(54) Titre : VEGETAUX COMPORTANT DES SEQUENCES MUTANTES CONFERANT DES PROFILS D'ACIDES GRAS MODIFIES

(54) Title: PLANTS HAVING MUTANT SEQUENCES THAT CONFER ALTERED FATTY ACID PROFILES

(57) **Abrégé/Abstract:**

Seeds, plants and oils are provided having low FDA saturates; high oleic acid; low linoleic acid; high or low palmitic acid; low stearic acid; and low linoleic acid plus linolenic acid; and advantageous functional or nutritional properties. Plants are disclosed that contain a mutation in a delta-12 or delta-15 fatty acid desaturase gene. Preferred plants are rapeseed and sunflower plants. Plants carrying such mutant genes have altered fatty acid composition in seeds. In one embodiment, a plant contains a mutation in a region having the conserved motif His-Xaa-Xaa-Xaa-His, found in delta-12 and delta-15 fatty acid desaturases. A preferred motif has the sequence His-Glu-Cys-Gly-His. A preferred mutation in this motif has the amino acid sequence His-Lys-Cys-Gly-His. Nucleic acid fragments are disclosed that comprise a mutant delta-12 or delta-15 fatty acid desaturase gene sequence.

5 PLANTS HAVING MUTANT SEQUENCES THAT CONFER ALTERED
 FATTY ACID PROFILES

Technical Field

 This invention relates to *Brassica* seeds and plants having mutant sequences which confer altered fatty acid profiles on the seed oil. More particularly, the
10 invention relates to mutant delta-12 and delta-15 fatty acid desaturase sequences in such plants which confer such profiles.

Background of the Invention

 Diets high in saturated fats increase low density
15 lipoproteins (LDL) which mediate the deposition of cholesterol on blood vessels. High plasma levels of serum cholesterol are closely correlated with atherosclerosis and coronary heart disease (Conner et al., *Coronary Heart Disease: Prevention, Complications,*
20 *and Treatment*, pp. 43-64, 1985). By producing oilseed *Brassica* varieties with reduced levels of individual and total saturated fats in the seed oil, oil-based food products which contain less saturated fats can be produced. Such products will benefit public health by
25 reducing the incidence of atherosclerosis and coronary heart disease.

 The dietary effects of monounsaturated fats have also been shown to have dramatic effects on health. Oleic acid, the only monounsaturated fat in most edible
30 vegetable oils, lowers LDL as effectively as linoleic acid, but does not affect high density lipoproteins (HDL) levels (Mattson, F.H., *J. Am. Diet. Assoc.*, 89:387-391, 1989; Mensink et al., *New England J. Med.*, 321:436-441, 1989). Oleic acid is at least as effective in lowering
35 plasma cholesterol as a diet low in fat and high in

- 2 -

carbohydrates (Grundy, S.M., New England J. Med.,
314:745-748, 1986; Mensink et al., New England J. Med.,
321:436-441, 1989). In fact, a high oleic acid diet is
preferable to low fat, high carbohydrate diets for
5 diabetics (Garg et al., New England J. Med., 319:829-834,
1988). Diets high in monounsaturated fats are also
correlated with reduced systolic blood pressure (Williams
et al., J. Am. Med. Assoc., 257:3251-3256, 1987).
Epidemiological studies have demonstrated that the
10 "Mediterranean" diet, which is high in fat and
monounsaturates, is not associated with coronary heart
disease (Keys, A., Circulation, 44(Suppl):1, 1970).

Many breeding studies have been conducted to
improve the fatty acid profile of *Brassica* varieties.
15 Pleines and Freidt, Fat Sci. Technol., 90(5), 167-171
(1988) describe plant lines with reduced $C_{18:3}$ levels (2.5-
5.8%) combined with high oleic content (73-79%). Rakow
and McGregor, J. Amer. Oil Chem. Soc., 50, 400-403 (Oct.
1973) discuss problems associated with selecting mutants
20 for linoleic and linolenic acids. In. Can. J. Plant
Sci., 68, 509-511 (Apr. 1988) Stellar summer rape
producing seed oil with 3% linolenic acid and 28%
linoleic acid is disclosed. Roy and Tarr, Z.
Pflanzenzuchtg, 95(3), 201-209 (1985) teaches transfer of
25 genes through an interspecific cross from *Brassica juncea*
into *Brassica napus* resulting in a reconstituted line
combining high linoleic with low linolenic acid content.
Roy and Tarr, Plant Breeding, 98, 89-96 (1987) discuss
prospects for development of *B. napus* L. having improved
30 linolenic and linolenic acid content. European Patent
application 323,751 published July 12, 1989 discloses
seeds and oils having greater than 79% oleic acid
combined with less than 3.5% linolenic acid. Canvin,
Can. J. Botany, 43, 63-69 (1965) discusses the effect of

- 3 -

temperature on the fatty acid composition of oils from several seed crops including rapeseed.

Mutations typically are induced with extremely high doses of radiation and/or chemical mutagens (Gaul, 5 H. Radiation Botany (1964) 4:155-232). High dose levels which exceed LD50, and typically reach LD90, led to maximum achievable mutation rates. In mutation breeding of *Brassica* varieties high levels of chemical mutagens alone or combined with radiation have induced a limited 10 number of fatty acid mutations (Rakow, G.Z. Pflanzenzuchtg (1973) 69:62-82). The low α -linolenic acid mutation derived from the Rakow mutation breeding program did not have direct commercial application because of low seed yield. The first commercial cultivar 15 using the low α -linolenic acid mutation derived in 1973 was released in 1988 as the variety Stellar (Scarth, R. et al., Can. J. Plant Sci. (1988) 68:509-511). Stellar was 20% lower yielding than commercial cultivars at the time of its release.

20 Canola-quality oilseed *Brassica* varieties with reduced levels of saturated fatty acids in the seed oil could be used to produce food products which promote cardiovascular health. Canola lines which are individually low in palmitic and stearic acid content or 25 low in combination will reduce the levels of saturated fatty acids. Similarly, *Brassica* varieties with increased monounsaturate levels in the seed oil, and products derived from such oil, would improve lipid nutrition. Canola lines which are low in linoleic acid 30 tend to have high oleic acid content, and can be used in the development of varieties having even higher oleic acid content.

Increased palmitic acid content provides a functional improvement in food applications. Oils high 35 in palmitic acid content are particularly useful in the

- 4 -

formulation of margarines. Thus, there is a need for manufacturing purposes for oils high in palmitic acid content.

Decreased α -linolenic acid content provides a functional improvement in food applications. Oils which are low in linolenic acid have increased stability. The rate of oxidation of lipid fatty acids increases with higher levels of linolenic acid leading to off-flavors and off-odors in foods. There is a need in the food industry for oils low in alpha linolenic acid.

Delta-12 fatty acid desaturase (also known as oleic desaturase) is involved in the enzymatic conversion of oleic acid to linoleic acid. Delta-15 fatty acid desaturase (also known as linoleic acid desaturase) is involved in the enzymatic conversion of linoleic acid to α -linolenic acid. A microsomal delta-12 desaturase has been cloned and characterized using T-DNA tagging. Okuley, et al., Plant Cell 6:147-158 (1994). The nucleotide sequences of higher plant genes encoding microsomal delta-12 fatty acid desaturase are described in Lightner et al., WO94/11516. Sequences of higher plant genes encoding microsomal and plastid delta-15 fatty acid desaturases are disclosed in Yadav, N., et al., Plant Physiol., 103:467-476 (1993), WO 93/11245 and Arondel, V. et al., Science, 258:1353-1355 (1992). However, there are no teachings that disclose mutations in delta-12 or delta-15 fatty acid desaturase coding sequences from plants. Furthermore, no methods have been described for developing plant lines that contain delta-12 or delta-15 fatty acid desaturase gene sequence mutations effective for altering the fatty acid composition of seeds.

- 5 -

Summary of the Invention

The present invention comprises canola seeds, plant lines producing seeds, and plants producing seed, said seeds having a maximum content of FDA saturates of about 5% and a maximum erucic acid content of about 2% based upon total extractable oil and belonging to a line in which said saturates content has been stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds and canola oil having a maximum erucic acid content of about 2%, based upon total extractable oil, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having an FDA saturates content of from about 4.2% to about 5.0% based upon total extractable oil.

The present invention further comprises *Brassica* seeds, plant lines producing seeds, and plants producing seeds, said seeds having a minimum oleic acid content of about 71% based upon total extractable oil and belonging to a line in which said oleic acid content has been stabilized for both the generation to which the seed belongs and its parent generation. A further aspect of this invention is such high oleic acid seeds additionally having a maximum erucic acid content of about 2% based upon total extractable oil. Progeny of said seeds; and *Brassica* oil having 1) a minimum oleic acid content of about 71% or 2) a minimum oleic acid content of about 71% and a maximum erucic content of about 2% are also included in this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having an oleic acid content of from about 71.2% to about 78.3% based upon total extractable oil.

The present invention further comprises canola seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum linoleic acid content

- 6 -

of about 14% and a maximum erucic acid content of about 2% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent
5 generation. Progeny of said seeds and canola oil having a maximum linoleic acid content of about 14% and a maximum erucic acid content of about 2%, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said
10 seeds having a linoleic acid content of from about 8.4% to about 9.4% based upon total extractable oil.

The present invention further comprises *Brassica* seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum palmitic acid content
15 of about 3.5% and a maximum erucic acid content of about 2% based on total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds and canola having a
20 maximum palmitic acid content of about 3.5% and a maximum erucic acid content of about 2%, are additional aspects of this invention. Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having a palmitic acid content of from about 2.7% to
25 about 3.1% based upon total extractable oil.

The present invention further comprises *Brassica* seeds, plant lines producing seeds, and plants producing seeds, said seeds having a minimum palmitic acid content of about 9.0% based upon total extractable oil and
30 belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. A further aspect of this invention is such high palmitic acid seeds additionally having a maximum erucic acid content of
35 about 2% based upon total extractable oil. Progeny of

- 7 -

said seeds; and *Brassica* oil having 1) a minimum palmitic acid content of about 9.0%, or 2) a minimum palmitic acid content of about 9.0% and a maximum erucic acid content of about 2% are also included in this invention.

- 5 Preferred are seeds, plant lines producing seeds, and plants producing seeds, said seeds having a palmitic acid content of from about 9.1% to about 11.7% based upon total extractable oil.

The present invention further comprises *Brassica*
10 seeds, plant lines producing seeds, and plants producing seeds, said seeds having a maximum stearic acid content of about 1.1% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed
15 belongs and its parent generation. Progeny of said seeds have a canola oil having a maximum stearic acid content of about 1.1% and maximum erucic acid content of about 2%. Preferred are seeds, plant lines producing seeds, and plants producing seeds having a palmitic acid content
20 of from about 0.8% to about 1.1% based on total extractable oil.

The present invention further comprises *Brassica* seeds, plant lines producing seeds, and plants producing seeds, said seeds having a sum of linoleic acid content
25 and linolenic acid content of a maximum of about 14% based upon total extractable oil and belonging to a line in which said acid content is stabilized for both the generation to which the seed belongs and its parent generation. Progeny of said seeds have a canola oil
30 having a sum of linoleic acid content and linolenic acid content of a maximum of about 14% and a maximum erucic acid content of about 2%. Preferred are seeds, plant lines producing seeds, and plants producing seeds having a sum of linoleic acid content and linolenic acid content

- 8 -

of from about 11.8% to about 12.5% based on total extractable oil.

The invention further comprises *Brassicaceae* or *Helianthus* seeds, plants and plant lines having at least
5 one mutation that controls the levels of unsaturated fatty acids in plants. One embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a mutant delta-12 fatty acid desaturase conferring altered fatty composition in seeds
10 when the fragment is present in a plant. A preferred sequence comprises a mutant sequence as shown in SEQ ID NO:3. Another embodiment of the invention is an isolated nucleic acid fragment comprising a nucleotide sequence encoding a mutant delta-15 fatty acid desaturase. A
15 plant in this embodiment may be soybean, oilseed *Brassica* species, sunflower, castor bean or corn. The mutant sequence may be derived from, for example, a *Brassica napus*, *Brassica rapa*, *Brassica juncea* or *Helianthus* delta-12 or delta-15 gene.

20 Another embodiment of the invention involves a method of producing a *Brassicaceae* or *Helianthus* plant line comprising the steps of: (a) inducing mutagenesis in cells of a starting variety of a *Brassicaceae* or *Helianthus* species; (b) obtaining progeny plants from the
25 mutagenized cells; (c) identifying progeny plants that contain a mutation in a delta-12 or delta-15 fatty acid desaturase gene; and (d) producing a plant line by selfing.

Yet another embodiment of the invention involves a
30 method of producing plant lines containing altered levels of unsaturated fatty acids comprising: (a) crossing a first plant with a second plant having a mutant delta-12 or delta-15 fatty acid desaturase; (b) obtaining seeds from the cross of step (a); (c) growing fertile plants
35 from such seeds; (d) obtaining progeny seed the plants of

step (c); and (e) identifying those seeds among the progeny that have altered fatty acid composition. Suitable plants are soybean, rapeseed, sunflower, safflower, castor bean and corn. Preferred plants are rapeseed and sunflower.

5 The invention is also embodied in vegetable oil obtained from plants disclosed herein, which vegetable oil has an altered fatty acid composition.

 In accordance with an object of an aspect of the present invention there is provided an isolated nucleic
10 acid fragment comprising a full-length coding sequence of a *Brassicaceae* or *Helianthus* delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one
15 mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said at least one mutation renders the product of said desaturase gene non-functional.

 In accordance with another object of an aspect of the present invention there is provided an isolated nucleic
20 acid fragment comprising a full-length coding sequence of a *Brassicaceae* or *Helianthus* delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a Tyr-Leu-Asn-
25 Asn-Pro amino acid motif, wherein said at least one mutation renders the product of said desaturase gene non-functional and wherein said sequence includes said at least one mutation.

 In accordance with yet another object of an aspect of the present invention there is provided a plant cell of the
30 *Brassicaceae* or *Helianthus* families other than *Brassica napus*, said plant cell containing a full-length coding sequence of a delta-12 fatty acid desaturase gene, said

9a

coding sequence having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein
5 said mutation confers an altered fatty acid composition in seeds obtained from said plant cell.

In accordance with another object of an aspect of the present invention there is provided an isolated nucleic acid fragment comprising a full-length coding sequence of a
10 *Brassicaceae* delta-15 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon
15 encoding Asp, and wherein said at least one mutation renders the product of said desaturase gene non-functional.

In accordance with yet another object of an aspect of the present invention there is provided a *Brassicaceae* plant cell containing a full-length coding sequence of a
20 delta-15 fatty acid desaturase gene, said coding sequence having at least one mutation, in a region encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Asp, and wherein said mutation
25 confers an altered fatty acid composition in 'seeds obtained from said plant cell.

In accordance with another object of an aspect of the present invention there is a *Brassicaceae* plant cell containing:

30 a) a full-length coding sequence of a delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, said at least one mutation in said motif

9b

comprising a codon encoding Lys in place of a codon encoding Glu;

- b) a full-length coding sequence of a delta-15 fatty acid desaturase gene having at least one mutation, said at least one delta-15 gene mutation in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif, said delta-12 gene mutation and said delta-15 gene mutation conferring an altered fatty acid composition in seeds obtained from said plant cell.

In accordance with yet another object of an aspect of the present invention there is provided a *Brassicaceae* or *Helianthus* plant cell containing a full-length coding sequence of a delta-12 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a Tyr-Leu-Asn-Asn-Pro amino acid motif and wherein said mutation confers an altered fatty acid composition in seeds obtained from said plant cell.

In accordance with another object of an aspect of the present invention there is provided a method for producing a *Brassicaceae* or *Helianthus* plant cell line, comprising the steps of:

- a) inducing mutagenesis in cells of a starting variety of a *Brassicaceae* or *Helianthus* species;
- (b) obtaining one or more progeny plants from said cells;
- (c) identifying at least one of said progeny plants that contains a delta-12 fatty acid desaturase gene having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said delta-12 gene mutation renders the product of said delta-12 desaturase gene non-functional; and

9c

(d) producing said plant cell line from said at least one progeny plant by self-or cross-pollination, said plant cell line having said at least one delta-12 gene mutation.

In accordance with another object of an aspect of the present invention there is provided a method for producing a *Brassicaceae* plant cell line, comprising the steps of:

- a) inducing mutagenesis in cells of a starting variety of a *Brassicaceae* species;
- b) obtaining one or more progeny plants from said cells;
- 10 c) identifying at least one of said progeny plants that contains a delta-15 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon
15 encoding Lys in place of a codon encoding Asp, and wherein said at least one mutation renders the product of said delta-15 desaturase gene non-functional; and
- d) producing said plant cell line from said at least one progeny plant by self- or cross-pollination, said plant cell
20 line having said delta-15 gene mutation.

In accordance with yet another object of an aspect of the present invention there is provided a method for identifying a mutation in a *Brassicaceae* plant, comprising:

- a) providing a *Brassicaceae* plant having a decreased -
25 linolenic acid content as compared with a corresponding control *Brassicaceae* plant; and
- b) identifying at least one mutation in a delta-15 fatty acid desaturase gene of said plant, said at least one mutation in a region encoding a His-Asp-Cys-Gly-His amino
30 acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Asp, and wherein said mutation renders the product of said delta-15 fatty acid desaturase gene non-functional.

9d

In accordance with another object of an aspect of the present invention there is provided a method for identifying a mutation in a *Brassicaceae* or *Helianthus* plant, comprising:

- 5 a) providing a *Brassicaceae* or *Helianthus* plant having an increased oleic acid content as compared with a corresponding control *Brassicaceae* or *Helianthus* plant;
- b) identifying at least one mutation in a delta-12 fatty acid desaturase gene of said plant, said at least one
- 10 mutation in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said mutation renders the product of said delta-12 fatty acid desaturase gene non-functional.

- 15 In accordance with a further aspect of the present invention there is provided a *Brassicaceae* or *Helianthus* plant cell, said plant cell containing first and second delta-12 fatty acid desaturase genes, each said gene having at least one mutation, wherein at least one of said
- 20 mutations is in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said region encoding said His-Glu-Cys-Gly-His amino acid motif comprises a codon encoding Lys in place of a codon encoding Glu and wherein said at least one mutation renders
- 25 the product of said desaturase gene non-functional and confers an altered fatty acid composition in seeds obtained from said plant cell.

- 9 e -

5 As used herein, a "line" is a group of plants that
display little or no genetic variation between
individuals for at least one trait. Such lines may be
created by several generations of self-pollination and
selection, or vegetative propagation from a single parent
10 using tissue or cell culture techniques. As used herein,
the term "variety" refers to a line which is used for
commercial production.

15

20

25

30

- 10 -

The term "mutagenesis" refers to the use of a mutagenic agent to induce random genetic mutations within a population of individuals. The treated population, or a subsequent generation of that population, is then
5 screened for usable trait(s) that result from the mutations. A "population" is any group of individuals that share a common gene pool. As used herein " M_0 " is untreated seed. As used herein, " M_1 " is the seed (and resulting plants) exposed to a mutagenic agent, while " M_2 "
10 is the progeny (seeds and plants) of self-pollinated M_1 plants, " M_3 " is the progeny of self-pollinated M_2 plants, and " M_4 " is the progeny of self-pollinated M_3 plants. " M_5 " is the progeny of self-pollinated M_4 plants. " M_6 ", " M_7 ", etc. are each the progeny of self-pollinated plants
15 of the previous generation. The term "selfed" as used herein means self-pollinated.

"Stability" or "stable" as used herein means that with respect to a given fatty acid component, the component is maintained from generation to generation for
20 at least two generations and preferably at least three generations at substantially the same level, e.g., preferably $\pm 5\%$. The method of invention is capable of creating lines with improved fatty acid compositions stable up to $\pm 5\%$ from generation to generation. The
25 above stability may be affected by temperature, location, stress and time of planting. Thus, comparison of fatty acid profiles should be made from seeds produced under similar growing conditions. Stability may be measured based on knowledge of prior generation.

30 Intensive breeding has produced *Brassica* plants whose seed oil contains less than 2% erucic acid. The same varieties have also been bred so that the defatted meal contains less than 30 μmol glucosinolates/gram. "Canola" as used herein refers to plant variety seed or

- 11 -

oil which contains less than 2% erucic acid ($C_{22:1}$), and meal with less than 30 μmol glucosinolates/gram.

Applicants have discovered plants with mutations in a delta-12 fatty acid desaturase gene. Such plants have useful alterations in the fatty acid compositions of the seed oil. Such mutations confer, for example, an elevated oleic acid content, a decreased, stabilized linoleic acid content, or both elevated oleic acid and decreased, stabilized linoleic acid content.

Applicants have further discovered plants with mutations in a delta-15 fatty acid desaturase gene. Such plants have useful alterations in the fatty acid composition of the seed oil, e.g., a decreased, stabilized level of α -linolenic acid.

Applicants have further discovered isolated nucleic acid fragments comprising sequences that carry mutations within the coding sequence of delta-12 or delta-15 desaturases. The mutations confer desirable alterations in fatty acid levels in the seed oil of plants carrying such mutations. Delta-12 fatty acid desaturase is also known as omega-6 fatty acid desaturase and is sometimes referred to herein as 12-DES. Delta-15 fatty acid desaturase is also known as omega-3 fatty acid desaturase and is sometimes referred to herein as 15-DES.

A nucleic acid fragment of the invention contains a mutation in a microsomal delta-12 fatty acid desaturase coding sequence or in a microsomal delta-15 fatty acid desaturase coding sequence. Such a mutation renders the resulting desaturase gene product non-functional in plants, relative to the function of the gene product encoded by the wild-type sequence. The non-functionality of the 12-DES gene product can be inferred from the decreased level of reaction product (linoleic acid) and increased level of substrate (oleic acid) in plant tissues expressing the mutant sequence, compared to the

- 12 -

corresponding levels in plant tissues expressing the wild-type sequence. The non-functionality of the 15-DES gene product can be inferred from the decreased level of reaction product (α -linolenic acid) and the increased
5 level of substrate (linoleic acid) in plant tissues expressing the mutant sequence, compared to the corresponding levels in plant tissues expressing the wild-type sequence.

A nucleic acid fragment of the invention may
10 comprise a portion of the coding sequence, e.g., at least about 10 nucleotides, provided that the fragment contains at least one mutation in the coding sequence. The length of a desired fragment depends upon the purpose for which the fragment will be used, e.g., PCR primer, site-
15 directed mutagenesis and the like. In one embodiment, a nucleic acid fragment of the invention comprises the full length coding sequence of a mutant delta-12 or mutant delta-15 fatty acid desaturase.

A mutation in a nucleic acid fragment of the
20 invention may be in any portion of the coding sequence that renders the resulting gene product non-functional. Suitable types of mutations include, without limitation, insertions of nucleotides, deletions of nucleotides, or transitions and transversions in the wild-type coding
25 sequence. Such mutations result in insertions of one or more amino acids, deletions of one or more amino acids, and non-conservative amino acid substitutions in the corresponding gene product. In some embodiments, the sequence of a nucleic acid fragment may comprise more
30 than one mutation or more than one type of mutation.

Insertion or deletion of amino acids in a coding sequence may, for example, disrupt the conformation of essential alpha-helical or beta-pleated sheet regions of the resulting gene product. Amino acid insertions or
35 deletions may also disrupt binding or catalytic sites

- 13 -

important for gene product activity. It is known in the art that the insertion or deletion of a larger number of contiguous amino acids is more likely to render the gene product non-functional, compared to a smaller number of
5 inserted or deleted amino acids.

Non-conservative amino acid substitutions may replace an amino acid of one class with an amino acid of a different class. Non-conservative substitutions may make a substantial change in the charge or hydrophobicity
10 of the gene product. Non-conservative amino acid substitutions may also make a substantial change in the bulk of the residue side chain, e.g., substituting an alanyl residue for a isoleucyl residue.

Examples of non-conservative substitutions include
15 the substitution of a basic amino acid for a non-polar amino acid, or a polar amino acid for an acidic amino acid. Because there are only 20 amino acids encoded in a gene, substitutions that result in a non-functional gene product may be determined by routine experimentation,
20 incorporating amino acids of a different class in the region of the gene product targeted for mutation.

Preferred mutations are in a region of the nucleic acid having an amino acid sequence motif that is conserved among delta-12 fatty acid desaturases or delta-
25 15 fatty acid desaturases, such as a His-Xaa-Xaa-Xaa-His motif (Tables 1-3). An example of a suitable region has a conserved HECGH motif that is found, for example, in nucleotides corresponding to amino acids 105 to 109 of the *Arabidopsis* and *Brassica* delta-12 desaturase
30 sequences, in nucleotides corresponding to amino acids 101 to 105 of the soybean delta-12 desaturase sequence and in nucleotides corresponding to amino acids 111 to 115 of the maize delta-12 desaturase sequence. See e.g., WO 94/11516 ; Okuley et al., Plant Cell 6:147-158 (1994).
35 The one letter amino acid designations used herein are

- 14 -

described in Alberts, B. et al., Molecular Biology of the Cell, 3rd edition, Garland Publishing, New York, 1994. Amino acids flanking this motif are also highly conserved among delta-12 and delta-15 desaturases and are also
5 suitable candidates for mutations in fragments of the invention. An illustrative embodiment of a mutation in a nucleic acid fragment of the invention is a Glu to Lys substitution in the HECGH motif of a Brassica microsomal delta-12 desaturase sequence, either the D form or the F
10 form. This mutation results in the sequence HECGH being changed to HKCGH as seen by comparing SEQ ID NO:2 (wild-type D form) to SEQ ID NO:4 (mutant D form).

A similar motif may be found at amino acids 101 to 105 of the Arabidopsis microsomal delta-15 fatty acid
15 desaturase, as well as in the corresponding rape and soybean desaturases (Table 5). See, e.g., WO 93/11245; Arondel, V. et al., Science, 258:1153-1155 (1992); Yadav, N. et al., Plant Physiol., 103:467-476 (1993). Plastid delta-15 fatty acids have a similar motif (Table 5).

20 Among the types of mutations in an HECGH motif that render the resulting gene product non-functional are non-conservative substitutions. An illustrative example of a non-conservative substitution is substitution of a glycine residue for either the first or second histidine.
25 Such a substitution replaces a polar residue (histidine) with a non-polar residue (glycine). Another type of mutation that renders the resulting gene product non-functional is an insertion mutation, e.g., insertion of a glycine between the cystine and glutamic acid residues in
30 the HECGH motif.

Other regions having suitable conserved amino acid motifs include the HRRHH motif shown in Table 2, the HRTTH motif shown in Table 6 and the HVAHH motif shown in Table 3. See, e.g., WO 94/11516; Hitz, W. et al., Plant

- 15 -

Physiol., 105:635-641 (1994); Okuley, J., et al., supra; and Yadav, N. et al., supra.

Another region suitable for a mutation in a delta-12 desaturase sequence contains the motif KYLNNP at 5 nucleotides corresponding to amino acids 171 to 175 of the *Brassica* desaturase sequence. An illustrative example of a mutation in this region is a Leu to His substitution, resulting in the amino acid sequence (Table 4) KYHNN (Compare wild-type SEQ ID NO:6 to mutant SEQ ID 10 NO:8).

^a Plastid sequences

The conservation of amino acid motifs and their relative positions indicates that regions of a delta-12 or delta-15 fatty acid desaturase that can be mutated in one species to generate a non-functional desaturase can be mutated in the corresponding region from other species to generate a non-functional 12-DES or 15-DES gene product in that species.

Mutations in any of the regions of Tables 1-6 are specifically included within the scope of the invention, provided that such mutation (or mutations) renders the resulting desaturase gene product non-functional, as discussed hereinabove.

A nucleic acid fragment containing a mutant sequence can be generated by techniques known to the skilled artisan. Such techniques include, without limitation, site-directed mutagenesis of wild-type sequences and direct synthesis using automated DNA synthesizers.

A nucleic acid fragment containing a mutant sequence can also be generated by mutagenesis of plant seeds or regenerable plant tissue by, e.g., ethyl methane sulfonate, X-rays or other mutagens. With mutagenesis, mutant plants having the desired fatty acid phenotype in seeds are identified by known techniques and a nucleic acid fragment containing the desired mutation is isolated from genomic DNA or RNA of the mutant line. The site of

- 18 -

the specific mutation is then determined by sequencing the coding region of the 12-DES or 15-DES gene.

Alternatively, labeled nucleic acid probes that are specific for desired mutational events can be used to
5 rapidly screen a mutagenized population.

Seeds of Westar, a Canadian (*Brassica napus*) spring canola variety, were subjected to chemical mutagenesis. Mutagenized seeds were planted in the greenhouse and the plants were self-pollinated. The
10 progeny plants were individually analyzed for fatty acid composition, and regrown either in the greenhouse or in the field. After four successive generations of self-pollinations, followed by chemical analysis of the seed oil at each cycle, several lines were shown to carry
15 stably inherited mutations in specific fatty acid components, including reduced palmitic acid ($C_{16:0}$), increased palmitic acid, reduced stearic acid ($C_{18:0}$), increased oleic acid ($C_{18:1}$), reduced linoleic acid ($C_{18:2}$) and reduced linolenic acid ($C_{18:3}$), in the seed oil.

20 The general experimental scheme for developing lines with stable fatty acid mutations is shown in Scheme I hereinafter.

- 19 -

SCHEME I

Westar seeds (M_0) were mutagenized with ethylmethanesulfonate (EMS). Westar is a registered Canadian spring variety with canola quality. The fatty acid composition of field-grown Westar, 3.9% $C_{16:0}$, 1.9% $C_{18:0}$, 67.5% $C_{18:1}$, 17.6% $C_{18:2}$, 7.4% $C_{18:3}$, <2% $C_{20:1}$ + $C_{22:1}$, has remained stable under commercial production, with $\leq \pm 10\%$ deviation, since 1982. The disclosed method may be applied to all oilseed *Brassica* species, and to both Spring and Winter maturing types within each species. Physical mutagens, including but not limited to X-rays,

- 20 -

UV rays, and other physical treatments which cause chromosome damage, and other chemical mutagens, including but not limited to ethidium bromide, nitrosoguanidine, diepoxybutane etc. may also be used to induce mutations.

5 The mutagenesis treatment may also be applied to other stages of plant development, including but not limited to cell cultures, embryos, microspores and shoot apices. The M_1 seeds were planted in the greenhouse and M_1 plants were individually self-pollinated.

10 M_2 seed was harvested from the greenhouse and planted in the field in a plant-to-row design. Each plot contained six rows, and five M_2 lines were planted in each plot. Every other plot contained a row of non-mutagenized Westar as a control. Based on gas
15 chromatographic analysis of M_2 seed, those lines which had altered fatty acid composition were self-pollinated and individually harvested.

M_3 seeds were evaluated for mutations on the basis of a Z-distribution. An extremely stringent 1 in 10,000
20 rejection rate was employed to establish statistical thresholds to distinguish mutation events from existing variation. Mean and standard deviation values were determined from the non-mutagenized Westar control population in the field. The upper and lower statistical
25 thresholds for each fatty acid were determined from the mean value of the population $\pm$ the standard deviation, multiplied by the Z-distribution. Based on a population size of 10,000, the confidence interval is 99.99%.

Seeds (M_3) from those M_2 lines which exceeded
30 either the upper or lower statistical thresholds were replanted in the greenhouse and self-pollinated. This planting also included Westar controls. The M_4 seed was re-analyzed using new statistical thresholds established with a new control population. Those M_4 lines which
35 exceeded the new statistical thresholds for selected

- 21 -

fatty acid compositions were advanced to the nursery. Following self-pollination, M₅ seed from the field were re-analyzed once again for fatty acid composition. Those lines which remained stable for the selected fatty acids
5 were considered stable mutations.

"Stable mutations" as used herein are defined as M₅ or more advanced lines which maintain a selected altered fatty acid profile for a minimum of three generations, including a minimum of two generations under
10 field conditions, and exceeding established statistical thresholds for a minimum of two generations, as determined by gas chromatographic analysis of a minimum of 10 randomly selected seeds bulked together. Alternatively, stability may be measured in the same way
15 by comparing to subsequent generations. In subsequent generations, stability is defined as having similar fatty acid profiles in the seed as that of the prior or subsequent generation when grown under substantially similar conditions.

20 The amount of variability for fatty acid content in a seed population is quite significant when single seeds are analyzed. Randomly selected single seeds and a ten seed bulk sample of a commercial variety were compared. Significant variation among the single seeds
25 was detected (Table A). The half-seed technique (Downey, R.K. and B.L. Harvey, Can. J. Plant Sci., 43:271 [1963]) in which one cotyledon of the germinating seed is analyzed for fatty acid composition and the remaining embryo grown into a plant has been very useful to plant
30 breeding work to select individuals in a population for further generation analysis. The large variation seen in the single seed analysis (Table A) is reflected in the half-seed technique.

- 22 -

Values expressed as percent of total oil

30 Plant breeders using the half-seed technique have
found it unreliable in selecting stable genetically
controlled fatty acid mutations (Stefanson, B.R., In;
High and Low Erucic Acid Rapeseed Oils, Ed. N.T.
Kenthies, Academic Press, Inc., Canada (1983) pp. 145-
35 159). Although valuable in selecting individuals from a
population, the selected traits are not always
transmitted to subsequent generations (Rakow, G. and
McGregor, D.I., J. Amer. Oil Chem. Soc. (1973) 50:400-
403. To determine the genetic stability of the selected
40 plants several self-pollinated generations are required
(Robelen, G. In: Biotechnology for the Oils and Fats
Industry, Ed. C. Ratledge, P. Dawson and J. Rattray,

- 23 -

American Oil Chemists Society (1984) pp. 97-105) with chemical analysis of a bulk seed sample.

Mutation breeding has traditionally produced plants carrying, in addition to the trait of interest, multiple, deleterious traits, e.g., reduced plant vigor and reduced fertility. Such traits may indirectly affect fatty acid composition, producing an unstable mutation; and/or reduce yield, thereby reducing the commercial utility of the invention. To eliminate the occurrence of deleterious mutations and reduce the load of mutations carried by the plant a low mutagen dose was used in the seed treatments to create an LD30 population. This allowed for the rapid selection of single gene mutations for fatty acid traits in agronomic backgrounds which produce acceptable yields.

Other than changes in the fatty acid composition of the seed oil, the mutant lines described here have normal plant phenotype when grown under field conditions, and are commercially useful. "Commercial utility" is defined as having a yield, as measured by total pounds of seed or oil produced per acre, within 15% of the average yield of the starting (M_0) canola variety grown in the same region. To be commercially useful, plant vigor and high fertility are such that the crop can be produced in this yield by farmers using conventional farming equipment, and the oil with altered fatty acid composition can be extracted using conventional crushing and extraction equipment.

The seeds of several different fatty acid lines have been deposited with the American Type Culture Collection and have the following accession numbers.

- 24 -

In some plant species or varieties more than one form of endogenous microsomal delta-12 desaturase may be found. In amphidiploids, each form may be derived from one of the parent genomes making up the species under consideration. Plants with mutations in both forms have a fatty acid profile that differs from plants with a mutation in only one form. An example of such a plant is *Brassica napus* line Q508, a doubly-mutagenized line containing a mutant D-form of delta-12 desaturase (SEQ ID NO:1) and a mutant F-form of delta-12 desaturase (SEQ ID NO:5).

Preferred host or recipient organisms for introduction of a nucleic acid fragment of the invention are the oil-producing species, such as soybean (*Glycine max*), rapeseed (e.g., *Brassica napus*, *B. rapa* and *B. juncea*), sunflower (*Helianthus annus*), castor bean (*Ricinus communis*), corn (*Zea mays*), and safflower (*Carthamus tinctorius*).

Plants according to the invention preferably contain an altered fatty acid profile. For example, oil obtained from seeds of such plants may have from about 69 to about 90% oleic acid, based on the total fatty acid composition of the seed. Such oil preferably has from about 74 to about 90% oleic acid, more preferably from about 80 to about 90% oleic acid. In some embodiments, oil obtained from seeds produced by plants of the

- 25 -

invention may have from about 2.0% to about 5.0% saturated fatty acids, based on total fatty acid composition of the seeds. In some embodiments, oil obtained from seeds of the invention may have from about 5 1.0% to about 14.0% linoleic acid, or from about 0.5% to about 10.0% α -linolenic acid.

In one embodiment of the claimed invention, a plant contains both a 12-DES mutation and a 15-DES mutation. Such plants can have a fatty acid composition 10 comprising very high oleic acid and very low alpha-linolenic acid levels. Mutations in 12-DES and 15-DES may be combined in a plant by making a genetic cross between 12-DES and 15-DES single mutant lines. A plant having a mutation in delta-12 fatty acid desaturase is 15 crossed or mated with a second plant having a mutation in delta-15 fatty acid desaturase. Seeds produced from the cross are planted and the resulting plants are selfed in order to obtain progeny seeds. These progeny seeds are then screened in order to identify those seeds carrying 20 both mutant genes.

Alternatively, a line possessing either a 12-DES or a 15-DES mutation can be subjected to mutagenesis to generate a plant or plant line having mutations in both 12-DES and 15-DES. For example, the IMC 129 line has a 25 mutation in the coding region (Glu₁₀₆ to Lys₁₀₆) of the D form of the microsomal delta-12 desaturase structural gene. Cells (e.g., seeds) of this line can be mutagenized to induce a mutation in a 15-DES gene, resulting in a plant or plant line carrying a mutation in 30 a delta-12 fatty acid desaturase gene and a mutation in a delta-15 fatty acid desaturase gene.

Progeny includes descendants of a particular plant or plant line, e.g., seeds developed on an instant plant. Progeny of an instant plant include seeds formed on F₁,

- 26 -

F₂, F₃, and subsequent generation plants, or seeds formed on BC₁, BC₂, BC₃ and subsequent generation plants.

Those seeds having an altered fatty acid composition may be identified by techniques known to the skilled artisan, e.g., gas-liquid chromatography (GLC) analysis of a bulked seed sample or of a single half-seed. Half-seed analysis is well known in the art to be useful because the viability of the embryo is maintained and thus those seeds having a desired fatty acid profile may be planted to from the next generation. However, half-seed analysis is also known to be an inaccurate representation of genotype of the seed being analyzed. Bulk seed analysis typically yields a more accurate representation of the fatty acid profile of a given genotype.

The nucleic acid fragments of the invention can be used as markers in plant genetic mapping and plant breeding programs. Such markers may include restriction fragment length polymorphism (RFLP), random amplification polymorphism detection (RAPD), polymerase chain reaction (PCR) or self-sustained sequence replication (3SR) markers, for example. Marker-assisted breeding techniques may be used to identify and follow a desired fatty acid composition during the breeding process. Marker-assisted breeding techniques may be used in addition to, or as an alternative to, other sorts of identification techniques. An example of marker-assisted breeding is the use of PCR primers that specifically amplify a sequence containing a desired mutation in 12-DES or 15-DES.

Methods according to the invention are useful in that the resulting plants and plant lines have desirable seed fatty acid compositions as well as superior agronomic properties compared to known lines having altered seed fatty acid composition. Superior agronomic

- 27 -

characteristics include, for example, increased seed germination percentage, increased seedling vigor, increased resistance to seedling fungal diseases (damping off, root rot and the like), increased yield, and
5 improved standability.

While the invention is susceptible to various modifications and alternative forms, certain specific embodiments thereof are described in the general methods and examples set forth below. For example the invention
10 may be applied to all Brassica species, including *B. rapa*, *B. juncea*, and *B. hirta*, to produce substantially similar results. It should be understood, however, that these examples are not intended to limit the invention to the particular forms disclosed but, instead the invention
15 is to cover all modifications, equivalents and alternatives falling within the scope of the invention. This includes the use of somaclonal variation; physical or chemical mutagenesis of plant parts; anther, microspore or ovary culture followed by chromosome
20 doubling; or self- or cross-pollination to transmit the fatty acid trait, alone or in combination with other traits, to develop new Brassica lines.

EXAMPLE 1

Selection of Low FDA Saturates

25 Prior to mutagenesis, 30,000 seeds of *B. napus* cv. Westar seeds were preimbibed in 300-seed lots for two hours on wet filter paper to soften the seed coat. The preimbibed seeds were placed in 80 mM ethylmethanesulfonate (EMS) for four hours. Following
30 mutagenesis, the seeds were rinsed three times in distilled water. The seeds were sown in 48-well flats containing Pro-Mix*. Sixty-eight percent of the mutagenized seed germinated. The plants were maintained at 25°C/15°C, 14/10 hr day/night conditions in the

* trademark

- 28 -

greenhouse. At flowering, each plant was individually self-pollinated.

M₂ seed from individual plants were individually catalogued and stored, approximately 15,000 M₂ lines was
5 planted in a summer nursery in Carman, Manitoba. The seed from each selfed plant were planted in 3-meter rows with 6-inch row spacing. Westar was planted as the check variety. Selected lines in the field were selfed by bagging the main raceme of each plant. At maturity, the
10 selfed plants were individually harvested and seeds were catalogued and stored to ensure that the source of the seed was known.

Self-pollinated M₃ seed and Westar controls were analyzed in 10-seed bulk samples for fatty acid
15 composition via gas chromatography. Statistical thresholds for each fatty acid component were established using a Z-distribution with a stringency level of 1 in 10,000. The selected M₃ seeds were planted in the greenhouse along with Westar controls. The seed was sown
20 in 4-inch pots containing Pro-Mix soil and the plants were maintained at 25°C/15°C, 14/10 hr day/night cycle in the greenhouse. At flowering, the terminal raceme was self-pollinated by bagging. At maturity, selfed M₄ seed was individually harvested from each plant, labelled, and
25 stored to ensure that the source of the seed was known.

The M₄ seed was analyzed in 10-seed bulk samples. Statistical thresholds for each fatty acid component were established from 259 control samples using a Z-distribution of 1 in 800. Selected M₄ lines were planted
30 in a field trial in Carman, Manitoba in 3-meter rows with 6-inch spacing. Ten M₄ plants in each row were bagged for self-pollination. At maturity, the selfed plants were individually harvested and the open pollinated plants in the row were bulk harvested. The M₅ seed from single

- 29 -

plant selections was analyzed in 10-seed bulk samples and the bulk row harvest in 50-seed bulk samples.

Selected M_5 lines were planted in the greenhouse along with Westar controls. The seed was grown as previously described. At flowering the terminal raceme was self-pollinated by bagging. At maturity, selfed M_6 seed was individually harvested from each plant and analyzed in 10-seed bulk samples for fatty acid composition.

Selected M_6 lines were entered into field trials in Eastern Idaho. The four trial locations were selected for the wide variability in growing conditions. The locations included Burley, Tetonia, Lamont and Shelley (Table I). The lines were planted in four 3-meter rows with an 8-inch spacing, each plot was replicated four times. The planting design was determined using a Randomized Complete Block Design. The commercial cultivar Westar was used as a check cultivar. At maturity the plots were harvested to determine yield. Yield of the entries in the trial was determined by taking the statistical average of the four replications. The Least Significant Difference Test was used to rank the entries in the randomized complete block design.

TABLE I

Trial Locations for Selected Fatty Acid Mutants

<u>LOCATION</u>	<u>SITE CHARACTERIZATIONS</u>
BURLEY	Irrigated. Long season. High temperatures during flowering.
TETONIA	Dryland. Short season. Cool temperatures.
LAMONT	Dryland. Short season. Cool temperatures.
SHELLEY	Irrigated. Medium season. High temperatures during flowering.

- 30 -

To determine the fatty acid profile of entries, plants in each plot were bagged for self-pollination. The M_7 seed from single plants was analyzed for fatty acids in ten-seed bulk samples.

5 To determine the genetic relationships of the selected fatty acid mutants crosses were made. Flowers of M_6 or later generation mutations were used in crossing. F_1 seed was harvested and analyzed for fatty acid composition to determine the mode of gene action. The F_1
10 progeny were planted in the greenhouse. The resulting plants were self-pollinated, the F_2 seed harvested and analyzed for fatty acid composition for allelism studies. The F_2 seed and parent line seed was planted in the greenhouse, individual plants were self-pollinated. The
15 F_3 seed of individual plants was tested for fatty acid composition using 10-seed bulk samples as described previously.

In the analysis of some genetic relationships dihaploid populations were made from the microspores of
20 the F_1 hybrids. Self-pollinated seed from dihaploid plants were analyzed for fatty acid analysis using methods described previously.

For chemical analysis, 10-seed bulk samples were hand ground with a glass rod in a 15-mL polypropylene
25 tube and extracted in 1.2 mL 0.25 N KOH in 1:1 ether/methanol. The sample was vortexed for 30 sec. and heated for 60 sec. in a 60°C water bath. Four mL of saturated NaCl and 2.4 mL of iso-octane were added, and the mixture was vortexed again. After phase separation,
30 600 μ L of the upper organic phase were pipetted into individual vials and stored under nitrogen at -5°C. One μ L samples were injected into a*Supelco SP-2330 fused silica capillary column (0.25 mm ID, 30 M length, 0.20 μ m df).

At the M₃ generation, twelve lines exceeded the lower statistical threshold for palmitic acid ($\leq 3.3\%$). Line W13097.4 had 3.1% palmitic acid and an FDA saturate content of 4.5%. After a cycle in the greenhouse, M₄ seed

- 32 -

from line W13097.4 (designated line A144) was analyzed. Line W13097.4.1(A144.1) had 3.1% C_{16:0}, exceeding the lower statistical threshold of 3.6%. The FDA saturate content for A144.1 was 4.5%. The fatty acid compositions for the 5 M₃, M₄ and M₅ generations of this family are summarized in Table III.

These reduced levels have remained stable to the M₇ generations in both greenhouse and field conditions.

30 These reduced levels have remained stable to the M₇ generation in multiple location field trails. Over all locations, the self-pollinated plants (A144) averaged 2.9% palmitic acid and FDA saturates of 4.6%. The fatty

- 34 -

acid composition of the A144 lines for each Idaho location are summarized in Table V. In the multiple location replicated trial the yield of A144 was not significantly different in yield from the parent cultivar Westar. By means of seed mutagenesis, the level of saturated fatty acids of canola (*B. napus*) was reduced from 5.9% to 4.6%. The palmitic acid content was reduced from 3.9% to 2.9%.

TABLE V

Fatty Acid Composition of a Mutant Low Palmitic Acid/Low FDA Saturate Canola Line at Different Field Locations in Idaho

Trial Location	Percent Fatty Acids

			Expected 143

EXAMPLE 2

10 An additional low FDA saturate line, designated A149.3 (ATCC 40814), was also produced by the method of Example 1. A 50-seed bulk analysis of this line showed the following fatty acid composition: $C_{16:0}$ - 3.6%, $C_{18:0}$ - 1.4%, $C_{18:1}$ - 65.5%, $C_{18:2}$ - 18.3%, $C_{18:3}$ - 8.2%, FDA Sats - 5.0%, Total Sats - 5.9%. This line has also stably maintained its mutant fatty acid composition to the M_5 generation. In a multiple location replicated trial the yield of A149 was not significantly different in yield from the parent cultivar Westar.

EXAMPLE 3

20 An additional low palmitic acid and low FDA saturate line, designated M3094.4 (ATCC 75023), was also produced by the method of Example 1. A 10-seed bulk analysis of this line showed the following fatty acid composition: $C_{16:0}$ - 2.7%, $C_{18:0}$ - 1.6%, $C_{18:1}$ - 66.6%, $C_{18:2}$ - 20.0%, $C_{18:3}$ - 6.1%, $C_{20:1}$ - 1.4%, $C_{22:1}$ - 0.0%, FDA Saturate - 4.3%, Total Saturates - 5.2%. This line has stably maintained its mutant fatty acid composition to the M_5 generation. In a single replicated trial the yield of M3094 was not significantly different in yield from the parent cultivar.

M3094.4 was crossed to A144, a low palmitic acid mutation (Example 1) for allelism studies. Fatty acid composition of the F_2 seed showed the two lines to be

- 36 -

allelic. The mutational events in A144 and M3094, although different in origin, are in the same gene.

EXAMPLE 4

In the studies of Example 1, at the M₃ generation, 470 lines exceed the upper statistical threshold for palmitic acid ($\geq 4.3\%$). One M₃ line, W14538.6, contained 9.2% palmitic acid. Selfed progenies of this line, since designated M3007.4 (ATCC 75022), continued to exceed to the upper statistical threshold for high palmitic acid at both the M₄ and M₅ generations with palmitic acid levels of 11.7% and 9.1%, respectively. The fatty acid composition of this high palmitic acid mutant, which was stable to the M₇ generation under both field and greenhouse conditions, is summarized in Table VI.

TABLE VI

Fatty Acid Composition of a High Palmitic Acid Canola Line Produced by Seed Mutagenesis

Genotype	Percent Fatty Acids					Sats*
	C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}

EXAMPLE 5Selection of Low Stearic Acid Canola Lines

In the studies of Example 1, at the M₃ generation, 42 lines exceeded the lower statistical threshold for stearic acid (<1.4%). Line W14859.6 had 1.3% stearic acid. At the M₅ generation, its selfed progeny (M3052.1) continued to fall within the lower statistical threshold for C_{18:0} with 0.8% stearic acid. The fatty acid composition of this low stearic acid mutant, which was stable under both field and greenhouse conditions is summarized in Table VIII. In a single location replicated yield trial M3052.1 was not significantly different in yield from the parent cultivar Westar.

TABLE VIII

Fatty Acid Composition of a Low Stearic Acid Canola Line Produced by Seed Mutagenesis

		<u>Percent Fatty Acids</u>				
<u>Genotype</u>	C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}	Sats
Westar	3.9	1.9	67.5	17.6	7.4	5.9
W14859.6 (M ₃)	5.3	1.3	56.1	23.7	9.6	7.5
M3052.1 (M ₄)	4.9	0.9	58.9	22.7	9.3	5.8
M3052.6 (M ₅)	4.4	0.8	62.1	21.2	7.9	5.2

To determine the genetic relationship of the low stearic acid mutation of M3052.1 to other fatty acid mutations it was crossed to the low palmitic acid mutation A144 (Example 1). Seed from over 300 dihaploid progeny were harvested and analyzed for fatty acid composition. The results are summarized in Table VIIIB. Independent segregation of the palmitic acid and stearic acid traits was observed. The low stearic acid mutation

- 39 -

was genetically different from the low palmitic acid mutations found in A144 and M3094.

TABLE VIIIB
Genetic Studies of M3052 X A144

5 —	Genotype	C _{16:0} + C _{18:0} Content (%)	Frequency	
			Observed	Expected
	p-p-s-s-	<4.9%	87	77
10	p-p-s-s-/p+p+s-s-	4.0%<X<5.6%	152	154
	p+p+s+s+	>5.6%	70	77

An additional M₅ line, M3051.10, contained 0.9% and 1.1% stearic acid in the greenhouse and field respectively. A ten-seed analysis of this line showed
 15 the following fatty acid composition: C_{16:0} - 3.9%, C_{18:0} - 1.1%, C_{18:1} - 61.7%, C_{18:2} - 23.0%, C_{18:3} - 7.6%, FDA saturates - 5.0%, Total Saturates - 5.8%. In a single location replicated yield trial M3051.10 was not significantly different in yield from the parent cultivar
 20 Westar. M3051.10 was crossed to M3052.1 for allelism studies. Fatty acid composition of the F₂ seed showed the two lines to be allelic. The mutational events in M3051.10 and M3052.1 although different in origin were in the same gene.

25 An additional M₅ line, M3054.7, contained 1.0% and 1.3% stearic acid in the greenhouse and field respectively. A ten-seed analysis of this line showed the following fatty acid composition: C_{16:0} - 4.0%, C_{18:0} - 1.0%, C_{18:1} - 66.5%, C_{18:2} - 18.4%, C_{18:3} - 7.2%, saturates -
 30 5.0%, Total Saturates - 6.1%. In a single location replicated yield trial M3054.7 was not significantly different in yield from the parent cultivar Westar. M3054.7 was crossed to M3052.1 for allelism studies.

- 40 -

Fatty acid composition of the F_2 seed showed the two lines to be allelic. The mutational events in M3054.7, M3051.10 and M3052.1 although different in origin were in the same gene.

5

EXAMPLE 6

High Oleic Acid Canola Lines

In the studies of Example 1, at the M_3 generation, 31 lines exceeded the upper statistical threshold for oleic acid ($\geq 71.0\%$). Line W7608.3 had 71.2% oleic acid. At the M_4 generation, its selfed progeny (W7608.3.5, since designated A129.5) continued to exceed the upper statistical threshold for $C_{18:1}$ with 78.8% oleic acid. M_5 seed of five self-pollinated plants of line A129.5 (ATCC 40811) averaged 75.0% oleic acid. A single plant selection, A129.5.3 had 75.6% oleic acid. The fatty acid composition of this high oleic acid mutant, which was stable under both field and greenhouse conditions to the M_7 generation, is summarized in Table IX. This line also stably maintained its mutant fatty acid composition to the M_7 generation in field trials in multiple locations. Over all locations the self-pollinated plants (A129) averaged 78.3% oleic acid. The fatty acid composition of the A129 for each Idaho trial location are summarized in Table X. In multiple location replicated yield trials, A129 was not significantly different in yield from the parent cultivar Westar.

The canola oil of A129, after commercial processing, was found to have superior oxidative stability compared to Westar when measured by the Accelerated Oxygen Method (AOM), American Oil Chemists' Society Official Method Cd 12-57 for fat stability; Active Oxygen Method (revised 1989). The AOM of Westar was 18 AOM hours and for A129 was 30 AOM hours.

Sats=Total Saturate Content

The genetic relationship of the high oleic acid
 25 mutation A129 to other oleic desaturases was demonstrated
 in crosses made to commercial canola cultivars and a low
 linolenic acid mutation. A129 was crossed to the
 commercial cultivar Global (C_{16:0} - 4.5%, C_{18:0} - 1.5%, C_{18:1}
 - 62.9%, C_{18:2} - 20.0%, C_{18:3} - 7.3%). Approximately 200 F₂
 30 individuals were analyzed for fatty acid composition.
 The results are summarized in Table XB. The segregation
 fit 1:2:1 ratio suggesting a single co-dominant gene

WO 97/21340

PCT/US96/20090

- 42 -

controlled the inheritance of the high oleic acid phenotype.

TABLE XB
Genetic Studies of A129 X Global

5	Genotype	C _{18:0} Content (%)	Frequency	
			Observed	Expected
10	od-od-	77.3	43	47
	od-od+	71.7	106	94
	od+od+	66.1	49	47

A cross between A129 and IMC 01, a low linolenic acid variety (C_{16:0} - 4.1%, C_{18:0} - 1.9%, C_{18:1} - 66.4%, C_{18:2} - 18.1%, C_{18:3} - 5.7%), was made to determine the inheritance of the oleic acid desaturase and linoleic acid desaturase. In the F₁ hybrids both the oleic acid and linoleic acid desaturase genes approached the mid-parent values indicating a co-dominant gene actions. Fatty acid analysis of the F₂ individuals confirmed a 1:2:1:2:4:2:1:2:1 segregation of two independent, co-dominant genes (Table XC). A line was selected from the cross of A129 and IMC01 and designated as IMC130 (ATCC deposit no. 75446) as described in U.S. Patent 5,969,169.

- 43 -

An additional high oleic acid line, designated A128.3, was also produced by the disclosed method. A 50-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.5%, C_{18:0} - 1.8%, C_{18:1} - 77.3%, C_{18:2} - 9.0%, C_{18:3} - 5.6%, FDA Sats - 5.3%, Total Sats - 6.4%. This line also stably maintained its mutant fatty acid composition to the M₇ generation. In multiple locations replicated yield trials, A128 was not significantly different in yield from the parent cultivar Westar.

A129 was crossed to A128.3 for allelism studies. Fatty acid composition of the F₂ seed showed the two lines to be allelic. The mutational events in A129 and A128.3 although different in origin were in the same gene.

An additional high oleic acid line, designated M3028.-10 (ATCC 75026), was also produced by the disclosed method in Example 1. A 10-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.5%, C_{18:0} - 1.8%, C_{18:1} - 77.3%, C_{18:2} - 9.0%, C_{18:3} - 5.6%, FDA Saturates - 5.3%, Total Saturates - 6.4%. In a single location replicated yield trial M3028.10 was not significantly different in yield from the parent cultivar Westar.

EXAMPLE 7

Low Linoleic Acid Canola

In the studies of Example 1, at the M₃ generation, 80 lines exceeded the lower statistical threshold for linoleic acid ($\leq 13.2\%$). Line W12638.8 had 9.4% linoleic acid. At the M₄ and M₅ generations, its selfed progenies [W12638.8, since designated A133.1 (ATCC 40812)] continued to exceed the statistical threshold for low C_{18:2} with linoleic acid levels of 10.2% and 8.4%, respectively. The fatty acid composition of this low linoleic acid mutant, which was stable to the M₇ generation under both field and greenhouse conditions, is

- 44 -

summarized in Table XI. In multiple location replicated yield trials, A133 was not significantly different in yield from the parent cultivar Westar. An additional low linoleic acid line, designated M3062.8 (ATCC 75025), was also produced by the disclosed method. A 10-seed bulk analysis of this line showed the following fatty acid composition: C_{16:0} - 3.8%, C_{18:0} - 2.3%, C_{18:1} - 77.1%, C_{18:2} - 8.9%, C_{18:3} - 4.3%, FDA Sats-6.1%. This line has also stably maintained its mutant fatty acid composition in the field and greenhouse.

TABLE XI

Fatty Acid Composition of a Low
Linoleic Acid Canola Line Produced by Seed Mutagenesis

		Percent Fatty Acids

^bSats=Total Saturate Content

EXAMPLE 8Low Linolenic and Linoleic Acid Canola

In the studies of Example 1, at the M₃ generation, 57 lines exceeded the lower statistical threshold for linolenic acid ($\leq 5.3\%$). Line W14749.8 had 5.3% linolenic acid and 15.0% linoleic acid. At the M₄ and M₅

- 45 -

generations, its selfed progenies [W14749.8, since designated M3032 (ATCC 75021)] continued to exceed the statistical threshold for low $C_{18:3}$ with linolenic acid levels of 2.7% and 2.3%, respectively, and for a low sum of linolenic and linoleic acids with totals of 11.8% and 12.5% respectively. The fatty acid composition of this low linolenic acid plus linoleic acid mutant, which was stable to the M_5 generation under both field and greenhouse conditions, is summarized in Table XII. In a single location replicated yield trial M3032 was not significantly different in yield from the parent cultivar (Westar).

EXAMPLE 9

The high oleic acid mutation of A129 was introduced into different genetic backgrounds by crossing and selecting for fatty acid and agronomic characteristics. A129 (now renamed IMC 129) was crossed to Legend, a commercial spring *Brassica napus* variety. Legend has the following fatty acid composition: $C_{16:0}$ - 3.8%, $C_{18:0}$ - 2.1%, $C_{18:1}$ - 63.1%, $C_{18:2}$ - 17.8%, $C_{18:3}$ - 9.3%.

- 46 -

The cross and progeny resulting from were coded as 89B60303.

The F_1 seed resulting from the cross was planted in the greenhouse and self-pollinated to produce F_2 seed.
5 The F_2 seed was planted in the field for evaluation. Individual plants were selected in the field for agronomic characteristics. At maturity, the F_3 seed was harvested from each selected plant and analyzed for fatty acid composition.

10 Individuals which had fatty acid profiles similar to the high oleic acid parent (IMC 129) were advanced back to the field. Seeds (F_3) of selected individuals were planted in the field as selfing rows and in plots for preliminary yield and agronomic evaluations. At
15 flowering the F_3 plants in the selfing rows were self-pollinated. At maturity the F_4 seed was harvested from individual plants to determine fatty acid composition. Yield of the individual selections was determined from the harvested plots.

20 Based on fatty acid composition of the individual plants and yield and agronomic characteristics of the plots F_4 lines were selected and advanced to the next generation in the greenhouse. Five plants from each selected line were self-pollinated. At maturity the F_5
25 seed was harvested from each and analyzed for fatty acid composition.

The F_5 line with the highest oleic fatty profile was advanced to the field as a selfing row. The remaining F_5 seed from the five plants was bulked together
30 for planting the yield plots in the field. At flowering, the F_5 plants in each selfing-row were self-pollinated. At maturity the F_6 self-pollinated seed was harvest from the selfing row to determine fatty acid composition and select for the high oleic acid trait. Yield of the

- 47 -

individual selections was determined from the harvested plots.

Fifteen F_6 lines having the high oleic fatty profile of IMC 129 and the desired agronomic characteristics were advanced to the greenhouse to increase seed for field trialing. At flowering the F_6 plants were self-pollinated. At maturity the F_7 seed was harvested and analyzed for fatty acid composition. Three F_7 seed lines which had fatty acid profiles most similar to IMC 129 (Table XIII) were selected and planted in the field as selfing rows, the remaining seed was bulked together for yield trialing. The high oleic fatty acid profile of IMC 129 was maintained through seven generations of selection for fatty acid and agronomic traits in an agronomic background of *Brassica napus* which was different from the parental lines. Thus, the genetic trait from IMC 129 for high oleic acid can be used in the development of new high oleic *Brassica napus* varieties.

TABLE XIII

Fatty Acid Composition of Advanced Breeding Generation with High Oleic Acid Trait (IMC 129 X Legend)

F ₇ Selections of 89B60303	Fatty Acid Composition(%)				
	C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}
93.06194	3.8	1.6	78.3	7.7	4.4
93.06196	4.0	2.8	77.3	6.8	3.4
93.06198	3.7	2.2	78.0	7.4	4.2

The high oleic acid trait of IMC 129 was also introduced into a different genetic background by combining crossing and selection methods with the generation of dihaploid populations from the microspores of the F_1 hybrids. IMC 129 was crossed to Hyola 41, a commercial spring *Brassica napus* variety. Hyola 41 has the following fatty acid composition: C_{16:0} - 3.8%, C_{18:0} -

- 48 -

2.7%, $C_{18:1}$ - 64.9%, $C_{18:2}$ - 16.2%, $C_{18:3}$ - 9.1%. The cross and progeny resulting from the cross were labeled 90DU.146.

The F_1 seed was planted from the cross and a
5 dihaploid (DH_1) population was made from the F_1
microspores using standard procedures for *Brassica napus*.
Each DH_1 plant was self-pollinated at flowering to produce
 DH_1 seed. At maturity the DH_1 seed was harvested and
analyzed for fatty acid composition. DH_1 individuals
10 which expressed the high oleic fatty acid profile of IMC
129 were advanced to the next generation in the
greenhouse. For each individual selected five DH_1 seeds
were planted. At flowering the DH_2 plants were self-
pollinated. At maturity the DH_2 seed was harvested and
15 analyzed for fatty acid composition. The DH_2 seed which
was similar in fatty acid composition to the IMC 129
parent was advanced to the field as a selfing row. The
remaining DH_2 seed of that group was bulked and planted in
plots to determine yield and agronomic characteristics of
20 the line. At flowering individual DH_3 plants in the
selfing row were self-pollinated. At maturity the DH_3
seed was harvested from the individual plants to
determine fatty acid composition. Yield of the
selections was determined from the harvested plots.
25 Based on fatty acid composition, yield and agronomic
characteristics selections were advanced to the next
generation in the greenhouse. The DH_4 seed produced in
the greenhouse by self-pollination was analyzed for fatty
acid composition. Individuals which were similar to the
30 fatty acid composition of the IMC 129 parent were
advanced to the field to test for fatty acid stability
and yield evaluation. The harvested DH_5 seed from six
locations maintained the fatty acid profile of the IMC
129 parent (Table XIV).

15

EXAMPLE 10Canola Lines Q508 and Q4275

Seeds of the *B. napus* line IMC-129 were
mutagenized with methyl N-nitrosoguanidine (MNNG). The
MNNG treatment consisted of three parts: pre-soak,
20 mutagen application, and wash. A 0.05M Sorenson's
phosphate buffer was used to maintain pre-soak and
mutagen treatment pH at 6.1. Two hundred seeds were
treated at one time on filter paper (Whatman #3M) in a
petri dish (100mm x 15mm). The seeds were pre-soaked in
25 15 mls of 0.05M Sorenson's buffer, pH 6.1, under
continued agitation for two hours. At the end of the
pre-soak period, the buffer was removed from the plate.

A 10mM concentration of MNNG in 0.05M Sorenson's
buffer, pH 6.1, was prepared prior to use. Fifteen ml of
30 10m MNNG was added to the seeds in each plate. The seeds
were incubated at 22°C±3°C in the dark under constant
agitation for four (4) hours. At the end of the
incubation period, the mutagen solution was removed.

The seeds were washed with three changes of
35 distilled water at 10 minute intervals. The fourth wash

- 50 -

was for thirty minutes. This treatment regime produced an LD60 population.

Treated seeds were planted in standard greenhouse potting soil and placed into an environmentally
5 controlled greenhouse. The plants were grown under sixteen hours of light. At flowering, the racemes were bagged to produce selfed seed. At maturity, the M2 seed was harvested. Each M2 line was given an identifying number. The entire MNNG-treated seed population was
10 designated as the Q series.

Harvested M2 seeds was planted in the greenhouse. The growth conditions were maintained as previously described. The racemes were bagged at flowering for selfing. At maturity, the selfed M3 seed was harvested
15 and analyzed for fatty acid composition. For each M3 seed line, approximately 10-15 seeds were analyzed in bulk as described in Example 1.

High oleic-low linoleic M3 lines were selected from the M3 population using a cutoff of >82% oleic acid
20 and <5.0% linoleic. From the first 1600 M3 lines screened for fatty acid composition, Q508 was identified. The Q508 M3 generation was advanced to the M4 generation in the greenhouse. Table XV shows the fatty acid composition of Q508 and IMC 129. The M4 selfed seed
25 maintained the selected high oleic-low linoleic acid phenotype (Table XVI).

TABLE XV

Fatty Acid Composition of A129 and High
Oleic Acid M3 Mutant Q508

30	<u>Line #</u>	<u>16:0</u>	<u>18:0</u>	<u>18:1</u>	<u>18:2</u>	<u>18:3</u>
	A129*	4.0	2.4	77.7	7.8	4.2
	<u>Q508</u>	<u>3.9</u>	<u>2.1</u>	<u>84.9</u>	<u>2.4</u>	<u>2.9</u>

*Fatty acid composition of A129 is the average of
35 50 self-pollinated plants grown with the M3 population

- 51 -

M₄ generation Q508 plants had poor agronomic qualities in the field compared to Westar. Typical plants were slow growing relative to Westar, lacked early vegetative vigor, were short in stature, tended to be chlorotic and had short pods. The yield of Q508 was very low compared to Westar.

The M₄ generation Q508 plants in the greenhouse tended to be reduced in vigor compared to Westar. However, Q508 yields in the greenhouse were greater than Q508 yields in the field.

TABLE XVI

Fatty Acid Composition of Seed Oil
from Greenhouse-Grown Q508, IMC 129 and Westar.

Q508 ^c	3.9	2.1	84.9	2.4	2.9	6.0

^aAverage of 50 self-pollinated plants

^bData from Example 1

^cAverage of 50 self-pollinated plants

Nine other M₄ high-oleic low-linoleic lines were also identified: Q3603, Q3733, Q4249, Q6284, Q6601, Q6761, Q7415, Q4275, and Q6676. Some of these lines had good agronomic characteristics and an elevated oleic acid level in seeds of about 80% to about 84%.

Q4275 was crossed to the variety Cyclone. After selfing for seven generations, mature seed was harvested from 93GS34-179, a progeny line of the Q4275 Cyclone cross. Referring to Table XVII, fatty acid composition of a bulk seed sample shows that 93GS34 retained the seed fatty acid composition of Q4275. 93GS34-179 also maintained agronomically desirable characteristics.

- 52 -

After more than seven generations of selfing of Q4275, plants of Q4275, IMC 129 and 93GS34 were field grown during the summer season. The selections were tested in 4 replicated plots (5 feet X 20 feet) in a randomized block design. Plants were open pollinated. No selfed seed was produced. Each plot was harvested at maturity, and a sample of the bulk harvested seed from each line was analyzed for fatty acid composition as described above. The fatty acid compositions of the selected lines are shown in Table XVII.

Table XVII
Fatty Acid Composition of
Field Grown IMC 129, Q4275 and 93GS34 Seeds

Line	Fatty Acid Composition (%)					
	C _{16:0}	C _{18:0}	C _{18:1}	C _{18:2}	C _{18:3}	FDA Sats
IMC 129	3.3	2.4	76.7	8.7	5.2	5.7
Q4275	3.7	3.1	82.1	4.0	3.5	6.8
93GS34-179	2.6	2.7	85.0	2.8	3.3	5.3

The results shown in Table XVII show that Q4275 maintained the selected high oleic - low linoleic acid phenotype under field conditions. The agronomic characteristics of Q4275 plants were superior to those of Q508.

M₄ generation Q508 plants were crossed to a dihaploid selection of Westar, with Westar serving as the female parent. The resulting F₁ seed was termed the 92EF population. About 126 F₁ individuals that appeared to have better agronomic characteristics than the Q508 parent were selected for selfing. A portion of the F₂ seed from such individuals was replanted in the field. Each F₂ plant was selfed and a portion of the resulting F₃ seed was analyzed for fatty acid composition. The content of oleic acid in F₃ seed ranged from 59 to 79%.

- 53 -

No high oleic (>80%) individuals were recovered with good agronomic type.

A portion of the F₂ seed of the 92EF population was planted in the greenhouse to analyze the genetics of the Q508 line. F₃ seed was analyzed from 380 F₂ individuals. The C_{18:1} levels of F₃ seed from the greenhouse experiment is depicted in Figure 1. The data were tested against the hypothesis that Q508 contains two mutant genes that are semi-dominant and additive: the original IMC 129 mutation as well as one additional mutation. The hypothesis also assumes that homozygous Q508 has greater than 85% oleic acid and homozygous Westar has 62-67% oleic acid. The possible genotypes at each gene in a cross of Q508 by Westar may be designated as:

AA = Westar Fad2^a

BB = Westar Fad2^b

aa = Q508 Fad2^{a-}

bb = Q508 Fad2^{b-}

Assuming independent segregation, a 1:4:6:4:1 ratio of phenotypes is expected. The phenotypes of heterozygous plants are assumed to be indistinguishable and, thus, the data were tested for fit to a 1:14:1 ratio of homozygous Westar: heterozygous plants: homozygous Q508.

Phenotypic	# of	
<u>Ratio</u>	<u>Westar Alleles</u>	<u>Genotype</u>
1	4	AABB (Westar)
4	3	AABb, AaBB, AABb, AaBB
6	2	AaBb, AAbb, AaBb, AaBb, aaBB, AaBb
4	1	Aabb, aaBb, Aabb, aaBb
1	0	aabb (Q508)

Using Chi-square analysis, the oleic acid data fit a 1:14:1 ratio. It was concluded that Q508 differs from

- 54 -

Westar by two major genes that are semi-dominant and additive and that segregate independently. By comparison, the genotype of IMC 129 is aaBB.

The fatty acid composition of representative F₃ individuals having greater than 85% oleic acid in seed oil is shown in Table XVIII. The levels of saturated fatty acids are seen to be decreased in such plants, compared to Westar.

TABLE XVIII

10 92EF F₃ Individuals with >85% C_{18:1} in Seed Oil

- 55 -

EXAMPLE 11Leaf and Root Fatty Acid Profiles of Canola
Lines IMC-129, Q508, and Westar

Plants of Q508, IMC 129 and Westar were grown in
5 the greenhouse. Mature leaves, primary expanding leaves,
petioles and roots were harvested at the 6-8 leaf stage,
frozen in liquid nitrogen and stored at -70°C. Lipid
extracts were analyzed by GLC as described in Example 1.
The fatty acid profile data are shown in Table XIX.

10 The data in Table XIX indicate that total leaf
lipids in Q508 are higher in $C_{18:1}$ content than the $C_{18:2}$
plus $C_{18:3}$ content. The reverse is true for Westar and IMC
129. The difference in total leaf lipids between Q508
and IMC 129 is consistent with the hypothesis that a
15 second Fad2 gene is mutated in Q508.

The $C_{16:3}$ content in the total lipid fraction was
about the same for all three lines, suggesting that the
plastid FadC gene product was not affected by the Q508
mutations. To confirm that the FadC gene was not
20 mutated, chloroplast lipids were separated and analyzed.
No changes in chloroplast $C_{16:1}$, $C_{16:2}$ or $C_{16:3}$ fatty acids
were detected in the three lines. The similarity in
plastid leaf lipids among Q508, Westar and IMC 129 is
consistent with the hypothesis that the second mutation
25 in Q508 affects a microsomal Fad2 gene and not a plastid
FadC gene.

- 56 -

TABLE XIX

EXAMPLE 12

Sequences of Mutant and Wild-Type Delta-12 Fatty Acid
Desaturases from *B. napus*

Primers specific for the FAD2 structural gene were used to clone the entire open reading frame (ORF) of the D and F 12-DES genes by reverse transcriptase polymerase chain reaction (RT-PCR). RNA from seeds of IMC 129, Q508 and Westar plants was isolated by standard methods and was used as template. The RT-amplified fragments were used for nucleotide sequence determination. The DNA sequence of each gene from each line was determined from both strands by standard dideoxy sequencing methods.

Sequence analysis revealed a G to A transversion at nucleotide 316 (from the translation initiation codon) of the D gene in both IMC 129 (SEQ ID NO:3) and Q508, compared to the sequence of Westar (SEQ ID NO:1). The transversion changes the codon at this position from GAG to AAG and results in a non-conservative substitution of glutamic acid, an acidic residue, for lysine a basic residue. The presence of the same mutation in both lines was expected since the Q508 line was derived from IMC 129. The same base change was also detected in Q508

- 57 -

and IMC 129 when RNA from leaf tissue was used as template.

The G to A mutation at nucleotide 316 was confirmed by sequencing several independent clones
5 containing fragments amplified directly from genomic DNA of IMC 129 and Westar. These results eliminated the possibility of a rare mutation introduced during reverse transcription and PCR in the RT-PCR protocol. It was concluded that the IMC 129 mutant is due to a single base
10 transversion at nucleotide 316 in the coding region of the D gene of rapeseed microsomal delta 12-desaturase.

A single base transition from T to A at nucleotide 515 of the F gene was detected in Q508 compared to the Westar sequence. The mutation changes the codon at this
15 position from CTC to CAC, resulting in the non-conservative substitution of a non-polar residue, leucine, for a polar residue, histidine, in the resulting gene product. No mutations were found in the F gene sequence of IMC 129 compared to the F gene sequence of
20 Westar.

These data support the conclusion that a mutation in a delta-12 desaturase gene sequence results in alterations in the fatty acid profile of plants containing such a mutated gene. Moreover, the data show
25 that when a plant line or species contains two delta-12 desaturase loci, the fatty acid profile of an individual having two mutated loci differs from the fatty acid profile of an individual having one mutated locus.

The mutation in the D gene of IMC 129 and Q508
30 mapped to a region having a conserved amino acid motif (His-Xaa-Xaa-Xaa-His) found in cloned delta-12 and delta-15 membrane bound-desaturases (Table XX).

- 58 -

Table XX

Alignment of Amino Acid Sequences
of Cloned Canola Membrane Bound-Desaturases

	Desaturase Gene	Sequence ^a	Position
5	Canola-fad2-D (mutant)	AHKCGH	109-114
	Canola-Fad2-D	AHECGH	109-114
	Canola-Fad2-F	AHECGH	109-114
	Canola-FadC	<u>GH</u> D CAH	170-175
	Canola-fad3 (mutant)	<u>GH</u> KCGH	94-99
10	Canola-Fad3	<u>GH</u> D CGH	94-99
	Canola-FadD	<u>GH</u> D CGH	125-130

(FadD = Plastid delta 15, Fad3 = Microsomal delta-15),
(FadC = Plastid delta-12, Fad2 = Microsomal delta-12)

^a One letter amino acid code; conservative substitutions
15 are underlined; non-conservative substitutions are in
bold.

EXAMPLE 13

Transcription and Translation of Microsomal Delta-12
Fatty Acid Desaturases

20 Transcription in vivo was analyzed by RT-PCR
analysis of stage II and stage III developing seeds and
leaf tissue. The primers used to specifically amplify
12-DES F gene RNA from the indicated tissues were sense
primer 5'-GGATATGATGATGGTGAAAGA-3' and antisense primer
25 5'-TCTTTCACCATCATCATATCC-3'. The primers used to
specifically amplify 12-DES D gene RNA from the indicated
tissues were sense primer 5'-GTTATGAAGCAAAGAAGAAAC-3' and
antisense primer 5'-GTTTCTTCTTTGCTTCATAAC-3'. The
results indicated that mRNA of both the D and F gene was
30 expressed in seed and leaf tissues of IMC 129, Q508 and
wild type Westar plants.

- 59 -

In vitro transcription and translation analysis showed that a peptide of about 46 kD was made. This is the expected size of both the D gene product and the F gene product, based on sum of the deduced amino acid
5 sequence of each gene and the cotranslational addition of a microsomal membrane peptide.

These results rule out the possibility that non-sense or frameshift mutations, resulting in a truncated polypeptide gene product, are present in either the
10 mutant D gene or the mutant F gene. The data, in conjunction with the data of Example 12, support the conclusion that the mutations in Q508 and IMC 129 are in delta-12 fatty acid desaturase structural genes encoding desaturase enzymes, rather than in regulatory genes.

15

EXAMPLE 14

Development of Gene-Specific PCR Markers

Based on the single base change in the mutant D gene of IMC 129 described in above, two 5' PCR primers were designed. The nucleotide sequence of the primers
20 differed only in the base (G for Westar and A for IMC 129) at the 3' end. The primers allow one to distinguish between mutant fad2-D and wild-type Fad2-D alleles in a DNA-based PCR assay. Since there is only a single base difference in the 5' PCR primers, the PCR assay is very
25 sensitive to the PCR conditions such as annealing temperature, cycle number, amount, and purity of DNA templates used. Assay conditions have been established that distinguish between the mutant gene and the wild type gene using genomic DNA from IMC 129 and wild type
30 plants as templates. Conditions may be further optimized by varying PCR parameters, particularly with variable crude DNA samples. A PCR assay distinguishing the single base mutation in IMC 129 from the wild type gene along with fatty acid composition analysis provides a means to

- 60 -

simplify segregation and selection analysis of genetic crosses involving plants having a delta-12 fatty acid desaturase mutation.

EXAMPLE 15

5 Transformation with Mutant and Wild Type Fad3 Genes

B. napus cultivar Westar was transformed with mutant and wild type Fad3 genes to demonstrate that the mutant Fad3 gene for canola cytoplasmic linoleic desaturase 15-DES is nonfunctional. Transformation and
10 regeneration were performed using disarmed *Agrobacterium tumefaciens* essentially following the procedure described in WO 94/11516.

Two disarmed *Agrobacterium* strains were engineered, each containing a Ti plasmid having the
15 appropriate gene linked to a seed-specific promoter and a corresponding termination sequence. The first plasmid, pIMC110, was prepared by inserting into a disarmed Ti vector the full length wild type Fad3 gene in sense orientation (nucleotides 208 to 1336 of SEQ ID 6 in WO
20 93/11245), flanked by a napin promoter sequence positioned 5' to the Fad3 gene and a napin termination sequence positioned 3' to the Fad3 gene. The rapeseed napin promoter is described in EP 0255378.

The second plasmid, pIMC205, was prepared by
25 inserting a mutated Fad3 gene in sense orientation into a disarmed Ti vector. The mutant sequence contained mutations at nucleotides 411 and 413 of the microsomal Fad3 gene described in WO93/11245, thus changing the sequence for codon 96 from GAC to AAG. The amino acid at
30 codon 96 of the gene product was thereby changed from aspartic acid to lysine. See Table XX. A bean (*Phaseolus vulgaris*) phaseolin (7S seed storage protein) promoter fragment of 495 base pairs, starting with 5'-TGGTCTTTTGGT-3', was placed 5' to the mutant Fad3 gene
35 and a phaseolin termination sequence was placed 3' to the

- 61 -

mutant Fad3 gene. The phaseolin sequence is described in Doyle et al., (1986) J. Biol. Chem. 261:9228-9238) and Slightom et al., (1983) Proc. Natl. Acad. Sci. USA 80:1897-1901.

5 The appropriate plasmids were engineered and transferred separately to *Agrobacterium* strain LBA4404. Each engineered strain was used to infect 5 mm segments of hypocotyl explants from Westar seeds by cocultivation. Infected hypocotyls were transferred to callus medium
10 and, subsequently, to regeneration medium. Once discernable stems formed from the callus, shoots were excised and transferred to elongation medium. The elongated shoots were cut, dipped in Rootone™, rooted on an agar medium and transplanted to potting soil to obtain
15 fertile T1 plants. T2 seeds were obtained by selfing the resulting T1 plants.

 Fatty acid analysis of T2 seeds was carried out as described above. The results are summarized in Table XXI. Of the 40 transformants obtained using the pIMC110
20 plasmid, 17 plants demonstrated wild type fatty acid profiles and 16 demonstrated overexpression. A proportion of the transformants are expected to display an overexpression phenotype when a functioning gene is transformed in sense orientation into plants.

25 Of the 307 transformed plants having the pIMC205 gene, none exhibited a fatty acid composition indicative of overexpression. This result indicates that the mutant fad3 gene product is non-functional, since some of the transformants would have exhibited an overexpression
30 phenotype if the gene product were functional.

- 62 -

Table XXI

Overexpression and Co-suppression Events in
Westar Populations Transformed with pIMC205 or pIMC110.

Construct	Number of Transformants	α -Linolenic Acid Range (%)	Overexpression Events (>10% linolenic)	Co-Suppression Events (<4.0% linolenic)	Wild Type Events
pIMC110	40	2.4 - 20.6	16	7	17
pIMC205	307	4.6 - 10.4	0	0	307

Fatty acid compositions of representative transformed plants are presented in Table XXII. Lines 652-09 and 663-40 are representative of plants containing pIMC110 and exhibiting an overexpression and a co-suppression phenotype, respectively. Line 205-284 is representative of plants containing pIMC205 and having the mutant fad3 gene.

Table XXII

Fatty Acid Composition of T2 Seed
From Westar Transformed With pIMC205 or pIMC110.

Line	Fatty Acid Composition (%)				
	C16:0	C18:0	C18:1	C18:2	C18:3
652-09 pIMC110 overexpression	4.7	3.3	65.6	8.1	14.8
663-40 pIMC110 co-suppression	4.9	2.1	62.5	23.2	3.6
205-284 pIMC205	3.7	1.8	68.8	15.9	6.7

To the extent not already indicated, it will be understood by those of ordinary skill in the art that any one of the various specific embodiments herein described and illustrated may be further modified to incorporate features shown in other of the specific embodiments.

The foregoing detailed description has been provided for a better understanding of the invention only and no unnecessary limitation should be understood therefrom as some modifications will be apparent to those

WO 97/21340

1. An isolated nucleic acid fragment comprising a full-length coding sequence of a *Brassicaceae* or *Helianthus* delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a His-Glu-Cys-Gly-His amino acid motif,
5 wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said at least one mutation renders the product of said desaturase gene non-functional.
- 10 2. The nucleic acid fragment of claim 1, wherein said mutant desaturase gene encodes a microsomal gene product.
3. The nucleic acid fragment of claim 1, wherein said mutant desaturase gene is from a *Brassica napus* plant.
4. An isolated nucleic acid fragment comprising a full-length coding sequence of a *Brassicaceae* or *Helianthus*
15 delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a Tyr-Leu-Asn-Asn-Pro amino acid motif, wherein said at least one mutation renders the product of
20 said desaturase gene non-functional and wherein said sequence includes said at least one mutation.
5. A plant cell of the *Brassicaceae* or *Helianthus* families other than *Brassica napus*, said plant cell containing a full-length coding sequence of a delta-12
25 fatty acid desaturase gene, said coding sequence having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said mutation confers an
30 altered fatty acid composition in seeds obtained from said plant cell.

6. The plant cell of claim 5, wherein said gene is from a *Brassica napus* plant.
7. The plant cell of claim 5, wherein said plant cell is a *Brassica rapa* plant cell.
- 5 8. An isolated nucleic acid fragment comprising a full-length coding sequence of a *Brassicaceae* delta-15 fatty acid desaturase gene, said coding sequence having at least one mutation in a region of said desaturase gene encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least
10 one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Asp, and wherein said at least one mutation renders the product of said desaturase gene non-functional.
- 15 9. The nucleic acid fragment of claim 8, wherein said mutant desaturase gene is from a *Brassica napus* plant.
10. A *Brassicaceae* plant cell containing a full-length coding sequence of a delta-15 fatty acid desaturase gene, said coding sequence having at least one mutation, in a region encoding a His-Asp-Cys-Gly-His amino acid motif,
20 wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Asp, and wherein said mutation confers an altered fatty acid composition in 'seeds obtained from said plant cell.
- 25 11. The plant cell of claim 10, wherein said mutant desaturase gene is from a *Brassica napus* plant.
12. The plant cell of claim 10, wherein said plant cell is a *Brassica napus* plant cell.
13. A *Brassicaceae* plant cell containing:

a) a full-length coding sequence of a delta-12 fatty acid desaturase gene, said coding sequence having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, said at least one mutation in said motif
5 comprising a codon encoding Lys in place of a codon encoding Glu;

b) a full-length coding sequence of a delta-15 fatty acid desaturase gene having at least one mutation, said at least one delta-15 gene mutation in a region encoding a
10 His-Xaa-Xaa-Xaa-His amino acid motif, said delta-12 gene mutation and said delta-15 gene mutation conferring an altered fatty acid composition in seeds obtained from said plant cell.

14. A *Brassicaceae* or *Helianthus* plant cell containing a
15 full-length coding sequence of a delta-12 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a Tyr-Leu-Asn-Asn-Pro amino acid motif and wherein said mutation confers an altered fatty acid composition in seeds obtained from said
20 plant cell.

15. A method for producing a *Brassicaceae* or *Helianthus* plant cell line, comprising the steps of:

a) inducing mutagenesis in cells of a starting variety of a *Brassicaceae* or *Helianthus* species;
25 (b) obtaining one or more progeny plants from said cells;

(c) identifying at least one of said progeny plants that contains a delta-12 fatty acid desaturase gene having at least one mutation, in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one
30 mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said delta-12

gene mutation renders the product of said delta-12 desaturase gene non-functional; and

(d) producing said plant cell line from said at least one progeny plant by self-or cross-pollination, said plant
5 cell line having said at least one delta-12 gene mutation.

16. The method of claim 15, wherein said plant cell line yields an oil having a stabilized linoleic acid content from about 2.0 % to about 12.0 %.

17. The method of claim 15, further comprising the steps
10 of:

e) inducing mutagenesis in cells of said plant cell line;

f) obtaining one or more progeny plants from said plant cell line cells;

15 g) identifying at least one of said plant cell line progeny plants that contains a delta-15 fatty acid desaturase gene having at least one mutation, in a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif, wherein said delta15 gene mutation renders the product of said
20 delta-15 desaturase gene non-functional; and

h) producing a second plant cell line from said at least one progeny plant by self-or cross-pollination, said second plant cell line having said at least one delta-12 gene mutation and said at least one delta-15 gene mutation.

25 18. The method of claim 15, wherein said starting variety is a *Brassica napus* variety.

19. The method of claim 15, further comprising the step of crossing a plant cell of said plant cell line to a plant cell having a mutation in a different delta-12 fatty acid
30 desaturase gene.

20. The method of claim 19, wherein a second mutation is in a region other than a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif.

21. The method of claim 18, further comprising the steps
5 of:

e) inducing mutagenesis in cells of said plant cell line;

f) obtaining one or more progeny plants from said plant cell line cells;

10 g) identifying at least one of said plant cell line progeny plants that contains a second delta-12 fatty acid desaturase gene having at least one mutation, said second gene mutation in a region other than a region encoding a His-Xaa-Xaa-Xaa-His amino acid motif; and

15 h) producing a second plant cell line from said at least one plant cell line progeny plant by self-or cross-pollination, said second plant cell line having said first and second delta-12 gene mutations.

22. The method of claim 15, wherein said identifying step
20 comprises a technique selected from the group consisting of: PCR, 3SR and direct polynucleotide sequencing.

23. A method for producing a *Brassicaceae* plant cell line, comprising the steps of:

25 a) inducing mutagenesis in cells of a starting variety of a *Brassicaceae* species;

b) obtaining one or more progeny plants from said cells;

30 c) identifying at least one of said progeny plants that contains a delta-15 fatty acid desaturase gene having at least one mutation, said at least one mutation in a region encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises

a codon encoding Lys in place of a codon encoding Asp, and wherein said at least one mutation renders the product of said delta-15 desaturase gene non-functional; and

5 d) producing said plant cell line from said at least one progeny plant by self- or cross-pollination, said plant cell line having said delta-15 gene mutation.

24. The method of claim 23, wherein said identifying step comprises a technique selected from the group consisting of: PCR, 3SR and direct polynucleotide sequencing.

10 25. A method for identifying a mutation in a *Brassicaceae* plant, comprising:

a) providing a *Brassicaceae* plant having a decreased -linolenic acid content as compared with a corresponding control *Brassicaceae* plant; and

15 b) identifying at least one mutation in a delta-15 fatty acid desaturase gene of said plant, said at least one mutation in a region encoding a His-Asp-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon
20 encoding Asp, and wherein said mutation renders the product of said delta-15 fatty acid desaturase gene nonfunctional.

26. The method of claim 25, wherein said identifying step comprises a technique selected from the group consisting of: PCR., 3SR and direct polynucleotide sequencing.

25 27. A method for identifying a mutation in a *Brassicaceae* or *Helianthus* plant, comprising:

a) providing a *Brassicaceae* or *Helianthus* plant having an increased oleic acid content as compared with a corresponding control *Brassicaceae* or *Helianthus* and plant;

30 b) identifying at least one mutation in a delta-12 fatty acid desaturase gene of said plant, said at least one

mutation in a region encoding a His-Glu-Cys-Gly-His amino acid motif, wherein said at least one mutation in said motif comprises a codon encoding Lys in place of a codon encoding Glu, and wherein said mutation renders the product
5 of said delta-12 fatty acid desaturase gene non-functional.

28. The method of claim 27, wherein said identifying step comprises a technique selected from the group consisting of: PCR, 3SR and direct polynucleotide sequencing.

10 29. A *Brassicaceae* or *Helianthus* plant cell, said plant cell containing first and second delta-12 fatty acid desaturase genes, each said gene having at least one mutation, wherein at least one of said mutations is in a region encoding a His-Glu-Cys-Gly-His amino acid motif,
15 wherein said at least one mutation in said region encoding said His-Glu-Cys-Gly-His amino acid motif comprises a codon encoding Lys in place of a codon encoding Glu and wherein said at least one mutation renders the product of said desaturase gene non-functional and confers an altered fatty
20 acid composition in seeds obtained from said plant cell.
