(54) **Title**: A METHOD AND APPARATUS FOR CREATING A GENERALIZED RESPONSE MODEL FOR A SHEET FORMING MACHINE

(57) **Abstract**: A method and apparatus for creating a generalized response model for a sheet forming machine are provided. Sheet property profiles are measured while the setpoint of an actuator is changed. A response (or change) profile of the sheet property resulting from a setpoint change is calculated. A finite set of critical points are selected from the property response profile. Using the selected critical points, the property response profile is classified in one of a finite number of response types. Under each of the response types, the property response profile is fitted with a plurality of continuous functions associated therewith. These continuous functions are combined to form the response model that minimizes the deviation between the property response and the fitted combination of continuous functions.

WO 2010/080869 A1

A METHOD AND APPARATUS FOR CREATING A GENERALIZED RESPONSE MODEL FOR A SHEET FORMING MACHINE

BACKGROUND OF THE INVENTION

[0001] The present invention relates in general to controlling sheet forming processes and, more particularly, to improving the control of such processes.

[0002] In a sheet forming machine, the properties of a sheet vary in the two directions of the sheet, namely the machine direction (MD) which is the direction of sheet movement during production and the cross machine direction (CD), which is perpendicular to the MD and is the direction across the width of the sheet during production. Different sets of actuators are used to control the variations in each direction. The machine direction (MD) is associated with the direction of sheet moving speed, hence MD is also considered as temporal direction (TD). Similarly, the cross machine direction is associated with the width of the sheet, hence CD is also considered as spatial direction (SD).

[0003] The MD variations are generally affected by factors that impact the entire width of the sheet, such as machine speed, the source of base materials like wood fiber being formed into a sheet by the machine, common supplies of working fluids like steam, water and similar factors.

[0004] The CD variations are normally influenced by arrays of actuators located side-by-side across the width of the machine. Each actuator represents a zone of the overall actuator set. In a paper machine, the typical CD actuators are slice screws of a headbox, headbox dilution valves, steam boxes, water spraying nozzles, induction actuators, and other known devices. CD actuators present a great challenge for papermakers since a sheet-forming machine may have multiple sets of CD actuators, each with multiple numbers of zones spread across the entire width of a machine. Each set of CD actuators is installed at a different location of a sheet-making machine. There are different numbers of individual zones in each set of CD actuators. The width of each zone might also be different within the same set. Therefore, each set of CD actuators could have very different impacts on different sheet properties.

[0005] Measurements of sheet properties may be obtained from fixed sensors or from scanning sensors that traverse back and forth across the width of a sheet. The sensors are usually located downstream from those actuators that are used to adjust the sheet properties. The sensors measure the sheet properties while traveling across the sheet and use the measurement to develop a property profile across the sheet. The sheet property profile is typically discretized in a finite number of points across the sheet called “databoxes”. Presently, a sheet property profile is usually expressed in several hundreds to more than a thousand databoxes. The sheet property profiles accumulated in time form a two-dimensional matrix. The sheet property measurement at a fixed databox over a period of time can also be viewed like a profile in “temporal” direction or MD. The term “profile” is used with respect to either CD or MD. The sheet property profile is used by a quality control system (QCS) to derive control actions for the appropriate actuators so that the sheet property profile is changed toward a desired target profile. The target shape can be uniformly flat, smile, frown, or other gentle shapes. In order to control sheet property profiles with multiple set of CD actuators, it is important to measure and identify how each CD actuator influences the profiles.

[0006] Since the sensors are often located a considerable distance downstream from the CD actuators, the portion of the sheet (in the CD direction) influenced by a CD actuator zone but measured by the downstream sensors is not always perfectly aligned (in the CD direction) with the CD actuator zone, due to sheet shrinkage in the drying process or the sheet wandering sideways while the sheet is traveling through the machine. Furthermore, each CD actuator zone typically affects a portion of the profile that is wider than the portion corresponding to the width of the CD actuator zone. Thus, for controlling the CD profile of a sheet-forming machine, it is important to know which portion of the profile is affected by each CD actuator zone. The functional relationship that describes which portion of the profile is affected by each CD actuator zone is called "mapping" of the CD actuator zones.

[0007] In addition to knowing which portion of the profile is affected by which CD actuator zone, it is also important to know how each CD actuator

zone affects the profile. The functional curve that illustrates how the sheet property profile is changed by the adjustment of a CD actuator zone is called the "response model" of the CD actuator zones. Conventionally, the response model for a CD actuator zone is represented with an array of discrete values or is modeled with wave propagation equations if the response is related to the spread of the slurry on the Fourdrinier wire. For a typical set of CD actuators, there are easily tens to a few hundreds of zones. For each actuator zone, if the response model is represented by an array of uniform discrete points, the model will be specified in either actuator resolution, which is the number actuator zones, or property profile resolution, which could have hundreds to more than a thousand points. Many paper machines today are equipped with multiple sets of CD actuators. The number of points needed to represent the response model for one sheet property profile for all actuator zones is the number of points per actuator zone multiplied by the total number of zones of multiple sets of CD actuators. In practice each set of actuators can change several sheet property profiles at the same time, and each sheet property profile may also be affected by multiple sets of CD actuators with different responses. These different responses are classified as different response types. The number of points needed to represent a complete response model is further multiplied by the number of sheet property profiles. A complete response model that relates the multiple sets of CD actuators and the multiple high-resolution sheet property profiles specified by the conventional approach will need a massive number of points. This is very inefficient, rigid, and subjects to errors in practice.

[0008] For specifying response models for a multivariable sheet-making process, the conventional approaches become extremely cumbersome and impractical. An effective and generalized framework for specifying the response model of all CD actuators is needed to implement a better CD control for a sheet-making machine. Therefore, it would be desirable, if a response model could be effectively described using one or a few critical points and continuous functions. The present invention is directed to such a method and apparatus for creating a generalized response model using one or a few critical points and continuous functions in an effective and user-friendly manner.

SUMMARY OF THE INVENTION

[0009] In accordance with the present invention, a computer-implemented method is provided for creating a generalized response model for an actuator operable to control properties of a sheet. In accordance with the method, sheet property profiles are measured while the setpoint of an actuator is changed. A sheet property response profile is calculated from the change made to the setpoint of the actuator and the measured property profile of the sheet. Critical points of the sheet property response profile are determined and a response type is selected based on the sheet property response profile. Pairs of adjacent critical points are connected with continuous functions, respectively. The deviation is minimized between the sheet property response profile and the continuous functions by adjusting the critical points and the continuous functions. Also provided in accordance with the present invention is a computer system that is operable to perform the foregoing method.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] The features, aspects, and advantages of the present invention will become better understood with regard to the following description, appended claims, and accompanying drawings where:

[0011] Fig. 1 shows a schematic view of a paper machine and the relationship between a CD actuator bump test and its impacts on sheet property profiles;

[0012] Fig. 2 shows typical response types from CD actuators;

[0013] Fig. 3 shows a typical sheet property response profile and a generalized response model;

[0014] Fig. 4 shows a first type of a generalized response model;

[0015] Fig. 5 shows a fourth type of a generalized response model;

[0016] Fig. 6 shows a screen of a graphical user interface that permits a user to control the creation and modification of a generalized response model; and

[0017] Fig. 7 shows the screen with a pair of cross hairs that have been activated to move a critical point; and

[0018] Fig. 8 shows an example of a generalized response model in MD.

DETAILED DESCRIPTION OF ILLUSTRATIVE EMBODIMENTS

[0019] While the present invention is generally applicable to machines for processing wood fiber, metal, plastics, and other materials in the form of a sheet, it is particularly applicable to paper making machines and accordingly will be described herein with reference to such a machine. Referring now to Fig. 1, there is shown a paper making machine 10 that generally includes a stock approaching system 30, a headbox 12, a wire section 14, a press section 16, first and second dryer sections 18, 22, a sizing section 20, a calendar stack 24 and a roll-up spool 26. The paper making machine 10 makes a paper sheet by receiving furnished materials (including wood fibers and chemicals) that are diluted in water (the mixture being called "stock") through an in-flow 30, passing the stock through the headbox 12, dispersing the stock on the wire section 14, draining water to form a wet sheet 32, squeezing more water out at the press section 16, evaporating the remaining water at the dryer sections 18 and 22, treating the surface of the sheet 32 at the sizing section 20 and the calender stack 24 before rolling the sheet 32 on to the roll-up spool 26. The calender 24 stack also alters sheet thickness.

[0020] A computer system 28 is provided for use with the paper making machine 10. The computer system 28 includes a QCS for monitoring and controlling the paper making machine 10. The QCS comprises one or more controllers and one or more computers. The computer system 28 may further include one or more other computers for performing off-line tasks related to the paper making machine 10 and/or the QCS. At least one of the computers of the computer system 28 has user interface devices (UI) that includes one or more display devices, such as a monitor (with or without a touch screen) or a hand-held devices such as a cell phone for displaying graphics, and one or more entry devices, such as a keyboard, a mouse, a track ball, a joystick, a hand-held and/or voice-activated devices.

[0021] At the output side of the headbox 12 there is a narrow opening, also known as "slice opening", that disperses the furnished flow on the wire to form the paper sheet 32. The slice opening is adjusted by an array of slice screws 34 extending across the sheet width. The position settings of the slice screws 34 change the opening gap of the headbox 12 and influence the distribution and the uniformity of sheet weight, moisture content, fiber orientation, and

sheet thickness in the CD direction. The slice screws 34 are often controlled by CD actuators attached to the slice screws 34. The position of each slice screw 34 is controlled by setting a target position, also known as a "setpoint" for the corresponding CD actuator zone. Near the end of the wire section 14 or in the press section 16, one or multiple arrays of steam nozzles 36 that extend across the sheet web are often installed in order to heat the water content in the sheet 32 and allow the moisture content of the sheet 32 to be adjusted. The amount of steam that goes through the nozzles 36 is regulated by the target or setpoint selected for each nozzle 36. Further downstream in dryer sections 18 or 22, one or multiple arrays of water spray nozzles 42 that extend across the web are often installed in order to spray misty water drops on the sheet 32 to achieve uniform moisture profile. The amount of water sprayed on the paper sheet is regulated by the target or setpoint selected for each spray nozzle 42. Near the end of paper machine 10, one or multiple sets of induction heating zones 44 that extend across the web can also be installed in order to alter sheet glossiness and sheet thickness. The amount of heat applied by the different induction heating zones 44 is regulated by the target or setpoint selected for each induction heating zone 44. The influence of multiple sets of CD actuators (including those described above) can be seen on multiple sheet properties that are measured by sensors in one or multiple frames 38, 40, and/or 46. Usually, each frame has one or multiple sensors, each of which measures a different sheet property. For example, the frame 40 in Fig. 1 may have weight, moisture, and fiber orientation sensors which measure weight, moisture and fiber angle profiles, respectively. It is clear that a paper-making process is a multivariable process having multiple input variables and multiple output variables. In order to effectively control the multiple sheet properties with multiple set of CD actuators, it is important to use a multivariable control system.

[0022] The change of a sheet property profile as the result of a control action applied to a CD actuator zone is identified from the sheet-forming machines by performing actuator tests. There are various actuator tests that can be performed in order to identify profile responses (for example, see US 6,233,495). For simplicity of explanation, the simple "bump" or "step" test is illustrated here as an example. A "step test" or "bump test" applies a step

change to the input, also known as the "setpoint", of a zone in a set of CD actuators while the sheet measuring sensors are measuring the sheet properties. The change of a sheet property profile induced by a unit setpoint change of a CD zone is called a "property response profile", or simply "response profile". Referring to Fig. 1, bump tests are applied to the setpoints of zones "a" and "b" of the set of slice screws 34. The setpoint changes are illustrated by the plot 48 where the changes are applied to zones "a" and "b" but to no other zones. The responses of sheet weight, moisture, fiber angle and other sheet properties resulting from the step setpoint changes applied to zones "a" and "b" are measured by the sensors on the frame 40. As an example, the weight response profile 52, moisture response profile 50, and fiber angle response profile 54 are illustrated in Fig. 1. The shape and the magnitude of each response from each unit change of a zone setpoint can be quite different from the others. The response profile of a zone has certain distinct local maximum, local minimum, inflection, and/or corner points. These points are called "critical points". Critical points can be determined either manually by a person using the UI devices of the computer system 28 or automatically by a critical point analysis program stored in memory and executed by a processor of the computer system 28. Referring to Fig. 7, as an example, in an embodiment where critical points are determined manually by a user, the user clicks on a plotting window to activate a pair of cross hairs (vertical and horizontal lines on the plotting window) and moves the center of the cross hairs to a critical point, the coordinates of the selection point are registered for the selected point. Referring to Fig. 7, as another example, in the current embodiment where critical points are determined manually, the user enters the locations and gains of critical points directly. If the critical point is determined automatically, the computer programs use *min*, *max*, and *derivative* functions to locate the critical points using basic calculus principles. For example, the local maximum and local minimum both have their first derivatives equal to zero. The second derivative of a maximum point is negative and for a minimum point it is positive. For an inflection point, its second derivative is zero. For a corner point, the absolute value of its first derivative is one.

[0023] Using information obtained from an extensive study of various commercially available CD actuators and their effects on a wide range of sheet-making machines, the present invention classifies the response profile of a CD actuator zone into one of five major categories, also called "response types". Each response type is mainly defined by the number of its critical points and the relationship among its critical points. A response profile of a CD actuator zone may be classified into one of the response types either manually by a person using the UI devices of the computer system 28 or automatically by a classification program stored in memory and executed by a processor of the computer system 28.

[0024] Referring to Fig. 2, an example of five different response types is illustrated. The first response type 60 is commonly obtained from the CD actuators, such as dilution profilers, steam boxes, water sprays and induction profilers. The first response type 60 has only three critical points CP0, CP1, and CP2. The center critical point CP0 is the location of the maximal response magnitude and the other two critical points are the locations of the ends of the response. The second response type 62 is sometimes obtained from an infra-red heating profiler or a steam box. This type of response has five critical points, CP0 to CP2, CP5 and CP6. The two additional critical points CP5 and CP6 adjacent to the center critical point CP0 typically have larger magnitudes than the center critical point CP0 and their signs are the same as that of the center critical point CP0. The third and fourth response types 64, 66 are common to weight responses from slice screw actuators. The third response type 64 also has five critical points. In this response type, the two critical points, CP3 and CP4, adjacent to the center critical point CP0 have the opposite sign of the center critical point CP0. The fourth response type 64 has seven critical points: CP0 to CP6. The first two critical points CP5 and CP6 adjacent to the center critical point CP0 have larger magnitudes than the center critical point CP0 and the sign of their magnitudes is the same as that of the center critical point CP0. The critical points CP3 and CP4 have the opposite sign of the center critical point CP0. The fifth response type 68 is observed as the fiber angle response from slice screw actuators. The fifth response type 68 has either five or seven critical points. For the fifth response type 68, the center critical point CP0 is usually an inflection point with a

magnitude at or close to zero. Its immediate adjacent critical points CP5 and CP6 have significant magnitudes but opposite signs. The next pair of critical points CP3 and CP4 have the same sign as their adjacent critical points CP5 and CP6 respectively. Without a generalized model, it is rather difficult to handle these diverse responses effectively for implementing a multivariable control scheme.

[0025] A measured response profile (such as the weight response profile 52 in Fig. 1) that is obtained from a machine usually includes both the true property response and some disturbances. An example of a measured property response is shown in Fig. 3 and is designated by the reference numeral 70. The measured response profile 70 obtained from a machine is usually expressed in an array of values r(j) where "j" is the index of each databox as shown in Fig.3. The present invention uses the finite number of critical points (CP0 to CP6) and a finite set of continuous functions 72 to connect those critical points for modeling the true property response. As an example, the continuous functions are selected from a group of functions or their combinations that resemble a portion of the response profile such as Gaussian, sinusoidal, Mexican-hat wavelet, exponential, and/or polynomial functions. These functions are typically expressed as follows:

Gaussian function:

$$h(x) = be^{-a(x-x_p)^2} \qquad x_p < x$$

Sinusoidal functions:

$$h(x) = a + b\cos(c\pi(x - x_c)/(x_p - x_c)) \qquad x_c < x < x_p$$

$$h(x) = a + b\sin(c\pi(x - x_c)/(x_p - x_c)) \qquad x_c < x < x_p$$

Mexican-hat wavelet function

$$h(x) = [1 - b(x - x_p)^2]e^{-a(x-x_p)^2} \qquad x_p < x$$

Exponential function

$$h(x) = a(1 - e^{-(x-x_p)/b}) \qquad x_p < x$$

Polynomial function

$$h(x)=c_0+c_1(x-x_p)+c_2(x-x_p)^2+c_3(x-x_p)^3+... \qquad x_p<x$$

where "x" represents the continuous points along the CD axis;

x_p, x_c.are locations of critical points;

a, b, c, c_0, c_1, c_2, c_3, …are constant coefficients for functions.

Based on the responses obtained from a wide range of CD actuators and various sheet properties, the actual property responses are classified into a finite number of response types. As discussed above, Fig. 2 illustrates five different response types that have been obtained from a wide range of paper machines. A response profile of a CD actuator zone is first classified into one of the predetermined response types using the critical points obtained in the manner described above. This classification step may be performed manually by a person viewing a display of the actual response profile on a screen of the UI devices of the computer system 28 and then manually selecting one of the predetermined response types. Alternately, the classification step may be automatically performed by the classification program stored in memory and executed by a processor of the computer system 28. Once a response type has been selected, the critical points and the continuous functions are modified to properly fit with the measured response profile. This fitting is automatically performed by a fitting program that is stored in memory and executed by a processor of the computer system 28. The fitting program minimizes a quadratic function of the deviations between the measured response $r(j)$ and the generalized response model $g(x(j))$ at each databox j where "x" represents the continuous points along the CD axis of Fig. 3. The quadratic function Q of the deviations is illustrated in the following expression:

$$Q=\sum_{j=DB1}^{DB2}\left(r(j)-g(x(j))\right)^2/\left(DB2-DB1\right)$$

where DB1 and DB2 are the starting and ending databoxes of a response profile, respectively.

After the continuous functions have been fitted, the fitting program may optimize the critical points and the continuous functions by perturbing the

critical points slightly and fitting the continuous functions accordingly until the minimal quadratic value is achieved.

[0026] While the present invention is generally applicable to a wide variety of response types, those most commonly encountered response types are described and illustrated herein. The application of the generalized response models for two of these response types (namely the first response type 60 and the second response type 62) is discussed in detail below. A first generalized response model 90 for a response of the first response type 60 is shown in Fig. 4. The first generalized response model 90 is the most common generalized response model. The impact of many CD actuators such as dilution profilers, water spray profilers, and induction profilers on sheet property profiles such as weight, moisture and caliper, respectively, can be modeled with the first generalized response model 90. As shown, the first generalized response model 90 has three critical points 92, 94, and 96 (i.e. CP0, CP1, and CP2) and two continuous functions 98 and 100; the first continuous function 98 connects the critical point CP0 and CP1 and the second continuous function 100 connects the critical points CP0 and CP2. At each critical point, two connected functions should have smooth connections, i.e. two connected functions should have the same slope at each connection point (i.e. critical point).

[0027] The center critical point CP0 is considered the center of the first generalized response model 90. The location of the center critical point CP0, x_c, and its magnitude g_c, the locations of the other two critical points CP1, x_{rz}, and CP2 , x_{lz}, and the pre-selected continuous functions are the only information needed to create a first generalized response model 90. A first generalized response model 90 for a response of the first response type 60 is produced by connecting together the following two continuous functions:

$$g(x) = g_C e^{-a_{rp}(x-x_c)^2} \qquad x_c < x < x_{rz}$$

$$g(x) = g_C e^{-a_{lp}(x-x_c)^2} \qquad x_c > x > x_{lz}$$

where

x_c location of the center of the response CP0

g_c response magnitude at the center CP0

x_{rz} location of the right-side end point CP1

a_{rp} parameter to adjust the right-side Gaussian function

x_{lz} location of the left-side end point CP2

a_{lp} parameter to adjust the left-side Gaussian function

[0028] A plot of a second generalized response model 150 for a response of the fourth response type 66 is shown in Fig. 5. This type of the generalized response model is commonly obtained from the movement of slice screw actuators for slower paper machines or machines producing heavier grades of paper such as linerboard or kraftpaper. As shown in Fig. 5, the second generalized response model 150 has seven critical points 152, 154, 156, 158, 160, 162, and 164 (i.e. CP0, CP1, CP2, CP3, CP4, CP5 and CP6), two sinusoidal functions 166, 168 and four Mexican-hat wavelet functions 170, 172, 174, and 176. The first Mexican-hat wavelet function 174 connects the critical point CP1 and CP3. The second Mexican-hat wavelet function 170 connects the critical points CP3 and CP5. The first sinusoidal function 166 connects the critical points CP5 and CP0. The second sinusoidal function 168 connects the critical points CP0 and CP6. The third Mexican-hat wavelet function 172 connects critical points CP6 and CP4 and the last Mexican hat wavelet function 176 connects the critical points CP4 and CP2. At each critical point, two connected functions should have smooth connections, i.e. two connected functions should have the same slope at each connection point (i.e. critical point).

[0029] The center critical point CP0 is considered the center of the second generalized response model 150. The location of the center critical point CP0, x_c, and its magnitude g_c, the locations of the other six critical points and their magnitudes, x_{rp} and g_{rp} of CP5 (peak), x_{lp} and g_{lp} of CP6 (peak), x_{rn} and g_{rn} of CP3 (trough), x_{ln} and g_{ln} of CP4 (trough), x_{rz} of CP1 (end) and x_{lz} *of* CP2 (end), the sinusoidal functions and the Mexican hat wavelet functions are the only information needed to create a second generalized response model 150. The peak gains, g_{rp} and g_{lp} must have the same sign as that of the center gain g_c. The trough gains, g_{rn} and g_{ln} must have the opposite sign as that of the center gain g_c. A second generalized response model 150 for the fourth

response type 66 is produced by connecting together the following six continuous functions:

$$g(x)=g_{rp}[1-b_{rp}(x-x_{rp})^2]e^{-a_{rp}(x-x_{rp})^2} \qquad x_{rp}<x<x_{rn}$$

$$g(x)=g_{p}[1-b_{rn}(x-x_{rn})^2]e^{-a_{rn}(x-x_{rn})^2} \qquad x_{rn}<x<x_{rz}$$

$$g(x)=(g_{rp}+g_c)/2-[(g_{rp}-g_c)/2]\cos(\pi(x-x_c)/(x_{rp}-x_c)) \qquad x_c<x<x_{rp}$$

$$g(x)=(g_{lp}+g_c)/2-[(g_{lp}-g_c)/2]\cos(\pi(x-x_c)/(x_{lp}-x_c)) \qquad x_c>x>x_{lp}$$

$$g(x)=g_{lp}[1-b_{lp}(x-x_{lp})^2]e^{-a_{lp}(x-x_{lp})^2} \qquad x_{lp}>x>x_{ln}$$

$$g(x)=g_{p}[1-b_{ln}(x-x_{ln})^2]e^{-a_{ln}(x-x_{ln})^2} \qquad x_{ln}>x>x_{lz}$$

where

x_c	location of the center critical point CP0 (center of the response)
g_c	magnitude of the center critical point CP0
x_{rp}	location of the right-side peak CP5
g_{rp}	magnitude of the right-side peak CP5
x_{lp}	location of the left-side peak CP6
g_{lp}	magnitude of the left-side peak CP6
x_{rn}	location of the right-side trough CP3
g_{rn}	magnitude of the right-side trough CP3
x_{ln}	location of the left-side trough CP4
g_{ln}	magnitude of the left-side trough CP4
x_{rz}	location of the right-side end point CP1
a_{rp},b_{rp}	parameters to adjust the right-side response (from CP5 to CP3)
a_{rn},b_{rn}	parameters to adjust the right-side response (from CP3 to CP1)
x_{lz}	location of the left-side end point CP2
a_{lp},b_{lp}	parameters to adjust the left-side response (from CP6 to CP4)
a_{ln},b_{ln}	parameters to adjust the left-side response (from CP4 to CP2)

[0030] The creation of generalized response models, such as described above, is not limited to the example response types. The same modeling methodology can be extended to other response types with the properly defined critical points and properly selected continuous functions. As indicated in the previous five response types, there are no more than seven critical points needed to fully define a complete response curve. In practice, no more than ten critical points would be sufficient for the majority of applications.

[0031] Referring now to Figs. 6 and 7, there is shown a screen 200 of the UI that permits a user to control the creation and modification of a generalized response model. The screen 200 generally includes a graph 202, a measurement box 204, an actuator box 206, a zone index box 208, a response type auto-select button 210, a critical point auto-select button 212, a quadratic deviation box 214, a plurality of critical point buttons designated CP0, CP1, etc, and location and gain boxes associated with the critical point buttons, respectively.

[0032] The measurement box 204 and the actuator box 206 may be drop-down boxes that list the available measured properties (output variables) and actuators (input variables), respectively. A selection of a particular measured property and a particular actuator causes the screen 200 to be populated with the measured response profile and the generalized response model of that pair of input and output variables. Below the measurement box 204, a zone index box 208 shows the specific actuator zone that was manipulated (such as in a bump test) to obtain an actual response profile. Typically, the actuator zone in the zone index box 208 is the bump-tested zone of the actuator in the actuator box 206.

[0033] The graph 202 displays the plot 216 of a measured response profile between the property measurement and actuator selected in the measurement and actuator boxes 204, 206, respectively. In addition, the graph 202 displays the plot 218 of a generalized response model developed for the measured response profile, with the plot 218 of the model overlying the plot 216 of the measured response profile. The critical points used to develop the generalized response model are indicated by enlarged dots that may be highlighted with a different color than the plots 216, 218 of the actual response profile and the model for user friendliness.

[0034] The response type auto-select button 210 permits a user to select whether the classification of a response profile of a CD actuator zone into one of the predetermined number of response types (e.g. the first response type 60, etc.) is performed automatically by the classification program or manually by a user. More specifically, if the button 210 is activated (as indicated by a dot in the center thereof), the classification program automatically classifies the response profile. If the button 210 is deactivated, the response profile is classified pursuant to the response type that is manually entered by a user in the box 220 associated with the button 210. The default for the response type auto-select button 210 may either be the activated state (i.e., the classification program performs the classification) or the deactivated state (i.e., the classification is done manually). Typically, the activated state is the default. Even if the activated state is the default, a user may change the response type from the one selected by the classification program simply by entering a different response type into the box 220. In Figs. 6 and 7, the number "4" in the box 220 indicates that the fourth response type 64 has been selected.

[0035] The critical point auto-select button 212 permits a user to select whether the determination of the critical points of a response profile of a CD actuator is performed automatically by the critical point analysis program or manually by a user. More specifically, if the button 212 is activated (as indicated by a dot in the center thereof), the critical point analysis program automatically determines the critical points, whereas if the button 212 is deactivated, the critical points are manually determined. The default for the critical point auto-select button 212 may either be the activated state (i.e., the critical point analysis program performs the determination) or the deactivated state (i.e., the determination is done manually). Typically, the activated state is the default. To manually determine a particular critical point, a user activates the critical point button for the particular critical point, which, if not already done so, deactivates the button 212. A pair of cross hairs 224 (shown in Fig. 7) appears on the graph 202. A user moves the pair of cross hairs 224 with a pointing device (such as a mouse, track ball or touch screen) to the location on the graph 202 where the user believes the particular critical point should be located and then selects that location (such as by clicking the mouse). The coordinates (CD databox, Response magnitude) of the selected

location are then automatically registered into the location and gain boxes, respectively, for the particular critical point.

[0036] The critical point buttons that are displayed on the screen 200 may be determined by the response type that has been automatically or manually selected. For example, if the first response type 60 is selected, only three critical point buttons, CP0, CP1 and CP2, will be displayed on the screen, whereas, if the fourth response type 66 is selected (as shown in Figs. 6 and 7), seven critical point buttons, CPO-CP6, will be displayed.

[0037] The quadratic deviation box 214 displays the quadratic deviation that is obtained by the optimization program when it automatically fits or manually optimizes the critical points and continuous functions for a selected response type and determined critical points by a user. The magnitude of the quadratic deviation provides a measure of the fit of the generalized response model.

[0038] It should be appreciated that the GUI with the screen 200 is only one example of how the creation and modification of a generalized response model may be controlled by a user through a graphical computer interface. Other user interfaces may also be developed to perform the present invention based on different devices (such as touch screens, voice activated devices and laser pointers), as well as different user preferences and/or requirements.

[0039] The present technique can also be extended to create the MD response function. Referring to Fig. 8, an example of a machine direction response profile is modeled by two critical points where 230 (CP7) is the point the response starts to appear and 232 (CP8) is the point the response reaches saturation. Between these two critical points, the measured response is modeled by a continuous exponential function 234:

$$h(x) = a(1 - e^{-(x - x_p)/b}) \qquad x_p < x$$

The similar steps and user interface (UI) for matching continuous exponential function with the measured response can also be applied to this example.

[0040] The implementation of the present invention in the computer system 28 may be summarized as follows. The first step is to identify critical points in a response profile obtained from actuator tests. The critical points are

determined either automatically by the analysis program or manually by user's entry through the UI devices.

[0041] After the critical points are identified, the second step is to determine or select the response type and fit the continuous functions for the selected response type by minimizing the quadratic function of the deviations between the generalized response model and the actual response profile. Based on the selected functions, a specific quadratic value of the deviation between the selected continuous functions and the measured response profile is calculated.

[0042] The third step is to perturb the critical points slightly and fit the continuous functions accordingly until the minimal quadratic value of the deviation between the selected continuous functions and the measured response profile is achieved.

[0043] It should be appreciated that the second and third steps may be performed for each of the possible response types. The response type that yields the minimal quadratic value of the deviation between the selected continuous functions and the measured response profile is considered optimal and is used for the generalized response model.

[0044] The present invention provides a number of benefits. A large number of different response models can be derived from this generalized response model by using only a small number of critical points (up to seven for five responses illustrated). This generalized response model provides a response profile at any resolution, which permits a generated response profile to be converted to any desired resolution for a particular application. In a multivariable control application, the generalized response models provide a unified expression for different types of property responses. The display of the output plot of a response model and the variable values of the response model permit a user to readily understand the modeling of a property response and helps reduce the risk of using an incorrect response model for control tuning.

[0045] As will be appreciated by one of skill in the art and as before mentioned, the present invention may be embodied as or take the form of the method previously described, a computing device or system having program code configured to carry out the operations, a computer program product on a

computer-usable or computer-readable medium having computer-usable program code embodied in the medium. The computer-usable or computer-readable medium may be any medium that can contain, store, communicate, propagate, or transport the program for use by or in connection with the instruction execution system, apparatus, or device and may by way of example but without limitation, be an electronic, magnetic, optical, electromagnetic, infrared, or semiconductor system, apparatus, device, or propagation medium or even be paper or other suitable medium upon which the program is printed. More specific examples (a non-exhaustive list) of the computer-readable medium would include: a portable computer diskette, a hard disk, a random access memory (RAM), a read-only memory (ROM), an erasable programmable read-only memory (EPROM or Flash memory), an optical fiber, a portable compact disc read-only memory (CD-ROM), an optical storage device, a transmission media such as those supporting the Internet or an intranet, or a magnetic storage device. Computer program code or instructions for carrying out operations of the present invention may be written in any suitable programming language provided it allows achieving the previously described technical results. The program code may execute entirely on the user's computing device, partly on the user's computing device, as a stand-alone software package, partly on the user's computer and partly on a remote computer or entirely on a remote computer or server or a virtual machine. In the latter scenario, the remote computer may be connected to the user's computer through a local area network (LAN) or a wide area network (WAN), or the connection may be made to an external computer (for example, through the Internet using an Internet Service Provider).

[0046] It is to be understood that the description of the foregoing exemplary embodiment(s) is (are) intended to be only illustrative, rather than exhaustive, of the present invention. Those of ordinary skill will be able to make certain additions, deletions, and/or modifications to the embodiment(s) of the disclosed subject matter without departing from the spirit of the invention or its scope, as defined by the appended claims.

What is claimed is:

1. A method of creating a generalized response model for an actuator zone operable to control properties of a sheet, the method comprising:

receiving a measured property profile of the sheet while a setpoint of the actuator zone is changed;

calculating a sheet property response profile from the change made to the setpoint of the actuator and the measured property profile of the sheet;

determining critical points of the sheet property response profile;

selecting a response type based on the sheet property response profile;

connecting pairs of adjacent critical points with continuous functions, respectively; and

minimizing the deviation between the sheet property response profile and the continuous functions by adjusting the critical points and the continuous functions.

2. The method of claim 1, wherein the method comprises measuring a plurality of property profiles of the sheet while the setpoint of the actuator zone is changed.

3. The method of claim 1, wherein the step of calculating a sheet response profile comprises: for each measured property profile of the sheet, calculating a sheet property response profile using the change of the setpoint of the actuator zone and the measured property profile of the sheet.

4. The method of claim 1, wherein the step of selecting the response type comprises selecting the response type from a finite number of response types.

5. The method of claim 1, wherein one or more of the critical points are selected from the group consisting of extremum points, local maximums, local minimums, inflection points, corner points and combinations of the foregoing.

6. The method of claim 5, wherein the critical points include at least one extremum point.

7. The method of claim 1, wherein one or more of the continuous functions are selected from a group of functions or their combinations that resemble a portion of the property response profile.

8. The method of claim 1, wherein one or more of the continuous functions are selected from the group consisting of Gaussian functions, sinusoidal functions, Mexican hat wavelet functions, exponential functions, polynomial functions and combinations of the foregoing.

9. The method of claim 1, wherein the minimization of deviation is performed by fine-adjusting the critical points until a quadratic deviation value is at minimal.

10. The method of claim 1, where the minimization of deviation is performed by iterating the minimization of deviation through multiple response types until a quadratic deviation value is minimal.

11. The method of claim 1, wherein the steps of determining the critical points and selecting response type are performed manually then further comprising plotting the generalized response model on a graph and displaying the graph with the values of the critical points of the plotted generalized response model on a screen of a user interface (UI).

12. The method of claim 11, further comprising plotting the sheet property response profile on the graph so as to be displayed on the screen of the UI together with the plotted generalized response model, and wherein graphical symbols for the critical points are displayed on the graph of the UI.

13. The method of claim 12, further comprising changing the coordinates of one of the critical points by moving the graphical symbol for the critical point or changing the values of the coordinates on the screen of the UI.

14. The method of claim 13, wherein the step of selecting the response type comprises selecting the response type from a finite number of response types; and wherein the selected response is indicated on the screen of the UI, and further comprising changing the response type to another one of the finite number of response types using the UI.

15. A computer system operable to perform a method of creating a generalized response model for an actuator zone that controls properties of a sheet, the method comprising:

receiving a measured property profile of the sheet while a setpoint of the actuator zone is changed;

calculating a sheet property response profile from the change made to the setpoint of the actuator and the measured property profile of the sheet;

determining critical points of the sheet property response profile;

selecting a response type based on the sheet property response profile;

connecting pairs of adjacent critical points with continuous functions, respectively; and

minimizing the deviation between the sheet property response profile and the continuous functions by adjusting the critical points and the continuous functions.

16. The computer system of claim 15, wherein the method comprises measuring a plurality of property profiles of the sheet while the setpoint of the actuator zone is changed.

17. The computer system of claim 15, wherein the step of calculating a sheet response profile comprises: for each measured property profile of the sheet, calculating a sheet property response profile using the change of the setpoint of the actuator zone and the measured property profile of the sheet.

18. The computer system of claim 15, wherein the step of selecting the response type comprises selecting the response type from a finite number of response types.

19. The computer system of claim 15, wherein one or more of the critical points are selected from the group consisting of extremum points, local maximums, local minimums, inflection points, corner points and combinations of the foregoing.

20. The computer system of claim 19, wherein the critical points include at least one extremum point.

21. The computer system of claim 15, wherein one or more of the continuous functions are selected from a group of functions or their combinations that resemble a portion of the property response profile.

22. The computer system of claim 15, wherein one or more of the continuous functions are selected from the group consisting of Gaussian functions, sinusoidal functions, Mexican hat wavelet functions, exponential functions, polynomial functions and combinations of the foregoing.

23. The computer system of claim 15, wherein the minimization of deviation is performed by fine-adjusting the critical points until a quadratic deviation value is at minimal.

24. The computer system of claim 15, wherein the minimization of deviation is performed by iterating the minimization of deviation through multiple response types until a quadratic deviation value is minimal.

25. The computer system of claim 15, wherein the steps of determining the critical points and selecting response type are performed manually then further comprising plotting the generalized response model on a graph and displaying the graph with the values of the critical points of the plotted generalized response model on a screen of a user interface (UI).

26. The computer system of claim 25, wherein the method further comprises plotting the sheet property response profile on the graph so as to be displayed on the screen of the UI together with the plotted generalized

response model, and wherein graphical symbols for the critical points are displayed on the graph of the UI.

27. The computer system of claim 26, wherein the method further comprises changing the coordinates of one of the critical points by moving the graphical symbol for the critical point or changing the values of the coordinates on the screen of the UI.

28. The computer system of claim 15, wherein the step of selecting the response type comprises selecting the response type from a finite number of response types; and wherein the selected response is indicated on the screen of the UI.
