2 \text{ conversion current}) = (\text{Total cell current}) \times (\text{Selectivity})
\]

[0022] An electrochemical device for converting CO₂ to a reaction product includes an anode, a cathode, and an anion-conducting polymer electrolyte membrane interposed between the anode and the cathode, wherein at least a portion, if not the entire of polymer electrolyte membrane, is a Helper Membrane. In some embodiments the membrane is essentially immiscible in water.

[0023] Reaction products include but are not limited to CO, HCO⁻, H₂CO, (HCO₂)⁻, H₂CO₂, CH₃OH, CH₄, C₂H₄, CH₃CH₂OH, CH₃COO⁻, CH₃COOH, C₂H₆, (COOH)₂, (COO⁻)₂, H₂C=CHCOOH, and CF₃COOH.

[0024] When the cathode is run essentially liquid free in an electrochemical device comprising a Helper Membrane, the faradic efficiency is at least 50%. In some embodiments the Helper Membrane comprises a polymer containing at least one of an imidazolium ligand, a pyridinium ligand, and a phosphonium ligand.
[0025] In some embodiments, the device also contains a Catalytically Active Element such as Au, Ag, Cu, Sn, Sb, Bi, or In.

[0026] In some embodiments the membranes are between 25 and 1000 micrometers thick.

[0027] In some embodiments, the membranes contain reinforcing polymers such polybenzimidazole (PBI), poly(p-phenylene oxide) (PPO), polyamide (Nylon), polyethylene (PE), or related reinforcing polymers.

Brief Description of the Drawings

[0028] FIG. 1 is a diagram of a typical electrochemical cell.

[0029] FIG. 2 shows the synthetic route for imidazolium based polymers. Imidazolium refers to positively charged imidazole ligands.

Detailed Description of Preferred Embodiment(s)

[0030] It is understood that the process is not limited to the particular methodology, protocols and reagents described herein, as these can vary as persons familiar with the technology involved here will recognize. It is also to be understood that the terminology used herein is used for the purpose of describing particular embodiments only, and is not intended to limit the scope of the process. It also is to be noted that as used herein and in the appended claims, the singular forms "a," "an," and "the" include the plural reference unless the context clearly dictates otherwise. Thus, for example, a reference to "a linker" is a reference to one or more linkers and equivalents thereof known to those skilled in the art. Similarly, the phrase "and/or" is used to indicate one or both stated cases can occur, for example, A and/or B includes (A and B) and (A
Unless defined otherwise, technical and scientific terms used herein have the same meanings as commonly understood by one of ordinary skill in the art to which the process pertains. The embodiments of the process and the various features and advantageous details thereof are explained more fully with reference to the non-limiting embodiments and/or illustrated in the accompanying drawings and detailed in the following description. It should be noted that the features illustrated in the drawings are not necessarily drawn to scale, and features of one embodiment can be employed with other embodiments as the skilled artisan would recognize, even if not explicitly stated herein.

Any numerical value ranges recited herein include all values from the lower value to the upper value in increments of one unit, provided that there is a separation of at least two units between any lower value and any higher value. As an example, if it is stated that the concentration of a component or value of a process variable such as, for example, size, angle size, pressure, time and the like, is, for example, from 1 to 98, specifically from 20 to 80, more specifically from 30 to 70, it is intended that values such as 15 to 85, 22 to 68, 43 to 51, 30 to 32, and the like, are expressly enumerated in this specification. For values which are less than one, one unit is considered to be 0.0001, 0.001, 0.01 or 0.1 as appropriate. These are only examples of what is specifically intended and all possible combinations of numerical values between the lowest value and the highest value are to be treated in a similar manner.

Moreover, provided immediately below is a "Definitions" section, where certain terms related to the process are defined specifically. Particular methods, devices, and materials are described, although any methods and
materials similar or equivalent to those described herein can be used in the practice or testing of the process.

Definitions

[0034] The term "electrochemical conversion of CO2" as used here refers to any electrochemical process where carbon dioxide, carbonate, or bicarbonate is converted into another chemical substance in any step of the process.

[0035] The term polymer electrolyte membrane refers to both cation exchange membranes, which generally comprise polymers having multiple covalently attached negatively charged groups, and anion exchange membranes, which generally comprise polymers having multiple covalently attached positively charged groups. Typical cation exchange membranes include proton conducting membranes, such as the perfluorosulfonic acid polymer available under the trade designation NAFION from E. I. du Pont de Nemours and Company (DuPont) of Wilmington, DE.

[0036] The term "anion exchange membrane electrolyzer" as used here refers to an electrolyzer with an anion-conducting polymer electrolyte membrane separating the anode from the cathode.

[0037] The term "liquid free cathode" refers to an electrolyzer where there are no bulk liquids in direct contact with the cathode during electrolysis. There can be a thin liquid film on or in the cathode, however, and occasional wash, or rehydration of the cathode with liquids could occur.

[0038] The term "faradaic efficiency" as used here refers to the fraction of the electrons applied to the cell that participate in reactions producing carbon containing products.
[0039] The term "EMIM" as used here refers to 1-ethyl-3-methylimidazolium cations.

[0040] The term "Hydrogen Evolution Reaction" also called "HER" as used here refers to the electrochemical reaction $2H^+ + 2e^- \rightarrow \frac{1}{2}H_2$.

[0041] The term "MEA" as used here refers to a membrane electrode assembly.

[0042] The Term "CV" refers to cyclic voltammetry.

[0043] The term "Millipore water" is water that is produced by a Millipore filtration system with a resistivity of at least 18.2 megaohm-cm.

[0044] The term "SPEEK" as used here refers to sulfonated poly (ether ether ketone).

[0045] The term "PVA" as used here refers to polyvinyl alcohol.

[0046] The term "PEI" as used here refers to polyethylenimine.

[0047] The term "GC" as used here refers to a gas chromatograph.

[0048] The term "imidazolium" as used here refers to a positively charged ligand containing an imidazole group. This includes a bare imidazole or a substituted imidazole. Ligands of the form:

![Imidazolium Ligand](image-url)
where R_i - R_5 are selected from hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryl, and polymers thereof are specifically included.

[0049] The term "pyridinium" as used here refers to a positively charged ligand containing a pyridine group. This includes a bare pyridine or a substituted pyridine. Ligands of the form

\[
\text{where } R_6 - R_{10} \text{ are selected from hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryl, heteroalkylaryl, and polymers thereof are specifically included.}
\]

[0050] The term "phosphonium" as used here refers to a positively charged ligand containing phosphorus. This includes substituted phosphorus. Ligands of the form:

\[
P^+ (R_{12} R_{13} R_{14} R_{15})
\]

where R_{12} - R_{15} are selected from hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryl, heteroalkylaryl, and polymers thereof are specifically included.

**Specific Description**

[0051] Generally an electrochemical cell contains anode 50, cathode 51 and
electrolyte 53 as indicated in FIG. 1. A membrane 52 can also be included in the cell. Catalysts may be placed on anode 50, and/or cathode 51, and/or in electrolyte 53 to promote the desired chemical reactions. During operation, reactants or a solution containing reactants is fed into the cell. Then a voltage is applied between the anode and the cathode, to promote an electrochemical reaction.

[0052] Alternately, when the device is used as a fuel cell, reactants or a solution containing reactants is fed into the cell, and a voltage spontaneously develops between the anode and cathode. This voltage can produce a current through an external circuit connecting the anode and cathode.

[0053] When an electrochemical cell is used as a CO2 conversion system, a reactant comprising CO2, carbonate or bicarbonate is fed into the cell. A voltage is applied to the cell, and the CO2 reacts to form new chemical compounds.

[0054] The present electrochemical device for the electrochemical conversion of CO2, water, carbonate, and/or bicarbonate into another chemical substance has an anode, a cathode, and a Helper Membrane.

[0055] In some embodiments there are no, or substantially no, bulk liquids in contact with the cathode during cell operation, and the faradaic efficiency for CO2 conversion is at least 33%, more preferably at least 50%, or most preferably at least 80%.

[0056] The device can also include at least one Catalytically Active Element. "Catalytically Active Element" as used here refers to a chemical element that can serve as a catalyst for the electrochemical conversion of CO2 or another species of interest in a desired reaction. In particular, the device can include one or more of the following Catalytically Active Elements: V, Cr, Mn, Fe, Co, Ni,
Cu, Sn, Zr, Nb, Mo, Ru, Rh, Pd, Ag, Cd, Hf, Ta, W, Re, Ir, Pt, Au, Hg, Al, Si, In, Ti, Pb, Bi, Sb, Te, U, Sm, Tb, La, Ce, and Nd. Research has established that Pt, Pd, Au, Ag, Cu, Ni, Fe, Sn, Bi, Co, In, Ru and Rh work well with Au, Ag, Cu, Sn, Sb, Bi, and In working especially well. The products of the reaction can include, among other things: CO, HCO\(^-\), H\(_2\)CO, (HCO\(_2\))^-, H\(_2\)CO\(_2\), CH\(_3\)OH, CH\(_4\), C\(_2\)H\(_4\), CH\(_3\)CH\(_2\)OH, CH\(_3\)COO\(^-\), CH\(_3\)COOH, C\(_2\)H\(_6\), (COOH)\(_2\), (COO\(^-\))\(_2\), H\(_2\)C=CHCOOH, CF\(_3\)COOH, other organic acids, carbonates, di-phenyl carbonate, and polycarbonates.

[0057] Without further elaboration, it is believed that persons familiar with the technology involved here using the preceding description can utilize the invention to the fullest extent. The following examples are illustrative only, and are not meant to be an exhaustive list of all possible embodiments, applications or modifications of the invention.

**Specific Example 1**

[0058] Specific Example 1 illustrates a procedure to create an electrolyzer with a Helper Membrane. The embodiment of Specific Example 1 demonstrates improved performance over earlier electrochemical cells used for CO\(_2\) conversion.

[0059] Measurements were conducted in an electrolysis cell with an anode, cathode, and anion-conducting polymer electrolyte membrane held in Fuel Cell Technologies 5 cm\(^2\) fuel cell hardware with serpentine flow fields.

[0060] The cathode in Specific Example 1 was prepared as follows. Silver ink was made by mixing 30 mg of silver nanoparticles (20-40 nm, 45509, Alfa Aesar, Ward Hill, MA) with 0.1 ml deionized water (18.2 Mohm, EMD Millipore, Billerica, MA) and 0.2 ml isopropanol (3032-16, Macron Fine
Chemicals, Avantor Performance Materials, Center Valley, PA). The mixture was then sonicated for 1 minute. The silver ink was then hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power Inc., New Castle, DE) covering an area of 2.5 cm x 2.5 cm.

[0061] The anode in Specific Example 1 was prepared as follows. RuO2 ink was made by mixing 15 mg of RuO2 (11804, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm Millipore), 0.2 ml isopropanol (3032-16, Macron) and 0.1 ml of 5% Nafion solution (1100EW, DuPont, Wilmington, DE). The RuO2 ink was then hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power, Inc.) covering an area of 2.5 cm x 2.5 cm.

[0062] The PSMMIM membrane was prepared following the synthetic route in FIG. 2. "PSMMIM" refers to a co-polymer of polystyrene and poly l-(p-vinylbenzyl)-3-methyl-imidazolium:

\[
\begin{align*}
\text{polystyrene} & \quad \text{poly l-(p-vinylbenzyl)-3-methyl-imidazolium} \\
\end{align*}
\]

where X\(^-\) is an anion and m > 0 and n > 0.

[0063] The first inhibitor free styrene was prepared by washing styrene (Sigma Aldrich, Saint Louis, MO) with two equal volumes of 7.5% aqueous sodium hydroxide. The inhibitor free styrene was then washed with four equal volumes of water to make sure it was neutralized, and was then dried over anhydrous magnesium sulfate. Inhibitor TBC in 4-vinylbenzyl chloride (4-VBC) was removed by extraction with 0.5% potassium hydroxide solution until
a colorless extract was obtained. This extract was washed with water until neutral and then was dried over anhydrous magnesium sulfate.

[0064] Poly(4-vinylbenzyl chloride-co-styrene) was then synthesized by heating a solution of inhibitor free styrene (Sigma-Aldrich) (10.0581 g, 96.57 mmol) and 4-vinylbenzyl chloride (Sigma-Aldrich) (6.2323 g, 40.84 mmol) in chlorobenzene (Sigma-Aldrich) (15 ml) at 60-65°C in an oil bath for 12-18 hours under argon gas with AIBN (α,α'-Azoisobutyronitrile, Sigma-Aldrich) (0.1613 g, 0.99 wt% based on the total monomers weight) as initiator. The copolymer was precipitated in CH3OH/THF (methanol/tetrahydrofuran) and dried under vacuum.

[0065] Polystyrene methyl-methylimidazolium chloride (PSMMIM 2.3: 1) was synthesized by adding 1-methylimidazole (Sigma-Aldrich) (2.8650 g, 0.0349 mol) to the solution of the poly(4-VBC-co-St) (5.0034g) in anhydrous N,N-Dimethylformamide (DMF) (Sigma-Aldrich) (30 mL). The mixture was then stirred at room temperature for 0.5-1 hour, and then heated at 110-120°C for 50.3 hours to form a PSMMIM 2.3:1 solution.

[0066] "4-VBC-co-St" or "poly(4-vinylbenzyl chloride-co-styrene)" as used here refers to a co-polymer of styrene and 4-vinylbenzyl chloride:

[0067] The membranes were prepared by casting the PSMMIM solution prepared above directly onto a flat glass surface. The thickness of the solution
on the glass was controlled by a film applicator (MTI Corporation, Richmond, CA) with an adjustable doctor blade. The membranes were then dried in a vacuum oven at 80°C for 300 minutes, and then 120°C for 200 minutes. Chloride ion in the membranes was removed by soaking the membranes in 1 M KOH solution for 24 hours.

[0068] The resultant membrane was tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The membrane was sandwiched between the anode and the cathode with the metal layers on the anode and cathode facing the membrane, and the whole assembly was mounted in a Fuel Cell Technologies 5 cm² fuel cell with serpentine flow fields.

[0069] CO2 humidified at 50°C was fed into the cathode at a rate of 5 seem, 3.0 V were applied to the cell, and the output composition was analyzed with an Agilent 6890 gas chromatograph (GC)/TCD (Agilent Technologies, Santa Clara, CA) equipped with a Carboxen 1010 PLOT GC column (30 m x 320 um) (Sigma Aldrich). No heating was applied to the cell.

[0070] Initially the cell produced 100 mA/cm², but the current dropped and held steady at 80 mA/cm² after a few minutes of operation. GC analysis after 30 minutes of operation showed that the output of the cell contained CO2, CO and a small amount of hydrogen. Selectivity was calculated at 94% where:

\[
\text{Selectivity} = \frac{\text{(CO Production rate)}}{\text{(CO production rate} + \text{H}_2\text{ production rate)}}
\]

[0071] Therefore PSMMIM is properly classified as a Helper Membrane.

[0072] In a second trial, water was fed into the anode of the cell to keep the PSMMIM hydrated. In that case the membrane was able to maintain over 90%
selectivity for 200 hours.

[0073] During both runs the leakage current was checked and was negligible. Furthermore there were no other products on the cathode. As such, the faradaic efficiency was equal to the Selectivity.

**Comparative Example 1**

[0074] Comparative Example 1 measured the steady state current and faradaic efficiency of an electrolyzer constructed following the teachings of the '583 publication, which claimed to disclose a system that "may provide selectivity of methanol as part of the organic product mixture, with a 30% to 95% faradaic yield for carbon dioxide to methanol, with the remainder evolving hydrogen." However the '583 publication fails to provide data demonstrating a 30% to 95% faradaic yield when the cathode is liquid free. In Comparative Example 1 a cell was built following the teachings in the '583 publication and the faradaic efficiency was measured at room temperature with a liquid free cathode.

[0075] Following the teachings in the '583 publication, the cathode was prepared as follows. First a platinum nanoparticle ink was made by mixing 10 mg of platinum black (12755, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm Millipore) and 0.2 ml isopropanol (3032-16, Macron). The mixture was then sonicated for 1 minute. The platinum nanoparticle ink was then hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm.

[0076] The platinum catalyst layer was then coated with a thin layer of poly (4-vinylpyridine) (P4VP, average MW: -60,000, Sigma Aldrich) by brushing 0.2 ml of 1% P4VP ethanol solution. Then the platinum catalyst layer was
immersed in 1 M H₂SO₄ solution (A300C-212, Fisher Chemical, Pittsburg, PA) to protonate pyridine.

[0077] The anode was prepared as in Specific Example 1. Specifically, RuO₂ ink was made by mixing 15 mg of RuO₂ (11804, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm Millipore), 0.2 ml isopropanol (3032-16, Macron) and 0.1 ml of 5% Nafion solution (1100EW, DuPont). The RuO₂ ink was then hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm.

[0078] Next a proton exchange membrane (Nafion 117, DuPont) was sandwiched between the anode and cathode with the metal coatings facing the membrane, and the whole assembly was mounted in Fuel Cell Technologies 5 cm² fuel cell hardware with serpentine flow fields.

[0079] The cell was tested using the procedures in Specific Example 1. Specifically CO₂ humidified at 50°C was fed into the cathode at a rate of 5 seem, 3.0 V were applied to the cell, and the output composition was analyzed with an Agilent 6890 gas chromatograph (GC)/TCD equipped with a Carboxen 1010 PLOT GC column (30 m x 320 um). No heating was applied to the cell.

[0080] The total cell current was found to be 80 mA/cm² but no methanol or other CO₂ reduction products could be detected. Instead hydrogen was the only product detected by GC. There was no evidence for methanol condensation in the tubing. Based on the measurements, the selectivity and faradaic efficiency of a cell constructed following the teachings of the '583 publication with a liquid free cathode is near zero. The CO₂ current is also near zero at room temperature.

[0081] Note that the GC results show that the methanol concentration in the gas phase is negligible, and methanol cannot condense at room temperature.
until the partial pressure of methanol in the gas phase reaches about 13 kPa, where 13 kPa is the vapor pressure of methanol at room temperature.

[0082] SHIRONITA I also was unable to detect CO2 reduction products in a similar experiment, but was able to detect products when heating the cell to 90°C. However in any case the faradaic efficiency was still low.

[0083] Table 1 lists the observed faradaic efficiencies and CO2 conversion currents at room temperature for various membranes and catalyst(s) combinations for various cells disclosed in prior research as well as the results from Specific Example 1 and Comparative Example 1. The faradaic efficiencies were calculated after 1 hour in a steady state, constant voltage experiment. In some cases higher efficiencies are reported by cycling the potential. As can be seen, the use of the Helper Membrane raised the faradaic efficiency by roughly a factor of 3 and the product current by a factor of 16.

Comparative Example 2

Comparative Example 2 was conducted to determine whether Nafion, sulfonated Poly(Ether Ether Ketone) "SPEEK", polyvinyl alcohol (PVA), polyethylenimine (PEI), CMI-7000, AMI 7001, phosphoric acid doped PBI or Neosepta membranes act as Helper Membranes when pretreated as described in the earlier literature as described in Table 1.

Nafion 117 was purchased from Ion Power Technologies, Inc., of Wilmington, DE. It was boiled in 5% H2O2 for 1 hour and it was then boiled in Millipore water for 1 hour. The Nafion 117 was then boiled in 0.5 M sulfuric acid for an hour, and then boiled again in Millipore water for 1 hour.

Neosepta BP-1E was purchased from Ameridia Division of Eurodia Industrie S.A. in Somerset, NJ. It was pretreated by dipping it in water as recommended by the manufacturer. It was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The selectivity was 34%, below the 50% require to be classified as a Helper Membrane.

CMI-7000 and AMI-700 I were purchased from Membranes International Inc. of Ringwood, NJ. An alkali doped AMI-700 I was prepared following the procedure outlined in Aeshala, L., et al., "Effect of cationic and anionic solid polymer electrolyte on direct electrochemical reduction of gaseous CO2 to fuel", Journal of CO2 Utilization 3 (2013), pages 49-55 ("AESHALA I"). First the AMI-700 I was soaked in a 0.5 molar potassium hydroxide (KOH) solution overnight to create basic sites in the membrane. Excess KOH was then washed off by soaking the membrane in water for 6 hours. The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the
present application. Both the selectivity (25%) and product current (2.5 mA/cm$^2$) were low, as reported in Table 2 below, indicating that an alkali doped AMI-700 I membrane as pretreated according to AESHALA I is not a Helper Membrane.

Similarly, the acid doped CMI-7000 was pretreated following the procedure outlined in AESHALA I. First the membrane was soaked in 0.5 M H$_2$SO$_4$ overnight, then it was soaked in water for 6 hours. The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. GC analysis showed only traces of CO formation, indicating that this membrane is not a Helper Membrane.

Alkali doped PVA was synthesized following the procedure outlined in Aeshala, L., et al., "Effect of solid polymer electrolyte on electrochemical reduction of CO$_2$", Separation and Purification Technology 94 (2012), pages 131-137 ("AESHALA II"). PVA (stock #363081) was purchased from Sigma-Aldrich Corporation. 9 grams of PVA were dissolved in 90 ml of water at 90°C. The solution was cast onto a petri dish. After the cast films had dried, they were immersed in glutaraldehyde (10% in acetone solutions) mixed with small quantities of catalytic HCl for one hour to encourage cross-linking. The films were then rinsed several times with Millipore water, activated by immersion in 0.5 M NaOH for 24 hours, and then rinsed before use. The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. While the selectivity (52%) was relatively high, the product current (7.5 mA/cm$^2$) was low, as reported in Table 2 below, indicating that an alkali doped PVA membrane as pretreated according to AESHALA II is not a
Helper Membrane.

[0090] An alkali doped PVA/PEI composite was synthesized following the procedure outlined in Aeshala, L., et al., "Electrochemical conversion of CO2 to fuels: tuning of the reaction zone using suitable functional groups in a solid polymer electrolyte", Phys. Chem. Chem. Phys. 16 (2014), pages 17588-17594 (AESHALA III). A PEI (item number 408727) was purchased from Sigma-Aldrich Corporation. 6 grams of PVA and 3 grams of PEI were dissolved in 90 ml of water at 90°C. The solution was cast onto a petri dish. After the cast films had dried, they were immersed in glutaraldehyde (10% in acetone solutions) mixed with small quantities of catalytic HC1 for one hour to encourage cross-linking. The films were then rinsed several times with Millipore water. They were then activated by immersion in 0.5 M NaOH for 24 hours and then rinsed before use.

[0091] The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. Both the selectivity (16%) and the product current (1.6 mA/cm²) were low, as reported in Table 2 below, indicating that an alkali doped PEI/PVA membrane as pretreated according to AESHALA III is not a Helper Membrane.

[0092] SPEEK was prepared following the procedure in the procedure outlined in AESHALA II. A PEEK film was purchased from CS Hyde Company (Lake Villa, IL). 1 g of the PEEK was exposed to 50 ml of concentrated sulfuric acid for 50 hours under constant agitation. All of the PEEK had dissolved at the end of the 50 hours and had converted to SPEEK. 200 ml of Millipore water was placed in an ice bath and allowed to cool to near 0°C. The SPEEK solution was then slowly poured into the Millipore water
under constant agitation. The SPEEK precipitated out of the water solution, was filtered, and was then washed multiple times to remove excess sulfuric acid. The SPEEK was then dried at 100°C for 8 hours in a vacuum oven. Next the SPEEK was dissolved in dimethylacetamide. The resultant solution was cast on a glass slide. The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. Both the selectivity (2.5%) and the product current (0.13 mA/cm²) were low, as reported in Table 2 below, indicating that a SPEEK membrane as pretreated according to AESHALA II is not a Helper Membrane.

[0093] Phosphoric Acid doped PBI was prepared as follows. PBI was purchased from PBI Performance Products, Inc. (Rock Hill, SC) and acid doped by immersing it in 0.5 M H₃PO₄ for 24 hours. It was then soaked in water for 1 hour to remove excess acid. The membrane was then tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. Again the current and selectivity were low.

[0094] Notice that Nafion, SPEEK, alkali doped PVA, alkali doped PVA/PEI, Acid doped CMI-7000, Alkali doped AMI-7001 Neosepta, and P-PBI are not Helper Membranes.

Specific Example 2

[0095] The object of this example was to determine whether changes in the membrane doping could activate a membrane for CO₂ conversion. AMI-7001 and CMI-7000 were chosen as test examples since they have the same polystyrene backbone as in PSMMIM and PSDMIM, but different amine groups, so they might be able to be activated.
The AMI-700 was pretreated by soaking the membrane in a 1 M NaCl solution for one hour, followed by soaking in water for about 3 hours.

The selectivity rose to 70%. The current density was still low (3.5 mA/cm²). So this membrane is still not a Helper Membrane but its performance is much better.

The CMI-7000 was pretreated using the same procedure. Again, the selectivity rose to 72%. The current density was still low (15 mA/cm²).

Still, it is likely that the current could be raised if thinner membranes were made with the same bulk composition as AMI-7001 and CMI-7000, and then the membranes were doped with NaCl. Such a membrane could be a Helper Membrane.

**Specific Example 3**

The objective of Specific Example 3 is to provide another example of a Helper Membrane.

Preparation of PSDMIM: Poly(4-vinylbenzyl chloride-co-styrene) was prepared as in Specific Example 2. 1,2-dimethylimidazole (Sigma-Aldrich) (2.8455 g, 0.0296 mol) is added to the solution of the poly(4-VBC-co-St) (5.0907 g) in anhydrous N,N-Dimethylformamide (DMF) (Sigma-Aldrich) (30 mL). The mixture was stirred at room temperature for 0.5-1 hour, and then heated at 110-120°C for 66.92 hours. PSDMIM was obtained as a yellowish solid after purification by precipitation into diethyl ether.

A PSDMIM membrane was formed as in Specific Example 2. Then the membrane was tested as in Specific Example 1. The results are given in Table 2 below. PSDMIM refers to a co-polymer of styrene and l-(p-
Specific Example 4

[0103] The objective of Specific Example 4 is to provide an example of a Helper Membrane with a pyridinium group.

[0104] Preparation of PSMP: poly(4-vinylbenzyl chloride-co-styrene) was prepared as in Specific Example 2. Pyridine (Sigma-Aldrich) is added to the solution of the poly(4-VBC-co-St) (5.0907 g) in anhydrous N,N-Dimethylformamide (DMF) (Sigma-Aldrich) (30 mL). The mixture was stirred at room temperature for 0.5 - 1 hour, and then heated at 110-120°C for 66.92 hours. PSMP was obtained as a brownish solid after purification by precipitation into diethyl ether. PSMP refers to a material that contains a co-polymer of styrene and l-(p-vinylbenzyl)-pyridinium.

[0105] A PSMP membrane was formed as in Specific Example 2. The resultant membrane did not have a uniform thickness, but the membrane was still suitable to test. The film was tested as in Specific Example 1 and qualified as a Helper Membrane.

[0106] Table 2 shows the faradaic efficacies and currents observed for the
Helper Membranes disclosed in this application along with those of the membranes discussed in earlier studies. In all cases the membranes were tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application.

**Specific Example 5**

[0107] The objective of this example was to examine the effects of the
fraction of the amine in the polymer on the performance. The Helper Membrane was made from methylimidazolium-poly(4-vinylbenzylchloride-co-styrene) chloride (PSMIM-C1) polymer solution of various compositions.

[0108] PSMIM-C1 solution (in anhydrous dimethylformamide) was prepared by a two-step reaction process: (1) Poly(4-VBC-co-St) synthesis from the reaction of styrene (St) with 4-vinylbenzyl chloride (4-VBC) in chlorobenzene under argon gas (S.J. Smith, Urbana, IL) protection with 2,2'-Azobis(2-methylpropionitrile) (AIBN) as initiator. (2) Poly(4-VBC-co-St) was reacted with 1-methylimidazole at 50-120°C for more than 48 hours to obtained PSMIM-C1 polymer solution.

[0109] Synthesis of poly(4-vinylbenzyl chloride-co-styrene): A solution of inhibitor free styrene (Sigma-Aldrich) (10.0581 g, 96.57 mmol) and 4-vinylbenzyl chloride (Sigma-Aldrich) (6.2323 g, 40.84 mmol) in chlorobenzene (Sigma-Aldrich) (15 ml) was heated at 60-65°C in an oil bath for 12-18 hours under argon gas with AIBN (Sigma-Aldrich) (0.1613 g, 0.99 wt% based on the total monomers weight) as initiator. The copolymer was precipitated in CH3OH/THF and dried under vacuum. VBC content in the copolymer was 38.26 wt%.

[0110] Synthesis of methylimidazolium-poly(4-VBC-co-St) chloride (MIM-poly(4-VBC-co-St)-Cl): 1-methylimidazole (Sigma-Aldrich) (2.8650 g, 0.0349 mol) was added to the solution of the poly(4-VBC-co-St) (5.0034 g) in anhydrous N,N-Dimethylformamide (DMF) (Sigma-Aldrich) (30 ml). The mixture was stirred at room temperature for 0.5-1 hour, and then heated at 110-120°C for 50.3 hours.

[0111] Membranes preparation: The membrane preparation steps were: (1) Cast PSMIM-C1 polymer solution prepared above onto a flat glass (8 cm x 10
cm) with a 0.1 to 1 ml pipette. (2) Put the glass plate with membranes in an oven (MTI Corporation); the membranes were then dried at 80°C for 4 hours and then 120°C for another 2 hours under the protection of nitrogen. (3) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in a 1 M KOH (Fisher Scientific, Fair Lawn, NJ) bath. Membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for complete anion exchange (Cl\(^-\) \rightarrow OH\(^-\)) before testing.

The synthesis procedure for the PSMIM-Cl polymer solution with VBC content of 38.26 wt% and the membrane fabrication procedure were used for the synthesis of PSMIM-Cl with VBC compositions of 46 wt% and 59 wt% respectively. The testing results of these membranes are summarized in Table 3 below. Membrane current density increases with increasing functional group VBC content in the copolymer, while mechanical strength of membranes get worse. The membrane with 59 wt% VBC is very soft and its mechanical strength is very weak.

Fitting the data to an exponential curve, and extrapolating to lower VBC content shows that the current will be above 20 mA/cm² whenever there is at least 15% VBC in the polymer. This corresponds to a styrene to (p-
vinylbenzyl)-3-methyl-imidazolium ratio of no more than 7.

**Specific Example 6**

[0114] The objective of this example is to provide examples of reinforced helper membranes. In particular, Helper Membranes will be provided made from blends of methylimidazolium-poly(4-vinylbenzylchloride-co-styrene) chloride (PSMIM-C1) and polymer matrix such as polybenzimidazole (PBI), poly(2,6-dimethyl-1,2-phenylene oxide) (PPO), Nylon 6/6, or polyethylene (PE).

[0115] PSMIM-C1 solution (in anhydrous dimethylformamide) was prepared by a two-step reaction process: (1) poly(4-VBC-co-St) was synthesized from the reaction of styrene (St) with 4-vinylbenzyl chloride (4-VBC) in chlorobenzene under argon gas (S.J. Smith) protection with 2,2'-Azobis(2-methylpropionitrile) (AIBN) as initiator; 2) poly(4-VBC-co-St) was reacted with imidazole at 50-120°C for more than 48 hours to obtained PSMIM-C1 solution.

[0116] PBI polymer solution was prepared by diluting 27.5264 g of about 26.6 wt% PBI solution (PBI Performance Products. Inc., Charlotte, NC) with anhydrous dimethylacetamide (DMAc) (Sigma Aldrich) to 78.3578 g. The concentration of the resulting PBI solution was 9.34 wt%.

[0117] Nylon 6/6 solution was prepared by adding 4.6065 g of Nylon 6/6 (Sigma Aldrich) into 24.3218 g of about 97% formic acid (Acros Organics, Geel, Belgium) and 2.5625 g anhydrous methanol (Avantor Performance Materials Inc.) mixture. Nylon pellets were allowed to dissolve for several hours at room temperature, then in a Branson 2510 sonication bath (Sonics Online, Richmond, VA) until a homogeneous white emulsion was obtained. The concentration of the resulting Nylon solution is 14.83 wt%.
10.2 wt% PPO solution was prepared by dissolving 0.5099 g of PPO (Sigma Aldrich) in 5 mL chlorobenzene (Fisher Scientific).

15 wt% PE solution was prepared by dissolving 4.5 g of PE (Sigma Aldrich) in 30 mL xylenes (Fisher Scientific). PE completely dissolved in xylenes at 70-80°C.

Preparation procedure of Helper Membrane #4 from blends of PSMIM-Cl and PBI: (1) Add 0.1 mL PBI polymer solution into 4 mL PSMIM-Cl solution (VBC content in the copolymer was 46 wt%) and light brown precipitate was immediately formed. The solid in the polymer solution was dispersed by ultra-sonication with an ultrasonic probe (tip diameter 3 mm) (Sonic & Materials, Inc., Newtown, CT) until a homogeneous brown emulsion was obtained. (2) Cast the resulting polymer solution on a glass plate (8 cm x 10 cm) with a 0.1 to 1 mL pipette. (3) Put the glass plate with membranes in an oven (MTI Corporation); the membranes were then dried at 80°C for 4 hours and then 120°C for another 3 hours under the protection of nitrogen. (4) After oven temperature cooled down to room temperature, take the membranes out and soaked in a 1M KOH (Fisher Scientific) bath, membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

The obtained light brown PSMIM-Cl and PBI blend membranes were transparent and homogeneous with very good mechanical strength.

The PSMIM-Cl and PBI blend membrane #4 preparation procedure was used for the preparation of PSMIM-Cl and PBI blend membranes #5, 6 and 7. The ratio of PSMIM-Cl solution to PBI solution was varied, as shown in Table 4 below.
The membranes were tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The testing results are summarized in Table 4 below.

Preparation procedure of Helper Membrane from blends of PSMIM-C1 and PPO: (1) Add 0.5 ml of 10.2 wt% PPO polymer solution into 4 ml of PSMIM-C1 solution (VBC content in copolymer was 46 wt%) and white precipitate was immediately formed. The solid in the polymer solution was dispersed by ultra-sonication with an ultrasonic probe (tip diameter 3 mm) (Sonic & Materials. Inc.) until no obvious large particles were observed. (2) The resulting polymer solution was cast on a glass plate (8 cm x 10 cm) with a 0.1 to 1 ml pipette. Polymer phase separation was observed. (3) The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 80°C for 4 hours and then 120°C for another 3 hours under the protection of nitrogen. (4) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in a 1 M KOH (Fisher
Scientific) bath, membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

[0125] The dried PSMIM-C1 and PPO blend membrane was transparent, and it turned white in KOH solution. The membrane mechanical strength was good.

[0126] The membranes were tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The testing results are summarized in Table 5 below.

[0127] Preparation procedure for Helper Membrane #9 from blends of PSMIM-C1 and Nylon: (1) Added 1 ml 14.83 wt% nylon polymer solution into 4 ml PSMIM-C1 solution (VBC content in copolymer was 38 wt%) and white precipitate was immediately formed. The solid in the polymer solution was dispersed by ultra-sonication with an ultrasonic probe (tip diameter 3 mm) (Sonic & Materials, Inc.) until a homogeneous polymer solution was obtained. (2) The resulting polymer solution was cast on a glass plate (8 cm x 10 cm) with
a 0.1 to 1 ml pipette. (3) The membrane was air dried in the hood at room
temperature overnight. (4) The glass plate with membranes was put in an oven
(MTI Corporation); the membranes were then dried at 80°C for 4 hours and
then 120°C for another 3 hours under nitrogen protection. (5) After the oven
temperature cooled down to room temperature, the membranes were taken out
and soaked in a 1 M KOH (Fisher Scientific) bath, then the membranes were
peeled off from the substrates and soaked in 1 M KOH solution for at least 24
hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

[0128] The obtained PSMIM-C1 and Nylon membrane was off-white and
homogenous with decent mechanical strength.

[0129] The PSMIM-C1 and Nylon blend membrane #9 preparation procedure
was used for the preparation of PSMIM-C1 and Nylon blend membranes #10.
The ratio of PSMIM-C1 solution to Nylon solution.

[0130] The membranes were tested and determined to meet the classification
as a Helper Membrane according to the test set forth in the Summary of the
Invention section of the present application. The testing results are summarized
in Table 6 below.

Preparation procedure for Helper Membrane #11 from blends of PSMIM-Cl and PE: (1) 1 ml 15 wt% PE hot polymer solution was added into 4 ml of PSMIM-Cl solution (VBC content in copolymer was 46 wt%) and a white precipitate was immediately formed. The solid in the polymer solution was dispersed by ultra-sonication with an ultrasonic probe (tip diameter 3 mm) (Sonic & Materials. Inc.) until a homogeneous polymer solution was obtained. (2) The resulting polymer solution was cast on a glass plate (8 cm x 10 cm) with a 0.1 to 1 ml pipette. Polymer phase separation was observed. (3) The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 80°C for 4 hours and then 120°C for another 3 hours under nitrogen protection. (4) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in a 1M KOH (Fisher Scientific) bath, then the membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

The obtained PSMIM-Cl and PE membrane was off-white with decent mechanical strength.
The PSMIM-Cl and PE blend membrane #11 preparation procedure was used for the preparation of PSMIM-Cl and PE blend membrane #12. The ratio of PSMIM-Cl solution to PE solution is shown in Table 7 below.

The membranes were tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The test results are summarized in Table 7 below.

Notice that these four polymer mixtures are Helper Membranes, and they are all stronger than PSMMIM.

Many polymers related to PBI, PPO, Nylon and PE could also be added to the membrane to improve its strength. PE is a polyolefm. Other polyolefms and chlorinated or fluorinated polyolefms could also be blended with PSMMIM to produce a helper catalyst. PBI contains cyclic amines in its repeat unit. Other polymers containing cyclic amines could also be blended with PSMMIM to produce a Helper Membrane. PPO contains phenylene groups. Other polymers containing phenylene or phenyl groups could also be blended
with PSMMIM to produce a Helper Membrane. Nylon contains amine and carboxylate linkages. Other polymers containing amine or carboxylate linkages could also be blended with PSMMIM to produce a Helper Membrane.

**Specific Example 7**

[0137] The objective of this example is to identify a Helper Membrane that does not contain styrene. In particular it will be shown that a terpolymer of methyl methacrylate (MMA), butyl acrylate (BA), and the 1-methyl imidazole adduct of VBC, which will be referred to as methylimidazolium-poly(vinylbenzylchloride-co-methyl methacrylate-co-butylacrylate) chloride (PVMBMIM-C1) is a Helper Membrane.

[0138] PVMBMIM-C1 solution was prepared by a two-step reaction process: (1) poly(VBC-co-MMA-co-BA) synthesis from the reaction of 4-vinylbenzyl chloride (VBC), methyl methacrylate (MMA) and butylacrylate (BA) in toluene under nitrogen gas (S.J. Smith) protection with 2,2’-Azobis(2-methylpropionitrile) (AIBN) as initiator; then (2) reacting poly(VBC-co-MMA-co-BA) with 1-methylimidazole at room temperature for more than 24 hours to obtained PVMBMIM-C1 polymer solution.

[0139] Synthesis of poly(4-vinylbenzyl chloride-co-methyl methacrylate-co-butylacrylate): monomers (Sigma-Aldrich) (MMA: 4.511 g, BA: 4.702 g, VBC: 4.701 g) were polymerized in toluene (Sigma-Aldrich) (25 ml) with AIBN (0.0811 g) as initiator. The reaction was kept at 50-55°C for 41.62 hours under nitrogen protection with vigorous stirring. Terpolymer was precipitated out in methanol (Avantor Performance Materials Inc.) and washed with methanol for several times. The obtained polymer powder was dried in an oven at 80°C for 2 hours and then 120°C for another 2 hours. 6.4319 g polymer powder was collected (yield: 46.23%). VBC content in the copolymer was 33.79 wt%.
[0140] Synthesis of methylimidazolium-poly(VBC-co-MMA-co-BA) chloride (PVMBMIM-C1): 1-methylimidazole (Sigma-Aldrich) (0.55 ml, 0.5616 g) was added to the solution of the poly(VBC-co-MMA-co-BA) (2.06 g) in anhydrous N,N-Dimethylformamide (DMF) (Sigma-Aldrich) (15 ml). The mixture was stirred at room temperature for more than 26 hours.

[0141] Membrane preparation: 1) PVMBMIM-C1 polymer solution prepared above was cast onto a flat glass (8 cm x 10 cm) with a 0.1 to 1 ml pipette. (2) The membrane was air dried at room temperature for overnight. (3) The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 80°C for 2 hours and then 120°C for another 2 hours under the protection of nitrogen. (4) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in a 1 M KOH (Fisher Scientific) bath. Membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for completely anion exchange (Cl⁻ → OH⁻) before testing.

[0142] The PVMBMIM-C1 membrane was transparent with very good mechanical strength. The membranes were tested according to the test set forth in the Summary of the Invention section of the present application with results set forth in Table 8 below.

The membranes were tested and determined to meet the classification as a Helper Membrane according to the test set forth in the Summary of the Invention section of the present application. The membrane supported 55 mA/cm² of CO₂ conversion current at an applied potential of 2.8 V. The selectivity was about 90%. Therefore, PVMBMIM is a Helper Membrane.

**Specific Example 8**

The objective of this example is to demonstrate that hydrophilic materials can be added to the membrane to improve water retention. In this example, hygroscopic oxide materials were introduced during the membrane preparation to improve water uptake and water retention in the membrane. Hygroscopic oxide materials include silica (SiO₂), zirconia (ZrO₂), and titania (TiO₂). In this example, zirconia was tested.

Zirconium (IV) propoxide (70 wt. % in propanol, 333972, Sigma-Aldrich) was mixed with the polymer solution prepared as set forth in Specific Example 1 for the synthetic route depicted in FIG. 2 to 15 wt% in DMF. The mixture was sonicated in an ultrasonic bath for 30 minutes to obtain a homogeneous solution. The solution containing zirconia was cast to form a membrane on a glass slide following the procedure set forth in Specific Example 1 for casting the PSMMIM solution. The membrane was dried at 80°C for 1 hour and 120°C for 30 minutes in a vacuum oven. Then the membrane was detached from the glass slide in 1 M KOH solution and allowed to exchange to the hydroxide form. The membrane was rinsed with deionized water to remove free KOH and was sandwiched between an Ag cathode and a RuO₂ anode following the procedure set forth in the Summary of the Invention section of the present application to classify as a Helper Membrane. The whole assembly was mounted in a Fuel Cell Technologies 5cm² fuel cell. The membrane showed 60
mA/cm² at 2.8 V with 84% selectivity so the membrane is a Helper Membrane.

**Specific Example 9**

[0146] The objective of this example is to demonstrate that a deliquescent material, ZnBr, can be added to the membrane to improve water retention.

[0147] The cathode was prepared as follows. First a silver nanoparticle ink was prepared via the addition of 50 mg of silver nanoparticles (20-40 nm, 45509, Alfa Aesar) to 0.8 mL of deionized water (18.2 Mohm, Millipore) and 0.4 mL of isopropanol (3032-16, Macron). The mixture was then sonicated for one minute. The resulting silver ink was air-brushed onto carbon fiber paper (Toray Paper 120, 40% wet-proofing, Toray Industries Inc., Tokyo, Japan) covering an area of 5 cm x 5 cm. This square was then cut into four equally-sized squares of 2.5 cm x 2.5 cm each.

[0148] The anode was prepared the same way in each cell, as follows. First a ruthenium oxide nanoparticle ink was prepared via the addition of 50 mg of R11O2 nanoparticles (11804, Alfa Aesar) to 0.8 mL of deionized water (18.2 Mohm, Millipore) and 0.4 mL of isopropanol (3032-16, Macron). The mixture was then sonicated for one minute. The resulting R11O2 ink was air-brushed onto carbon fiber paper (Toray Paper 120, 40% wet-proofing) covering an area of 5 cm x 5 cm. This square was then cut into four equally-sized squares of 2.5 cm x 2.5 cm each.

[0149] For the cell with ZnBr added to the membrane surface, 25 mg of ZnBr (Sigma Aldrich, 02128) were spread across the surface of a PSMMIM membrane prepared as set forth in Specific Example 5 for the synthesis of poly(4-vinylbenzyl chloride-co-styrene). For the cell with ZnBr incorporated into the membrane solution, 7.5 mg of ZnBr were added to 3 mL of membrane
solution prior to casting. The PSMMIM membrane was then cast and prepared in the typical fashion as described previously.

[0150] For each cell, the cathode, PSMIM membrane, and anode were sandwiched together such that the metal catalysts of each electrode faced the membrane. The assembly was mounted in a Fuel Cell Technologies 5 cm² fuel cell with serpentine graphite flow fields.

[0151] Each cell was tested by holding the cell at 2.8 V for at least one hour. Air was permitted to flow over the anode flow field while humidified CO₂ was passed through the cathode flow field at a flow rate of 15 secm.

[0152] In the case of the membrane with a ZnBr coating, the initial current was only 22 mA/cm² but it was very stable. No membrane dry-out was detected.

[0153] The membrane that had been soaked in ZnBr initially showed 60 mA/cm² current, but fell to 22 mA/cm² after about 1 hour.

[0154] Still, both membranes are Helper Membranes.

**Specific Example 10**

[0155] The objective of this experiment is to demonstrate that Helper Membranes are useful for water electrolyzers.

[0156] A 50-300 micron thick PSMMIM membrane was synthesized as in Specific Example 1. The membrane was sandwiched between the anode and the cathode with the catalysts facing the membrane. A cathode is prepared as follows: a cathode ink was made by mixing 30 mg of IrO₂ nanoparticles (A17849, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm, Millipore) and 0.4 ml isopropanol (3032-16, Macron). The mixture was then sonicated for 1 minute. The cathode ink was sprayed onto a gas diffusion layer (Sigracet 35 BC
GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm. An anode was prepared as follows: a catalyst ink was made by mixing 15 mg of Pt black (43838, Alfa Aesar) with 0.2 ml deionized water (18.2 Mohm Millipore), 0.2 ml isopropanol (3032-16, Macron). The anode catalyst ink was hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm. The whole assembly was mounted in Fuel Cell Technologies 5 cm² fuel cell hardware with serpentine flow fields. A 1 M KOH solution of water is fed to both cathode and anode chambers at a flow rate of 5 seem. The cell was run at room temperature either potential dynamically or at constant current. For instance, the current output was 300 and 400 mA/cm² at a cell potential of 1.8 V and 1.9 V, respectively.

[0157] The use of an anion exchange membrane also enables the use of non-precious metal as catalysts. Nickel foam (EQ-bcnf-16m, MTI) was used as both cathode and anode. A current density of 80 mA/cm² was achieved at a cell potential of 2 V and room temperature.

**Specific Example 11**

[0158] This example shows that Helper Membranes are also useful for alkaline membrane fuel cells.

[0159] Pt black (43838, Alfa Aesar) was used as the catalysts for both cathode and anode. The catalysts ink was made by mixing 15 mg of Pt black with 0.4 ml of anion exchange polymer solution (1 wt% in DMF) and was hand-painted onto a gas diffusion layer (Sigracet 35 BC GDL, Ion Power) covering an area of 2.5 cm x 2.5 cm. The electrodes were dried under vacuum at 120°C for 30 minutes. A 50-300 micrometer thick membrane prepared as set forth in Specific Example 1 for the preparation of the first inhibitor-free styrene was sandwiched between cathode and anode, with the respective catalysts facing the
membrane. The entire assembly was mounted in Fuel Cell Technologies 5 cm² fuel cell hardware with serpentine flow fields. \( \frac{3}{4} \) and \( \text{O}_2 \) were humidified via 350 cc water bottles at room temperature, and were fed to anode and cathode chambers at 20 ccm, respectively. The cell was run at room temperature and atmosphere pressure. The cell was conditioned by repeatedly applying a cell potential of 0.3 V and 0.6 V for 1 hour until the cell performance was stable. Currents of 60 mA and 150 mA were achieved at 0.6 V and 0.2 V, respectively. A power of 36 mW was attained at ambient conditions.

**Specific Example 12**

[0160] The objective of this example is to provide a Helper Membrane made from methylimidazolium-poly(2,6-dimethyl-1,4-phenylene oxide) bromide (PPOMIM-Br) polymer solution.

[0161] PPOMIM-Br solution was prepared by a two-step reaction process: (1) Methyl-brominated poly(2,6-dimethyl-1,4-phenylene oxide) (PPO-Br) synthesis from the reaction of poly (2,6-dimethyl-1,4-phenylene oxide) (PPO) with N-bromosuccinimide (NBS) in chlorobenzene under argon gas (S.J. Smith) protection with 2,2'-Azobis(2-methylpropionitrile) (AIBN) as initiator. (2) PPO-Br was reacted with 1-methylimidazole at room temperature to 60°C for more than 15 hours to obtained PPOMIM-Br polymer solution.

![Chemical Diagram]

[0162] Synthesis of methyl-brominated poly(2,6-dimethyl- 1,4-phenylene
oxide) (PPO-Br). PPO-Br #14 with low bromination ratio was synthesized according to the literature (Reactive & Functional Polymers 70 (2010) 944-950), a detail procedure can be summarized as follows: NBS (2.84g, 15.96 mmol) (Sigma-Aldrich) and AIBN (0.12g, 0.73 mmol) were added to a solution of PPO (2.839, 24.08 mmol) (Sigma-Aldrich) in chlorobenzene (200 ml). The mixture was stirred at 125-135°C for 4-6 hours under nitrogen protection, the reaction mixture was then added to excess methanol to precipitate the product. After filtration and washing with methanol for several times, the polymer was dried at room temperature under vacuum for more than 2 days. 2.45 g of light yellow powder was collected (yield: 51.14%). The bromination ratio of PPO-Br was calculated from the integration of the NMR methyl peak and methylene peak (18.3%):

\[
\frac{3 \times I_{CH_2}}{2 \times I_{CH_3} + \frac{1}{2} \times I_{CH_3}} \times 10^6
\]

[0163] PPO-Br membrane #14a with high bromination ratio was synthesized according to the literature (Journal of Membrane Science 425-426 (2013) 13 1-140), a detail procedure can be summarized as follows: NBS (6.27g, 35.2mmol) (Sigma-Aldrich) and AIBN (0.4g, 2.4 mmol) were added to a solution of PPO (2.89, 24.1 mmol) (Sigma-Aldrich) in chlorobenzene (160ml). The mixture was stirred at 125-135°C for 18 hours under nitrogen protection, the reaction mixture was then added to excess Methanol to precipitate the product. After filtration and washing with methanol for several times, the polymer was dried at room temperature under vacuum for more than 2 days. 3.04 g of light yellow powder was collected (yield: 63.4%). Bromination ratio: 56.6%

[0164] Synthesis of methylimidazolium-poly(2,6-dimethyl-1,4-phenylene oxide) bromide (PPOMIM-Br membrane #14): 1-methylimidazole (Sigma-
Aldrich) (0.37 ml, 4.6 mmol) was added to the solution of the PPO-Br membrane #14 (1.0g) in 15 ml tetrahydrofuran (THF) (Sigma-Aldrich) and 5 ml methanol (Avantor Performance Materials Inc.). The mixture was refluxed at 55-65°C for 18 hours.

[0165] Synthesis of methylimidazolium-poly(2,6-dimethyl-1,4-phenylene oxide) bromide (PPOMIM-Br membrane #14a): 1-methylimidazole (Sigma-Aldrich) (0.67 ml, 8.5 mmol) was added to the solution of the PPO-Br membrane #14a (1.5g) in 24 ml tetrahydrofuran (THF) and 8 ml methanol. The mixture was stirred at room temperature to 65°C for 18 hours. Brown polymer separated from the solution at the end of the reaction.

[0166] Membrane preparation: (1) Cast PPOMIM-Br #14 polymer solution prepared above onto a flat glass (8 cm x 10 cm) with a 0.1 to 1 ml pipette. (2) The membrane was air dried at room temperature for overnight for solvent evaporation. (3) The membrane was soaked in a 1 M KOH (Fisher Scientific) bath for at least 24 hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

[0167] PPOMIM-Br membrane #14a polymer solution was taken after 4 hours reaction of PPO-Br with 1-methylimidazole at room temperature for membrane casting. PPOMIM-Br membrane #14a membrane was very soft and mechanical strength was very weak. The text results are set forth in Table 9 below.
### Specific Example 13

**[0168]** The objective of this example is to determine whether a methylimidazolium-poly(4-vinylbenzylchloride) membrane with no styrene is also a Helper Membrane.

**[0169]** The objective of this example is to provide a Helper Membrane made from methylimidazolium-poly(vinylbenzylchloride) chloride (PVMIM-Cl) polymer solution.

**[0170]** PVMIM-Cl solution was prepared from commercial available poly(vinylbenzyl chloride) (PVBC) and 1-methylimidazole as shown in the structural diagram below.

```
[Diagram of the reaction between methylimidazole and PVBC leading to PVMIM-Cl]
```

**[0171]** Synthesis of methylimidazolium-PVBC (PVMIM-Cl): 1-methylimidazole (Sigma-Aldrich) (2.33 ml, 29.23 mmol) was added to the solution of the PVBC (Sigma-Aldrich) (4.9466 g) in anhydrous $N,N$-
Dimethylformamide (DMF) (Sigma-Aldrich) (40 mL). The mixture was stirred at room temperature for 46.9 hours. PVMIM-Cl polymer solution was not stable and not suitable for long time storage.

Membranes preparation: (1) Cast PVMIM-Cl polymer solution prepared above onto a flat glass (8 cm x 10 cm) with a 0.1 to 1 ml pipette. (2) Put the glass plate with membranes in an oven (MTI Corporation); the membranes were then dried at 80°C for 4 hours and then 120°C for another 2 hours under the protection of nitrogen. (3) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in a 1 M KOH (Fisher Scientific) bath. Membranes were peeled off from the substrates and soaked in 1 M KOH solution for at least 24 hours for complete anion exchange (Cl⁻ → OH⁻) before testing.

In this case, when the membrane was exposed to water, it swelled to form a gel-like structure which was too soft to test. So it is uncertain as to whether the membrane is a Helper Membrane. This example indicates that methylimidazolium-poly(4-vinylbenzylchloride membrane with no styrene, PBI or other copolymers is not a suitable membrane. Instead, at least 10% of one of another polymer such as styrene or PBI is needed to make a suitable membrane.

Specific Example 14

The objective of this example is to provide a Helper Membrane made from blends of poly(vinylbenzyl chloride) (PVBC) and polybenzimidazole (PBI).

Two methods were tried for the preparation of Helper Membrane from PVBC and PBI. (1) A PBI and PVBC crosslinked membrane was prepared, which was then reacted with 1-methylimidazole. (2) PBI and PVBC were
crosslinked in the solution and 1-methylimidazole was added during the crosslinking process.

[0176] Membrane preparation procedure from the first method: (1) Prepared 2 wt% (in DMAc) PBI and 2 wt% PVBC (in DMAc) solution polymer solution. (2) Added 3.2 ml PBI (2 wt%) solution into 2 wt% PVBC solution (2 ml). (3) The mixtures were kept at room temperature and ultrasonicated for 1 hour. (4) The resulting polymer solution was cast on a glass plate (8 cm x 10 cm) with a 0.1 to 1 ml pipette. (5) The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 70°C overnight and then 120°C for another 3 hours under vacuum. (6) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in DI water. (7) The membrane was dried at 200°C for 1 hour. (8) The PVBC/PBI membrane was soaked in 1-methylimidazole solution for 2 days. (9) The membrane was rinsed with DI water and the membrane was then soaked in a 1 M KOH (Fisher Scientific) bath for at least 24 hours for complete anion exchange (Cl− −→ OH−) before testing.

[0177] The membranes were tested according to the test protocol set forth in the Summary of the Invention section of the present application with results set forth in Table 10 below.
Membrane preparation procedure:

1. 16.83 mmol PVBC was dissolved in 20 ml dimethylacetamide (DMAc).
2. 1.01 mmol PBI (in 15 ml DMAc) solution was added into the PVBC/DMAc solution.
3. A heater was turned on to increase temperature gradually to 90°C for crosslinking of PBI with PVBC; part of polymer solution turned into gel after 2-3 hours reaction.
4. The heater was turned off and let the solution cool to room temperature, then 15.1 mmol 1-methylimidazole was added to the polymer solution and the reaction was kept at room temperature for 4-6 hours.
5. The polymer solution was cast onto a flat glass plate (8 cm x 10 cm) with a 0.1 to 1 ml pipette.
6. The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 70°C overnight and then 120°C for another 3 hours under vacuum.
7. After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in 1 M KOH bath for at least 24 hours for complete anion exchange (Cl\(^-\) \(-\rightarrow\) OH\(^-\)) before testing.

The membranes were tested according to the test protocol set forth in the Summary of the Invention section of the present application with results set forth in Table 11 below.

[0178] Membrane #17 preparation procedure: (1) 16.83 mmol PVBC was dissolved in 20 ml dimethylacetamide (DMAc). (2) 1.01 mmol PBI (in 15 ml DMAc) solution was added into the PVBC/DMAc solution. (3) A heater was turned on to increase temperature gradually to 90°C for crosslinking of PBI with PVBC; part of polymer solution turned into gel after 2-3 hours reaction. (4) The heater was turned off and to let the solution cool to room temperature, then 15.1 mmol 1-methylimidazole was added to the polymer solution and the reaction was kept at room temperature for 4-6 hours. (5) The polymer solution was cast onto a flat glass plate (8 cm x 10 cm) with a 0.1 to 1 ml pipette. (6) The glass plate with membranes was put in an oven (MTI Corporation); the membranes were then dried at 70°C overnight and then 120°C for another 3 hours under vacuum. (7) After the oven temperature cooled down to room temperature, the membranes were taken out and soaked in 1 M KOH bath for at least 24 hours for complete anion exchange (Cl\(^-\) \(-\rightarrow\) OH\(^-\)) before testing.

[0179] The membranes were tested according to the test protocol set forth in the Summary of the Invention section of the present application with results set forth in Table 11 below.
This result shows that unlike the membrane that was 100% methylimidazolium-poly(vinylbenzylchloride), a membrane with 81.75% methylimidazolium-poly(vinylbenzylchloride) is still a Helper Membrane. Extrapolation of the data indicates that up to 90% methylimidazolium-poly(vinylbenzylchloride) can be present in the membrane, and still have suitable performance.

**Specific Example 15**

The objective of this example is to illustrate a procedure to convert CO2 to formic acid in an electrochemical device by using a tin cathode catalyst and the PBI/PSMIM-C1 anion exchange membrane #6 in Table 4 above.

The electrolysis was conducted in an electrolysis cell with an anode, a cathode and an anion exchange membrane assembled in a modified 5 cm² fuel cell hardware (Fuel Cell Technologies) with gas and liquid channels and serpentine flow fields.

The anode in this example was prepared as follows. A RuO2 ink solution was prepared by mixing 18 mg of RuO2 (11804, Alfa Aesar) and 2 mg of graphene nanoplatelets (A-12, Graphene Laboratories, Calverton, NY) with 0.4 ml deionized water (18.2 Mohm Millipore water), 0.4 ml isopropanol (3032-
16, Macron) and 0.14 ml of 5% Nafion solution (1100EW, DuPont). The RuO$_2$ ink was sonicated for 1 min and then hand-painted onto a gas diffusion layer (TGP-H-120 40% wet proofing Toray Paper, Fuel Cell Earth, Woburn, MA) with an area of 3.0 cm x 3.0 cm.

[0184] The cathode in this example was prepared as follows. A Sn ink solution was prepared by mixing 18 mg of Sn nanoparticles (60-80 nm) (SN-M-04-NP, American Elements, Los Angeles, CA) and 2 mg of graphene nanopowders (A-12, Graphene Laboratories) with 0.4 ml deionized water (18.2 Mohm Millipore water), 0.4 ml isopropanol (3032-16, Macron) and 0.14 ml of 5% Nafion solution (1100EW, DuPont). The Sn ink solution was sonicated for 1 min and then hand-painted onto a gas diffusion layer (TGP-H-120 40% wet proofing Toray Paper, Fuel Cell Earth) with an area of 3.0 cm x 3.0 cm.

[0185] The anion exchange membrane used for this test was PBI/PSMIM-C1 membrane #6, as described above in Table 4. Before use, the membrane was soaked in 1 M KOH solution for at least 12 hours.

[0186] The electrolyte solution was prepared with deionized water (18.2 Mohm Millipore water).

[0187] In this example, 10 mL of catholyte was subjected to recirculation run for 5 hours, while 20 mL anolyte was replaced with fresh anolyte solution after every 1 hour of electrolysis.

[0188] The formate produced was detected and analyzed as follows. The formate produced was first subjected to derivitization at 60°C for 1 hour in the presence of 2% sulfuric acid solution in ethanol. The product was then analyzed by an Agilent Technologies 6890N GC/5973 MS equipped with a Phenomenex Zebron ZB-WAX-Plus capillary GC column (L =30 m x I.D.= 0.25mm x df =
Electrolysis conditions and results are summarized in Table 12 below:

While particular elements, embodiments and applications of the present invention have been shown and described, it will be understood that the invention is not limited thereto since modifications can be made by those skilled in the art without departing from the scope of the present disclosure, particularly in light of the foregoing teachings.

The examples given above are merely illustrative and are not meant to be an exhaustive list of all possible embodiments, applications or modifications of the present electrochemical device. Thus, various modifications and variations of the described methods and systems of the invention will be apparent to those skilled in the art without departing from the scope and spirit of the invention. Although the invention has been described in connection with
specific embodiments, it should be understood that the invention as claimed should not be unduly limited to such specific embodiments. Indeed, various modifications of the described modes for carrying out the invention which are obvious to those skilled in the chemical arts or in the relevant fields are intended to be within the scope of the appended claims.
What is claimed is:

1. An electrochemical device for converting CO2 to a reaction product comprising:
   (a) an anode;
   (b) a cathode; and
   (c) a polymer electrolyte membrane interposed between the anode and the cathode, wherein at least a portion of the polymer electrolyte membrane is a Helper Membrane identifiable by applying a test comprising:
      (1) preparing a cathode comprising 6 mg/cm² of silver nanoparticles on a carbon paper gas diffusion layer;
      (2) preparing an anode comprising 3 mg/cm² of RuO₂ on a carbon paper gas diffusion paper;
      (3) preparing a polymer electrolyte membrane test material;
      (4) interposing the membrane test material between the anode and the cathode, the side of cathode having the silver nanoparticles disposed thereon facing one side of the membrane and the side of the anode having RuO₂ disposed thereon facing the other side of the membrane, thereby forming a membrane electrode assembly;
      (5) mounting the membrane electrode assembly in a fuel cell having reactant fluid flow channels;
      (6) directing a stream of CO₂ humidified at 50 °C into the reactant flow field channels facing the cathode;
      (7) applying a cell potential of 3.0 V via an electrical connection between the anode and the cathode;
      (8) measuring the current across the cell and concentration of
CO and H\textsubscript{2} at the exit of the cathode flow channel;

(9) calculating the CO selectivity as follows:

$$\text{Selectivity} = \frac{\text{CO production rate}}{\text{CO production rate} + \text{H}_2\text{production rate}}; \text{ and}$$

(10) identifying the membrane as a Helper Membrane if the average current density at the membrane is at least 20 mA/cm\textsuperscript{2} and the selectivity is at least 50\% at a cell potential of 3.0 V.

2. The electrochemical device of claim 1, wherein the polymer electrolyte membrane is entirely a Helper Membrane.

3. The electrochemical device of claim 1, wherein faradaic efficiency toward the desired reaction product is above 50\% when the cathode is operated essentially liquid free such that no bulk liquid is in direct contact with the cathode during electrolysis.

4. The electrochemical device of claim 1, wherein the Helper Membrane comprises a polymer containing at least one of an imidazolium ligand, a pyridinium ligand, and a phosphonium ligand.

5. The electrochemical device of claim 1, wherein the anode has a catalyst coating facing the membrane and the cathode has a catalyst coating facing the membrane.

6. The electrochemical device of claim 1, wherein the polymer electrolyte membrane is essentially immiscible in water.

7. The electrochemical device of claim 1, wherein the reaction product is selected from the group consisting of CO, HCO\textsuperscript{-}, H\textsubscript{2}CO, (HCO\textsubscript{2})\textsuperscript{-},
H2CO2, CH3OH, CH4, C2H4, CH3CH2OH, CH3COO-, CH3COOH, C6H6, (COOH)2, (COO-)2, H2C=CHCOOH, and CF3COOH.

8. The electrochemical device of claim 1, further comprising a Catalytically Active Element.

9. The electrochemical device of claim 8, wherein the Catalytically Active Element is selected from the group consisting of Au, Ag, Cu, Sn, Sb, Bi, Zn and In.

10. A polymer electrolyte membrane comprising a polymer in which at least one constituent monomer is (p-vinylbenzyl)-R, wherein R is selected from the group consisting of imidazoliums, pyridiniums and phosphoniums, and wherein the membrane comprises at least 15% and up to 90% polymerized (p-vinylbenzyl)-R by weight.

11. The membrane of claim 10, wherein the membrane comprises polystyrene.

12. The membrane of claim 10, wherein the membrane is between 25 and 1000 micrometers in thickness.

13. The membrane of claim 10, further comprising a copolymer of at least one of methyl methacrylate and butyl acrylate.

14. The membrane of claim 12, further comprising at least one of a polyolefin, a chlorinated polyolefin, a fluorinated polyolefin, and a polymer containing cyclic amines, phenyls, nitrogen and carboxylate (COO) groups in its repeating unit.

15. The membrane in claim 12, further comprising at least one of
polybenzimidazole, poly(p-phenylene oxide), a polyamide (Nylon) and polyethylene.

16. The membrane of claim 12 further comprising a hygroscopic material.

17. The membrane of claim 16 wherein the hygroscopic material comprises at least one of zirconium oxide, silica and alumina.

18. The membrane of claim 12, further comprising a deliquescent material.

19. The membrane of claim 10, wherein R is selected from at least one of:
   (a) imidazoliums of the formula:

   where R1 - R5 are each independently selected from the group consisting of hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryls, heteroalkylaryls, and polymers thereof;
   (b) pyridiniums of the formula:
where $R_6 - R_n$ are selected from the group consisting of hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryls, heteroalkylaryls, and polymers thereof; and

(c) phosphoniums of the formula:

$$P^+(R_i^2 R_3 R_4 R_5)$$

where $R_i^2 - R_5$ are selected from the group consisting of hydrogen, halides, linear alkyls, branched alkyls, cyclic alkyls, heteroalkyls, aryls, heteroaryls, alkylaryls, heteroalkylaryls, and polymers thereof.

20. The membrane of claim 19 wherein $R$ is an imidazolium, pyridinium, or polymer thereof wherein no aromatic nitrogen is attached to hydrogen.
