TRI-ARYL ACID DERIVATIVES AS PPAR RECEPTOR LIGANDS

Background of the Invention

This invention is directed to the use of triaryl acid derivatives and their pharmaceutical compositions as PPAR ligand receptor binders. The PPAR ligand receptor binders of this invention are useful as agonists or antagonists of the PPAR receptor.

Field of the Invention

Peroxisome proliferator-activated receptors (PPAR) can be subdivided into three subtypes, namely: PPAR α , PPAR δ , and PPAR γ . These are encoded by different genes (Motojima, Cell Structure and Function, 18:267-277, 1993). Moreover, 2 isoforms of PPAR γ also exist, PPAR γ_1 and γ_2 . These 2 proteins differ in their NH₂-terminal-30 amino acids and are the result of alternative promoter usage and differential mRNA splicing (Vidal-Puig, Jimenez, Linan, Lowell, Hamann, Hu, Spiegelman, Flier, Moller, J. Clin. Invest., 97:2553-2561, 1996).

Biological processes modulated by PPAR are those modulated by receptors, or receptor combinations, which are responsive to the PPAR receptor ligands described herein. These processes include, for example, plasma lipid transport and fatty acid catabolism, regulation of insulin sensitivity and blood glucose levels, which are involved in hypoglycemia/hyperinsulinism (resulting from, for example, abnormal pancreatic beta cell function, insulin secreting tumors and /or autoimmune hypoglycemia due to autoantibodies to insulin, the insulin receptor, or autoantibodies that are stimulatory to pancreatic beta cells), macrophage differentiation which lead to the formation of atherosclerotic plaques, inflammatory response, carcinogenesis, hyperplasia or adipocyte differentiation.

Obesity is an excessive accumulation of adipose tissue. Recent work in this area indicates that PPAR γ plays a central role in the adipocyte gene expression and differentiation. Excess adipose tissue is associated with the development of serious medical conditions, for example, non-insulin-dependent diabetes mellitus (NIDDM), hypertension, coronary artery disease, hyperlipidemia and certain malignancies. The adipocyte may also influence glucose homeostasis through the production of tumor necrosis factor α (TNF α) and other molecules.

Non-insulin-dependent diabetes mellitus (NIDDM), or Type II diabetes, is the more common form of diabetes, with 90-95% of hyperglycemic patients experiencing this form of the disease. In NIDDM there appears to be a reduction in the pancreatic β -cell mass, several distinct defects in insulin secretion or a decrease in tissue sensitivity to insulin. The symptoms of this form of diabetes include fatigue, frequent urination, thirst, blurred vision, frequent infections and slow healing of sores, diabetic nerve damage and renal disease.

Resistance to the metabolic actions of insulin is one of the key features of non-insulin dependent diabetes (NIDDM). Insulin resistance is characterised by impaired uptake and utilization of glucose in insulin-sensitive target organs, for example, adipocytes and skeletal muscle, and by impaired inhibition of hepatic glucose output. The functional insulin deficiency and the failure of insulin to suppress hepatic glucose output results in fasting hyperglycemia. Pancreatic β -cells compensate for the insulin resistance by secreting increased levels of insulin. However, the β -cells are unable to maintain this high output of insulin, and, eventually, the glucose-induced insulin secretion falls, leading to the deterioration of glucose homeostasis and to the subsequent development of overt diabetes.

Hyperinsulinemia is also linked to insulin resistance, hypertriglyceridaemia and increased plasma concentration of low density lipoproteins. The association of insulin resistance and hyperinsulinemia with these metabolic disorders has been termed "Syndrome X" and has been strongly linked to an increased risk of hypertension and coronary artery disease.

Metformin is known in the art to be used in the treatment of diabetes in humans (US Patent No. 3,174,901). Metformin acts primarily to decrease liver glucose production. Troglitazone® is known to work primarily on enhancing the ability of skeletal muscle to respond to insulin and take up glucose. It is known that combination therapy comprising metformin and troglitazone can be used in the treatment of abnormalities associated with diabetes (DDT 3:79-88, 1998).

PPAR γ activators, in particular Troglitazone®, have been found to convert cancerous tissue to normal cells in liposarcoma, a tumor of fat (PNAS 96:3951-3956, 1999). Furthermore, it has been suggested that PPAR γ activators may be useful in the treatment of breast and colon cancer (PNAS 95:8806-8811, 1998, Nature Medicine 4:1046-1052, 1998).

Moreover, PPAR γ activators, for example Troglitazone®, have been implicated in the treatment of polycystic ovary syndrome (PCO). This is a syndrome in women that is characterized by chronic anovulation and hyperandrogenism. Women with this syndrome often have insulin resistance and an increased risk for the development of noninsulin-dependent diabetes mellitus. (Dunaif, Scott, Finegood, Quintana, Whitcomb, J. Clin. Endocrinol. Metab., 81:3299, 1996).

Furthermore, PPAR γ activators have recently been discovered to increase the production of progesterone and inhibit steroidogenesis in granulosa cell cultures and therefore may be useful in the treatment of climacteric. (United States Patent 5,814,647 Urban et al. September 29, 1998; B. Lohrke et al. Journal of Endocrinology, 159, 429-39, 1998). Climacteric is defined as the syndrome of endocrine, somatic and psychological changes occurring at the termination of the reproductive period in the female.

Peroxisomes are cellular organelles which play a role in controlling the redox potential and oxidative stress of cells by metabolizing a variety of substrates such as hydrogen peroxide. There are a number of disorders associated with oxidative stress. For example, inflammatory response to tissue injury, pathogenesis of emphysema, ischemia-associated organ injury (shock), doxorubicin-induced

cardiac injury, drug-induced hepatotoxicity, atherosclerosis, and hyperoxic lung injuries, are each associated with the production of reactive oxygen species and a change in the reductive capacity of the cell. Therefore, it is envisaged that PPAR α activators, among other things, regulate the redox potential and oxidative stress in cells, would be effective in the treatment of these disorders (Poynter et al, J. Biol. Chem. 273, 32833-41, 1998).

It has also been discovered that PPAR α agonists inhibit NF κ B-mediated transcription thereby modulating various inflammatory responses such as the inducible nitric oxide synthase (NOS) and cyclooxygenase-2 (COX-2) enzyme pathways (Pineda-Torra, I. T al, 1999, Curr. Opinion in Lipidology, 10,151-9) and thus can be used in the therapeutic intervention of a wide variety of inflammatory diseases and other pathologies (Colville-Nash, et al., Journal of Immunology, 161, 978-84, 1998; Staels et al, Nature, 393, 790-3, 1998).

Peroxisome proliferators activate PPAR , which in turn, acts as a transcription factor, and causes differentiation, cell growth and proliferation of peroxisomes. PPAR activators are also thought to play a role in hyperplasia and carcinogenesis as well as altering the enzymatic capability of animal cells, such as rodent cells, but these PPAR activators appear to have minimal negative effects in human cells (Green, Biochem. Pharm. 43(3):393, 1992). Activation of PPAR results in the rapid increase of gamma glutamyl transpeptidase and catalase.

PPAR α is activated by a number of medium and long-chain fatty acids and is involved in stimulating β -oxidation of fatty acids in tissues such as liver, heart, skeletal muscle, and brown adipose tissue (Isseman and Green, supra; Beck et al., Proc. R. Soc. Lond. 247:83-87, 1992; Gottlicher et al, Proc. Natl. Acad. Sci. USA 89:4653-4657, 1992). Pharmacological PPAR α activators, for example fenofibrate, clofibrate, genfibrozil, and bezafibrate, are also involved in substantial reduction in plasma triglycerides along with moderate reduction in LDL cholesterol, and they are used particularly for the treatment of hypertriglyceridemia, hyperlipidemia and obesity. PPAR α is also known to be involved in inflammatory disorders. (Schoonjans, K., Current Opinion in Lipidology, 8, 159-66, 1997).

The human nuclear receptor PPAR δ has been cloned from a human osteosarcoma cell cDNA library and is fully described in A. Schmidt et al., Molecular Endocrinology, 6:1634-1641 (1992), the contents of which are hereby incorporated herein by reference. It should be noted that PPAR δ is also referred to in the literature as PPAR β and as NUC1, and each of these names refers to the same receptor. For example, in A. Schmidt et al., Molecular Endocrinology, 6: pp. 1634-1641, 1992, the receptor is referred to as NUC1. PPAR δ is observed in both embryo and adult tissues. This receptor has been reported to be involved in regulating the expression of some fat-specific genes, and plays a role in the adipogenic process (Amri, E. et al., J. Biol. Chem. 270, 2367-71, 1995).

Atherosclerotic disease is known to be caused by a number of factors, for example, hypertension, diabetes, low levels of high density lipoprotein (HDL), and high levels of low density lipoprotein (LDL).

In addition to risk reduction via effects on plasma lipid concentrations and other risk factors, PPAR α agonists exert direct atheroprotective effects (Frick, M. H., et al. 1997.. Circulation 96:2137-2143, de Faire, et al. 1997. Cardiovasc. Drugs Ther. 11 Suppl 1:257-63:257-263).

5 It has recently been discovered that PPAR δ agonists are useful in raising HDL levels and therefore useful in treating atherosclerotic diseases. (Leibowitz et al.; WO/9728149). Atherosclerotic diseases include vascular disease, coronary heart disease, cerebrovascular disease and peripheral vessel disease. Coronary heart disease includes CHD death, myocardial infarction, and coronary
10 revascularization. Cerebrovascular disease includes ischemic or hemorrhagic stroke and transient ischemic attacks.

PPAR γ subtypes are involved in activating adipocyte differentiation, and are not involved in stimulating peroxisome proliferation in the liver. Activation of PPAR γ is implicated in adipocyte differentiation through the activation of adipocyte-specific gene expression (Lehmann, Moore, Smith-Oliver, Wilkison, Willson, Kliewer, J. Biol. Chem., 270:12953-12956, 1995). The DNA sequences for
15 the PPAR γ receptors are described in Elbrecht et al., BBRC 224:431-437 (1996). Although peroxisome proliferators, including fibrates and fatty acids, activate the transcriptional activity of PPAR's, only prostaglandin J₂ derivatives such as the arachidonic acid metabolite 15-deoxy- $\Delta^{12,14}$ -prostaglandin J₂ (15d-PGJ₂) have been identified as natural ligands specific for the PPAR γ subtype, which also binds thiazolidinediones. This prostaglandin activates PPAR γ -dependent adipogenesis, but activates PPAR α
20 only at high concentrations (Forman, Tontonoz, Chen, Brun, Spiegelman, Evans, Cell, 83:803-812, 1995; Kliewer, Lenhard, Wilson, Patel, Morris, Lehman, Cell, 83:813-819, 1995). This is further evidence that the PPAR family subtypes are distinct from one another in their pharmacological response to ligands.

It has been suggested that compounds activating both PPAR α and PPAR γ should be potent hypotriglyceridemic drugs, which could be used in the treatment of dyslipidemia associated with
25 atherosclerosis, non-insulin dependent diabetes mellitus, Syndrome X, (Staels, B. et al., Curr. Pharm. Des., 3 (1), 1-14 (1997)) and familial combined hyperlipidemia (FCH). Syndrome X is the syndrome characterized by an initial insulin resistant state, generating hyperinsulinaemia, dyslipidaemia and impaired glucose tolerance, which can progress to non-insulin dependent diabetes mellitus (Type II diabetes), characterized by hyperglycemia. FCH is characterized by hypercholesterolemia and
30 hypertriglyceridemia within the same patient and family.

The present invention is directed to a series of compounds that are useful in modulating PPAR receptors, as well as to a number of other pharmaceutical uses associated therewith.

Combination therapy includes administration of a single pharmaceutical dosage formulation which contains a compound of Formula I and one or more additional hypoglycemic agent, as well as administration of the compound of Formula I and each additional hypoglycemic agents in its own separate pharmaceutical dosage formulation. For example, a compound of Formula I and hypoglycemic agent can be administered to the patient together in a single oral dosage composition such as a tablet or capsule, or each agent administered in separate oral dosage formulations. Where separate dosage formulations are used, the compound of Formula I and one or more additional hypoglycemic agents can be administered at essentially the same time, i.e., concurrently, or at separately staggered times, i.e., sequentially.

This invention also encompasses all combinations of preferred aspects of the invention noted herein.

Compounds useful according to this invention can be prepared in segments as is common to a long chain molecule. Thus it is convenient to synthesize these molecules by employing condensation reactions at the A, B and D sites of the molecule. Compounds of Formula I can be prepared by the application or adaptation of known methods, by which is meant methods used heretofore or described in the literature. Compounds of Formula I are preparable by recognized procedures from known compounds or readily preparable intermediates. Thus, in order to prepare a compound of the below formula, where Z is generally CN or CO₂R

The following reactions or combinations of reactions are employable:

Scheme 1

Scheme 2

Scheme 3

In the above schemes (1-3) a displacement reaction can be used when A, B and D are O, S or NR, and L is a leaving group such as halo, tosylate or mesylate. A base such as sodium hydride, sodium hydroxide, potassium carbonate or triethylamine may be used when A, B or D is O or S.

An alternative coupling reaction is the Mitsunobu reaction (diethylazodicarboxylate/triphenylphosphine see *Synthesis*, 1981, 1). This chemistry can be used to condense fragments when the functionality is amenable to this reaction. An example of this would be the coupling of compounds of scheme 1 where formula VI (L = OH, a > 0) and formula VII (A = O, b = 0)

Reaction temperatures are in the range of about -78 °C to 80 °C and reaction times vary from about 1 to 48 hours. The reactions are usually carried out in an inert solvent that will dissolve the reactants. Solvents include, but are not limited to N,N-dimethylformamide, acetone, acetonitrile, tetrahydrofuran.

Alternatively, the reactions shown in Schemes 1-3 can be accomplished using a fragment of the described Formula. For example, as shown in Scheme 4, a compound of Formula VI (Scheme 1) may be combined with a compound of Formula VII, where Formula VII optionally contains Ar III and Z. This notation used for Formula VII in Scheme 4 is used throughout this document and is used to generalize the described reaction. Therefore, all of the reactions of Schemes 1-3 may be accomplished as shown or by using a fragment of the described formula. In some instances, the use of a protecting group may be required when a fragment of a formula is used.

Scheme 4

One method for the preparation of compounds where Z = tetrazole is the reaction of an intermediate where Z = CN with sodium azide and ammonium chloride at an elevated temperature.

One method for the preparation of compounds where $Z = \text{CO}_2\text{H}$, is the hydrolysis of an intermediate where Z is CN or CO_2R . This can be accomplished under acidic or basic conditions, with the preferred method generally being sodium or potassium hydroxide in a protic solvent such as aqueous ethanol at a temperature of about 20°C to 100°C .

An alternative method for the conversion of a nitrile to a carboxylic acid is to reduce the nitrile to the corresponding aldehyde using a reducing agent such as diisobutylaluminum hydride, followed by oxidation of the aldehyde to the carboxylic acid using a reagent such as sodium chlorite, sodium dihydrogen phosphate, isobutene (See, JACS 1980, 45, 1176) or other standard conditions.

Another alternative method for the preparation of compounds where $Z = \text{CO}_2\text{H}$ is the oxidation of a primary alcohol using an appropriate oxidant such as PDC in DMF, $\text{RuCl}_3 / \text{NaIO}_4$ in 3:2:2 water acetonitrile : CCl_4 or the Swern system (to produce the intermediate aldehyde then oxidation of this functionality to the carboxylic acid as described above).

Some other methods for the preparation of compounds where $Z = \text{CO}_2\text{H}$ are shown in Scheme 5. A carboxylic acid (2) can be generated directly by halogen-metal exchange of the corresponding aromatic halide (1) with an alkyl lithium reagent such as *n*-butyllithium, followed by quenching the resulting anion with carbon dioxide. Alternatively, alkoxy-carbonylation of an aromatic bromide, iodide or triflate can be accomplished in a carbon monoxide atmosphere in the presence of a suitable alcohol (usually methanol) using a catalyst such as $\text{Pd}(\text{PPh}_3)_2\text{Cl}_2 / \text{Et}_3\text{NH}$, $\text{Pd}(\text{Ph}_2\text{P}(\text{CH}_2)_3\text{PPh}_2)_2 / \text{Et}_3\text{N}$ or alternatively cobalt, i.e. $\text{Co}(\text{OAc})_2$, plus a base (NaH or K_2CO_3). The resulting benzoate (3) is then converted to the benzoic acid by hydrolysis as described above.

Scheme 5

Preparation of phenylacetic acid derivatives can be accomplished from an appropriate aryl halide or triflate as illustrated in Scheme 6. Stille coupling of this type of compound with a vinyl stannane using a palladium catalyst such as $\text{Pd}(\text{OAc})_2$, $\text{P}(\text{o-tolyl})_3$ provides an olefin, (5). Hydroboration of this

vinylbenzene derivative, followed by oxidation of the resulting primary alcohol with an oxidant, such as Jones' reagent, provides the phenylacetic acid (6).

Scheme 6

In one embodiment of the current invention, ArI can be a five membered ring heterocycle thus generating astructures of the general form shown in Figure 1.

Figure 1

In particular, the heterocycle can be a substituted thiazole, oxazole, oxadiazole, imidazole, isoxazole, pyrazole, thiadiazole or triazole. These systems can be prepared using methods known in the chemical literature (for reviews see Katritzky, A.R.; Rees, C.W. Eds. *Comprehensive Heterocyclic Chemistry*, Vol. 5; Pergamon Press (1984); Katritzky, A.R.; Rees, C.W.; Scriven, E.F.V. Eds. *Comprehensive Heterocyclic Chemistry II*; Vols 3 & 4, Pergamon Press (1996)). More specifically, oxazoles, imidazoles and thiazoles can be prepared by fusion of an amide, amidine or a thioamide, respectively, with an α -halo-ketone at temperatures ranging from about 40 °C to 150 °C (Scheme 7).

Scheme 7

These reactions may be carried out neat, or in a solvent such as toluene, dichlorobenzene, or ethanol. Substituted oxazoles can also be prepared from a diazoketone and a nitrile using BF_3 etherate (Scheme 8), Ibata, T.; Isogami, Y. *Bull. Chem. Soc. Jpn.* **1989**, *62*, 618).

Scheme 8

1,2,4-Oxadiazoles can be prepared by reaction of a nitrile with hydroxylamine followed by condensation of the resulting hydroxy-amidine with an acid chloride in the presence of a base and heating the adduct in a solvent such as toluene or dichlorobenzene to effect ring closure. (Scheme 9, Banavara, L.M.; Beyer, T.A.; Scott, P.J.; Aldinger, C.E.; Dee, M.F.; siegel, T.W.; Zembrowsky, W.J. *J. Med. Chem.*, **1992**, *35*, 457).

Scheme 9

1,3,4-oxadiazoles are prepared (Scheme 10) by condensation of an acylhydrazide with an acid synthon (such as an ester, acid chloride acyl azide) then cyclization of the resulting diacyl-hydrazide by heating in a solvent such as benzene or ethanol with or without an acid catalyst such as sulphuric acid (for examples see Weidinger, H.; Kranz, *J. Chem. Ber.*, **1963**, *96*, 1049 and Vakula, T.R.; Srinivarsan, V.R. *Indian J. Chem.*, **1973**, *11*, 732).

Scheme 10

Substituted 1,2,4-thiadiazoles can be prepared by condensation of a thioamide with an N,N -dimethylamide dimethyl acetal derivative in a solvent such as benzene (Scheme 11, MacLeod, A.; Baker, R.; Freedman, S.F.; Patel, S.; Merchant, K.J.; Roe, M. Saunders, J. *J. Med. Chem.*, **1990**, *33*, 2052. also Patzel, M. Liebscher, J.; Siegfried, A. Schmitz, E. *Synthesis*, **1990**, 1071) followed by reaction with an electrophilic aminating agent such as mesitylsulphonyloxyamine in methanol or dialkyloxaziridine in a solvent such as toluene.

Scheme 11

In another embodiment of this invention ArI can be a 1,3,4-thiadiazole. This system is assembled by condensation of a dithioester with an imidate ester salt in a solvent such as ethanol at a temperature between room temperature and reflux (Scheme 12. Stillings, M.R.; Welbourn, A.P.; Walter, D.S. *J. Med. Chem.*, **1986**, *29*, 2280). The dithioester precursor is obtained from the corresponding Grignard reagent and carbon disulphide / MeI. The imidate ester is prepared from the corresponding nitrile by reaction with HCl gas in the presence of an appropriate alcohol.

57

Scheme 12

Pyrazoles can be prepared by condensation of a 1,3-diketone (Scheme 13) or a synthetic equivalent with a substituted hydrazine (for example, a β -aminoenone. Alberola, A.; Calvo, L.; Ortega, A.G.; Sadaba, M.L.; Sanudo, M.C.; Granda, S.G.; Rodriguez, E.G., *Heterocycles*, 1999, 51, 2675).

Scheme 13

Similarly, isoxazoles can be prepared by reaction of a 1,3 dicarbonyl compound with hydroxyl amine (Scheme 14. Pei, Y.; Wickham, B.O.S.; *Tetrahedron Letts*, 1993, 34, 7509) in a solvent such as ethanol at a temperature between 20 °C to reflux temperature.

Scheme 14

Alternatively, isoxazoles can be prepared by condensation of a hydroxamyl chloride with an alkyne (Scheme 15, Kano, H.; Adachi, I.; Kido, R.; Hirose, K. *J. Med. Chem.* 1967, 10, 411) in the presence of

a base such as triethylamine. The hydroxamyl chloride unit can, in turn, be prepared from the corresponding oxime by oxidation with chlorine gas at low temperature (such as -60°C) in a solvent such as ether (Casanti, G. Ricca, A. *Tetrahedron Lett.*, 1967, 4, 327).

Scheme 15

Triazoles are prepared by the Einhorn-Brunner reaction or a variant thereof (Scheme 16)

Scheme 16

In addition, 5-hydroxymethyl substituted 1,2,4-triazoles can be prepared by condensation of an imide ester with an 2-hydroxy-acetohydrazide unit (Scheme 17. Browne, E. J.; Nunn, E. E.; Polya, J. B. *J. Chem. Soc., C* 1970, 1515).

Scheme 17

The five membered heterocycles, so formed, can, in certain cases, be coupled directly with a fragment containing ArII using standard methodology detailed elsewhere in the description of this invention (Schemes 1-4). These methods include alkylation of metal alkoxide containing ArII with a chloromethyl substituted heterocycle, or conversely, alkylation of a hydroxyl appended heterocycle (in the presence of a base) with a chloromethyl reagent containing ArII.

In another approach to fragment condensation, the substituents on the preformed heterocycle are first modified to incorporate suitable reactive functionality then this system is coupled to a fragment

containing ArII. For example (Scheme 18), treatment of a 1,4-disubstituted imidazole with a base such as n-butyl lithium at a temperature of around -78 °C followed by alkylation of the resulting anion with an electrophile such as ethylene oxide provides the hydroxyethyl-substituted imidazole (other useful electrophiles are DMF or formaldehyde. For example see Manoharan, T.S.; Brown, R.S. *J. Org. Chem.*, 1989, 54, 1439). This intermediate can then be coupled to an ArII fragment containing an aromatic alcohol via a Mitsunobu reaction.

Scheme 18

Another example of this general approach is shown in Scheme 19. A ring substituent such as an ester can be reduced to the corresponding alcohol using a reagent such as lithium aluminum hydride or lithium borohydride in a solvent such as THF or ether. Followed by halogenation of the resulting alcohol with a reagent system such as NCS / Ph₃P, Ph₃P / Br₂ or PBr₃ (Pei, Y.; Wickham, B.O.S.; *Tetrahedron Lett.*, 1993, 34, 7509). The alkyl halide produced in this manner can be coupled with a nucleophilic substituent attached to ArII, using a base such as K₂CO₃ in the case of an aromatic alcohol, (thiol) or NaH in the case of an aliphatic alcohol (thiol).

Scheme 19

In a third general approach to fragment condensation, Ar II can be incorporated into a precursor of the five membered heterocycle. For example (Scheme 20), amination of the 3-aryl-propionate and thionation of the resulting amide provides a suitable functionalized system for thiazole ring synthesis. Similarly formation of the thio-urea from the arylmethyl amine (path B) provides a suitable precursor for fusion with an α -haloketone leading to a 2-amino-substituted thiazole (Collins, J.L.; Blanchard, S. G.; Boswell, G. E.; Charifson, P. S.; Cobb, J. E.; Henke, B. R.; Hull-Ryde, E. A.; Kazmierski, W. M.; Lake, D. H.; Leesnitzer, L. M.; Lehmann, J.; Lenhard, J. M.; Orband-Miller L.A.; Gray-Nunez, Y.; Parks, D. J.; Plunkett, K. D.; Tong, Wei-Qin. *J. Med. Chem.* 1998, 41, 5037).

Scheme 20

In another embodiment of this invention, ArI is a five membered heterocycle of general formula shown in Figure 2.

Provided that when A = O, N, or S then "a" is > 1

Figure 2

In particular, this heterocycle can be a pyrazole, an imidazole or a triazole. These systems can be prepared by alkylation of an *N*-unsubstituted heterocycle using a base such as sodium hydride, in a solvent such as DMF, THF, DMPU or a combination of these solvents, at or around 0 °C and an electrophile such as an alkyl halide, cyclic carbonate or an epoxide (Scheme 21).

Scheme 21

These electrophiles can incorporate ArII or the alkylation products can be further modified and coupled to a fragment containing ArII in a subsequent step as described above. For example (Scheme 22), The 3,5-disubstituted pyrazole is prepared by reacting an aldehyde with a β -tosylhydrazinophosphonate, using the literature procedure (Almirante, N.; Benicchio, A.; Cerri, A.; Fedrizzi, G.; Marazzi, G.; Santagostino, M. *Synlett* 1999, 299). This intermediate can then be alkylated with sodium hydride / ethylene carbonate in DMF (for a specific example see Collins, J.L.; Blanchard, S. G.; Boswell, G. E.; Charifson, P. S.; Cobb, J. E.; Henke, B. R.; Hull-Ryde, E. A.; Kazmierski, W. M.; Lake, D. H.; Leesnitzer, L. M.; Lehmann, J.; Lenhard, J. M.; Orband-Miller L.A.; Gray-Nunez, Y.; Parks, D. J.; Plunkett, K. D.; Tong, Wei-Qin. *J. Med. Chem.* 1998, 41, 5037). This intermediate can in turn be coupled to a fragment containing ArII by a Mitsunobu reaction as described above.

Scheme 22

In another embodiment of this invention ArI is a substituted benzene, pyridine, pyrimidine, pyrazine or pyridazine (Figure 3). These systems can be prepared by applying several of the general synthetic methods detailed elsewhere in the description of this invention.

Figure 3

More specifically (Scheme 23), treatment of the known 5-bromo-2-methyl-pyridine (Graf, *J. Prakt. Chem.*, 1932, 133, 19.) with LDA then formaldehyde in THF at low temperature (typically around -78 °C) followed by Mitsunobu coupling of the resulting alcohol to an aromatic alcohol containing ArII gives the bromo-pyridine derivative which can be further modified to give various alkyl and aryl substituted pyridines by cross coupling with an appropriate alkyl or aryl organometallic under palladium or nickel catalysis (For general reviews see Knight, D.W. and Billington, D.C in *Comprehensive Organic Synthesis* Vol. 3, p 413 and 481, Trost, B.M. and Fleming, I; Eds. Pergamon Press 1993).

Scheme 23

Similar procedures using the appropriate 5-bromo-2-methyl-pyrimidine (Kosolapoff, G.M.; Roy, C.H. *J. Org. Chem.*, 1961, 26, 1895), 2-iodo-5-methyl-pyrazine (Hirshberg, A.; Spoerr, P.E.; *J. Org. Chem.*, 1961, 26, 1907) and 3-bromo-6-methyl-pyridazine (Counotte-Potman, A.; van der Plas, H.C.; *J.*

Heterocyclic Chem., **1983**, *20*, 1259) provide access to the corresponding pyrimidines, pyrazines and pyridazines respectively.

In another variant of this general class, ArI is a 3-heteroatom-substituted pyridazine. For example (Scheme 24), treatment of the known 3,6-dibromo-pyridazine with a metal alkoxide (containing ArII and derived from the corresponding alcohol and sodium hydride) in a solvent such as DMSO provides the alkoxy-substituted bromo-pyridazine. The bromide can be converted into a range of substituents as described above for pyridines. In particular, Suzuki coupling with a boronic acid in the presence of a base and a palladium catalyst provides the corresponding aryl substituted pyridazines.

Scheme 24

In another embodiment of this invention ArI can be a substituted quinoxaline (Figure 4). These systems are assembled by condensation of a 1,2-dicarbonyl compound with a 1,2 diamino-benzene (for a review, see Katritzky, A.R.; Rees, C.W.; Scriven, E.F.V. Eds. *Comprehensive Heterocyclic Chemistry II*; Vol 6 Pergamon Press (1996).

Figure 4

Functionalization of these systems and coupling to ArII can be effected using procedures described for the related pyrazines. For example (Scheme 25), condensation of 1,2-diamino-benzene with 2,3-butanedione provides the 2,3-dimethyl quinoxaline. *N*-oxidation of this intermediate with a peroxy-carboxylic acid and treatment of the product with acetyl chloride gives the 2-chloromethyl-3-methyl quinoxaline (Ahmed,

Y.; Habib, M.S.; Bakhtiari, B. Bakhtiari, Z. *J. Org. Chem.*, **1966**, *31*, 2613). This intermediate is then coupled to a fragment containing Ar II under standard conditions.

Scheme 25

In another embodiment of the current invention ArI can be a quinazoline (Scheme 26). Such systems are commonly prepared by condensation of an o-amino-benzaldehyde or o-amino-aryl-ketone derivative with an acid chloride followed by heating with ammonia. For example, condensation of o-amino-benzaldehyde with chloroacetyl chloride in the presence of pyridine followed by reaction of the product with ethanolic ammonia at room temperature (Armarego, W.L.F.; Smith, J. I. C. *J. Chem. Soc.*, C, **1966**, 234) provides a 2-chloromethyl substituted quinazoline which can be coupled to a fragment containing ArII as described above.

Scheme 26

The related quinazolin-4-one ring system (Scheme 27) can be prepared by condensation of an o-amino-benzonitrile and an acid chloride followed by ring closure using a reagent such as urea hydrogen peroxide in the presence of a base such as potassium carbonate (Bavetsias, V. *Synth. Commun.* **1998**, *28*, 4547). In another variant of the quinazoline system, 4-heteroatom substituted quinazolines can be prepared by condensation of an amino-benzonitrile with chloroacetonitrile in the presence of an acid such as HCl or HBr (Chhabria, M. T.; Shishoo, C. J. *Heterocycles* **1999**, *51*, 2723.). The resulting system can be coupled to ArII as described above. The 4-halo-substituent can then be modified by nucleophilic displacement by a metal alkoxide in a solvent such as DMSO.

Scheme 27

A general reaction for the preparation of reagents such compounds of formulas VI, IX, X, XIII and XIV (schemes 1-3) is shown in Scheme 28. Halogenation of a methyl substituted aromatic with a reagent such as N-bromosuccinimide under free radical conditions provides the halomethyl substituted aromatic reagents.

Scheme 28

An alternative preparation of certain alkylating reagents is shown in Scheme 29. For example, substituted 2-chloromethyl quinoline derivatives can be prepared using a two step procedure (See, J. Med. Chem. 1991, 34, 3224). Oxidation of the nitrogen to form the N-oxide can be achieved with an oxidant such as m-chloroperbenzoic acid or hydrogen peroxide. Reaction of the N₂-oxide with a reagent such as toluene sulfonylchloride at elevated temperatures can produce the target chloromethyl derivative. This chemistry can also be extended to 2-picoline derivatives where the 6-position is non-hydrogen.

67

Scheme 29

Preparation of reagents which can be used as alkylating agents of formula VI (scheme 1) are shown in Scheme 30. With the quinoxaline ring system the use of trichloroisocyanuric acid (TCC) can produce the corresponding chloromethyl analog (See, Chem. Ber. 1987, 120, 649).

Scheme 30

In a particular embodiment of this invention, B of Formula I can be an amide linker of either of the general forms shown in Figure 5. Compounds of this formula can be prepared from a carboxylic acid fragment and an amine fragment using standard peptide coupling reagents. They can also be prepared by reaction with an activated carboxylic acid derivative such as, but not limited to, an acid chloride or anhydride in combination with an amine fragment in the presence of a suitable base such as triethylamine. It should be clear that essentially the same procedures can be used in the case where group A of Formula I is an amide using the appropriate carboxylic acid and amine fragments.

Figure 5

More specifically, the 2-aminomethyl-6-substituted-benzoic acid system (7) can be prepared using the chemistry shown in Scheme 31. Selective reduction of the substituted phthalic anhydride (9) with a

sterically hindered lithium trialkylborohydride, such as L-selectride, provides lactone (10) regioselectively (See Krishnamurthy, *Heterocycles*, **1982**, *18*, 4525). Reaction of this lactone with potassium phthalimide provides the protected amine according to the procedure of Bornstein, *Org.Syn. Collective Vol IV*, **1963**, 810. Removal of the phthalimide protecting group using standard deprotection conditions with hydrazine can provide the amino acid (7).

Scheme 31

1,2-Carboxylic acid-half esters such as 12 (Scheme 32) are precursors to amide linked structures (Figure 5) in which the ArIII containing fragment is the acyl donor. These systems can be prepared in several ways: Alcoholysis of the phthalic anhydride (9) can provide selectively isomer (11) plus smaller amounts of isomer (12). Esterification to provide the diester (13) can be accomplished using a variety of conditions, such as Fisher esterification. Hydrolysis of the diester can provide the regioisomer (12) as the major isomer in addition to isomer (11).

Scheme 32

Phthalic anhydride derivatives such as (9) can, in turn, be prepared from the corresponding diacid (14) as shown in Scheme 33 using dehydrating conditions such as, but not limited to, hot acetic anhydride.

Scheme 33

In one embodiment of this invention, $ArIII-(CR_9R_{10})_e-D-(CR_{11}R_{12})_f-E-Z$ taken together constitutes a substituted benzoic acid. A useful sequence of reactions for constructing this kind of system is shown in Scheme 34. A lactone (obtained as described in Scheme 31) can be heated with hydrobromic acid to provide the bromomethyl carboxylic acid. The carboxylate can be esterified by preparing the acid chloride, followed by reaction with an alcohol to provide an intermediate bromide which can be used as outlined in Scheme 2, Formula XIII.

Scheme 34

An alternative benzoate substitution pattern can be accessed using the Alder-Rickert reaction as shown in Scheme 35 (See, *J. Org. Chem.* 1995, 60, 560). A 2-silyloxydiene can be formed from an enone using a strong base such as LDA and trapping the enolate with a silylating reagent. Heating this diene with an acetylenedicarboxylate at elevated temperatures can then yield the Alder-Rickert product. Alkylation of the phenolic hydroxyl under standard conditions (using the alkylating reagent $R'-L$, where L is a leaving group) followed by saponification of the diester can provide a diacid intermediate which can be manipulated according to the chemistry described in figures 31-34 to provide useful intermediates for the preparation of compounds of Formula I.

Scheme 35

Another particular embodiment of this invention is one in which the substituted benzoic acid moiety described above has a 6-alkyl-2-alkoxy substituent pattern. The preparation of this kind of system is illustrated using the 6-methyl derivative shown in Scheme 36 (See Hamada, *Tetrahedron*, **1991**, *47*, 8635). Ethyl acetoacetate and crotonaldehyde can be condensed to form the cyclic β -ketoester. Subsequent lithium chloride / cupric chloride mediated aromatization of this intermediate can be accomplished at elevated temperatures to provide the target salicylate ester. The phenolic hydroxyl of this system can be further derivatized by alkylation as outlined elsewhere in the description of this invention.

Scheme 36

Additionally, 6-alkyl-2-alkoxy benzoate systems can be prepared by aromatic nucleophilic substitution of a 2-fluorobenzaldehyde, at elevated temperatures, with an alkoxide (Scheme 37) to produce a 2-alkoxybenzaldehyde. Oxidation of the aldehyde to the acid can then be accomplished using conditions such as sodium chlorite, sodium dihydrogen phosphate, isobutene (See, *JACS* **1980**, *45*, 1176).

Scheme 37

In another embodiment of this invention, B of Formula I can be a sulfur atom forming a thioether linkage (Scheme 2, Formulas (XI and XII)). This type of system can be prepared by standard thiol alkylation using a suitable base (such as sodium or potassium carbonate, hydroxide, hydride or an amine such as triethylamine) to form an anion of the thiol and then reaction of this species with an appropriate electrophile such as an alkyl halide or sulphonate ester. Similarly, the groups A and D of Formula I can also be, independently, a sulfur atom. It should be clear that the same transformations described in the Schemes below can be applied to compounds of Formulas (VII, VIII, XI, XII and XVI; schemes 1-3).

Aromatic thiols can be prepared from the corresponding phenols. For example, preparation of a 2-thio-benzoate (10) from the salicylate (7), can be carried out as shown in Scheme 38. (See, Guise J. Chem Soc., Perkin Trans. 1, 1982, 8, 1637). The thionocarbamate (8) can be obtained from the corresponding phenol (7) using a thiocarbamoyl chloride. Pyrolysis of (8) (>300 °C) can yield the rearrangement product (9) which upon hydrolysis can yield the thiol (10).

Scheme 38

Another useful ring substituent transformation is the conversion of an aniline to an aromatic thiol. As shown in Scheme 39, diazotization of an aniline such as (11) is followed by conversion of the diazonium salt (12) to a disulfide (13) using sodium sulfide. Reduction of the disulfide with zinc/acetic acid can yield the thiol (14) (See, Guise J. Chem Soc., Perkin Trans. 1, 1982, 8, 1637).

Scheme 39

In a particular embodiment of this invention, ArIII can be a halo-substituted aromatic. Synthesis of a particularly relevant system is outlined in scheme 40. Regioselective halogenation of a 2,6-disubstituted-phenol to provide the 4-halophenol system can be accomplished with a halogenating reagent such as sulfuryl chloride (See, J. Het. Chem. 1989, 26, 1547). The phenolic hydroxyl group can be further derivitized as outlined elsewhere in the description of this invention.

Scheme 40

An alternative method for the preparation of a halo (or alkoxy)-substituted benzoate is shown in Scheme 41. An aniline is first converted to its diazonium salt using nitrous acid, followed by transformation to the corresponding nitrile using a reagent such as cuprous cyanide (See Chem. Ber. 1983, 116, 1183). The cyano group is then hydrolyzed to the acid (see, Fuson, JACS 1941, 63, 1679). The acid may then be protected as an ester to allow further derivitization of the system as outlined elsewhere in the description of this invention.

X = halogen or alkoxy

Scheme 41

An ortho-halo-benzoate can be prepared similarly, by diazotization of an o-carboxy aniline, followed by reaction with a copper halide (Scheme 42).

Scheme 42

In another embodiment of this invention, ArIII is a benzofuranyl or dihydrobenzofuranyl carboxylic acid as illustrated in Figure 6

Figure 6

Benzofuran-2-carboxylate derivatives can be prepared as shown in Scheme 43 by cyclization of the appropriately substituted 2-carbonyl-phenoxyacetate under basic conditions. Reduction of the resulting benzofuran to the corresponding 2,3-dihydro-benzofuran can be accomplished using sodium mercury amalgam under basic conditions. (See, J. Med Chem. 1984, 27, 570).

Scheme 43

An alternative synthesis of the 2,3-dihydrobenzofuran-2-carboxylate ring system is shown in Scheme 44 (See, J. Med. Chem. 1981, 865). Claisen rearrangement of a substituted allyl-phenyl ether at an elevated temperature such as 250 °C either neat or in a solvent such as dimethylaniline, can provide the o-allyl-phenol. Peracid oxidation of this intermediate provides the 2-hydroxymethyl-2,3-dihydrobenzofuran, which can be further oxidized to the carboxylic acid using a variety of oxidizing agents such as Jones' reagent.

Scheme 44

In another embodiment of this invention "A" can be an imidazolidin-2-one, a tetrahydropyrimidin-2-one, an imidazoline-2,4-dione, or a tetrahydropyrimidin-2,4-dione (Figure 7).

X, Y = (CR₁R₂)_n, C=O
n = 1, 2

Figure 7

These systems are prepared from an amine containing ArI by sequential acylation, aminolysis, ring closure and reduction, as illustrated in Scheme 45 (For examples see Kitazaki, T.; Asaka, A.; Tamura, N.; Matsushita, Y.; Hosono, H.; Hayashi, R.; Okonogi, K.; Itoh, K. *Chem. Pharm. Bull.*, 1999, 47, 351 and Basha, A.; *Tetrahedron Lett.*, 1988, 29, 2525). Coupling to ArII can be effected by derivitization of the cyclic urea N by treatment with a base such as NaH in THF at around 0 °C then alkylation of the resulting anion with an electrophile such as an alkyl bromide / triflate containing ArII).

Scheme 45

In another embodiment of this invention ArII is a six membered ring aromatic of general form substituted shown in Figure 8. In particular, ArII is a substituted benzene, pyridine, pyrimidine, pyridazine or pyrazine.

Figure 8

In principle, appropriately functionalized ring systems of this kind can be prepared by functionalization of specific precursors followed by ring synthesis or by derivatization of a preformed ring system. There are numerous approaches to the synthesis and functionalization of the aforementioned cyclic frameworks in the chemical literature (for examples, see (a) Katritzky, A.R.; Rees, C.W.; Scriven,

E.F.V. Eds. *Comprehensive Heterocyclic Chemistry II*, Vol 5 and Vol 6. Elsevier Science 1996 and references therein). For example, (Scheme 46) alkylation of methyl glycolate with an alkyl halide containing ArI using a base such as sodium hydride in a solvent such as THF or DMSO provides the ester. Claisen condensation of this ester with *t*-butyl acetate at low temperature (typically below -15 °C) using a base such as LDA in THF provides the keto ester intermediate. This is reacted with formamidine acetate in the presence of a base such as sodium methoxide in methanol to give the pyrimidinone (Butters, M. J. *Heterocyclic Chem.*, 1992, 29, 1369). This type of substituted aromatic system can be further functionalized to incorporate ArI as described elsewhere in the description of this invention.

Scheme 46

In certain cases, ArII (in Figure 8) can be assembled by ring transformation of another heterocycle, for example, treatment of the known 4-bromo-2-methoxy-furan (Scheme 47, Marini-Bettolo, R.; Flecker, P.; Tsai, T. Y. R.; Wiesner, K. *Can. J. Chem.* 1981, 59, 1403) with an alkyl lithium at low temperature and reaction of this anion with an electrophile containing ArIII (such as a bromide, aldehyde, epoxide) provides the 4-substituted furan. Oxidative cleavage of this intermediate with dioxirane followed by treatment with hydrazine provides the pyridazinone which can be further modified to incorporate ArI as illustrated elsewhere in the description of this invention.

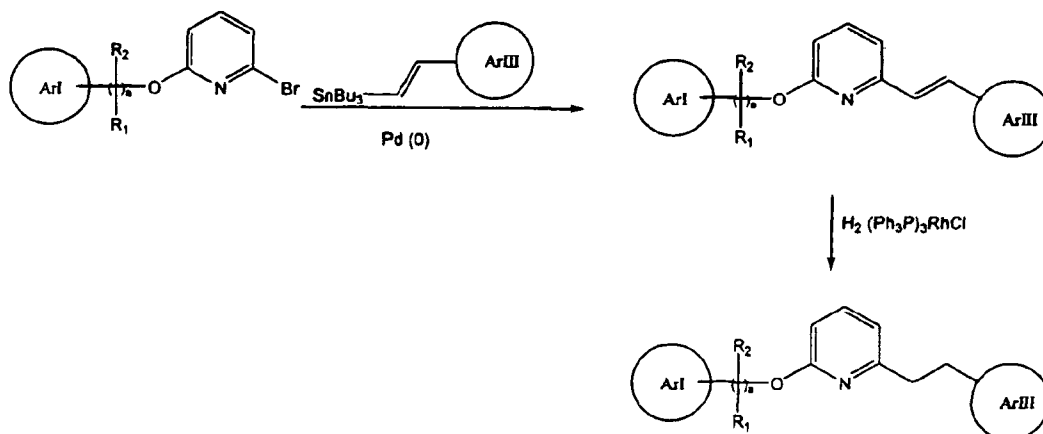

Scheme 47

A particularly useful protocol with regard to functionalization of heterocycles involves Mitsunobu etherification of hydroxyl substituted heterocycles (or keto-tautomers) such as outlined in Scheme 48. Treatment of the known 6-bromo-pyridin-2-one (Wibaut, J.P.; Waayman, P.W.; Vandijk, J. *Rec. Trav. Chim. Pays-Bas*, 1940, 59, 202) with an alcohol containing an ArI (or ArIII) under Mitsunobu's conditions provides the corresponding bromo-substituted pyridyl ether. (for typical procedures see Mitsunobu, O., *Synthesis*, 1981, 1).

Scheme 48

The heterocyclic bromide, so formed, can be further functionalized in a number of ways. For example, coupling with a vinyl stannane can be effected under palladium (0) catalysis to provide systems with alkenyl linkers (Scheme 49).

Scheme 49

The choice of catalyst and reaction temperature for this transformation depends on the substrate employed but is most commonly tetrakis(triphenylphosphine) palladium, bis(triphenylphosphine)palladium chloride, 1,1'-bis(diphenylphosphino)ferrocene / bis-dibenzylideneacetone palladium or 1,2 bis-(diphenylphosphino)ethane / bis(acetonitrile)dichloropalladium at a temperature between 50 and 150 °C. Suitable solvents include DMF, DMPU, HMPA, DMSO, toluene, and DME. (for examples see Farina, V. Krishnamurthy, V.; Scott, W.J. *Organic Reactions*, 1997, 50, 1). Reduction of the olefin using, for example, Wilkinson's catalyst in a solvent such as toluene, THF or an alcohol at a temperature between about 20 and 80 °C provides the corresponding alkane linked system.

In certain heterocyclic systems in which a bromide or chloride is situated ortho or para to a ring nitrogen, the halogen can be readily displaced by an alcohol (in the presence of base such as sodium hydride in a solvent such as Toluene, DMSO, THF, DMPU or HMPA) at or above room temperature (For examples see Kelly, T.R. et al. *J. Amer. Chem. Soc.*, 1994, 116, 3657 and Newcome, G.R. et al. *J. Org. Chem.*, 1977, 42, 1500). For example, alcoholysis of a 2,4-dichloro-pyrimidine (Scheme 50) using a controlled stoichiometric amount of an alcohol reagent containing ArI (or ArIII) provides the alkoxy substituted-bromo-pyrimidine. Subsequent reaction of this product (generally above room temperature) with a further equivalent of another alcohol containing ArIII (or ArI) provides the unsymmetrically dialkoxy-substituted heterocycle. Since the 4-position of the dichloro-pyrimidine is generally displaced first, the order in which the alkoxy substituents are introduced will dictate their orientation in the product.

Scheme 50

Similar procedures using 2,6-dibromo-pyridine or 2,6-dibromo-pyridazine provides the corresponding dialkoxy-substituted pyridines and pyridazines.

A simple alkoxy group positioned ortho to a nitrogen in these heterocyclic systems can be hydrolyzed to the corresponding hydroxy substituent using aqueous hydrochloric acid at a temperature normally between room temperature and reflux. (Scheme 51).

Scheme 51

For example (Scheme 51), treatment of the 2-methoxy-6-alkyl-substituted pyridine derivative with hydrochloric acid provides the 6-alkyl substituted pyridin-2-one. This intermediate, in turn, can be further derivatized to the corresponding 2-alkoxy or 2-alkenyl substituted systems as detailed elsewhere in the description of this invention.

A methyl, methylene or methine group positioned ortho to a ring nitrogen in these heterocyclic systems can be deprotonated with a base such as an alkyl lithium or LDA in a solvent such as THF, ether or HMPA, generally at low temperature (below 0°C) and the resulting anion reacted with electrophiles such as aldehydes, epoxides, alkyl halides or α,β -unsaturated carbonyl compounds to provide a variety of functionalized heterocycles.

Scheme 52

For example (Scheme 52) the 2-alkoxy-4-methyl-pyrimidine is treated, sequentially, with LDA and an aldehyde at -78°C to give the hydroxy substituted adduct. Subsequent dehydration of this intermediate with martin sulfurane in a solvent such as dichloromethane at ambient temperature followed by hydrogenation of the resulting olefin provides the 4-ArI-containing-alkyl-2-alkoxy-pyrimidine. Similar procedures applied to 2-chloro-6-methyl-pyrazine (Karmas, G.; Spoerri, P.E.; *J. Amer. Chem. Soc.*, 1952, 74, 1580) leads to the corresponding pyrazine.

In another embodiment of this invention, A can be an amide thus generating compounds of the formulas shown in Figure 9.

Figure 9

The preparation of an illustrative example within this series is shown in scheme 53. A hydroxy aldehyde can be reacted with a bromoalkyl-ester to provide an aldehyde-ester intermediate. Reductive amination of the aldehyde followed by acylation can provide the amide.

Scheme 53

Furthermore, compounds of the invention may be easily synthesized by solid phase methods, as illustrated in Schemes 54 and 55, using inputs (XII) - (XVII) listed in Table I.

An additional exemplification of the amide linker is shown in Scheme 56. Reaction of an activated carboxylic acid derivative such as, but not limited to, an acid chloride or anhydride with an amine of general formula (15) and a suitable base such as triethylamine provides the amide (16). More explicit exemplification is shown in Scheme 57. Carboxylic acid (17) is activated with oxalyl chloride to provide the acid chloride and then 2-amino-6-methylbenzoic acid (18), is added to provide the amide (19). Alternatively, 2-aminomethyl-6-methylbenzoic acid (20) can be used to provide the amide (21).

Scheme 56

Scheme 57

The preparation of 2-aminomethyl-6-methylbenzoic acid, (20), can be accomplished using the chemistry shown in Scheme 31 (X = Me, R' = H).

Compounds useful according to the invention may also be prepared by the application or adaptation of known methods, by which is meant methods used heretofore or described in the literature, for example those described by R. C. Larock in *Comprehensive Organic Transformations*, VCH publishers, 1989.

In the reactions described hereinafter, it may be necessary to protect reactive functional groups, for example hydroxy, amino, imino, thio or carboxy groups, where these are desired in the final product, to avoid their unwanted participation in the reactions. Conventional protecting groups may be used in accordance with standard practice, for examples see T.W. Green and P.G.M. Wuts in "Protective Groups in Organic Chemistry" John Wiley and Sons, 1991; J. F. W. McOmie in "Protective Groups in Organic Chemistry" Plenum Press, 1973.

According to a further feature of the present invention, compounds useful according to the invention may be prepared by interconversion of other compounds of the invention.

A compound of the invention including a group containing one or more nitrogen ring atoms, preferably imine (=N-), may be converted to the corresponding compound wherein one or more nitrogen ring atom of the group is oxidized to an N-oxide, preferably by reacting with a peracid, for example peracetic acid in acetic acid or m-chloroperoxybenzoic acid in an inert solvent such as dichloromethane, at a temperature from about room temperature to reflux, preferably at elevated temperature.

The products of this invention may be obtained as racemic mixtures of their dextro and levorotatory isomers since at least one asymmetric carbon atom may be present. When two asymmetric carbon atoms are present, the product may exist as a mixtures of diastereomers based on syn and anti configurations. These diastereomers may be separated by fractional crystallization. Each diastereomer may then be resolved into dextro and levorotatory optical isomers by conventional methods.

It will also be apparent to those skilled in the art that certain compounds of Formula I may exhibit geometrical isomerism. Geometrical isomers include the cis and trans forms of compounds of the invention having an alkenyl moiety. The present invention comprises the individual geometrical isomers and stereoisomers and mixtures thereof.

Such isomers can be separated from their mixtures, by the application or adaptation of known methods, for example chromatographic techniques and recrystallization techniques, or they are separately prepared from the appropriate isomers of their intermediates, for example by the application or adaptation of methods described herein.

Resolution may best be carried out in the intermediate stage where it is convenient to combine the racemic compound with an optically active compound by salt formation, ester formation, or amide formation to form two diastereomeric products. If an acid is added to an optically active base, then two diastereomeric salts are produced which possess different properties and different solubilities and can be separated by fractional crystallization. When the salts have been completely separated by repeated crystallization, the base is split off by acid hydrolysis and enantiomerically purified acids are obtained.

Compounds useful according to the invention are useful in the form of the free base or acid or in the form of a pharmaceutically acceptable salt thereof. All forms are within the scope of the invention.

Where a compound useful according to the invention is substituted with a basic moiety, acid addition salts are formed and are simply a more convenient form for use; in practice, use of the salt form inherently amounts to use of the free base form. The acids which can be used to prepare the acid addition salts include preferably those which produce, when combined with the free base, pharmaceutically acceptable salts, that is, salts whose anions are non-toxic to the patient in pharmaceutical doses of the salts, so that the beneficial pharmaceutical effects of these compounds in the free base are not vitiated by side effects ascribable to the anions. Although pharmaceutically acceptable salts of said basic compounds are preferred, all acid addition salts are useful as sources of the free base form even if the particular salt, per se, is desired only as an intermediate product as, for example, when the salt is formed only for purposes of purification, and identification, or when it is used as an intermediate in preparing a pharmaceutically acceptable salt by ion exchange procedures. Pharmaceutically acceptable salts useful within the scope of the invention are those derived from the following acids: mineral acids such as hydrochloric acid, trifluoroacetic acid, sulfuric acid, phosphoric acid and sulfamic acid; and organic acids such as acetic acid, citric acid, lactic acid, tartaric acid, malonic acid, methanesulfonic acid, ethanesulfonic acid, benzenesulfonic acid, p-toluenesulfonic acid, cyclohexylsulfamic acid, quinic acid, and the like. The corresponding acid addition salts comprise the following: hydrohalides, e.g. hydrochloride and hydrobromide, trifluoroacetate, sulfate, phosphate, nitrate, sulfamate, acetate, citrate, lactate, tartarate, malonate, oxalate, salicylate, propionate, succinate, fumarate, maleate, methylene-bis- β -hydroxynaphthoates, gentisates, mesylates, isothionates, di-p-toluoyletartrates, methanesulfonates, ethanesulfonates, benzenesulfonates, p-toluenesulfonates, cyclohexylsulfamate and quinate, respectively.

The acid addition salts of the compounds useful according to the invention are prepared by reaction of the free base with the appropriate acid, by the application or adaptation of known methods. For example, the acid addition salts of the compounds of this invention are prepared either by dissolving the free base in aqueous or aqueous-alcohol solution or other suitable solvents containing the appropriate

acid and isolating the salt by evaporating the solution, or by reacting the free base and acid in an organic solvent, in which case the salt separates directly or can be obtained by concentration of the solution.

The compounds useful according to the invention may be regenerated from the acid addition salts by the application or adaptation of known methods. For example, parent compounds useful according to the invention can be regenerated from their acid addition salts by treatment with an alkali, e.g., aqueous sodium bicarbonate solution or aqueous ammonia solution.

Where the compound useful according to the invention is substituted with an acidic moiety, base addition salts may be formed and are simply a more convenient form for use; in practice, use of the salt form inherently amounts to use of the free acid form. The bases which can be used to prepare the base addition salts include preferably those which produce, when combined with the free acid, pharmaceutically acceptable salts, that is, salts whose cations are non-toxic to the animal organism in pharmaceutical doses of the salts, so that the beneficial pharmaceutical effects on the activity of the compounds of the present invention in the free acid are not vitiated by side effects ascribable to the cations. Pharmaceutically acceptable salts useful according to the invention, include for example alkali and alkaline earth metal salts, including those derived from the following bases: sodium hydride, sodium hydroxide, potassium hydroxide, calcium hydroxide, aluminum hydroxide, lithium hydroxide, magnesium hydroxide, zinc hydroxide, ammonia, ethylenediamine, N-methyl-glucamine, lysine, arginine, ornithine, choline, N,N'-dibenzylethylenediamine, chlorprocaine, diethanolamine, procaine, diethylamine, N-benzylphenethylamine, piperazine, tris(hydroxymethyl)aminomethane, tetramethylammonium hydroxide, and the like.

Metal salts of compounds useful according to the present invention may be obtained by contacting a hydride, hydroxide, carbonate or similar reactive compound of the chosen metal in an aqueous or organic solvent with the free acid form of the compound. The aqueous solvent employed may be water or it may be a mixture of water with an organic solvent, preferably an alcohol such as methanol or ethanol, a ketone such as acetone, an aliphatic ether such as tetrahydrofuran, or an ester such as ethyl acetate. Such reactions are normally conducted at ambient temperature but they may, if desired, be conducted with heating.

Amine salts of compounds useful according to the present invention may be obtained by contacting an amine in an aqueous or organic solvent with the free acid form of the compound. Suitable aqueous solvents include water and mixtures of water with alcohols such as methanol or ethanol, ethers such as tetrahydrofuran, nitriles such as acetonitrile, or ketones such as acetone. Amino acid salts may be similarly prepared.

The base addition salts of the compounds useful according to the invention can be regenerated from the salts by the application or adaptation of known methods. For example, parent compounds useful according to the invention can be regenerated from their base addition salts by treatment with an acid; e.g. hydrochloric acid.

Salt forms useful according to the invention also include compounds having a quarternarized nitrogen. The quarternarized salts are formed by methods such as by alkylation of sp^3 or sp^2 hybridized nitrogen in the compounds.

As will be self-evident to those skilled in the art, some of the compounds useful according to the invention do not form stable salts. However, acid addition salts are most likely to be formed by compounds useful according to the invention having a nitrogen-containing heteroaryl group and/or wherein the compounds contain an amino group as a substituent. Preferable acid addition salts of the compounds useful according to the invention are those wherein there is not an acid labile group.

As well as being useful in themselves as active compounds, the salts of the compounds useful according to the invention are useful for the purposes of purification of the compounds, for example by exploitation of the solubility differences between the salts and the parent compounds, side products and/or starting materials by techniques well known to those skilled in the art.

Various substituents on the compounds useful according to the invention, e.g., as defined in R , R_1 and R_2 can be present in the starting compounds, added to any one of the intermediates or added after formation of the final products by known methods of substitution or conversion reactions. If the substituents themselves are reactive, then the substituents can themselves be protected according to the techniques known in the art. A variety of protecting groups known in the art may be employed. Examples of many of these possible groups may be found in "Protective Groups in Organic Synthesis" by T. W. Green, John Wiley and Sons, 1981. For example, nitro groups can be added to the aromatic ring by nitration, and the nitro group then converted to other groups, such as amino, by reduction, and halo, by diazotization of the amino group and replacement of the diazo group. Acyl groups can be substituted onto the aryl groups by Friedel-Crafts acylation. The acyl groups then can be transformed to the corresponding alkyl groups by various methods, including the Wolff-Kishner reduction and Clemmenson reduction. Amino groups can be alkylated to form mono and dialkylamino groups; and mercapto and hydroxy groups can be alkylated to form corresponding ethers. Primary alcohols can be oxidized by oxidizing agents known in the art to form carboxylic acids or aldehydes, and secondary alcohols can be oxidized to

form ketones. Thus, substitution or alteration reactions can be employed to provide a variety of substituents throughout the molecule of the starting material, intermediates, or the final product.

The starting materials, intermediates and some compounds of the invention are prepared by the application or adaptation of known methods, for example methods as described in US Patent No.s 4,920,132; 4,920,131; and 5,059,610; publications Huang, Fu Chih et al , J. Med. Chem. (1991), 34(5), 1704-7; and Huang, Fu Chih et al , J. Med. Chem. (1990), 33(4), 1194-200; and the Reference Examples or their obvious chemical equivalents.

The present invention is further exemplified but not limited by the following examples, which illustrate the preparation of the compounds according to the invention.

Example 1

Methyl 2,6-dimethyl-benzoate

- 5 To a cooled (0 °C) solution of 2,6-dimethylbenzoic acid (20.2g, 134 mmol) in dichloromethane (200 mL) is added DMF (1 mL) followed by oxalyl chloride (14 mL, 162 mmol). On completion of addition, the cold bath is removed and stirring continued for 3h. The resulting solution is concentrated under vacuum and the residue added slowly to a cooled (0 °C) solution comprising methanol (200 mL) and triethylamine (40 mL). On completion of addition, the
10 reaction mixture is stirred for 30 min. then poured into hydrochloric acid solution (400 mL, 2N) which is then extracted with ether. The ether extract is washed with hydrochloric acid solution (1N), sodium bicarbonate solution and brine then dried over MgSO₄ and concentrated to give the title compound which is used without further purification. MS (EI) 164 (M)⁺.

15 Example 2

Methyl 2-bromomethyl-6-methyl-benzoate

- To a solution of methyl 2,6-dimethyl-benzoate (22.0 g, 134 mmol, example 1) in CCl₄ (250 mL) is added *N*-bromo-succinimide (19g, 107 mmol) followed by benzoyl peroxide (1.0 g, 4.0
20 mmol). The resulting solution is warmed to reflux and stirred at this temperature for 20 min. The reaction mixture is then allowed to cool before being diluted with ether (200 mL), filtered and concentrated. The residue is purified by flash chromatography (silica, 4% acetone in hexanes) to give the title compound. This product (approx. 85% purity, remainder is methyl 2,6dimethyl benzoate) is used without further purification. MS (EI) 242, 244 (M⁺, Br pattern).

Example 3

3-(Quinolin-2-ylmethoxy)-phenol

- 2-Chloromethylquinoline hydrochloride (25.0 g, 117 mmol) and resorcinol monobenzoate (37.5
30 g, 175 mmol) are suspended in dimethylsulfoxide (180 mL) and are mixed with the aid of an overhead stirrer. The mixture is cooled to 15 °C and a 50% solution of sodium hydroxide (25 mL) is added slowly over 10 min with a slight exotherm. The reaction is allowed to come to room temperature and is allowed to stir overnight. The reaction is then heated to 95 °C and a

50% solution of sodium hydroxide (25 mL) is added over 10 min. After 20 min. hot water (300 mL) is added to the reaction and stirred 15 min. The reaction is hot filtered and the filtrate is cooled to provide a brick red solid which is dried *in vacuo* to provide the sodium salt pentahydrate. A portion of the salt (15.6 g, 43.0 mmol) is neutralized by heating in water (30 mL) with 1N HCl (43 mL) followed by cooling to provide a brown solid. The solid is dissolved in dichloromethane (550 mL) and methanol (14 mL), dried over magnesium sulfate, filtered and concentrated *in vacuo* to yield the title compound as a tan solid. A portion is recrystallized from ethyl acetate to provide an analytically pure sample; m.p. 152-153 °C, MS (ESI) 252 (M+H)⁺.

The reaction is poured into ethyl acetate (500 mL) and washed with water (4 x 120 mL) and brine (100 mL). The solution is dried over magnesium sulfate, filtered and concentrated *in vacuo* to provide a residue which is purified by column chromatography (silica, 10 to 20% ethyl acetate in hexane) to provide the title compound. Example 7

2-Methyl-6-[3-(quinolin-2-ylmethoxy)-phenoxymethyl]-benzoic acid

A solution of methyl 2-methyl-6-[3-(quinolin-2-ylmethoxy)-phenoxymethyl]-benzoate (1.6 g, 3.8 mmol, example 4) in ethanol (25 mL) is heated with a 10N sodium hydroxide solution (4.0 mL, 40 mmol) at 70 °C for 14 h. The reaction is cooled, neutralized with a 2N HCl solution (20 mL) and concentrated to remove the ethanol. Ethyl acetate is added and washed with water. The aqueous layer is saturated with sodium chloride and back extracted with ethyl acetate. The organic layers are combined, dried over magnesium sulfate, filtered and concentrated to yield a crude solid. The solid is purified by column chromatography (silica, 5 to 10% methanol in dichloromethane) to provide the title compound. An analytically pure sample is prepared by recrystallization from methanol: m.p. 167-168 °C, ¹H NMR (300 MHz, CDCl₃) δ.15 (d, 2H), 7.80 (d, 1H), 7.71 (t, 1H), 7.61-7.51 (m, 2H), 7.26-7.10 (m, 3H), 7.00 (t, 1H), 6.66 (s, 1H), 6.52 (d, 1H), 6.46 (d, 1H), 5.26 (s, 2H), 5.15 (s, 2H), 2.44 (s, 3H); MS (ESI) 400 (M+H)⁺.

An alternate set of conditions that can be used for the hydrolysis of a benzoate ester is to heat a 0.1 M solution of the ester in THF/methanol (1:1) with 10 equivalents of a sodium hydroxide solution (10 N) at 60 °C for 3 h or until starting material disappears, as monitored by TLC analysis.

Synthesis of a compound of Formula (VI)

A compound of Formula (VI) is prepared in a multi-step synthesis illustrated in the below scheme. The key starting material is quinaldine. In the first stage it is chlorinated to form 2-chloromethylquinoline which, without isolation, is reacted with hydroquinone to form the intermediate 4-(quinolin-2-yl-methoxy)phenol (VIII). This intermediate is then treated with α,α' -dichloro-*o*-xylene to form 2-[4-(quinolin-2-yl-methoxy)phenoxy]methyl]benzyl chloride, which is converted *in situ* to 2-[4-(quinolin-2-yl-methoxy)phenoxy]methyl]phenylacetonitrile (IX), the penultimate precursor to (VI).

(IX) is converted to (VI) crude, in a reaction with sodium azide and ammonium chloride which transforms the nitrile group into the tetrazole ring. The purification of the final product is accomplished by recrystallization of the crude material from methanol to afford pure (VI).

15 Solid Phase Synthesis of a Compound of Formula:

1. Acid Loading:

5 A 1L round bottom flask is charged with 4-(bromomethyl)benzoic acid (32.26 g, 150.0 mmole) and dichloromethane (650 mL). A stir bar is carefully added and the reaction flask is immersed in an ice-water bath. After approximately 15 minutes, oxalyl chloride (15.7 mL, 180 moles) is added. After approximately 15 minutes, N,N-dimethylformamide (500 mL, cat.) is added. The reaction began to bubble. After stirring for 1.5 hours, the ice-water bath is removed. After stirring for 3 hours at ambient
 10 temperature, the effervescence has ceased. At the end of this period, the stirbar is removed from the reaction mixture and the reaction solvent is removed *in vacuo*. After the solvent has been removed, more dichloromethane is added to the reaction flask and this too is removed *in vacuo*.

A three neck 3L round bottom flask is charged with dry N,N-dimethylformamide (1.3 L), N,N-diisopropylethylamine (39.19 mL, 225 mmoles), 4-N,N-dimethylaminopyridine (3.67 g, 30 mmole) and
 15 MicroKANS [1456, 15 mg of Wang resin (1.7 mmole/g loading) per MicroKANs, 25.5 micromoles/microKAN, 37.1 mmoles]. The flask is fitted with an overhead stirring apparatus. After stirring for approximately 15 minutes, a solution of the acid chloride as prepared above in dry N,N-dimethylformamide (200 mL) is transferred into the reaction flask. After 14 hours, the reaction solvent is removed. DMF (1.5 L) is added to the reaction flask. The flask was allowed to stir for approximately 15
 20 minutes and the solvent is drained. The MicroKANs are washed, stirred for 20 minutes and drained in the following sequence repeatedly: DMF (2 x 6 L), THF (3 x 6 L), dichloromethane (3 x 6 L) and ether (2 x 6 L). After the final washing the MicroKANs are dried by blowing a stream of nitrogen through the flask with intermittent agitation. After sufficient drying, the MicroKANs are sorted for the next reaction.

25 2. Phenol Displacement:

188

A three neck 3L round bottom flask is charged with 3-chloro-4-hydroxybenzaldehyde (21.9 g, 140 mmoles) and DMF (1.5 L). The reaction flask is fitted with an overhead stirrer and immersed in an ice-water bath. After approximately 15 minutes sodium hydride (60 % dispersion in oil, 6.48 g, 180 mmoles) is carefully added. After approximately 30 minutes, the ice-water bath is removed and the reaction allowed to stir at ambient temperature for 1 hour. At the end of this time, the MicroKANs [1274, 25.5 micromoles/microKAN, 32.5 mmoles] and potassium iodide (1.0 g) are added to the reaction mixture. The reaction flask is immersed into an oil bath which is heated to 60°C. After 14 hours, the reaction flask is removed from the oilbath and allowed to cool to ambient temperature. The reaction solvent is removed. DMF (1.2 L) is added to the reaction flask. The flask is allowed to stir for approximately 15 minutes and the solvent is drained. DMF : water (1:1, 1.2 L) is added to the reaction flask. The flask is allowed to stir for approximately 15 minutes and the solvent is drained. This sequence is repeated at least three times or until the effluent from the washing is clear, the reaction flasks are washed repeatedly in the following sequence: THF (2 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) and ether (1 x 4 L). After the final washing the MicroKANs are dried by blowing a stream of nitrogen through the flask with intermittent agitation. After sufficient drying, the MicroKANs are sorted for the next reaction.

3. Reductive Amination:

A three neck 2 L round bottom flask is charged with the MicroKANs [784, 25.5 micromoles/microKAN, 20.0 mmoles], trimethylorthoformate (850 mL) and 2-(2-aminoethyl)pyridine

20.79 g, 170 mmol). The reaction flask is fitted with an overhead stirrer. After 2 hours, sodium cyanoborohydride (21.37 g, 340 mmol) is added. After approximately 10 minutes, acetic acid (17.0 mL, 297 mmol) is added. After stirring for an additional hour, the reaction flask is drained. Methanol (800 mL) is added to the flask. After stirring for approximately 10 minutes, the flask is drained. The reaction flask is washed repeatedly in the following sequence: DMF (3 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) and ether (1 x 4 L). After the final washing the microKANs are dried by blowing a stream of nitrogen through the flask with intermittent agitation. After sufficient drying, the MicroKANs are sorted for the next reaction.

4. Acylation:

A three neck 2 L round bottom flask is charged with the MicroKANs [784, 15 mg of resin (1.7 mmole/g loading) per MicroKAN, 25.5 micromoles/microKAN, 20.0 mmoles], and dichloromethane (800 mL). The reaction flask is fitted with an overhead stirrer. N,N-diisopropylethylamine (20.9 mL, 120 mmoles) and 4-N,N-dimethylaminopyridine (195 mg, 1.6 mmoles) are added. After approximately 15 minutes, the cyclopentanecarbonyl chloride (10.6 g, 80.0 mmoles) is added. The reaction was allowed to stir for 61 hours, the reaction flask is drained. Dichloromethane (800 mL) is added to the reaction flask. After stirring for approximately 10 minutes, the flask is drained. This is repeated. The MicroKANs from all of the acylation reactions are randomly combined into two separate large flasks and washed repeatedly in the following sequence: dichloromethane (1 x 4 L), THF (2 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) then methanol (1 x 4 L), dichloromethane (1 x 4 L) and ether (1 x 4 L).

5. Cleavage:

The MicroKAN is sorted into individual wells of IRORI AccuCleave 96 cleavage station. The well is charged with dichloromethane (600 mL) and then with a TFA: dichloromethane mixture (1:1, 600 mL). After agitating for approximately forty minutes, the reaction well is drained into 2 mL microtube in an 96-well format. The reaction well is again charged with dichloromethane (600 mL). After manual agitation, this too is drained into the 2 mL microtube in an 96-well format. The cleavage cocktail is

removed *in vacuo* using a Savant Speedvac. The concentrated products from the cleavage mother plates are reconstituted with THF and transferred into two daughter plates utilizing a Packard MultiProbe liquid handler. The daughter plates are concentrated *in vacuo* utilizing a GenieVac.

Using a combination of the above Examples, various compounds may be made within the scope of this invention.

Compounds according to the invention exhibit marked pharmacological activities according to tests described in the literature which tests results are believed to correlate to pharmacological activity in humans and other mammals. The following pharmacological test results are typical characteristics of compounds of the present invention.

The compounds of the present invention have potent activity as PPAR ligand receptor binders and possess anti-diabetic, anti-lipidemic, anti-hypertensive, and anti-arteriosclerotic activity and are also anticipated to be effective in the treatment of diabetes, obesity and other related diseases.

hPPAR α Binding Assay

The activity of the compounds of the invention as PPAR α modulators may be examined in several relevant in vitro and in vivo preclinical assays, for example benchmarking with a known PPAR α modulator, for example, [3 H]-GW2331(2-(4-[2-(3-[2,4-Difluorophenyl]-1-heptylureido)-ethyl]phenoxy)-2-methylbutyric acid). (S. Kliewer, et al. Proc. Natl. Acad. Sci. USA 94 (1997).

Human peroxime proliferator-activated receptor a ligand binding domain(hPPAR α -LBD):

A binding assay for PPAR α could be carried out by the following procedure: cDNAs encoding the putative ligand binding domain of human PPAR α (amino acids 167-468) (Sher, T., Yi, H.-F., McBride, O. W. & Gonzalez, F. J. (1993) *Biochemistry* 32, 5598-5604) are amplified by PCR (Polymerase

Chain Reaction) and inserted in frame into the BamHI site of pGEX-2T plasmid (Pharmacia). The soluble fraction of GST-hPPAR α fusion proteins or glutathione S-transferase (GST) alone are overexpressed in *E. coli* BL21(DE3)pLysS cells and purified from bacteria extracts as described in (S. Kliewer, et al. Proc. Natl. Acad. Sci. USA 94 (1997), 4318-4323).

5

Gel-Filtration Assays: 30 ml of 90 nM GST-hPPAR α -LBD is mixed with 20 ml of 50 nM ^3H -GW2331 with or without 5 ml of 10 mM test compounds in the binding buffer containing 10 mM Tris, 50 mM KCl, 0.05% Tween 20 and 10 mM DTT. The reaction mixtures are incubated in 96-well plates for 2h at room temperature. 50 ml of the reaction mixtures are then loaded on a 96-well gel filtration block (following manufacture instructions)(EdgeBioSystems). The block placed on top of a clean 96-well plate is centrifuged at 1,500 rpm for 2 min. The block is discarded. 100 ml of Scintillation fluid is added to each well of the 96-well plate. After overnight equilibration, the plate is counted in the Microbeta counter (Wallac.).

10

15 Homogenous Scintillation Proximity Binding Assay. For the Scarchard analysis, glutathione coated SPA beads (1.5 mg/ml)(Amersham) are mixed with GST-hPPAR α -LBD (10 mg/ml) in the binding buffer. The resulting slurry is incubated at room temperature with agitation for 15 min. 20 ml of the slurry is then added in 30 ml of binding buffer containing various amount ^3H -GW2331(10~500 nM). Nonspecific binding is determined in the present of 100 mM of GW2331. For the competition binding assay, 20 ml of
20 the slurry is then added in 30 ml of the binding buffer containing 75 nM of ^3H -GW2331 and 0.03~20 mM of the test compounds. For the control experiments, the glutathione coated SPA beads (1.5 mg/ml) are coated with GST proteins (10 mg/ml). 20 ml of the slurry are mixed with 30 ml of 75 nM of ^3H -GW2331 with or without 10 mM of GW2331. The above experiments are all performed in a 96-well plates. The sealed plates with the reaction mixtures are allowed to equilibrate for 2 h and counted in the Microbeta
25 counter (Wallac.).

hPPAR γ Binding Assay

The activity of the compounds of the invention as PPAR γ modulators may be examined in several relevant in vitro and in vivo preclinical assays, for example benchmarking with a known PPAR γ
30 modulator, for example, [^3H]-BRL 49853 (Lehman L.J. et al, J. Biol. Chem. 270, 12953-12956; Lehman L.J. et al, J. Biol. Chem. 272, 3406-3410 (1997), and Nichols, J. S.; et al Analytical Biochemistry 257, 112-119(1998)).

Human peroxime proliferator-activated receptor α ligand binding domain(hPPAR γ -LBD).

A binding assay for PPAR γ could be carried out by the following procedure: cDNAs encoding the putative ligand binding domain of human PPAR γ (amino acids 176-477) (Green, M.E. et al. Gene expression 281-299(1995)) are amplified by PCR (polymerase chain reaction) and inserted in frame into the BamHI site of pGEX-2T plasmid (Pharmacia). The soluble fraction of GST-hPPAR γ fusion proteins or glutathione S-transferase (GST) alone are overexpressed in *E. coli* BL21(DE3)pLysS cells and purified from bacteria extracts.

Binding Assay: The fusion proteins, GST-PPAR γ -LBD in PBS (5 mg/100ml/well) are incubated in the glutathione coated 96 well plates for 4 hours. Unbound proteins are then discarded and the plates are washed two times with the wash buffer (10 mM Tris, 50 mM KCl and 0.05% Tween-20). 100 ml of reaction mixtures containing 60 nM of 3 H-BRL-49853 and 10 mM of the testing compounds (10 ml of 0.1mM compounds from each well of the child plates) in the binding buffer (10mM Tris, 50mM KCl and 10mM DTT) are then added and incubated at room temperature for 2.5h. The reaction mixtures are discarded and the plates are washed two times with the wash buffer. 100ml of scintillation fluid is added to each well and plates are counted on β -counter.

hPPAR δ Binding Assay

The activity of the compounds of the invention as PPAR δ modulators may be examined in several relevant in vitro and in vivo preclinical assays (See references WO 97/28149; Brown P. et al Chemistry & Biology, 4, 909-18, (1997)), for example benchmarking with a known PPAR δ modulator, for example [3 H $_2$] GW2433 or [3 H $_2$] Compound X

Compound X

The hPPAR δ binding assay comprises the steps of:

(a) preparing multiple test samples by incubating separate aliquots of the receptor hPPAR δ with a test compound in TEGM containing 5-10% COS-1 cell cytoplasmic lysate and 2.5 nM labeled ([3 H]Compound X, 17 Ci/mmol) for a minimum of 12 hours, and preferably for about 16 hours, at 4°C, wherein the concentration of the test compound in each test sample is different, and preparing a control sample by incubating a further separate aliquot of the receptor hPPAR δ under the same conditions but without the test compound; then

- (b) removing unbound ligand by adding dextran/gelatin-coated charcoal to each sample while maintaining the samples at 4°C and allowing at least 10 minutes to pass, then
- (c) subjecting each of the test samples and control sample from step (b) to centrifugation at 4°C until the charcoal is pelleted; then
- 5 (d) counting a portion of the supernatant fraction of each of the test samples and the control sample from step (c) in a liquid scintillation counter and analyzing the results to determine the IC₅₀ of the test compound.

10 In the hPPAR δ binding assay, preferably at least four test samples of varying concentrations of a single test compound are prepared in order to determine the IC₅₀.

The compounds useful according to the invention can be administered to a patient in a variety of forms adapted to the chosen route of administration, i.e., orally, or parenterally. Parenteral administration in this respect includes administration by the following routes: intravenous, intramuscular, subcutaneous, 15 intraocular, intrasynovial, transepthally including transdermal, ophthalmic, sublingual and buccal; topically including ophthalmic, dermal, ocular, rectal and nasal inhalation via insufflation and aerosol and rectal systemic.

The active compound may be orally administered, for example, with an inert diluent or with an 20 assimilable edible carrier, or it may be enclosed in hard or soft shell gelatin capsules, or it may be compressed into tablets, or it may be incorporated directly with the food of the diet. For oral therapeutic administration, the active compound may be incorporated with excipient and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups, wafers, and the like. Such compositions and preparations should contain at least 0.1% of active compound. The percentage of the 25 compositions and preparations may, of course, be varied and may conveniently be from about 2% to about 6% of the weight of the unit. The amount of active compound in such therapeutically useful compositions is such that a suitable dosage will be obtained. Preferred compositions or preparations according to the present invention are prepared so that an oral dosage unit form contains between about 50 and 300 mg of active compound.

30 The tablets, troches, pills, capsules and the like may also contain the following: A binder such as gum tragacanth, acacia, corn starch or gelatin; excipients such as dicalcium phosphate; a disintegrating agent such as corn starch, potato starch, alginic acid and the like; a lubricant such as magnesium stearate; and a sweetening agent such as sucrose, lactose or saccharin may be added or a flavoring agent such as 35 peppermint, oil of wintergreen, or cherry flavoring. When the dosage unit form is a capsule, it may contain, in addition to materials of the above type, a liquid carrier. Various other materials may be present

as coatings or to otherwise modify the physical form of the dosage unit. For instance, tablets, pills, or capsules may be coated with shellac, sugar or both. A syrup or elixir may contain the active compound, sucrose as a sweetening agent, methyl and propylparabens a preservatives, a dye and flavoring such as cherry or orange flavor. Of course, any material used in preparing any dosage unit form should be
5 pharmaceutically pure and substantially non-toxic in the amounts employed. In addition, the active compound may be incorporated into sustained-release preparations and formulations.

The active compound may also be administered parenterally or intraperitoneally. Solutions of the active compound as a free base or pharmacologically acceptable salt can be prepared in water suitably
10 mixed with a surfactant such as hydroxypropyl-cellulose. Dispersion can also be prepared in glycerol, liquid polyethylene glycols, and mixtures thereof and in oils. Under ordinary conditions of storage and use, these preparations contain a preservative to prevent the growth of microorganisms.

The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or
15 dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases, the form must be sterile and must be fluid to the extent that easy syringability exists. It may be stable under the conditions of manufacture and storage and must be preserved against the contaminating action of microorganisms such as bacteria and fungi. The carrier can be a solvent or dispersion medium containing, for example, water, ethanol, polyol (for example, glycerol, propylene
20 glycol, and liquid polyethylene glycol, and the like), suitable mixtures thereof, and vegetable oils. The proper fluidity can be maintained, for example, by the use of a coating such as lecithin, by the maintenance of the required particle size in the case of dispersion and by the use of surfactants. The prevention of the action of microorganisms can be brought about by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, thimerosal, and the like. In many cases,
25 it will be preferable to include isotonic agents, for example, sugars or sodium chloride. Prolonged absorption of the injectable compositions of agents delaying absorption, for example, aluminum monostearate and gelatin.

Sterile injectable solutions are prepared by incorporating the active compound in the required
30 amount in the appropriate solvent with various of the other ingredients enumerated above, as required, followed by filtered sterilization. Generally, dispersions are prepared by incorporating the various sterilized active ingredient into a sterile vehicle which contains the basic dispersion medium and the required other ingredients from those enumerated above. In the case of sterile powders for the preparation of sterile injectable solutions, the preferred methods of preparation are vacuum drying and the freeze
35 drying technique which yield a powder of the active ingredient plus any additional desired ingredient from previously sterile-filtered solution thereof.

The therapeutic compounds useful according to this invention may be administered to a patient alone or in combination with pharmaceutically acceptable carriers, as noted above, the proportion of which is determined by the solubility and chemical nature of the compound, chosen route of administration and standard pharmaceutical practice.

The physician will determine the dosage of the present therapeutic agents which will be most suitable for prophylaxis or treatment and it will vary with the form of administration and the particular compound chosen, and also, it will vary with the particular patient under treatment. He will generally wish to initiate treatment with small dosages by small increments until the optimum effect under the circumstances is reached. The therapeutic dosage will generally be from 0.1 to 100 mM/day or from about 0.1mg to about 50 mg/kg of body weight per day, or 10mg to about 50 mg/kg of body weight per day, or more preferably 30mg to about 50 mg/kg of body weight per day, and higher, although it may be administered in several different dosage units. Higher dosages are required for oral administration.

The compounds useful according to the invention may be administered as frequently as necessary in order to obtain the desired therapeutic effect. Some patients may respond rapidly to a higher or lower dose and may find much weaker maintenance doses adequate. For other patients, it may be necessary to have long-term treatments at the rate of 1 to 4 doses per day, in accordance with the physiological requirements of each particular patient. Generally, the active product may be administered orally 1 to 4 times per day. It goes without saying that, for other patients, it will be necessary to prescribe not more than one or two doses per day.

One skilled in the art will readily appreciate that the present invention is well adapted to carry out the objects of the invention and obtain the ends and advantages mentioned, as well as those inherent therein. The compounds, compositions and methods described herein are presented as representative of the preferred embodiments, or intended to be exemplary and not intended as limitations on the scope of the present invention.
