A method for non-invasive detection of coronary artery disease (CAD). The method includes acquiring a raw ECG signal from a patient, generating a denoised ECG signal by applying a first wavelet transform on the raw ECG signal, generating an artifact-free ECG signal by applying a second wavelet transform on the denoised ECG signal, generating a filtered ECG signal by applying a band-stop filter on the artifact-free ECG signal, extracting an averaged ECG signal of a plurality of averaged ECG signals from the filtered ECG signal, detecting an ST segment in the averaged ECG signal by applying a delineation algorithm on the averaged ECG signal, detecting an isoelectric line in the averaged ECG signal, determining an existence of CAD in the patient responsive to detecting a CAD detection condition, and determining a non-existence of CAD responsive to not detecting the CAD detection condition.

**NON-INVASIVE DETECTION OF
CORONARY ARTERY DISEASE****CROSS-REFERENCE TO RELATED
APPLICATION**

This application claims the benefit of priority from U.S. Provisional Patent Application Ser. No. 62/768,915, filed on Nov. 18, 2018, and entitled "A NOVEL SYSTEM AND APPARATUS FOR TIMELY AND NONINVASIVE DETECTION OF CORONARY ARTERY DISEASE (CAD) ONLY BY INTELLIGENT ANALYSIS OF ELECTROCARDIOGRAM (ECG)," which is incorporated herein by reference in its entirety.

TECHNICAL FIELD

The present disclosure generally relates to signal processing, and particularly, to biomedical signal processing.

BACKGROUND

Heart diseases are, generally, a leading cause of death worldwide. Coronary artery diseases (CADs) are among major heart diseases that cause myocardial ischemia and myocardial infarction (MI). A major cause of heart attack is a blockage of blood flow to heart muscles, caused by a damage or disease in a heart's major blood vessels (coronary arteries). Before an occurrence of a heart attack, a heart's myocyte may experience lack of enough oxygen due to a blockage of blood flow. A phase before an onset of any necrosis in myocyte and an occurrence of MI is called ischemia. Early detection of ischemia may be crucial because in most cases, effects of myocardial ischemia may be reversible if detected early enough. Myocardial ischemia is commonly seen as a warning sign of cardiac problems. Therefore, it may be beneficial for patients and cardiologists to be able to recognize signs and symptoms of ischemia before a permanent cardiac tissue death.

Electrocardiography (ECG) has been a major cardiovascular diagnostic tool. In spite of a rapid progress in development of new hardware and software approaches for ECG detection, cardiologists still mainly rely on direct visual assessment of ECG signals. However, in many myocardial ischemia cases such as silent ischemia and stable coronary heart disease, no specific changes may be observed in ECG, and therefore, due to a lack of diagnostic accuracy and frequent false alarms in ECG interpretation, electrocardiographic-based analysis of such patients may not be deemed reliable enough for cardiologists. There is, therefore, a need for a method for early detection of CAD by processing ECG signals that may include no observable change compared to normal ECG signals.

SUMMARY

This summary is intended to provide an overview of the subject matter of the present disclosure, and is not intended to identify essential elements or key elements of the subject matter, nor is it intended to be used to determine the scope of the claimed implementations. The proper scope of the present disclosure may be ascertained from the claims set forth below in view of the detailed description below and the drawings.

In one general aspect, the present disclosure describes an exemplary method for non-invasive detection of coronary artery disease (CAD). An exemplary method may include

2

acquiring a raw electrocardiography (ECG) signal from a patient, generating a denoised ECG signal by applying a first wavelet transform on the raw ECG signal, generating an artifact-free ECG signal by applying a second wavelet transform on the denoised ECG signal, generating a filtered ECG signal by applying a finite impulse response (FIR) filter on the artifact-free ECG signal, extracting an averaged ECG signal of a plurality of averaged ECG signals from the filtered ECG signal, detecting an ST segment and an isoelectric line in the averaged ECG signal, determining an existence of CAD in the patient responsive to detecting at least one of a plurality of CAD detection conditions, and determining a non-existence of CAD responsive to not detecting the at least one of the plurality of CAD detection conditions. An exemplary filtered ECG signal may include a plurality of QRS complexes.

In an exemplary embodiment, detecting the at least one of a plurality of CAD detection conditions may include detecting one of a depression or an elevation in the ST segment with respect to the isoelectric line, detecting a deformation in the ST segment, or detecting a plurality of abnormal morphologies in the plurality of averaged ECG signals.

In an exemplary embodiment, acquiring the raw ECG signal may include placing three precordial ECG leads on a chest of the patient and recording the raw ECG signal from the three precordial ECG leads.

In an exemplary embodiment, extracting the averaged ECG signal may include extracting five consecutive QRS complexes of the plurality of QRS complexes from the filtered ECG signal.

In an exemplary embodiment, detecting the one of the depression or the elevation in the ST segment may include measuring variations of the ST segment with respect to the isoelectric line, defining a first membership function associated with the variations of the ST segment, calculating a first membership value for the ST segment utilizing the first membership function, and determining an existence of the one of the depression or the elevation in the ST segment responsive to the first membership value being equal to or higher than a first threshold.

In an exemplary embodiment, detecting the deformation in the ST segment may include detecting a T-wave and an initial J-point in the averaged ECG signal, measuring a difference between the initial J-point and the isoelectric line, defining a second membership function associated with the difference, calculating a second membership value for the difference utilizing the second membership function, and determining an existence of the deformation in the ST segment responsive to the second membership function being equal to or larger than a second threshold. In an exemplary embodiment, detecting the T-wave may include detecting a type of the T-wave. An exemplary type of the T-wave may include one of a normal T-wave and an inverted T-wave.

An exemplary method may further include determining a modified J-point on the averaged ECG signal responsive to detecting the inverted T-wave by modifying a location of the initial J-point on the averaged ECG signal and replacing the initial J-point with the modified J-point prior to measuring the difference between the initial J-point and the isoelectric line.

In an exemplary embodiment, detecting the plurality of abnormal morphologies may include detecting each of the plurality of abnormal morphologies in a respective averaged ECG signal of the plurality of averaged ECG signals. In an exemplary embodiment, detecting each of the plurality of abnormal morphologies may include detecting an averaged

QRS complex in the respective averaged ECG signal, detecting an S-wave and an R-wave in the averaged QRS complex, detecting an averaged J-point in the respective averaged ECG signal based on the S-wave and the R-wave, extracting an updated QRS complex from the averaged QRS complex based on the averaged J-point, calculating a number of edges in the updated QRS complex, and determining an existence of an abnormal morphology of the plurality of abnormal morphologies in the respective averaged ECG signal responsive to a temporal duration of the updated QRS complex being less than a temporal threshold and the number of edges being larger than a lower limit.

In an exemplary embodiment, detecting the plurality of abnormal morphologies may include detecting the plurality of abnormal morphologies in at least 25% of the plurality of averaged ECG signals. In an exemplary embodiment, the plurality of averaged ECG signals may include a duration of at least 10 minutes.

Other exemplary systems, methods, features and advantages of the implementations will be, or will become, apparent to one of ordinary skill in the art upon examination of the following figures and detailed description. It is intended that all such additional systems, methods, features and advantages be included within this description and this summary, be within the scope of the implementations, and be protected by the claims herein.

BRIEF DESCRIPTION OF THE DRAWINGS

The drawing figures depict one or more implementations in accord with the present teachings, by way of example only, not by way of limitation. In the figures, like reference numerals refer to the same or similar elements.

FIG. 1A shows a flowchart of a method for non-invasive detection of coronary artery disease (CAD), consistent with one or more exemplary embodiments of the present disclosure.

FIG. 1B shows a flowchart for acquiring a raw ECG signal from a patient, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 1C shows a flowchart for determining an existence of CAD in a patient based on an ST segment and an isoelectric line, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 1D shows a flowchart for detecting one of a depression or an elevation in an ST segment, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 1E shows a flowchart for detecting a deformation in an ST segment, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 1F shows a flowchart for detecting an abnormal morphology in a respective averaged ECG signal of a plurality of averaged ECG signals, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 2 shows a schematic of a system for non-invasive detection of CAD, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3A shows a raw ECG signal, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3B shows a denoised ECG signal, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3C shows an artifact-free ECG signal, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3D shows a filtered ECG signal, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3E shows an averaged ECG signal, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 3F shows a plurality of averaged ECG signals that include a plurality of abnormal morphologies, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 4 shows a diagram of a first membership function, consistent with one or more exemplary embodiments of the present disclosure.

FIG. 5 shows a high-level functional block diagram of a computer system, consistent with one or more exemplary embodiments of the present disclosure.

DETAILED DESCRIPTION

In the following detailed description, numerous specific details are set forth by way of examples in order to provide a thorough understanding of the relevant teachings. However, it should be apparent that the present teachings may be practiced without such details. In other instances, well known methods, procedures, components, and/or circuitry have been described at a relatively high-level, without detail, in order to avoid unnecessarily obscuring aspects of the present teachings.

The following detailed description is presented to enable a person skilled in the art to make and use the methods and devices disclosed in exemplary embodiments of the present disclosure. For purposes of explanation, specific nomenclature is set forth to provide a thorough understanding of the present disclosure. However, it will be apparent to one skilled in the art that these specific details are not required to practice the disclosed exemplary embodiments. Descriptions of specific exemplary embodiments are provided only as representative examples. Various modifications to the exemplary implementations will be readily apparent to one skilled in the art, and the general principles defined herein may be applied to other implementations and applications without departing from the scope of the present disclosure. The present disclosure is not intended to be limited to the implementations shown, but is to be accorded the widest possible scope consistent with the principles and features disclosed herein.

Herein is disclosed an exemplary method and system for non-invasive detection of coronary artery disease (CAD). An exemplary method acquires raw electrocardiography (ECG) signals from a patient and after preprocessing acquired signals, extracts averaged ECG signals from the raw data. Exemplary averaged ECG signals include data of consecutive heartbeats that may be averaged over one heartbeat period. The averaged ECG signal may then be processed to extract different features from the signal, including a QRS complex, an ST segment, and signal morphology. Based on a fuzzy decision making technique, the extracted features may be analyzed to detect a CAD detection condition, such as an elevation/depression in the ST segment, a deformation in the ST segment, or an abnormal morphology in the QRS complex. This process may be repeated on several parts of the raw ECG signal and if the CAD detection conditions are detected in a considerable portion of acquired data (i.e., a number of detections exceeds a given threshold), CAD may be detected based on the ECG signal. Otherwise, the acquired ECG signal may be considered normal.

FIG. 1A shows a flowchart of a method for non-invasive detection of CAD, consistent with one or more exemplary embodiments of the present disclosure. An exemplary method **100** may include acquiring a raw electrocardiogra-

phy (ECG) signal from a patient (step 102), generating a denoised ECG signal by applying a first wavelet transform on the raw ECG signal (step 104), generating an artifact-free ECG signal by applying a second wavelet transform on the denoised ECG signal (step 106), generating a filtered ECG signal by applying a band-stop filter on the artifact-free ECG signal (step 107), extracting an averaged ECG signal of a plurality of averaged ECG signals from the filtered ECG signal (step 108), detecting an ST segment and an isoelectric line in the averaged ECG signal (step 110), and determining an existence of CAD in the patient based on the ST segment and the isoelectric line (step 112).

FIG. 2 shows a schematic of a system for non-invasive detection of CAD, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, different steps of method 100 may be implemented by utilizing an exemplary system 200. An exemplary system 200 may include a plurality of ECG leads 202, an ECG recorder 204, a memory 206, and a processor 208. In an exemplary embodiment, plurality of ECG leads 202 may be placed on a chest of a patient 210.

In further detail with respect to step 102, FIG. 1B shows a flowchart for acquiring a raw ECG signal from a patient, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, acquiring the raw ECG signal (step 102) may include placing three precordial ECG leads on the chest of the patient (step 116) and recording the raw ECG signal from the three precordial ECG leads (step 118).

For further detail regarding step 116, in an exemplary embodiment, plurality of ECG leads 202 may include three precordial ECG leads. Referring again to FIG. 2, the three precordial ECG leads may include ECG leads V2, V4, and V6. In an exemplary embodiment, seven electrodes (represented by V1-V7 in FIG. 2) may be placed on the chest of patient 210 for recording the three precordial ECG leads.

In further detail with regards to step 118, FIG. 3A shows a raw ECG signal, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, ECG recorder 204 may be utilized for recording a raw ECG signal 302. An exemplary ECG recorder may include a three-lead Holter monitor. In an exemplary embodiment, ECG recorder 204 may send raw ECG signal 302 to processor 208 to process raw ECG signal 302 according to steps 104-112 of method 100. In an exemplary embodiment, different steps of method 100 may be stored in memory 206 to be accessed and executed by processor 208.

Referring again to FIG. 1A, in an exemplary embodiment, step 104 may include generating a denoised ECG signal by applying a first wavelet transform on raw ECG signal 302. FIG. 3B shows a denoised ECG signal, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, the first wavelet transform may include a discrete wavelet transform. In an exemplary embodiment, noises of wavelet coefficients may be estimated by applying a discrete wavelet transform at on raw ECG signal 302. Then, by defining an appropriate threshold level, the noises may be removed and an exemplary denoised ECG signal 304 may be obtained.

In an exemplary embodiment, step 106 may include generating an artifact-free ECG signal by applying a second wavelet transform on denoised ECG signal 304. FIG. 3C shows an artifact-free ECG signal, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, the second wavelet transform may include a discrete wavelet transform. In an exemplary embodiment, artifact locations may be estimated by apply-

ing a discrete wavelet transform on denoised ECG signal 304. Exemplary artifacts may be a result of patient's motion or contacting with vibrating or electrical tools. In an exemplary embodiment, a sliding window may be moved on denoised ECG signal 304 and a discrete wavelet transform may be applied on a segment of denoised ECG signal 304 that is inside the sliding window. Then, noises of wavelet coefficients may be estimated. Next, by comparing obtained noise level with a proper threshold, the quality of the segment inside the sliding window is evaluated. If the noise level is above the threshold, an artifact may be identified within the segment. In an exemplary embodiment, this process may continue until the end of denoised ECG signal 304 and artifact locations may be identified throughout denoised ECG signal 304. Then, by selecting segments without any identified artifact, an exemplary artifact-free ECG signal 306 may be obtained.

In an exemplary embodiment, step 107 may include generating a filtered ECG signal by applying an FIR filter on artifact-free ECG signal 306. FIG. 3D shows a filtered ECG signal, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, the FIR filter may include a band-stop filter that may be applied on artifact-free ECG signal 306 to remove certain frequency related noises, such as power line noises in a range of about 48-51 Hz. In an exemplary embodiment, the FIR filter may further include a high pass filter that may be applied on artifact-free ECG signal 306 to eliminate low-frequency noises. By applying the FIR filter on artifact-free ECG signal 306, an exemplary filtered ECG signal 308 may be obtained. In an exemplary embodiment, filtered ECG signal 308 may include a plurality of QRS complexes 310. An exemplary QRS complex of plurality of QRS complexes 310 may include Q, R, and S edges.

In an exemplary embodiment, step 108 may include extracting an averaged ECG signal from filtered ECG signal 308. FIG. 3E shows an averaged ECG signal, consistent with one or more exemplary embodiments of the present disclosure. Extracting an exemplary averaged ECG signal 312 may include extracting five consecutive QRS complexes of plurality of QRS complexes 310 from filtered ECG signal 308. In an exemplary embodiment, each of the five consecutive QRS complexes may be delineated by applying a stationary wavelet transform (SWT, also known as a 'rout discrete wavelet transform) on filtered ECG signal 308. Each exemplary QRS complex may correspond to a heartbeat pulse that may be located between onsets of two exemplary consecutive P-waves in filtered ECG signal 308. In an exemplary embodiment, a respective onset of each P-wave may be detected in filtered ECG signal 308 similar to delineating an associated QRS complex. Next, five exemplary consecutive heartbeat pulses (each being located between two successive P-wave onsets) may be extracted from filtered ECG signal 308 and averaged to obtain an exemplary averaged ECG signal 310. As a result, in an exemplary embodiment, remaining noises in filtered ECG signal 308 may be considerably removed in averaged ECG signal 312. Referring to FIGS. 3D and 3E, in an exemplary embodiment, averaged ECG signal 312 may be smoother than filtered ECG signal 308.

Referring again to FIG. 1A, in an exemplary embodiment, step 110 may include detecting an ST segment 314 and an isoelectric line 316 in averaged ECG signal 312. In an exemplary embodiment, ST segment 314 may refer to a segment in averaged ECG signal 312 between an averaged QRS complex 318 and a T-wave. In an exemplary embodiment, isoelectric line 316 may refer to a baseline of averaged

ECG signal **312** where the signal has zero amplitude. In an exemplary embodiment, ST segment **314** and isoelectric line **316** may be detected by applying an SWT on averaged ECG signal **312**, similar to the aforementioned delineation processes.

For further detail with respect to step **112**, FIG. **1C** shows a flowchart for determining an existence of CAD in a patient based on an ST segment and an isoelectric line, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, step **112** may include determining an existence of CAD in patient **210** (step **120**) responsive to detecting at least one of a plurality of CAD detection conditions (steps **122**, **124**, or **126**, yes), and determining a non-existence of CAD (step **128**) responsive to not detecting the at least one of the plurality of CAD detection conditions (steps **122**, **124**, and **126**).

In an exemplary embodiment, detecting the at least one of a plurality of CAD detection conditions may include detecting one of a depression or an elevation in ST segment **314** with respect to isoelectric line **316** (step **122**, yes), detecting a deformation in ST segment **314** (step **124**, yes), or detecting a plurality of abnormal morphologies in the plurality of averaged ECG signals (step **126**, yes).

In further detail regarding step **122**, FIG. **1D** shows a flowchart for detecting one of a depression or an elevation in an ST segment, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, step **122** may include measuring variations of ST segment **314** with respect to isoelectric line **316** (step **130**), defining a first membership function associated with the variations of the ST segment (step **132**), calculating a first membership value for the ST segment utilizing the first membership function (step **134**), and determining an existence of the one of the depression or the elevation in the ST segment responsive to the first membership value being equal to or higher than a first threshold (step **136**).

For further detail with respect to step **130**, variations of an exemplary ST segment may include a depression or an elevation. In an exemplary embodiment, a depression may refer to a decrease of an ST segment's amplitude below an associated isoelectric line and an elevation may refer to an increase of an ST segment's amplitude above an associated isoelectric line. For example, referring to FIG. **3E**, the variations of ST segment **314** include a depression since ST segment **314** lies below isoelectric line **316**. In an exemplary embodiment, measuring ST segment **314** variations may include calculating an average of ST segment **314** variations with respect to isoelectric line **316**.

In further detail with regards to step **132**, FIG. **4** shows a diagram of a first membership function, consistent with one or more exemplary embodiments of the present disclosure. An exemplary first membership function **400** may be utilized for fuzzy decision making over the variations of ST segment **314**. In an exemplary embodiment, first membership function **400** may be obtained empirically by applying different functions on ST segment **314**.

For further detail with respect to step **134**, calculating the first membership value may include applying a measured value of variations of ST segment **314** to first membership function **400** and extracting a corresponding output of first membership function **400** as the first membership value for ST segment **314**.

In further detail regarding step **136**, in an exemplary embodiment, the first membership value may be compared with a first threshold. An exemplary first threshold may be set equal to about 0.8 based on examining different threshold values. In an exemplary embodiment, if the first membership

value is equal to or larger than the first threshold, an existence of a depression or an elevation may be determined in ST segment **314**.

Referring again to FIG. **1C**, in an exemplary embodiment, step **124** may include detecting a deformation in ST segment **314**. FIG. **1E** shows a flowchart for detecting a deformation in an ST segment, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, step **124** may include detecting a T-wave and an initial J-point in averaged ECG signal **312** (step **138**), measuring a difference between the initial J-point and the isoelectric line (step **140**), defining a second membership function associated with the difference (step **142**), calculating a second membership value for the difference utilizing the second membership function (step **144**), and determining an existence of the deformation in the ST segment responsive to the second membership function being equal to or larger than a second threshold (step **146**).

For further detail with respect to step **138**, referring to FIG. **3E**, an exemplary initial J-point may refer to an onset of ST segment **314**. Therefore, in an exemplary embodiment, detecting the initial J-point may include extracting an onset J of ST segment **314**. In an exemplary embodiment, detecting the T-wave may include detecting a (positive or negative) peak T of the T-wave by applying an SWT on averaged ECG signal **312**, similar to detecting ST segment **314**. In an exemplary embodiment, detecting the T-wave may include detecting a type of the T-wave. An exemplary type of the T-wave may include one of a normal T-wave and an inverted T-wave. In an exemplary embodiment, a normal T-wave may refer to a T-wave with a positive peak (i.e., a local maximum) and an inverted T-wave may refer to a T-wave with a negative peak (i.e., a local minimum). For example, the T-wave in averaged ECG signal **312** is a normal T-wave since it has a positive peak T.

In an exemplary embodiment, method **100** may further include determining a modified J-point on averaged ECG signal **312** responsive to detecting an inverted T-wave. An exemplary J-point modification may include modifying a location of the initial J-point on averaged ECG signal **312** by calculating a modified location J_m for the modified J-point according to an operation defined by the following:

$$J_m = J_i - f_s / 5 \quad \text{Equation (1)}$$

where:

J_i is a location of the initial J-point on averaged ECG signal **312**, and

f_s is a sampling frequency of raw ECG signal **302**.

In an exemplary embodiment, Equation (1) may be empirically obtained by relocating onset J at different modified locations and examining the impact of different relocations on the performance of method **100**. In an exemplary embodiment, method **100** may further include replacing the initial J-point with the modified J-point prior to measuring the difference between the initial J-point and isoelectric line **316** in step **140** according to Equation (1).

In further detail regarding step **140**, in an exemplary embodiment, measuring the difference between the initial J-point and isoelectric line **316** may include calculating an absolute value of averaged ECG signal **312** amplitude at onset J due to a zero amplitude of averaged ECG signal **312** on isoelectric line **316**.

In further detail with regards to step **142**, an exemplary second membership function may be selected similar to or different from first membership function **400**. An exemplary second membership function may be utilized for fuzzy decision making over the difference between the initial

J-point and isoelectric line **316**. An exemplary second membership function may be obtained empirically by applying different functions on averaged ECG signal **312**.

For further detail with respect to step **144**, calculating the second membership value may include applying a measured value of an exemplary difference between the initial J-point and isoelectric line **316** to the second membership function and extracting a corresponding output of the second membership function as the second membership value for ST segment **314**.

For further detail regarding step **146**, in an exemplary embodiment, the second membership value may be compared with a second threshold. An exemplary second threshold may be set equal to about 0.8 based on examining different threshold values. In an exemplary embodiment, if the second membership value is equal to or larger than the second threshold, an existence of a deformation may be determined in ST segment **314**.

Referring again to FIG. 1C, in an exemplary embodiment, step **126** may include detecting a plurality of abnormal morphologies in the plurality of averaged ECG signals. In an exemplary embodiment, detecting the plurality of abnormal morphologies may include detecting each of the plurality of abnormal morphologies in a respective averaged ECG signal of the plurality of averaged ECG signals.

FIG. 1F shows a flowchart for detecting an abnormal morphology in a respective averaged ECG signal of a plurality of averaged ECG signals, consistent with one or more exemplary embodiments of the present disclosure. In an exemplary embodiment, detecting each of the plurality of abnormal morphologies may include detecting an averaged QRS complex in the respective averaged ECG signal (step **148**), detecting an S-wave and an R-wave in the averaged QRS complex (step **150**), detecting an averaged J-point in the respective averaged ECG signal based on the S-wave and the R-wave (step **152**), extracting an updated QRS complex from the averaged QRS complex based on the averaged J-point (step **154**), calculating a number of edges in the updated QRS complex (step **156**), and determining an existence of an abnormal morphology of the plurality of abnormal morphologies in the respective averaged ECG signal responsive to a temporal duration of the updated QRS complex being less than a temporal threshold and the number of edges being larger than a lower limit (step **158**).

For further detail with respect to step **148**, in an exemplary embodiment, each of the plurality of averaged ECG signals may include an averaged QRS complex. For example, referring again to FIG. 3E, averaged ECG signal **312** may include averaged QRS complex **318**. In an exemplary embodiment, averaged QRS complex **318** may be detected by applying an SWT on averaged ECG signal **312** similar to detecting plurality of QRS complexes **310** in filtered ECG signal **308**.

In further detail regarding step **150**, in an exemplary embodiment, averaged QRS complex **318** may include an R-wave and an S-wave. An exemplary R-wave may include an exemplary edge R' and an exemplary S-wave may include an exemplary edge S'. Therefore, in an exemplary embodiment, each of the R-wave and an S-wave may be detected by detecting corresponding edges R' and S', respectively.

For further detail with regards to step **152**, in an exemplary embodiment, detecting the averaged J-point may include calculating a coefficient *cff* according to an operation defined by the following:

$$cff = \frac{R_m - Iso}{S_m - Iso} \quad \text{Equation (2)}$$

where:

R_m is a peak of the R-wave,

S_m is a peak of the S-wave, and

Iso is an amplitude of the isoelectric line.

In an exemplary embodiment, Equation (2) may be empirically obtained for compensating the impact of different shapes of averaged QRS complex **318** on an accuracy of averaged J-point detection. In an exemplary embodiment, step **152** may further include setting a width *W* of a search range that may satisfy a set of conditions defined by the following:

$$0.4f_s < W < 0.5f_s, cff \leq 0.1 \quad \text{Condition (1a)}$$

$$0.3f_s < W < 0.4f_s, 0.1 < cff \leq 1.5 \quad \text{Condition (1b)}$$

$$0.1f_s < W < 0.2f_s, cff > 1.5 \quad \text{Condition (1c)}$$

According to Condition (1a), in an exemplary embodiment, width *W* may be set equal to a value between $0.4f_s$ and $0.5f_s$ responsive to the coefficient *cff* being smaller than 0.1.

According to Condition (1b), in an exemplary embodiment, width *W* may be set equal to a value between $0.3f_s$ and $0.4f_s$ responsive to the coefficient *cff* being between 0.1 and 1.5.

According to Condition (1c), in an exemplary embodiment, width *W* may be set equal to a value between $0.1f_s$ and $0.2f_s$ responsive to the coefficient *cff* being larger than 1.5. In an exemplary embodiment, the averaged J-point may be obtained by finding a maximum amplitude of averaged ECG signal **312** in a range of $(t_s, t_s + W)$, where t_s is a time instance corresponding to peak S' of the S-wave. In an exemplary embodiment, point on averaged ECG signal **312** with a maximum amplitude in the selected range may be selected as the averaged J-point. Consequently, in an exemplary embodiment, the initial J-point may be replaced with the averaged J-point.

For further detail with respect to step **154**, after obtaining the averaged J-point, an exemplary updated QRS complex may be extracted from averaged QRS complex **318** utilizing the averaged J-point detected location. In an exemplary embodiment, the updated QRS complex may include updated Q, R, and S edges which may be detected on averaged ECG signal **312** similar to detecting corresponding edges of averaged QRS complex **318**, except that the initial J-point location may be replaced with the averaged J-point.

In further detail regarding step **156**, in an exemplary embodiment, the number of edges in the updated QRS complex may be calculated by counting a number of slope changes in the updated QRS complex. In an exemplary embodiment, a derivative of the updated QRS complex may be obtained and a number of zero-crossings of the derivative may indicate the number of slope changes, and hence, the number of edges of the updated QRS complex.

For further detail with regards to step **158**, in an exemplary embodiment, the temporal threshold may be set to 120 ms, which may be an upper limit for a narrow QRS complex.

Therefore, an exemplary precondition for detecting an abnormal morphology in averaged ECG signal **312** may be an existence of narrow QRS complex in averaged ECG signal **312**. In an exemplary embodiment, the lower limit for the number of edges of the updated QRS complex may be set to 3. In an exemplary embodiment, the lower limit for the number of edges may be empirically selected by examining different ECG signals associated with CAD. Therefore, in an

exemplary embodiment, an abnormal morphology may be detected in an averaged ECG signal with a narrow averaged QRS complex that may have more than 3 edges.

In an exemplary embodiment, detecting the plurality of abnormal morphologies may include detecting the plurality of abnormal morphologies in at least 25% of the plurality of averaged ECG signals. In an exemplary embodiment, the plurality of averaged ECG signals may include a duration of at least 10 minutes. Therefore, in an exemplary embodiment, if at least 25% of the plurality of averaged ECG signals which have a total duration of at least 10 minutes include abnormal morphologies, raw ECG signal **302** may be determined to contain abnormal morphologies. FIG. **3F** shows a plurality of averaged ECG signals **320** that include a plurality of abnormal morphologies **322**, consistent with one or more exemplary embodiments of the present disclosure.

FIG. **5** shows an example computer system **500** in which an embodiment of the present invention, or portions thereof, may be implemented as computer-readable code, consistent with exemplary embodiments of the present disclosure. For example, method **100** may be implemented in computer system **500** using hardware, software, firmware, tangible computer readable media having instructions stored thereon, or a combination thereof and may be implemented in one or more computer systems or other processing systems. Hardware, software, or any combination of such may embody any of the modules and components in FIGS. **1A-2**.

If programmable logic is used, such logic may execute on a commercially available processing platform or a special purpose device. One ordinary skill in the art may appreciate that an embodiment of the disclosed subject matter can be practiced with various computer system configurations, including multi-core multiprocessor systems, minicomputers, mainframe computers, computers linked or clustered with distributed functions, as well as pervasive or miniature computers that may be embedded into virtually any device.

For instance, a computing device having at least one processor device and a memory may be used to implement the above-described embodiments. A processor device may be a single processor, a plurality of processors, or combinations thereof. Processor devices may have one or more processor “cores.”

An embodiment of the invention is described in terms of this example computer system **500**. After reading this description, it will become apparent to a person skilled in the relevant art how to implement the invention using other computer systems and/or computer architectures. Although operations may be described as a sequential process, some of the operations may in fact be performed in parallel, concurrently, and/or in a distributed environment, and with program code stored locally or remotely for access by single or multi-processor machines. In addition, in some embodiments the order of operations may be rearranged without departing from the spirit of the disclosed subject matter.

Processor device **504** may be a special purpose or a general-purpose processor device. As will be appreciated by persons skilled in the relevant art, processor device **504** may also be a single processor in a multi-core/multiprocessor system, such system operating alone, or in a cluster of computing devices operating in a cluster or server farm. Processor device **504** may be connected to a communication infrastructure **506**, for example, a bus, message queue, network, or multi-core message-passing scheme.

In an exemplary embodiment, computer system **500** may include a display interface **502**, for example a video connector, to transfer data to a display unit **530**, for example, a monitor. Computer system **500** may also include a main

memory **508**, for example, random access memory (RAM), and may also include a secondary memory **510**. Secondary memory **510** may include, for example, a hard disk drive **512**, and a removable storage drive **514**. Removable storage drive **514** may include a floppy disk drive, a magnetic tape drive, an optical disk drive, a flash memory, or the like. Removable storage drive **514** may read from and/or write to a removable storage unit **518** in a well-known manner. Removable storage unit **518** may include a floppy disk, a magnetic tape, an optical disk, etc., which may be read by and written to by removable storage drive **514**. As will be appreciated by persons skilled in the relevant art, removable storage unit **518** may include a computer usable storage medium having stored therein computer software and/or data.

In alternative implementations, secondary memory **510** may include other similar means for allowing computer programs or other instructions to be loaded into computer system **500**. Such means may include, for example, a removable storage unit **522** and an interface **520**. Examples of such means may include a program cartridge and cartridge interface (such as that found in video game devices), a removable memory chip (such as an EPROM, or PROM) and associated socket, and other removable storage units **522** and interfaces **520** which allow software and data to be transferred from removable storage unit **522** to computer system **500**.

Computer system **500** may also include a communications interface **524**.

Communications interface **524** allows software and data to be transferred between computer system **500** and external devices. Communications interface **524** may include a modem, a network interface (such as an Ethernet card), a communications port, a PCMCIA slot and card, or the like. Software and data transferred via communications interface **524** may be in the form of signals, which may be electronic, electromagnetic, optical, or other signals capable of being received by communications interface **524**. These signals may be provided to communications interface **524** via a communications path **526**. Communications path **526** carries signals and may be implemented using wire or cable, fiber optics, a phone line, a cellular phone link, an RF link or other communications channels.

In this document, the terms “computer program medium” and “computer usable medium” are used to generally refer to media such as removable storage unit **518**, removable storage unit **522**, and a hard disk installed in hard disk drive **512**. Computer program medium and computer usable medium may also refer to memories, such as main memory **508** and secondary memory **510**, which may be memory semiconductors (e.g. DRAMs, etc.).

Computer programs (also called computer control logic) are stored in main memory **508** and/or secondary memory **510**. Computer programs may also be received via communications interface **524**. Such computer programs, when executed, enable computer system **500** to implement different embodiments of the present disclosure as discussed herein. In particular, the computer programs, when executed, enable processor device **504** to implement the processes of the present disclosure, such as the operations in method **100** illustrated by flowcharts of FIGS. **1A-1F** discussed above. Accordingly, such computer programs represent controllers of computer system **500**. Where an exemplary embodiment of method **100** is implemented using software, the software may be stored in a computer program product and loaded into computer system **500** using remov-

able storage drive **514**, interface **520**, and hard disk drive **512**, or communications interface **524**.

Embodiments of the present disclosure also may be directed to computer program products including software stored on any computer useable medium. Such software, when executed in one or more data processing device, causes a data processing device to operate as described herein. An embodiment of the present disclosure may employ any computer useable or readable medium. Examples of computer useable mediums include, but are not limited to, primary storage devices (e.g., any type of random access memory), secondary storage devices (e.g., hard drives, floppy disks, CD ROMS, ZIP disks, tapes, magnetic storage devices, and optical storage devices, MEMS, nano-technological storage device, etc.).

The embodiments have been described above with the aid of functional building blocks illustrating the implementation of specified functions and relationships thereof. The boundaries of these functional building blocks have been arbitrarily defined herein for the convenience of the description. Alternate boundaries can be defined so long as the specified functions and relationships thereof are appropriately performed.

EXAMPLE

In this example, an implementation of method **100** for CAD detection is demonstrated. Four specific datasets were collected from different cohorts of cardiac patients containing a total of 300 patients in a period of 72 months. The four aforementioned cohorts of patients consist of 200 patients from DAY General Hospital in Tehran, Iran, 54 patients from CHUV hospital in Lausanne, Switzerland, 20 patients from Masih Daneshvari Hospital in Tehran, Iran, and 26 CAD-cardiac electrophysiological patients from DAY General Hospital in Tehran, Iran. Also 50 individuals were selected either from other cardiac patients with no apparent symptom of coronary artery diseases, or from some young and apparently healthy volunteers as the control (Healthy) group.

Raw ECG signals were obtained before undergoing coronary angiography for a duration of approximately 10 minutes with three-lead ambulatory Holter ECG unit. For each of the cohorts of the CAD patients, coronary angiography was defined as the gold standard.

The anticipated evaluation population included a group of individuals of different ages from both sexes. For purpose of evaluation, such group of participating patients and individuals had no background of coronary angiography, no background of percutaneous transluminal coronary angioplasty (PTCA) or coronary artery bypass grafting (CABG), no recorded history of CADs and existing ambulatory holter ECG recording (at least for 10 minutes) taken at the hospital.

Patients who have such records were eliminated from population. Therefore, the population were divided into the two main groups of CAD patients and healthy individuals or the control group. The group of CAD patents included the four specific subgroups including a group of patients who had experienced chest pain and were referred to the CHUV, Day and Masih Daneshvari hospitals or cardiologist offices at these centers and based on the initial findings such as Troponin test, ECG interpretation or their clinical symptoms, were suspected of coronary artery blockage (coronary artery disease). All these patients were prescribed for angiography. This group of patients were divided into the four main subgroups including patients who definitely had CAD and suffered from acute CAD and had to undergo CABG, patients who definitely had CAD and suffered from

acute CAD, however, the quality of the artery occlusion was such that they did not require CABG, and therefore, the act of placing a stent or balloon in vessels, or PTCA was prescribed for them, and patients who had angiography and suffered from coronary artery occlusion, however, they did not need invasive therapy, on the other hand, the severity of occlusion was not insignificant and therefore had not been ignored and thus, medical follow up was prescribed for this group, and finally, individuals who had undergone coronary angiography and their coronary occlusion was negligible, hence they were considered normal population.

The second group, known as the healthy individuals or the control group, included the other cardiac patients with no apparent symptom of coronary artery diseases, and some young and apparently healthy volunteer students.

The four cohorts of patients included the cohort of cardiac patients from Day general hospital in Tehran, Iran, that included a total of 200 patients, cohort of the cardiac patients from Masih Daneshvari hospital in Tehran, Iran, that included 20 patients, the cohort of the cardiac patients from CHUV hospital in Lausanne, Switzerland, that included a total of 54 patients, and the cohort of the cardiac electrophysiological CAD patients from DAY general hospital in Tehran, that included a total of 25 patients.

The latter cohort included a group of electrophysiological patients having either a similar sign or symptom of the CAD, or having ECG signals resembling known criteria of CAD. Thus, these patients might incorrectly be diagnosed as CAD cases. This group of patients usually suffer from Left Bundle Branch Block (LBBB) or Right Bundle Branch Block (RBBB) arrhythmia. The Electrocardiogram (ECG) signals from a total of 25 patients of this cohort was obtained. Since most of these patients had presented with either typical or atypical CAD clinical symptoms, they had undergone coronary angiography for a superior assessment. Evaluation of method **100** with such particular cohort of patient may be essential because it may be so effective to reduce a false alarm and consequently increase negative predictive value accuracy. In this example, the presence of left or right bundle branch block arrhythmias is estimated using 3 leads of ambulatory Holter ECGs, and then, the left and right bundle branch blocks are separated from each other. Thereafter, CAD cases with bundle branch block arrhythmias are diagnosed from normal coronary bundle branch subjects.

Technical specifications of the ECG recorder used for data gathering process are as follows:

Number of ECG channels: 3 time synchronized differential inputs

Input resistance: 10 M Ohm/22 nF

Sensitivity: ± 7 mV

DC stability: ± 300 mV

Frequency response: 0.05-55 Hz

Resolution: 12 Bit

Sample rate: 200 Hz per ECG channel

An evaluation of method **100** with the available cohorts of cardiac patients was performed according to the comparison with the available ten-minute Holter from the normal coronary individuals. The obtained results are shown in TABLE 1.

TABLE 1

Database	Day general hospital electrophysiological database	Day general hospital database	CHUV hospital database	Masih Daneshvari hospital database
Sensitivity (%)	88.9%	90.91%	87.03%	84.6%
Positive predictive values (%)	81.25%	95.24%	94%	88%
Specificity (%)	72.7%	92.31%	94.23%	94.23%
Negative predictive values (%)	92.8%	85.71%	87.5%	92.45%
Average Accuracy (%)	84%	91.43%	90.56%	91.02%

While the foregoing has described what may be considered to be the best mode and/or other examples, it is understood that various modifications may be made therein and that the subject matter disclosed herein may be implemented in various forms and examples, and that the teachings may be applied in numerous applications, only some of which have been described herein. It is intended by the following claims to claim any and all applications, modifications and variations that fall within the true scope of the present teachings.

Unless otherwise stated, all measurements, values, ratings, positions, magnitudes, sizes, and other specifications that are set forth in this specification, including in the claims that follow, are approximate, not exact. They are intended to have a reasonable range that is consistent with the functions to which they relate and with what is customary in the art to which they pertain.

The scope of protection is limited solely by the claims that now follow. That scope is intended and should be interpreted to be as broad as is consistent with the ordinary meaning of the language that is used in the claims when interpreted in light of this specification and the prosecution history that follows and to encompass all structural and functional equivalents. Notwithstanding, none of the claims are intended to embrace subject matter that fails to satisfy the requirement of Sections 101, 102, or 103 of the Patent Act, nor should they be interpreted in such a way. Any unintended embracement of such subject matter is hereby disclaimed.

Except as stated immediately above, nothing that has been stated or illustrated is intended or should be interpreted to cause a dedication of any component, step, feature, object, benefit, advantage, or equivalent to the public, regardless of whether it is or is not recited in the claims.

It will be understood that the terms and expressions used herein have the ordinary meaning as is accorded to such terms and expressions with respect to their corresponding respective areas of inquiry and study except where specific meanings have otherwise been set forth herein. Relational terms such as first and second and the like may be used solely to distinguish one entity or action from another without necessarily requiring or implying any actual such relationship or order between such entities or actions. The terms “comprises,” “comprising,” or any other variation thereof, are intended to cover a non-exclusive inclusion, such that a process, method, article, or apparatus that comprises a list of elements does not include only those elements but may include other elements not expressly listed or inherent to such process, method, article, or apparatus. An

element proceeded by “a” or “an” does not, without further constraints, preclude the existence of additional identical elements in the process, method, article, or apparatus that comprises the element.

The Abstract of the Disclosure is provided to allow the reader to quickly ascertain the nature of the technical disclosure. It is submitted with the understanding that it will not be used to interpret or limit the scope or meaning of the claims. In addition, in the foregoing Detailed Description, it can be seen that various features are grouped together in various implementations. This is for purposes of streamlining the disclosure, and is not to be interpreted as reflecting an intention that the claimed implementations require more features than are expressly recited in each claim. Rather, as the following claims reflect, inventive subject matter lies in less than all features of a single disclosed implementation. Thus, the following claims are hereby incorporated into the Detailed Description, with each claim standing on its own as a separately claimed subject matter.

While various implementations have been described, the description is intended to be exemplary, rather than limiting and it will be apparent to those of ordinary skill in the art that many more implementations and implementations are possible that are within the scope of the implementations. Although many possible combinations of features are shown in the accompanying figures and discussed in this detailed description, many other combinations of the disclosed features are possible. Any feature of any implementation may be used in combination with or substituted for any other feature or element in any other implementation unless specifically restricted. Therefore, it will be understood that any of the features shown and/or discussed in the present disclosure may be implemented together in any suitable combination. Accordingly, the implementations are not to be restricted except in light of the attached claims and their equivalents. Also, various modifications and changes may be made within the scope of the attached claims.

What is claimed is:

1. A computer-implemented method for non-invasive detection of coronary artery disease (CAD), the method comprising:

- acquiring a raw electrocardiography (ECG) signal associated with a patient;
- generating, utilizing one or more processors, a denoised ECG signal by applying a first wavelet transform on the raw ECG signal;
- generating, utilizing the one or more processors, an artifact-free ECG signal by applying a second wavelet transform on the denoised ECG signal;
- generating, utilizing the one or more processors, a filtered ECG signal by applying a finite impulse response (FIR) filter on the artifact-free ECG signal, the filtered ECG signal comprising a plurality of QRS complexes;
- extracting, utilizing the one or more processors, an averaged ECG signal of a plurality of averaged ECG signals from the filtered ECG signal;
- detecting, utilizing the one or more processors, an ST segment and an isoelectric line in the averaged ECG signal;
- determining, utilizing the one or more processors, an existence of CAD in the patient responsive to detecting at least one of a plurality of CAD detection conditions, detecting the at least one of a plurality of CAD detection conditions comprising:

- detecting one of a depression or an elevation in the ST segment with respect to the isoelectric line; detecting a deformation in the ST segment; or detecting a plurality of abnormal morphologies in the plurality of averaged ECG signals; and
- 5 determining, utilizing the one or more processors, a non-existence of CAD responsive to not detecting the at least one of the plurality of CAD detection conditions.
2. The method of claim 1, wherein acquiring the raw ECG signal comprises:
- placing three precordial ECG leads on a chest of the patient; and
- recording the raw ECG signal from the three precordial ECG leads.
3. The method of claim 1, wherein extracting the averaged ECG signal comprises extracting five consecutive QRS complexes of the plurality of QRS complexes from the filtered ECG signal.
4. The method of claim 1, wherein detecting the one of the depression or the elevation in the ST segment comprises:
- measuring variations of the ST segment with respect to the isoelectric line;
- defining a first membership function associated with the variations of the ST segment;
- 15 calculating a first membership value for the ST segment utilizing the first membership function; and
- determining an existence of the one of the depression or the elevation in the ST segment responsive to the first membership value being equal to or higher than a first threshold.
5. The method of claim 4, wherein detecting the deformation in the ST segment comprises:
- detecting a T-wave and an initial J-point in the averaged ECG signal;
- 20 measuring a difference between the initial J-point and the isoelectric line;
- defining a second membership function associated with the difference;
- calculating a second membership value for the difference utilizing the second membership function; and
- 40 determining an existence of the deformation in the ST segment responsive to the second membership function being equal to or larger than a second threshold.
6. The method of claim 5, further comprising:
- 45 detecting a type of the T-wave comprising one of a normal T-wave and an inverted T-wave;
- determining a modified J-point on the averaged ECG signal responsive to detecting the inverted T-wave by modifying a location of the initial J-point on the averaged ECG signal; and
- 50 replacing the initial J-point with the modified J-point prior to measuring the difference between the initial J-point and the isoelectric line.
7. The method of claim 6, wherein modifying the location of the initial J-point comprises calculating a modified location J_m for the modified J-point according to an operation defined by the following:

$$J_m = J_i - f_s / 5,$$

where:

J_i is a location of the initial J-point on averaged ECG signal, and

f_s is a sampling frequency of the raw ECG signal.

8. The method of claim 1, wherein detecting the plurality of abnormal morphologies comprises detecting each of the plurality of abnormal morphologies in a respective averaged

ECG signal of the plurality of averaged ECG signals, detecting each of the plurality of abnormal morphologies comprising:

- 5 detecting an averaged QRS complex in the respective averaged ECG signal;
- detecting an S-wave and an R-wave in the averaged QRS complex;
- detecting an averaged J-point in the respective averaged ECG signal based on the S-wave and the R-wave;
- extracting an updated QRS complex from the averaged QRS complex based on the averaged J-point;
- calculating a number of edges in the updated QRS complex; and
- 15 determining an existence of an abnormal morphology of the plurality of abnormal morphologies in the respective averaged ECG signal responsive to:
- a temporal duration of the updated QRS complex being less than a temporal threshold; and
- the number of edges being larger than a lower limit.
9. The method of claim 8, wherein detecting the averaged J-point comprises:
- calculating a coefficient *cff* according to an operation defined by the following:

$$cff = \frac{R_m - Iso}{S_m - Iso},$$

where:

R_m is a peak of the R-wave,

S_m , is a peak of the S-wave, and

Iso is an amplitude of the isoelectric line;

- setting a width W of a search range equal to a value between $0.4f_s$ and $0.5f_s$ responsive to the coefficient *cff* being smaller than 0.1;
- setting a width W of a search range equal to a value between $0.3f_s$ and $0.4f_s$ responsive to the coefficient *cff* being between 0.1 and 1.5;
- setting a width W of a search range equal to a value between $0.1f_s$ and $0.2f_s$ responsive to the coefficient *cff* being larger than 1.5; and
- obtaining the averaged J-point by finding a maximum amplitude of the respective averaged ECG signal in a range of (t_s, t_s+W) , where t_s is a time instance corresponding to the peak of the S-wave.

10. The method of claim 1, wherein detecting the plurality of abnormal morphologies comprises detecting the plurality of abnormal morphologies in at least 25% of the plurality of averaged ECG signals, the plurality of averaged ECG signals comprising a duration of at least 10 minutes.

11. A system for non-invasive detection of coronary artery disease (CAD), the system comprising:

a plurality of precordial electrocardiography (ECG) leads configured to be placed on a chest of a patient and acquire a raw ECG signal from the patient;

an ECG recorder configured to record the raw ECG signal from the plurality of precordial ECG leads;

a memory having processor-readable instructions stored therein; and

one or more processors configured to access the memory and execute the processor-readable instructions, which, when executed by the one or more processors configures the one or more processors to perform a method, the method comprising:

19

receiving the raw ECG signal from the ECG recorder;
 generating a denoised ECG signal by applying a first
 wavelet transform on the raw ECG signal;
 generating an artifact-free ECG signal by applying a
 second wavelet transform on the denoised ECG
 signal;
 generating a filtered ECG signal by applying a finite
 impulse response (FIR) filter on the artifact-free
 ECG signal, the filtered ECG signal comprising a
 plurality of QRS complexes;
 extracting an averaged ECG signal of a plurality of
 averaged ECG signals from the filtered ECG signal;
 detecting an ST segment and an isoelectric line in the
 averaged ECG signal;
 determining an existence of CAD in the patient respon-
 sive to detecting at least one of a plurality of CAD
 detection conditions, detecting the at least one of a
 plurality of CAD detection conditions comprising:
 detecting one of a depression or an elevation in the
 ST segment with respect to the isoelectric line;
 detecting a deformation in the ST segment; or
 detecting a plurality of abnormal morphologies in the
 plurality of averaged ECG signals; and
 determining a non-existence of CAD responsive to not
 detecting the at least one of the plurality of CAD
 detection conditions.

12. The system of claim 11, wherein the plurality of ECG
 leads comprise three precordial ECG leads configured to be
 placed on a chest of the patient.

13. The system of claim 11, wherein extracting the
 averaged ECG signal comprises extracting five consecutive
 QRS complexes of the plurality of QRS complexes from the
 filtered ECG signal.

14. The system of claim 11, wherein detecting the one of
 the depression or the elevation in the ST segment comprises:
 measuring variations of the ST segment with respect to
 the isoelectric line;
 defining a first membership function associated with the
 variations of the ST segment;
 calculating a first membership value for the ST segment
 utilizing the first membership function; and
 determining an existence of the one of the depression or
 the elevation in the ST segment responsive to the first
 membership value being equal to or higher than a first
 threshold.

15. The system of claim 11, wherein detecting the defor-
 mation in the ST segment comprises:
 detecting a T-wave and an initial J-point in the averaged
 ECG signal;
 measuring a difference between the initial J-point and the
 isoelectric line;
 defining a second membership function associated with
 the difference;
 calculating a second membership value for the difference
 utilizing the second membership function; and
 determining an existence of the deformation in the ST
 segment responsive to the second membership function
 being equal to or larger than a second threshold.

16. The system of claim 15, wherein detecting the defor-
 mation in the ST segment further comprises:
 detecting a type of the T-wave comprising one of a normal
 T-wave and an inverted T-wave;
 determining a modified J-point on the averaged ECG
 signal responsive to detecting the inverted T-wave by
 modifying a location of the initial J-point on the
 averaged ECG signal; and

20

replacing the initial J-point with the modified J-point prior
 to measuring the difference between the initial J-point
 and the isoelectric line.

17. The system of claim 16, wherein modifying the
 location of the initial J-point comprises calculating a modi-
 fied location J_m for the modified J-point according to an
 operation defined by the following:

$$J_m = J_i - f_s / 5,$$

where:

J_i is a location of the initial J-point on averaged ECG
 signal, and

f_s is a sampling frequency of raw ECG signal.

18. The system of claim 11, wherein detecting the plu-
 rality of abnormal morphologies comprises detecting each of
 the plurality of abnormal morphologies in a respective
 averaged ECG signal of the plurality of averaged ECG
 signals, detecting each of the plurality of abnormal mor-
 phologies comprising:

detecting an averaged QRS complex in the respective
 averaged ECG signal;

detecting an S-wave and an R-wave in the averaged QRS
 complex;

detecting an averaged J-point in the respective averaged
 ECG signal based on the S-wave and the R-wave;

extracting an updated QRS complex from the averaged
 QRS complex based on the averaged J-point;

calculating a number of edges in the updated QRS com-
 plex; and

determining an existence of an abnormal morphology of
 the plurality of abnormal morphologies in the respec-
 tive averaged ECG signal responsive to:

a temporal duration of the updated QRS complex being
 less than a temporal threshold; and

the number of edges being larger than a lower limit.

19. The system of claim 18, wherein detecting the aver-
 aged J-point comprises:

calculating a coefficient cff according to an operation
 defined by the following:

$$cff = \frac{R_m - Iso}{S_m - Iso},$$

where:

R_m is a peak of the R-wave,

S_m is a peak of the S-wave, and

Iso is an amplitude of the isoelectric line;

setting a width W of a search range equal to a value
 between $0.4f_s$ and $0.5f_s$ responsive to the coefficient cff
 being smaller than 0.1;

setting a width W of a search range equal to a value
 between $0.3f_s$ and $0.4f_s$ responsive to the coefficient cff
 being between 0.1 and 1.5;

setting a width W of a search range equal to a value
 between $0.1f_s$ and $0.2f_s$ responsive to the coefficient cff
 being larger than 1.5; and

obtaining the averaged J-point by finding a maximum
 amplitude of the respective averaged ECG signal in a
 range of $(t_s, t_s + W)$, where t_s is a time instance corre-
 sponding to the peak of the S-wave.

20. The system of claim 11, wherein detecting the plu-
 rality of abnormal morphologies comprises detecting the
 plurality of abnormal morphologies in at least 25% of the

plurality of averaged ECG signals, the plurality of averaged ECG signals comprising a duration of at least 10 minutes.
