Fuel and fuel additives capable for use for internal combustion engines and process for the production thereof

The invention provides four products, wherein

Product A is a paraffin fraction comprising 98.0-99.9% by weight C4-C12 i- and n-paraffins with 1:4 to 4:1 i/n ratio and 0.1-2.0% by weight C4-C10 carboxylic acid esters, wherein the boiling range of the paraffin fraction is 20-250°C.

Product B is a paraffin fraction comprising 95.00-99.95% by weight C10-C25 i- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C12-C14 carboxylic acids and/or C12-C16 carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C.

Product C is a polar product mix comprising 5-20% by weight C9-C14 carboxylic acids and 80-95% by weight C10-C25 i- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C12-C14 carboxylic acids and/or C12-C16 carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C.

Product D is a polar product mix comprising 5-20% by weight C9-C14 carboxylic acids and 80-95% by weight C10-C25 i- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C12-C14 carboxylic acids and/or C12-C16 carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C.
C<sub>12</sub>-C<sub>19</sub> carboxylic acid esters.

Product D is a paraffin fraction comprising C<sub>10</sub>-C<sub>26</sub> i- and n- paraffins with 1.5: 1 to 5: 1 i/n ratio, wherein the boiling range of the paraffin fraction is 160-420°C.

The invention further provides a process for the production of paraffin fractions by a special hydrocracking, wherein the feedstock is treated with hydrogen in the presence of heterogeneous catalyst applied on a carrier at 160-420°C temperature and 5-100 bars pressure, where the volumetric hydrogen to feedstock ratio is 200-2000 Nm<sup>3</sup>/m<sup>3</sup> and the hourly feedstock load is up to 10 m<sup>3</sup> feedstock/m<sup>3</sup> catalyst.
This invention relates to fuels and fuel additives capable for use for internal combustion engines. An additional subject of this invention is a process for the environmentally-friendly production of said fuels and fuel additives by a special hydrocracking technology as well as the products obtained by said technology.

The various major types of internal combustion engines include the Otto motors, Diesel engines and the HCCI (homogeneously charged compression ignition) engines, such as the Diesel-Otto engines (Alikidas A.C.; "Combustion advancements in gasoline engines", Energy Conversation Management, 2007, 48, p. 2752-2761). The fuels and fuel additives capable for use for powering these, for example gasoline and diesel oil as well as the additives employed in these, such as lubricity improvers and similar agents, are produced usually from fossil energy carriers, primarily from crude oil. Because of the more and more depleting volume and geographically uneven distribution of crude oil sources major research efforts have been extended in recent years for the development of fuels and fuel additives originating from alternative sources. This effort is enhanced by the fact that products originating in crude oil entail significant environmentally harmful effects and therefore the utilization of alternate sources is supported also for environment protection and nature preservation considerations.

Vegetable oils rich in triglycerides, such as sunflower oil, rape-oil, soybean oil, palm oil and the like, as well as slaughterhouse fats and spent oils and fats from deep fat fryers, classified as hazardous waste - such as those generated in restaurants, public catering and similar facilities - plus alga oils and similar substances can be utilized for example as alternative sources of feedstock.

EP 1 396 531 A2 describes a process suitable for the conversion of triglycerides in at least two stages where oxygen removal takes place in the first stage and isomerization in the second, with dissolved gases being also removed between the two stages in specific cases. The preferred pressure is given as a value between 50 to 100 bars and the temperature as ranging from 300°C to 400°C. These pressure levels are disadvantageous in respect of both energetics and economics. The composition and main properties in respect of application technique of the products are not described.

US 4,992,605 describes a process suitable for producing C_{15-18} normal paraffins from triglycerides under very severe operating conditions with the application of catalysts on transient metal carrier. The temperature range is 350-400°C and the pressure ranges from 48 to 152 bars. The reasons for these high levels are the non-adequately active catalyst(s) and the commonly used reactor system. The flow properties of the effluent product mix (the CFPP value estimated from the hydrocarbon composition may range from +21°C to +28°C) do not satisfy the specifications of EN Standard 590:2009 April, particularly for moderate and cold climatic zones.

WO 2009/039333 A1 describes a technology processing mainly alga/weed oils where carbon dioxide generated during the production process is also utilized for algae culture. This solution focuses primarily on CO₂ recovery and the absorbent solution usable in the process. Commonly known catalysts and reaction conditions are described for the conversion of triglyceride containing feedstocks.

US 2006/0207166 A1 recommends catalysts containing only noble metals (Pt or Pd) on highly acidic carriers (such as fluorinated Al₂O₃, ZSM-22, ZSM-38, ZSM-48, SAPO-11 and similar carriers) for the conversion of triglycerides under very severe operating conditions, e.g. in the temperature range of 370-410°C, with the consequence of the product (fraction) yield falling greatly (by 15-30% absolute) behind the theoretically achievable value.

The main disadvantages of the catalytic hydrocracking processes presented are as follow:

- the catalytic systems [catalyst(s), reactor internals, placement of catalyst(s), distribution of feed/H₂ over the depth and cross-section of the catalyst bed(s), process conditions: temperature, pressure and the like, the continuous assurance of the most active and selective shape and composition of the catalyst(s) and similar factors] enable the achievement of only about 55-75% product yield by once-through operation. These values fall considerably behind the product yield to feed rate ratios achievable theoretically and falling possibly between 81-86% depending on the reaction mechanism, which is primarily the function of the catalyst and the reaction conditions used (theoretical values apply only to triglycerides containing solely oleic acid as the acidic component of the molecule);

- the application of low conversion ratio is explained in several cases by the necessity to recycle a significant portion (up to 70-80%) of the product because of the highly exothermic (heat generating) nature of the reactions, which greatly increases the size of the vessel along with the capital costs and - naturally - the energy costs and other
operating expenses as well due to recycling;
- heavier reaction products other than paraffins have to be recycled after separation for additional catalytic conversion
  - entailing considerable extra capital costs and operating expenses - and, furthermore, by-products are also produced
  from the recycle stream in the course of repeated catalytic conversion thus the achievable average output is further
  reduced due to cracking, without recycling provisions have to be made for the sale/disposal of by-products resulting
  in the reduced cost-effectiveness of the process;
- starting from traditional vegetable oils requires the use of high hydrogen flow because its demand is determined
  basically by the average number of double (olefinic) bonds in the fatty acid chains beyond the proportion of oxygen
  removal reactions (decarboxylation, hydrogenation and the like) and the length of hydrocarbon chains;
- the lubricity of the product consisting mostly of a mixture of C_{10}-C_{19} paraffins falling into the boiling range of light
  gas oil is insufficient, therefore its application requires the use of lubricity improving additives in order to avoid
  the excessive wear of fuel supply and injection pump components, which results in additional costs;
- beyond the maintenance of a nearly constant activity and selectivity of the catalysts for prolonged periods and the
  mode of achieving this objective - even under the conditions of continuous dosing of some sulfidizing agent - only
  rising the reaction temperature is mentioned, which is widely known and results in reduced product yield because
  of the increased proportion of cracking reactions as well as increasing the energy consumption - and thereby - also
  the CO_{2} emission rate of the process.

[0011] The yield of diesel engine fuel produced by the processes known to date (for example US 2007/0068845 A1,
US 2007/0170091 A1) by thermal splitting and catalytic hydrocracking of vegetable oils, animal fats and spent cooking
oils of deep fat fryers and similar materials with traditional fatty acid composition is only 63-68.6% even after thermal
splitting. Obviously, it will be even less (at least by about 8-10 percent absolute) after the conversion by hydrogenation
partly because of oxygen removal and partly because of the cracking of carbon chains. Thus the product yield falls
significantly behind that achievable theoretically (about 81-86%).

[0012] In the two-stage process proposed for converting spent cooking oils and fats disposed from deep fat fryers
quick thermal splitting of the feedstock is recommended as the first step in order to reduce hydrogen consumption and
for thermal splitting and the product separation unit requires considerable extra capital investment for the application of
this process and, furthermore, the 480-600°C temperature range as well as the supply of the necessary inert gas require
considerable additional energy consumption, which - among others - also results in higher CO_{2} emission rates. Addi-
tionally, the thermal cracking reactions also lead to the formation of low-value C_{1}-C_{6} hydrocarbons, resulting thereby
also in a further reduction of the achievable product yield. The volume of the coke-like substance formed in the process
is also significant: 1.4-3%.

[0013] We have recognized that the value of the theoretical yield is determined basically by the average length of the
hydrocarbon chain of the fatty acids contained in the triglycerides, therefore the feedstocks rich in triglycerides - chosen
and processed on the basis of the known solutions - theoretically limit the increase of product yield. In addition, relatively
less hydrogen is required for the oxygen removal from triglycerides containing fatty acids with longer carbon chains
and/or less CO and CO_{2} is generated. Further, we have recognized that the yield of hydrocracking can be increased
significantly and the cost-effectiveness of the process can be improved if the processing conditions - thus for example
the temperature and pressure levels - as well as the feedstock load on the catalyst and the hydrogen consumption rate
are adjusted within preset ranges.

[0014] We have found on the basis of the above recognition that feedstocks rich in triglycerides which contain triglyc-
erides including fatty acids with carbon numbers of C_{20} and higher in larger quantities than the feedstocks utilized to
date can be utilized advantageously for the production of fuels and/or fuel additives capable for use in internal combustion
engines. Further, we have found that fuels and/or fuel additives can be produced especially advantageously by a special
hydrocracking process. Finally we have found that new fuels and/or fuel additives - having more advantageous properties
compared to the known fuels and/or fuel additives - can be produced by said special hydrocracking process starting
from the above-mentioned feedstocks.

[0015] Accordingly, the invention relates to the following:

1. A paraffin fraction comprising 98.0-99.9% by weight C_{4}-C_{12} i- and n-paraffins with 1:4 to 4:1 i/n ratio and 0.1-2.0% by weight C_{4}-C_{10} carboxylic acid esters, wherein the boiling range of the paraffin fraction is 20-250°C (product A).
2. A paraffin fraction comprising 95.00-99.95% by weight C_{10}-C_{25} i- and n-paraffins with 1:9 to 3:2 i/n ratio and
0.05-1.00% by weight C_{12}-C_{14} carboxylic acids and/or C_{12}-C_{16} carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C (product B).
3. A polar product mix comprising 5-20% by weight C_{9}-C_{14} carboxylic acids and 80-95% by weight C_{12}-C_{19} carboxylic acid esters (product C).
4. A paraffin fraction comprising C_{10}-C_{26} i- and n-paraffins with 1.5:1 to 5:1 i/n mass ratio, wherein the boiling range
of the paraffin fraction is 160-420°C (product D).
5. A process for the production of paraffin fractions by special hydrocracking comprising the treatment of a feedstock with hydrogen at 160-420°C temperature and 5-100 bars pressure in the presence of a heterogeneous catalyst applied on a carrier, wherein the volumetric ratio of hydrogen to feedstock is 200-2000 Nm³/m³ and the hourly feedstock load is up to 10 m³ feed/m³ catalyst.
6. The process according to Item 5, wherein the feedstock comprises fatty acids and fatty acid esters, preferably fatty acids and/or fatty acid esters with carbon numbers of 6-28 or higher, and more preferably triglycerides.
7. The process according to Item 5 or 6, wherein paraffin fractions useful as fuels, fuel blend components and/or additives for fuels and fuel blends are produced.
8. The process according to any one of Items 5 to 7, wherein the process is carried out in one or more stages and in one or more reactors in each stage under identical or different conditions per stage and/or reactor.
9. The process according to any one of Items 5 to 8, wherein the heterogeneous catalyst applied to a carrier is selected from the group consisting of the metals of group VIII and/or VIIB of the periodic system and compounds thereof.
10. The process according to Item 9, wherein the metal of group VIII or VIIB is selected from the group consisting of nickel, cobalt, molybdenum and tungsten and the metal compound is selected from the group consisting of the oxides, sulfides, nitrides and phosphides of said metals.
11. The process according to Item 10, wherein the compound of the metals of group VIII and/or VIIB of the periodic system is selected from the sulfides thereof.
12. The process according to any one of Items 5 to 11, wherein the pressure range is 180-400°C, preferably 220-360°C.
13. The process according to any one of Items 5 to 12 wherein the temperature range is 10-70 bars, preferably 10-40 bars.
14. The process according to any one of Items 5 to 13, wherein the volumetric ratio of hydrogen to feedstock is 300-800 Nm³/m³, preferably 350-600 Nm³/m³.
15. The process according to any one of Items 5 to 14, wherein the hourly feedstock load is 0.2-10 m³ feedstock/m³ catalyst, preferably 0.4-3.0 m³ feedstock/m³ catalyst.
16. The process according to any one of Items 5 to 15, further comprising the addition of a sulfiding agent to maintain the sulfided state of the sulfide catalyst at a constant level.
17. The process according to Item 16, wherein the sulfiding agent is selected from the group consisting of hydrogen sulfide and/or a sulfur compound easily decomposing at the reaction temperature, preferably dialkyl sulfide, dialkyldisulfide and/or a sulfur compound containing oxygen and more preferably dimethyl disulfide, di-tert-butyl disulfide, diocytlosulfide and dimethyl-sulfoxide.
18. A process according to any one of Items 5 to 17, further comprising the addition of an agent inhibiting oxidation and/or gum formation as indifferent material for controlling the reaction.
19. A process according to Item 18, wherein the agent inhibiting oxidation and/or gum formation is selected from the group consisting of dialkyl phenols, polyalkyl phenols, dialkyl cresols and dialkyl biphenyl amines, preferably of di-tert-butyl phenol, 2,6-tert-butyl p cresol, diethyl-biphenyl-amine and ethyl-methyl-biphenyl-amine.
20. For the production of paraffin fractions, comprising the processing of feedstocks containing fatty acids and/or fatty acid esters with carbon numbers of 6-28 or more, preferably triglycerides by hydrocracking.
21. A process according to Item 20, wherein the paraffin fractions useful as fuels and fuel blend components and/or additives for fuels and fuel blends are produced.
22. A process according to Item 20 or 21, wherein hydrocracking is performed by a process according to any one of Items 5 to 21.
23. A paraffin fraction comprising 98.0-99.9% by weight C₅-C₁₂ ω- and n-paraffins with 1:4 to 3:2 i/n ratio and 0.1-2.0% by weight C₄-C₁₀ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 20-250°C, obtainable by the process according to any one of Items 5 to 22 (product A).
24. A paraffin fraction comprising 95.00-99.95% by weight C₁₀-C₂₂ ω- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C₁₂-C₁₄ carboxylic acids and/or C₁₄-C₁₆ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C, obtainable by the process according to any one of Items 5 to 22 (product B).
25. A polar product mix comprising 5-20% by weight C₉-C₁₂ carboxylic acids and 80-95% by weight C₁₃-C₁₇ carboxylic acid esters, obtainable by the process according to any one of Items 5 to 22 (product C).
26. A paraffin fraction comprising C₁₀-C₂₆ ω- and n-paraffins with 1.5:1 to 5:1 i/n mass ratio, wherein the boiling range of the paraffin fraction is 160-420°C, obtainable by the process according to any one of Items 5 to 22 (product D).
27. The use of the product according to Items 1 or 23 in internal combustion engines as fuel and/or fuel blends are produced.
28. The use of the product according to Items 2 or 24 in internal combustion engines as fuel and/or fuel blends are produced.
29. The use of the product according to Items 3 or 25 in internal combustion engines as lubricity improver additive.
30. The use of a product according to Items 4 or 26 in internal combustion engines as fuel and/or fuel blend component.

[0016] Product A according to this invention is a mixture of 98-99.9% by weight i- and n-paraffins containing four to twelve - preferably five to twelve - carbon atoms and 0.1-2.0% by weight - preferably 0.05-1.5% by weight and even more preferably 0.075-0.5% by weight - carboxylic acid esters containing four to ten, preferably four to six and even more preferably four to five carbon atoms.

[0017] The ratio of iso and normal isomers in the mixture of i- and n-paraffins (hereinafter i/n ratio) is generally 1:4 to 4:1, preferably 1:3 to 3:1 and even more preferably 2:3 to 3:2.

[0018] The boiling range of product A is 20-250°C, preferably 35-220°C and even more preferably 40-210°C.

[0019] As examples of paraffins occurring in the mixture of i- and n-paraffins, i- and n-pentane, i- and n-hexane, i- and n-heptane, i- and n-octane, i- and n-nonane, i- and n-decane, i- and n-undecane and i- and n-dodecane may be mentioned. The i-paraffins contained in the mixture of i- and n-paraffins are paraffins with branched carbon chains in which the location of branching is arbitrary, but preferably is located at the second to fifth carbon atom from the end of the chain and the side branch is preferably a methyl group and/or ethyl group. Advantageous components of the mixture of i- and n-paraffins are i-pentane, 2,2-dimethyl-butane, 2,3-dimethyl-butane, 2,2-dimethyl-pentane, 2,2,3-trimethyl-butane and 2,2,4-trimethyl-pentane.

[0020] As examples of carboxylic acid esters occurring in the mixture of carboxylic acid esters, butyl-formate, butylacetate, methyl-propionate, ethyl-propionate, propyl-propionate, butyl-propionate, heptyl-propionate and methyl-nonanoate may be mentioned. Advantageous component in the mixture of carboxylic acid esters is butyl-formate.

[0021] Product A according to this invention can be advantageously used in Otto and/or HCCI engines as a fuel having excellent inherent lubricity due to the mixture of carboxylic acid esters contained therein. Therefore product A may be used as motor fuel by itself, i.e. without the commonly used state of the art additives, as well as blended with the standard additives. Furthermore, product A can be used as a component of fuel blends, preferably as a lubricity improver component. The amount of product A in such fuel blends is generally 2-20% by weight, preferably 2-10% by weight and even more preferably 7-9% by weight.

[0022] The inherent lubricity of product A according to this invention is verified by the test results given in Table 1. It can be established from the data of Table 1 that mixtures of i- and n-paraffins with 5 to 12 carbon numbers and various ratios, falling outside of the scope of this invention (such as the mixtures of products yielded by the UOP HF alkylation technology [so-called alkylates] and C5-C7 i-paraffins) possess low lubricating capability by themselves and therefore result in a large wear diameter of the test specimen in the HFRR test described hereinafter. This means that these materials may cause significant wear in the fuel supply system, particularly in the fuel supply and injection pumps and the fuel injection nozzles. The data of Table 1 also show that the lubricity of product A according to this invention is clearly better and thus improves the lubricity of conventional fuels when blended into those and therefore eliminates the necessity of using separate lubricity improver additives.

[0023] Product B according to this invention is a mixture of 95.00-99.95% by weight i- and n-paraffins containing ten to twenty five, preferably twelve to twenty and even more preferably fourteen to eighteen carbon atoms, consisting in main bulk of n-paraffins and to a lesser degree of i-paraffins, and 0.05-1.00% by weight carboxylic acids containing twelve to fourteen carbon atoms and/or carboxylic acid esters containing twelve to sixteen carbon atoms.

[0024] The i/n ratio in the mixture of i- and n-paraffins is generally 1:9 to 5:6, preferably 1:4 to 2:3 and even more preferably 1:2 to 3:7.

[0025] The boiling range of product B is 160-400°C, preferably 180-360°C and even more preferably 180-345°C.

[0026] As examples of the i- and n-paraffins occurring in the mixture of i- and n-paraffins, i- and n-decane, i- and n-undecane, i- and n-dodecane, i- and n-tridecane, i- and n-tetradecane, i- and n-hexadecane, i- and n-heptadecane, i- and n-octadecane, i- and n-nonadecane and i- and n-eicosane may be mentioned. The i-paraffins contained in the mixture of i- and n-paraffins are paraffins with branched carbon chains in which the location of branching is arbitrary, but is located preferably at the second to seventh and especially preferably at the second and fifth carbon atoms.

atom from the end of the chain and the side branch is preferably a methyl group and/or ethyl group. Advantageous components of the mixture of i- and n-paraffins are n-pentadecane and n-hexadecane, as well as 5-methyl-hexadecane and 2-methyl-tridecane.

As examples of carboxylic acids occurring in the mixture of carboxylic acids and/or carboxylic acid esters, dodecanoic acid (lauric acid), tridecanoic acid and tetradecanoic acid may be mentioned. As examples of carboxylic acid ester, ethyl-caprinate, butyl-octanoate, propyl-laurate, methyl-myristate, butyl-laurate and ethyl-myristate may be mentioned. As preferred examples of carboxylic acids occurring in the mixture of carboxylic acids, and/or carboxylic acid esters, dodecanoic acid and tetradecanoic acid may be mentioned while methyl-esters may be mentioned as preferred examples of carboxylic acid esters.

The mass ratio of carboxylic acids to carboxylic acid esters in the mixture of carboxylic acids and/or carboxylic acid esters is 1:100, preferably 1:40 and even more preferably 1:30.

As examples of carboxylic acids occurring in the mixture of carboxylic acids and/or carboxylic acid esters, dodecanoic acid (lauric acid), tridecanoic acid and tetradecanoic acid may be mentioned. As examples of carboxylic acid ester, ethyl-caprinate, butyl-octanoate, propyl-laurate, methyl-myristate, butyl-laurate and ethyl-myristate may be mentioned. As preferred examples of carboxylic acids occurring in the mixture of carboxylic acids, and/or carboxylic acid esters, dodecanoic acid and tetradecanoic acid may be mentioned while methyl-esters may be mentioned as preferred examples of carboxylic acid esters.

The sulfur and nitrogen content of product B according to this invention is favorably less than 5 mg/kg, especially favorably less than 1 mg/kg as well as preferably containing aromatic and cycloalphatic components at only up to 2% by weight level and especially preferably at up to 1% by weight level. Additionally, its cetane number is at least 74, preferably 85-89 and especially preferably 90-95. Furthermore, product B possesses excellent inherent lubricity partly due to the i- and n-paraffins with higher carbon numbers and partly to the carboxylic acids and/or carboxylic acid esters contained therein.

Product B according to this invention can therefore be used advantageously in Diesel engines as a fuel where - due to its inherent lubricity - it may be used as motor fuel by itself, i.e. without the commonly used state of the art additives, or blended with the standard additives. Furthermore, Product B can be used as a component of fuel blends, preferably as a lubricity improver component. The amount of product B in such fuel blends is generally 2-30% by weight, preferably 4-25% by weight and especially preferably 5-20% by weight.

Product C according to this invention is a mixture of 5-20% by weight, preferably 7-10% by weight carboxylic acids containing nine to fourteen, preferably ten to twelve carbon atoms, and 80-95% by weight, preferably 90-93% by weight carboxylic acid esters containing twelve to nineteen carbon atoms.

As examples of the carboxylic acid occurring in the mixture of carboxylic acids, nonanoic acid, decanoic acid, undecanoic acid, dodecanoic acid, tridecanoic acid, tetradecanoic acid and palmitic oil acid may be mentioned. Preferred components of the carboxylic acid mixture are the decanoic acid and dodecanoic acid.

As examples of the carboxylic acid esters occurring in the mixture of carboxylic acid esters, methyl-palmitate, methyl-pentadecanoate, ethyl-pentadecanoate, methyl-tridecanoate, ethyl-tridecanoate, methyl-myristate, ethyl-myristate, ethyl-pentadecanoate, methyl-palmitoleate and methyl-oleate may be mentioned. Preferred components of the mixture of carboxylic acid esters are the methyl-tridecanoate, methyl-palmitoleate and methyl-oleate.

Product C according to this invention can be used as lubricity improver additive in motor fuels and fuel blends, preferably with low sulfur and nitrogen contents, as well in motor fuels and fuel blends with reduced aromatics levels, in an amount of 100-2000 mg/kg, advantageously in 200-1500 mg/kg and especially advantageously in 300-600 mg/kg. The lubricity improving effect of product C in fuel, such as in E85 (ASTM D5798) motor gasoline and diesel oil, is illustrated in Table 2 as determined by HFRR lubricity test.

Product D according to this invention is a mixture of i- and n-paraffins containing ten to twenty six, preferably ten to twenty four and even more preferably eleven to twenty two carbon atoms, where the i/n ratio is generally 1.5:1 to 5:1, preferably 2:1 to 4:1 and even more preferably 2.5:1 to 3.3:1.

The boiling range of product D is 160-420°C, preferably 180-370°C and even more preferably 190-360°C.

As examples of the i- and n-paraffins occurring in the mixture of i- and n-paraffins, i- and n-decanes, i- and n-undecane, i- and n-dodecanes, i- and n-tridecanes, i- and n-tetradecanes, i- and n-pentadecanes, i- and n-hexadecanes, i-
and n-heptadecane, i- and n-octadecane, i- and n-nonadecane, i- and n-eicosane, i- and n-heicosane, i- and n-docosane, i- and n-tricosane, i- and n-tetracosane, i- and n-pentacosane and i- and n-hexacosane may be mentioned. The i-paraffins contained in the mixture of i- and n-paraffins are paraffins with branched carbon chains in which the location of branching is arbitrary, but is located preferably at the second to seventh carbon atom from the end of the chain and the side branch is preferably a methyl group, ethyl group and/or propyl group. Especially advantageous components of the n-paraffins are n-paraffins containing fifteen to eighteen carbon atoms, such as n-pentadecane, n-hexadecane, n-heptadecane and n-octadecane, while especially advantageous components of i-paraffins are 2-methyl-undecane, 2-methyl-dodecane, 2-methyl-tridecane, 2-methyl-tetradecane, 2-methyl-pentadecane, 2-methyl-hexadecane, 2-methyl-heptadecane, 5-methyl-hexadecane, 5-methyl-heptadecane, 5-methyl-octadecane, 5-methyl-nonadecane, 5-methyl-eicosane and 2,4,6-trimethyl-nonadecane.

According to this invention the three paraffin fractions (products A, B and D) and the polar product mix (product C) are produced advantageously by a special hydrocracking process. This special hydrocracking process differs from the usual hydrocracking process (Hydrocarbon Processing, 1988, Refining Handbook, Houston, Gulf Publishing Co.) in that the processing parameters are adjusted between relatively narrow limits and their beneficial combination results in the course of the special hydrocracking process according to this invention the feedstock is treated with hydrogen at 160-420°C temperature and 5-100 bars pressure in the presence of a heterogeneous catalyst applied on a carrier, where the volumetric ratio of hydrogen to feedstock is 200-2000 Nm³/m³ and the hourly feedstock load (feed rate) is up to 10 m³ feed/m³ catalyst.

According to this invention the three paraffin fractions (products A, B and D) and the polar product mix (product C) are produced advantageously by a special hydrocracking process. This special hydrocracking process differs from the usual hydrocracking process (Hydrocarbon Processing, 1988, Refining Handbook, Houston, Gulf Publishing Co.) in that the processing parameters are adjusted between relatively narrow limits and their beneficial combination results in reaction products with new composition in an unexpected manner at a yield exceeding that achieved by the current state of the art. In the course of the special hydrocracking process according to this invention the feedstock is treated with hydrogen at 160-420°C temperature and 5-100 bars pressure in the presence of a heterogeneous catalyst applied on a carrier, where the volumetric ratio of hydrogen to feedstock is 200-2000 Nm³/m³ and the hourly feedstock load (feed rate) is up to 10 m³ feed/m³ catalyst.

In the course of the process according to this invention the feedstock is converted by contacting it with hydrogen and catalyst. The conversion of the feedstock takes place in several sequential reaction steps. The conversion starts with the hydrogenating saturation of the unsaturated carbon-carbon bonds, resulting in the formation of saturated triglycerides. The next step is the break-up of the ester bonds in the triglycerides, resulting in the formation of fatty acids (carboxylic acids) and propane. Further on the fatty acids are converted into paraffins, accompanied by water formation and/or carbon dioxide and carbon monoxide generation. The paraffins formed may undergo cracking to a small extent during the process and hydrocarbons with shorter carbon chains may form. The branched chain i-paraffins are formed in the course of isomerization reactions from straight chain hydrocarbons, particularly from n-paraffins.

Both the feedstock and the intermediate products may take part in secondary reactions during the process. Such a reaction is the formation of gum from the unsaturated triglycerides and fatty acids present in the feedstock. Another secondary reaction is the reaction of the formed fatty acid intermediate products with the alkaline metal and alkaline earth metal contaminants of the feedstock, during which tenside-like compounds (soaps) may form.

Any raw material suitable for the production of paraffin fractions, preferably paraffin fractions usable as motor
fuel, fuel blend component and/or additives of motor fuels and fuel blends can be used as the initial feedstock in the process according to this invention. Raw materials originating in renewable sources are preferred. As examples of such raw materials, oils and fats of vegetable and/or animal origin and mixtures of these can be mentioned, which contain triglycerides and/or fatty acids and/or fatty acid esters. These may originate partially or totally from the forestry and agriculture sectors, from the food industry (e.g. slaughter-houses, meat processing), family cooking and public catering and similar sources, for example vegetable oils [sunflower seed oil, rape oil, peanut oil, oils/fats produced from specially bred plants (from hybrid plants, such as hybrid plants containing erucic acid) or genetically modified plants], animal fats and tallow, spent cooking oils and fats from deep fryers (preferably spent fats of the special Hungarian hog, Mangalica), alga oils and similar substances. Blends of the above feedstocks and fossil energy carriers, such as mixtures of crude oil and derivatives thereof may also be utilized.

[0047] The carbon number of the fatty acid components of triglycerides and/or fatty acids and/or various fatty acid esters present in the feedstock is 6 to 28 or higher. Feedstocks containing fatty acids and/or fatty acid components with carbon numbers ranging from 20 to 28 are especially advantageous. The sulfur content included in the organic bonds of the feedstocks is preferably up to 1000 mg/kg and the aromatic hydrocarbon content is up to 10% by weight.

[0048] The initial feedstock undergoes optionally a pretreatment. Pretreatment can be realized for example by heat treatment and/or physical and/or chemical methods. Cleaning carried out with indifferent materials (such as bentonite, pearlite) for purification and/or filtration and mild pre-hydrogenation at 50-350°C, preferably at 150-200°C temperature and 5-60 bars, preferably 10-30 bars pressure may be mentioned as examples of feedstock pretreatment. The catalyst usable for pre-hydrogenation is one or more metal(s) included in group VIII and/or group VI B of the periodic system and/or compounds thereof, such as palladium, platinum, nickel-molybdenum, cobalt-molybdenum, nickel-cobalt-molybdenum, optionally applied onto some carrier, such as alumina, silica and/or zeolite carriers. The application of the nonpyrophoric Raney-nickel catalyst is particularly advantageous. In the course of pre-hydrogenation (pre-hardening) preferably not only the saturation of double olefinic bonds is carried out in order to avoid undesired secondary reactions, but the components poisonous for the catalyst(s) of the subsequent catalytic step(s) (alkaline metals, for example) are also removed.

[0049] In this special hydrocracking process the optionally pretreated feedstock is contacted with one or more heterogeneous catalyst(s) at temperatures ranging from 160°C to 420°C, preferably from 200°C to 310°C and especially preferably from 220°C to 360°C. The total pressure is 5-100 bars, preferably 10-70 bars and especially preferably 10-40 bars. The value of the hourly feedstock load (feed rate) is up to 10 m³ feedstock/m³ catalyst. The volumetric hydrogen to feedstock ratio is 200-2000 Nm³/m³, preferably 300-800 Nm³/m³ and especially preferably 350-600 Nm³/m³.

[0050] The special hydrocracking process is preferably carried out in the presence of some heterogeneous catalyst applied on some carrier. The suitable heterogeneous catalyst applied on some carrier is chosen as one or more metal(s) included in group VIII and/or VI B of the periodic system and compounds thereof applied on some carrier. As examples of the one or more metal(s) included in group VIII and/or VI B of the periodic system, nickel, cobalt, molybdenum, tungsten, nickel-molybdenum, cobalt-nickel-molybdenum and similar metals and alloys may be mentioned. As examples of metal compounds, oxides, sulfides, nitriles, phosphides and the like may be mentioned. Preferred metal compounds are the nickel-oxide, nickel-sulfide, molybdenum-oxide, molybdenum-sulfide, tungsten-oxide and tungsten-sulfide. Especially advantageous catalysts are the NiMo, MoCo, NiMoCo and NiW metal combinations and fully or partially sulfidized variants thereof, as well as the NiMoP and sulfidized NiMoP metal compound. Amorphous alumina, silica, amorphous Al₂O₃-SiO₂, magnesium-oxide and mixtures thereof are suitable as carrier media for example. Carriers with pore sizes of 2-50 nm in general but preferably of 5-30 nm, i.e. containing so-called mesopores, and having at least a specific surface area of 300 m²/g, can be used advantageously. As favorable examples of heterogeneous catalyst applied on carrier, NiMo/Al₂O₃, NiMoCo/Al₂O₃, NiW/Al₂O₃, NiMoP/Al₂O₃, sulfidized NiMoP/Al₂O₃ and NiMo/amorphous SiO₂-Al₂O₃ can be mentioned. The heterogeneous catalysts on carrier applied in the context of this invention optionally may also contain other elements and compounds as well, such as boron, zirconium-and/or titanium-oxides and/or phosphoric acid anhydrides. Catalysts containing phosphorous and/or boron are advantageous.

[0051] During the implementation of the process according to this invention, either the same catalyst may be used for the entire process, or the various stages of the process are carried out with two or more different catalysts. In this latter case two or more different catalyst beds are installed in the same vessel if one single reactor is used, or two or more different catalysts are installed both inside one reactor or in each reactor if several reactors are used.

[0052] Preferably the metals are present on the carrier in partially or totally sulfidized condition, i.e. in the form of metal-sulfides.

[0053] In order to maintain the sulfidized condition of the catalyst at a constant level, the catalyst system is preferably contacted with a sulfiding agent during the process, because the reversibly bound sulfur is carried away continuously from the catalyst surface by the effluent product mix. To make up this sulfur loss, hydrogen sulfide may be used as sulfiding agent, for example in the form of a gas containing hydrogen sulfide (e.g. in the form of the off-gas from a hydrodesulfurizing unit containing hydrogen sulfide) and/or a sulfur compound easily decomposing at the reaction temperature, for example dialkyl-disulfide, such as dimethyl-disulfide, diethyl-disulfide, ethyl-methyl-disulfide or di-tert-butyl-
disulfide, dialkyl-polysulfide, such as dioctyl-polysulfide, and/or sulfur compounds containing oxygen, such as dimethyl-sulfoxide or methyl-mercapto-acetate, ethyl-2-mercapto-acetate, ethyl-hexyl-mercapto-acetate or methyl-3-mercapto-propionate. The amount of the sulfidizing agent is generally at least 500 vppm, favorably minimum 0.15% (v/v) and especially advantageously 0.25% (v/v).

[0054] We have recognized that the activity and selectivity of the catalyst(s) employed remains at nearly constant level if agents inhibiting oxidation and/or gum formation are added to the feedstock as indifferent materials in the special hydrocracking process according to this invention. The cause of this is that the components containing olefinic double bonds of both the feedstock and the intermediate product undergo spontaneous reactions resulting in coke-like substances depositing on the catalyst and thereby deactivating it, which leads to increased pressure drop across the reactor, and in the worst case, to fouling/plugging thereof. Such agents inhibiting oxidation and/or gum formation are for example the following: dialkyl-phenols, such as di-tert-butyl-phenol, polyalkyl-phenols, dialkyl-cresols, such as the 2,6-di-tert-butyl-p-cresol, as well as dialkylbiphenyl-amines, such as the diethyl-biphenyl-amine or ethyl-methyl-biphenyl-amine and the like. The combined application of alkyl-biphenyl-amines and methyl--bis-di-tert-butyl-phenol (MBDTBP) is especially preferred. The agent inhibiting oxidation and/or gum formation is generally used in the range of 20-1000 mg/kg, preferably 200-1000 mg/kg and especially advantageously 300-400 mg/kg with respect to the amount of the feedstock.

[0055] In a preferred embodiment of the process according to this invention, the sulfidizing agent, for example dimethyl-disulfide, and the agent inhibiting oxidation and/or gum formation are employed simultaneously, contributing an especially advantageous synergistic effect in maintaining the catalyst activity at a constant level and in increasing the product yield.

[0056] The maintenance of the activity and selectivity of the catalyst(s) employed is further facilitated by the circumstance that the tenside-like compounds (soaps) formed as intermediate products from the feedstock (see above) prevent the adhesion of the precursors of gum and coke formation on the surface of the catalyst(s) due to their surface-active (detergent) effect, further extending the service life of the catalyst(s). In a subsequent phase of the process according to this invention these tenside-like compounds undergo additional reactions and reaction products containing the desired compounds are also formed from these. As the result of the combined effect of the sulfidizing agent as well as the agent inhibiting oxidation and/or gum formation dosed according to this invention, plus said tenside-like compounds, the service life (cycle time) of the catalyst(s) can be extended by 100-150%.

[0057] As mentioned above, during the process according to the invention the feedstock is converted to the desired one or more paraffin fractions through a series of operations comprising several reactions. These reactions may be divided into three main groups. In the first group of reactions, double bonds are saturated and the esters are decomposed. Thus, the decomposition of triglycerides is completed in the course of these reactions, and carboxylic acids, carboxylic acid esters as well as tenside-like compounds are formed. In the second group of reactions, the carboxylic acids, carboxylic acid esters as well as tenside-like compounds are further decomposed, resulting in the formation of n/paraffins. Finally in the third group of reactions, the desired concentrations of carboxylic acids and carboxylic acid esters is adjusted, as well as the sulfur content is removed. All the reactions taking place entail heat generation but the rate of heat generation differs from group to group. Thus the process according to this invention can be divided into several steps based on the reactions taking place, where the reactions taking place can be controlled on the basis of temperature increase occurring as the consequence of heat generation.

[0058] One preferred embodiment of the process is carried out according to the above series of reactions in one or more steps and in one or more reactors per step under identical or differing conditions per step and/or reactor. In an especially preferred embodiment, the process is carried out in three steps conforming to the above-mentioned three groups of the reactions taking place. The first step is realized in one or more, generally in up to 10, preferably in up to 6 and especially advantageously in up to 3 reactors. The second step is realized in one or more, generally in up to 12, preferably in up to 6 and especially advantageously in up to 2 reactors. Finally, the third step is realized in one or more, generally in up to 3, preferably in up to 2 reactors.

[0059] The temperatures of the reactors used in each step are adjusted on the basis of the heat generating properties of the reactions taking place as follows. The inlet temperature of the reactor is set as a function of the chemical properties of the feedstock (such as the specific number of double bonds, the concentration of triglycerides and the like) to a value enabling the temperature rise taking place in the reactor as the consequence of exothermic chemical reactions, i.e. the difference between the inlet and outlet temperatures of the stream, to reach the level desirable for the various reactions to take place in the reactor at the desired rates. In this way it will be possible to achieve the formation of the desired intermediate and/or final products (for example tenside-like compounds, oxygen-containing polar compounds) at the desired rates. The formation of the tenside-like compounds is desirable in the reactor used for the first step, therefore the feedstock has to be introduced into the reactor at a temperature lower than customary. The conversion of intermediate products to final products is desirable in the reactor of used for the third step and this can be achieved by introducing the feed stream into this reactor at a higher temperature than customary. In the way described, the temperature will increase along the reactor in the flow direction of the feed streams, i.e. the temperatures of the inlet and outlet streams will not be identical.

[0060] In a preferred embodiment of the process according to this invention, the inlet temperature used for the first
step is generally 160-300°C, preferably 180-280°C and especially advantageously 200-250°C. The inlet temperature used for the second step is generally 200-360°C, preferably 250-340°C and especially advantageously 280-300°C. The inlet temperature used for the third step is generally 300-400°C, preferably 320-380°C and especially advantageously 340-370°C.

[0061] The formation of the desired intermediate and/or final products in each step can be influenced - in addition to temperature, although to a lesser extent-by the proper adjustment of other process parameters.

[0062] In a preferred embodiment of the process according to this invention, the catalyst used in the first step is chosen arbitrarily from the catalyst applied on carrier as specified previously, preferably the metal, metal complex and metal compound catalysts applied on carrier. The catalyst used in the second step is preferably partially or fully sulfidized metals, metal-phosphides or the mixture of partially or fully sulfidized metals and metal-phosphides, where the carrier medium is preferably Al2O3 or amorphous SiO2-Al2O3, preferably sulfidized Ni-MoP/Al2O3.

[0063] In a preferred embodiment of the process according to this invention, the volumetric hydrogen to feed ratio is adjusted to 200-500 Nm3/m3 value in the first step, to 500-1500 Nm3/m3 value in the second step and to 600-2000 Nm3/m3 value in the third step.

[0064] In a preferred embodiment of the process according to this invention, the feed rate is continuously reduced in the sequence of the first, second and third steps. This is achieved advantageously by carrying out the subsequent step with identical feed charge rate but over increasing volumes of catalyst beds.

[0065] As mentioned above, an especially preferred embodiment of the process according to this invention is carried out in three steps with several reactors used in each step. The first step is realized generally in up to 10, preferably in up to 6 and especially advantageously in up to 3 reactors. The second step is realized generally in up to 12, preferably in up to 6 and especially advantageously in up to 2 reactors. And finally the third step is realized generally in up to 3 and preferably in up to 2 reactors.

[0066] In the case of using several reactors for each step, not only individual steps can be carried out under different conditions, but process conditions differing between the reactors can be adjusted also for the reactors used in the particular step.

[0067] In a preferred embodiment of the process according to this invention, the inlet temperature of each reactor is adjusted so as to achieve identical temperature rising rates in each reactor. In order to accomplish this, the inlet temperature of the feed stream charged to the first reactor is set to the advantageous value mentioned above and then the effluent of the first reactor is sent to the second reactor at a temperature adjusted to a lower value than its outlet temperature. Setting the inlet temperature is carried out in the same way for all the reactors used in the particular step. The preset value of the inlet temperature preferably increases at each subsequent reactor in direct proportion to the number of reactors, that is the inlet temperature of each subsequent reactor is higher than the inlet temperature of the preceding reactor. The rate of increase of inlet temperatures depends on the number of processing steps. The increase of the inlet temperature per reactor in the first step is generally 0-50°C, preferably 5-30°C and especially advantageously 10-20°C and the inlet temperatures are preferably increased logarithmically, depending on the number of reactors. The increase of the inlet temperature per reactor in the second step is generally 0-30°C, preferably 5-20°C and especially advantageously 10-15°C and the inlet temperatures are preferably increased logarithmically or linearly, depending on the number of reactors. The increase of the inlet temperature per reactor in the third step is generally 0-20°C, preferably 5-15°C and especially advantageously 5-10°C.

[0068] The above statement, i.e. that in addition to temperature control the formation of the desired intermediate and/or final products can be influenced also by the other operating conditions of the process, applies even in the case of employing several reactors for each step.

[0069] In another preferred embodiment of the process according to this invention, different catalysts are used in the reactors used for the first step. In the first, second and optionally the third reactor of the first step, advantageously metal catalysts on carrier, for example NiMo/Al2O3 or NiMoCo/Al2O3 are used, while the catalyst used in the further reactors are partially or fully sulfidized metals, metal-phosphides or the mixture of partially or fully sulfidized metals and metal-phosphides, where the carrier medium is preferably Al2O3 or amorphous SiO2-Al2O3, preferably sulfidized Ni-MoP/Al2O3.

[0070] In respect of the process according to this invention the interpretation of the term reactor covers all equipment and/or technical facilities that enable the realization of chemical reactions separated in space and/or time and in a controlled manner. The term reactor may mean therefore a reactor vessel, a tubular reactor, a column, and the like, or separate parts formed in the internal volume of these, for example chambers or sections inside columns as well as series of these.

[0071] Adjusting the desired inlet temperature of the subsequent reactor from the outlet temperature of a reactor effluent stream can be realized by any known method. In the case of using a series of reactors or columns, said temperature
The process according to this invention yields at least two products according to the invention (for example A+B, A+D, A+B+C, A+C+D) for feedstocks rich in triglycerides, preferably containing at least 50% by weight triglyceride.
In the course of isomerization, the n-paraffin components of the product are converted to i-paraffins in the presence of hydrogen gas and an isomerization catalyst. The isomerization catalyst partially breaks up a C-C bond in the paraffin chain and enables thereby the migration of the molecule portion inside the molecule. A new C-C bond in formed as the termination of migration, thereby creating a branch inside the molecule. The migrating molecule portion contains generally one or two carbon atoms, thus the isomer created will be an i-paraffin containing a methyl or ethyl branch. The catalysts applicable in the isomerization process are for example the following: Pt/HZSM-22; Pt/SAPO-11 (such as that described in HU 225912), Pt/Beta-zeolite, SBA/15 (Santa Barbara Amorphous), Pt/amorphous SiO2/Al2O3, and the like, with an average pore diameter of 2-50 nm, advantageously 5-30 nm, the so-called mesopores, and have a specific surface area of at least 300 m2/g. Among these Pt/SAPO-11 described in HU 225912 has proven to be especially advantageous as being applicable successfully for the isomerization of n-paraffins with 10-26 carbon numbers. The advantageous temperature range is 300-360°C, the advantageous pressure range is 30-100 bars and the advantageous hydrogen to hydrocarbon ratio is 250-500 Nm3/m3.

The paraffin fractions produced by the process according to this invention can be used directly or may be processed in additional steps. Processing is carried out by the methods commonly employed in oil refining, for which clarification, filtration, cleaning may be mentioned as examples.

As mentioned above, hydrocarbons with shorter carbon chains, primarily C1-C4 hydrocarbons are also formed in the course of cracking reactions taking place in the process according to this invention. These may be utilized as fuel gas in processing units, or the C3-C4 fraction as auto gas. They may also be utilized as the initial feed for hydrogen production, and the hydrogen thus produced can be recycled to the process according to this invention, improving significantly the cost-effectiveness of the process.

The process according to this invention is carried out generally in the commonly used equipment of oil refining, fitted with the generally employed devices and instruments. As examples of such equipment, the usual reactor vessels, heat exchangers, separators, distillation columns, pumps, compressors and gas scrubbers may be mentioned.

The composition, properties and applications of product A obtained by the process according to this invention are identical with the general and advantageous composition, properties and applications indicated above at the description of product A according to this invention.

The composition, properties and applications of product B obtained by the process according to this invention are identical with the general and advantageous composition, properties and applications indicated above at the description of product B according to this invention.

The composition, properties and applications of product C obtained by the process according to this invention are identical with the general and advantageous composition, properties and applications indicated above at the description of product C according to this invention.

The composition, properties and applications of product D obtained by the process according to this invention are identical with the general and advantageous composition, properties and applications indicated above at the description of product D according to this invention.

As mentioned above, products A, B and D according to this invention can be utilized as motor fuels by themselves or blended with standard additives. Products A, B and D according to this invention can be utilized furthermore as components of motor fuel blends, advantageously as lubricity improving components. Fuels originating in any other sources, such as crude oil based gasolines or diesel oils, Fischer-Tropsch gasolines or gas oils and similar products, as well as the usual additives may be utilized as additional components in motor fuel blends. Furthermore products A, B and D according to this invention may be employed for energetics purposes, e.g. as heating fuels, and chemical purposes, e.g. as raw materials for ethylene production. Product C according to this invention can be utilized as lubricity improving additive in motor fuels and motor fuel blends, for example in motor fuels and motor fuel blends containing product A, B or D.

As mentioned above, the determination of lubricity is the lubricity test conducted with a HFRR (High-Frequency Reciprocating Rig) high frequency abrasion apparatus primarily for determining the lubricity of and diesel fuels in accordance with the specifications of MSZ ISO Standard 12156-1. A modified version of this method can also be used for characterizing the lubricity of gasolines. The test result is the size of the wear mark in μm units.

The test method used for the determination of flow properties is the CFPP (Cold Filter Plugging Point) test measuring the limit temperature of filtration in cold condition according to EN Standard 116.

This invention is presented in more detail by the following examples without limiting the scope of protection to these examples:

**Example 1:** The catalytic conversion of rape oil containing C20 and C22 fatty acids in 38% by weight quantity (with 10.3% by weight oxygen content) as feedstock is carried out in a pilot plant containing several reactors and fitted with the
standard equipment and machinery units of industrial hydrogenating systems. Special hydrocracking according to this invention is carried out in two (2) reactors connected in series and containing a total volume of 200 cm$^3$ sulfidized NiMoP/Al$_2$O$_3$ catalyst. Reaction conditions: 240°C first reactor inlet temperature, 325°C second reactor outlet temperature, 25-35 bars total pressure, 550 Nm$^3$/m$^3$ volumetric H$_2$ to feedstock ratio, 1.1 m$^3$/m$^3$ combined hourly feedstock charge rate over the two catalyst beds. The sulfur content of the feed is 800 mg/kg (with dimethyl-disulfide dosing) and the concentration of indifferent materials for controlling the reaction is 150 mg/kg diethyl-biphenyl-amine and methyl-bis-di-tet-tert-butyl-phenol (MBDTBP) in 1:2 mass ratio. 14% of the intermediate product (not containing any unconverted triglycerides anymore) leaving the first reactor is blended with the effluent product of the second reactor. The liquid organic product stream obtained after the separation of the gaseous and aqueous phases is split into three (A, B and C) products. The respective yields are: product A - 3.2% (boiling range 38-202°C), product B - 80.6% (boiling range 216-342°C) and product C - 2.3% (bottoms). Their properties are identical with those indicated in the section describing the products according to this invention.

**Example 2:** The process according to Example 1 is repeated with the difference that a 15% portion of the volume of crude rape oil required for the experiment is mixed as a pretreatment step with adsorption clay equivalent to 0.75% of the total feed amount and the same volume of Pertfil indifferent filtration material. After mixing in cold condition, the pulp obtained is mixed to the balance (85%) of the feed not containing indirect clarification and filtration materials heated previously to 60°C temperature under 10-20 kPa vacuum. Mixing is continued for half an hour and the feedstock is strained through a press filter. The yield obtained in this way is 99.85%. Subsequently, the procedure described in Example 1 is followed with the only difference that the outlet temperature of the second reactor is 315°C. The yields of the products obtained in this way are: A - 2.4% (boiling range 54-215°C); B - 82.4% (boiling range 235-345°C); C - 1.2% (bottoms).

**Example 3:** The process according to Example 2 is repeated with the difference that the catalyst employed is not the one used for Example 1, but NiMoP/Al$_2$O$_3$ catalyst in non-sulfidized condition and without the addition of any sulfiding agent. The inlet temperature of the first reactor is 250°C, the outlet temperature of the second reactor 345°C and the total pressure is 30-40 bars, while the other reaction conditions are unchanged. The yields of the products obtained in this way are: A - 4.7% (boiling range 32-208°C); B - 76.9% (boiling range 212-335°C); C-4.1% (bottoms).

**Example 4:** The process according to Example 1 is repeated with the difference that 10% of the catalyst bed in the first reactor is non-pyrophoric Raney-nickel catalyst. The yields of the products obtained after catalytic conversion and separation carried out under identical conditions are: A - 2.6% (boiling range 56-215°C); B - 82.2% (boiling range 230-346°C); C - 1.1% (bottoms).

**Example 5:** The special hydrocracking of the feed defined in Example 1 is carried out in the way and under the conditions defined in the previous examples with the difference that the total effluent stream of the first reactor is sent to the second reactor. The effluent stream from the second reactor, after the separation of the gaseous and aqueous phases and the fraction containing C$_8$- and lighter hydrocarbons, is sent to a reactor loaded with an isomerization catalyst where it is converted on Pt/SAPo-11 catalyst described in HU 225912 at 330-340°C temperature, 50 bars pressure with 2.0 m$^3$/m$^3$ hourly feedstock charge (feed rate) and 300 Nm$^3$/m$^3$ H$_2$/feed ratio. The features of product D (boiling range 180-360°C) obtained in this way are: yield - 82.5% (on feed); i/n mass ratio - 3.2:1; cetane number - 81; lubricity - 410 μm (by HFRR wear test); cold filtration limit temperature (CFPP) is -14°C. (The reason for this latter, relatively low CFPP value is that paraffins with higher molecular weight are hydrocracked at the middle of the chain to C$_{11}$-C$_{12}$ hydrocarbons in addition to the rearrangement of the skeleton structure.)

**Example 6:** The process is carried out as described in Example 1 with the difference that the total effluent stream of the first reactor is sent to the second reactor and the total pressure is set to a value of 20 bars. The liquid organic product stream obtained after the separation of the gaseous and aqueous phases is split into three (A, B and C) products with the following yields: A - 1.2% (boiling range 123-250°C); B - 84.2% (boiling range 263-336°C); C-1.9% (bottoms).

**Example 7:** The catalytic conversion of sunflower oil (with 11% by weight oxygen content) as feedstock is carried out in a pilot plant containing several reactors and fitted with the standard equipment and machinery units of industrial hydrogenating systems. Special hydrocracking according to this invention is carried out in three reactors connected in series and containing catalysts in a total volume of 4000 cm$^3$. The first and third reactors contain sulfidized NiMo/Al$_2$O$_3$ catalyst, while the second reactor is loaded with NiMo/amorphous SiO$_2$-Al$_2$O$_3$ catalyst. Reaction conditions: 220°C inlet temperature and 324°C outlet temperature at the catalyst bed of the first reactor, 308°C inlet temperature and 385°C outlet temperature at the catalyst bed of the second reactor, and 321°C inlet temperature and 360°C outlet temperature at the catalyst bed of the third reactor. The internal temperature on the catalyst bed in the second reactor varied along length L due to exothermic reactors according to the temperature profile shown below:

<table>

The total pressure of the reactor system is 20 bars, the volumetric H₂ to feedstock ratio 600 Nm³/m³, the combined hourly feedstock charge rate over the total catalyst volume 0.5 m³/m³. The sulfur content of the feedstock is 1000 mg/kg (with dimethyl-disulfide dosing).

In the system operated under the above conditions 21% by weight of triglycerides decomposed in the first reactor with the formation of 13.6% by weight tenside-like substances (carboxylic acids, carboxylic acid esters), while 94% by weight of triglycerides decomposed in the second reactor but the intermediate products formed were also converted to final products and only 18% by weight of tenside-like substances exit from the second reactor. The adjustment of the concentration of the tenside-like substances to 2.4% by weight takes place in the third reactor. As a result, the yields of the final products leaving this reactor are: product A (boiling range 140-235°C) 4.1% and product D (boiling range 225-412°C) 78.3%.

The advantage of the process according to this invention is that it enables the production of new products applicable as motor fuels and fuel blend components and additives for motor fuels and fuel blends in a more economical way and with a lower emission rate of harmful substances than similar products known to date, by a special hydrocracking technology starting from environment-friendly feedstocks and imposing less harm to the environment than similar processes known to date.

### Claims

1. A paraffin fraction comprising 98.0-99.9% by weight C₄-C₁₂ i- and n-paraffins with 1:4 to 4:1 i/n ratio and 0.1-2.0% by weight C₄-C₁₀ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 20--250°C.

2. A paraffin fraction comprising 95.00-99.95% by weight C₁₀-C₂₅ i- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C₁₂-C₁₄ carboxylic acids and/or C₁₂-C₁₆ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C.

3. A polar product mix comprising 5-20% by weight C₉-C₁₄ carboxylic acids and 80-95% by weight C₁₂-C₁₉ carboxylic acid esters.

4. A paraffin fraction comprising C₁₀-C₂₆ i- and n-paraffins with 1.5:1 to 5:1 i/n mass ratio, wherein the boiling range of the paraffin fraction is 160-420°C.

5. A process for the production of paraffin fractions by special hydrocracking comprising the treatment of a feedstock with hydrogen at 160-420°C temperature and 5-100 bars pressure in the presence of a heterogeneous catalyst applied on a carrier, wherein the volumetric ratio of hydrogen to feedstock is 200-2000 Nm³/m³ and the hourly feedstock load is up to 10 m³ feed/m³ catalyst.

6. The process according to claim 5, wherein the feedstock comprises fatty acids and fatty acid esters, preferably fatty acids and/or fatty acid esters with carbon numbers of 6-28 or higher, and more preferably triglycerides.

7. The process according to claim 5 or 6, wherein paraffin fractions useful as fuels, fuel blend components and/or additives for fuels and fuel blends are produced.

8. The process according to any one of claims 5 to 7, wherein the process is carried out in one or more stages and in one or more reactors in each stage under identical or different conditions per stage and/or reactor.

9. The process according to any one of claims 5 to 8, wherein the heterogeneous catalyst applied to a carrier is selected from the group consisting of the metals of group VIII and/or VIB of the periodic system and compounds thereof.

10. The process according to claim 9, wherein the metal of group VIII or VIB is selected from the group consisting of nickel, cobalt, molybdenum and tungsten and the metal compound is selected from the group consisting of the oxides, sulfides, nitrides and phosphides of said metals.

11. The process according to claim 10, wherein the compound of the metals of group VIII and/or VIB of the periodic system is selected from the sulfides thereof.

12. The process according to any one of claims 5 to 11, wherein the temperature range is 180-400°C, preferably 220-360°C.

13. The process according to either one of claims 5 to 12 wherein the pressure range is 10-70 bars, preferably 10-40 bars.

14. The process according to any one of claims 5 to 13, wherein the volumetric ratio of hydrogen to feedstock is 300-800 Nm³/m³, preferably 350-600 Nm³/m³.

15. The process according to any one of claims 5 to 14, wherein the hourly feedstock load is 0.2-10 m³ feedstock/m³ catalyst, preferably 0.4-3.0 m³ feedstock/m³ catalyst.

16. The process according to any one of claims 9 to 15, further comprising the addition of a sulfidizing agent to maintain the sulfidized state of the sulfide catalyst at a constant level.

17. The process according to claim 16, wherein the sulfidizing agent is selected from the group consisting of hydrogen sulfide and/or a sulfur compound easily decomposing at the reaction temperature, preferably dialkyl-sulfide, dialkyl-polysulfide and/or a sulfur compound containing oxygen, and more preferably dimethyl-disulfide, di-tert-butyl-di-sulfide, diocetyl-polysulfide and dimethyl-sulfoxide.

18. A process according to any one of claims 5 to 17, further comprising the addition of an agent inhibiting oxidation and/or gum formation as indifferent material for controlling the reaction.

19. A process according to claim 18, wherein the agent inhibiting oxidation and/or gum formation is selected from the group consisting of dialkyl-phenols, polyalkyl-phenols, dialkyl-cresols and dialkyl-biphenyl-amine, preferably of di-tert-butyl-phenol, 2,6-tert-butyl-p-cresol, diethyl-biphenyl-amine and ethyl-methyl-biphenyl-amine.

20. A process for the production of paraffin fractions, comprising the processing of feedstocks containing fatty acids and/or fatty acid esters with carbon numbers of 6-28 or more, preferably triglycerides by hydrocracking.

21. A process according to claim 20, wherein the paraffin fractions useful as fuels and fuel blend components and/or additives for fuels and fuel blends are produced.

22. A process according to claim 20 or 21, wherein hydrocracking is performed by a process according to any one of claims 5 to 19.

23. A paraffin fraction comprising 98.0-99.9% by weight C₅-C₁₂ i- and n-paraffins with 1:4 to 3:2 i/n ratio and 0.1-2.0% by weight C₁₄-C₁₆ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 20-250°C, obtainable by the process according to any one of claims 5 to 22.

24. A paraffin fraction comprising 95.00-99.95% by weight C₁₀-C₂₂ i- and n-paraffins with 1:9 to 3:2 i/n ratio and 0.05-1.00% by weight C₁₂-C₁₆ carboxylic acids and/or C₁₄-C₁₆ carboxylic acid esters, wherein the boiling range of the paraffin fraction is 160-400°C, obtainable by the process according to any one of claims 5 to 22.

25. A polar product mix comprising 5-20% by weight C₂₇-C₃₉ carboxylic acids and 80-95% by weight C₁₃-C₁₇ carboxylic acid esters, obtainable by the process according to any one of claims 5 to 22.

26. A paraffin fraction comprising C₁₀-C₂₅ i- and n-paraffins with 1.5:1 to 5:1 i/n mass ratio, wherein the boiling range of the paraffin fraction is 160-420°C, obtainable by the process according to any one of claims 5 to 22.

27. The use of the product according to claims 1 or 23 in internal combustion engines as fuel and/or fuel blend component.
28. The use of the product according to claims 2 or 24 in internal combustion engines as fuel and/or fuel blend component.

29. The use of the product according to claims 3 or 25 in internal combustion engines as lubricity improver additive.

30. The use of a product according to claims 4 or 26 in internal combustion engines as fuel and/or fuel blend component.
