(57) **ABSTRACT**

A plate of substantially uniform thickness is formed from an electrically conductive material. The plate has a top surface defined to support a part to be measured. The plate has a bottom surface defined to be connected to a radiofrequency (RF) transmission rod such that RF power can be transmitted through the RF transmission rod to the plate. The plate is defined to have a number of holes cut vertically through the plate at a corresponding number of locations that underlie embedded conductive material items in the part to be measured when the part is positioned on the top surface of the plate.

ELECTRODE FOR USE IN MEASURING DIELECTRIC PROPERTIES OF PARTS

CLAIM OF PRIORITY

This application is a divisional application under 35 U.S.C. 121 of U.S. patent application Ser. No. 12/240,329, filed on Sep. 29, 2008, which claims priority under 35 U.S.C. 119(e) to each of the following U.S. Provisional Patent Applications: 1) U.S. Provisional Patent Application No. 60/978,082, filed Oct. 5, 2007; 2) U.S. Provisional Patent Application No. 60/978,085, filed Oct. 5, 2007; 3) U.S. Provisional Patent Application No. 60/978,087, filed Oct. 5, 2007; and 4) U.S. Provisional Patent Application No. 60/978,089, filed Oct. 5, 2007. Each of the above-identified provisional patent applications is incorporated herein by reference.

CROSS REFERENCE TO RELATED APPLICATIONS

This application is related to 1) U.S. patent application Ser. No. 12/240,291, entitled "Apparatus for Measuring Dielectric Properties of Parts," filed on Sep. 29, 2008, issued as U.S. Pat. No. 8,269,510, on Sep. 18, 2012, and 2) U.S. patent application Ser. No. 12/240,375, entitled "Methods for Measuring Dielectric Properties of Parts," filed on Sep. 29, 2008, issued as U.S. Pat. No. 7,911,213, on Mar. 22, 2011, and 3) U.S. patent application Ser. No. 12/240,414, entitled "Methods for Characterizing Dielectric Properties of Parts," filed on Sep. 29, 2008, issued as U.S. Pat. No. 7,777,500, on Aug. 17, 2010. The disclosure of each of the above-identified related applications is incorporated herein by reference.

BACKGROUND OF THE INVENTION

Semiconductor wafer ("wafer") fabrication often includes exposing a wafer to a plasma to allow the reactive constituents of the plasma to modify the surface of the wafer. Such plasma processing of a wafer can be performed in a plasma processing system in which a plasma is generated by transmitting radiofrequency (RF) power through a processing gas. The wafer characteristics resulting from the plasma processing operation are dependent on the process conditions, including the plasma conditions. Because the plasma conditions are closely tied to the RF power transmission through the system, it is beneficial to have an accurate knowledge of how the RF power is transmitted through the plasma processing system. Knowledge of how the RF power is transmitted through the plasma processing system is also necessary to match one plasma processing system to another, such that the plasma intensity in each plasma processing system is substantially the same for a given power input. To this end, it is necessary to have an accurate knowledge of the dielectric properties of the plasma processing system parts through which the RF power is transmitted.

Dielectric properties of interest can include the dielectric constant, and loss tangent of a particular part. One conventional technique for measuring dielectric properties of a part includes manufacturing the part with an attached sample coupon that can be removed and subjected to dielectric property measurement. In this conventional technique the sample coupon can be of a small size relative to the actual part. Because the material composition in some parts, e.g., ceramic parts, is subject to spatial variation, there is a potential that the relatively small sample coupon may not provide a true representation of the material composition of the part as a whole. In this situation, the dielectric properties measured for the

sample coupon may not be accurate with regard to the actual part as a whole. Also, the dielectric properties of a sample coupon for a given part, as reported by the manufacturer of the given part, may be measured at a frequency that is different than the frequency of the RF power to which the given part will be exposed during use. Because dielectric properties are frequency dependent, the reported dielectric properties of a given part may not be applicable to the frequency of the RF power to which the given part is to be exposed, thereby requiring an extrapolation from the reported dielectric properties of the given part and an assumption of the corresponding extrapolation error.

In view of the foregoing, a solution is needed to enable measurement of the dielectric properties of actual full-sized parts to be used in plasma processing systems, and at the operating frequency of the RF power to which the parts will be exposed during plasma processing operations.

SUMMARY OF THE INVENTION

In one embodiment, an electrode for use in measuring dielectric properties of a part is disclosed. The electrode includes a plate formed from an electrically conductive material. The plate has a top surface defined to support a part to be measured. The plate also has a bottom surface defined to be connected to a radiofrequency (RF) transmission rod, such that RF power can be transmitted through the RF transmission rod to the plate. The plate is also defined to have a number of holes cut vertically through the plate at a corresponding number of locations that underlie embedded conductive material items in the part to be measured, when the part is positioned on the top surface of the plate.

In another embodiment, a method is disclosed for defining an electrode for use in measuring dielectric properties of a part. The method includes an operation for forming a plate of electrically conductive material to have an outer perimeter defined to substantially match an outer perimeter of a part to be measured. The part to be measured is a dielectric part including a number of embedded conductive material items. The method also includes an operation for identifying a location of each embedded conductive material item within the part. The method further includes an operation for projecting the identified location of each embedded conductive material item within the part upon the plate, with the outer perimeters of the part and the plate substantially aligned. Additionally, an operation is performed to remove a portion of the plate at each embedded conductive material item location as projected upon the plate.

In another embodiment, an electrode for use in measuring dielectric properties of a ring-shaped part is disclosed. The ring-shaped part includes a number of embedded conductive material items circumferentially disposed within the ring-shaped part. The electrode includes a plate formed from an electrically conductive material. The plate includes a solid center region and a number of spokes extending radially outward from the solid center region by an extent sufficient to enable support of the ring-shaped part on a top surface of each of the number of spokes. The number of spokes are defined and spaced about the solid center region such that the number of spokes support the ring-shaped part at locations between adjacent embedded conductive material items within the ring-shaped part.

Other aspects and advantages of the invention will become more apparent from the following detailed description, taken

in conjunction with the accompanying drawings, illustrating by way of example the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 is an illustration showing an apparatus for measuring dielectric properties of parts, in accordance with one embodiment of the present invention;

FIG. 2A is an illustration showing the chamber configured to enable vertical movement of the upper electrode, in accordance with one embodiment of the present invention;

FIG. 2B is an illustration showing a top view of the chamber depicting the relative placement of the three vertical positioning devices, in accordance with one embodiment of the present invention;

FIG. 2C is an illustration showing the upper electrode lowered so as to rest upon a top surface of a part, in accordance with one embodiment of the present invention;

FIG. 3A is an illustration showing a hinged version of the chamber, in accordance with one embodiment of the present invention;

FIG. 3B is an illustration showing the hinged version of the chamber in an open state, in accordance with one embodiment of the present invention;

FIG. 4A is an illustration showing a closed version of the chamber having an access door, in accordance with another embodiment of the present invention;

FIG. 4B is an illustration showing the closed version of the chamber with the access door removed, in accordance with another embodiment of the present invention;

FIG. 5A is an illustration showing an exemplary hot electrode configured to accommodate a ring-shaped part including embedded conductive material, in accordance with one embodiment of the present invention;

FIG. 5B is a flowchart of a method for configuring the hot electrode for use with a particular part, in accordance with one embodiment of the present invention;

FIG. 6 is an illustration depicting capacitances between the hot electrode/RF rod and the grounded upper electrode/chamber when the exemplary part is disposed between the upper electrode and the hot electrode, in accordance with one embodiment of the present invention;

FIG. 7 is an illustration depicting capacitances between the hot electrode/RF rod and the grounded upper electrode/chamber when there is no part disposed between the upper electrode and the hot electrode, in accordance with one embodiment of the present invention;

FIG. 8 is an illustration showing an exemplary curve of part capacitance (C_{part}) versus part dielectric constant (k_{part});

FIG. 9 is an illustration showing a flowchart of a method for calibrating the relationship between the total capacitance ($C_{total_without_part}$) and the separation distance between the upper electrode and the hot electrode, in accordance with one embodiment of the present invention;

FIG. 10 is an illustration showing a method for determining a capacitance of a part (C_{part}), in accordance with one embodiment of the present invention;

FIG. 11 is an illustration showing a flowchart of a method for determining the dielectric constant of the part (k_{part}), in accordance with one embodiment of the present invention;

FIG. 12 is an illustration showing a flowchart of a method for determining a loss tangent of a part, in accordance with one embodiment of the present invention;

FIG. 13 is an illustration showing an equivalent electrical circuit representation of the apparatus with the part disposed

between the upper electrode and hot electrode, as depicted in FIG. 1, in accordance with one embodiment of the present invention; and

FIG. 14 is an illustration showing an exemplary fitting of Equation 5 based on gain versus frequency data measured and recorded in a frequency sweep of operation.

DETAILED DESCRIPTION

In the following description, numerous specific details are set forth in order to provide a thorough understanding of the present invention. It will be apparent, however, to one skilled in the art that the present invention may be practiced without some or all of these specific details. In other instances, well known process operations have not been described in detail in order not to unnecessarily obscure the present invention.

FIG. 1 is an illustration showing an apparatus 100 for measuring dielectric properties of parts, in accordance with one embodiment of the present invention. In one embodiment, the parts to have their dielectric properties measured are dielectric components of a plasma processing system. In this embodiment, the parts may correspond to components that will be exposed to RF power during the plasma processing operation, and thereby potentially influence the RF power transmission through the plasma processing system during the plasma processing operation.

The apparatus 100 includes a chamber 101 defined by a conductive material and electrically connected to a ground potential 141. In one embodiment, the chamber 101 is defined by a conductive material of substantially low electrical resistance such as copper. It should be understood, however, that in other embodiments, the chamber 101 can be defined by other low electrical resistance conductive materials, such as aluminum among others. The apparatus 100 also includes an electrical components housing 103 defined by a conductive material and electrically connected to a ground potential 139. In one embodiment, the electrical components housing 103 is positioned below the chamber 101 and is electrically connected to the chamber 101 so as to share a common ground potential with the chamber 101.

The chamber 101 includes an interior cavity 102 defined to house an upper electrode 105 and a hot electrode 109. The upper electrode 105 is disposed in an upper region of the interior cavity 102 over the hot electrode 109. In one embodiment, the upper electrode 105 is defined as a plate of conductive material of low electrical resistance, such as copper. In this embodiment, the upper electrode 105 plate is disposed horizontally in a substantially level orientation within the interior cavity 102. The thickness of the upper electrode 105 can vary so long as a rigidity of the upper electrode 105 is sufficient to maintain a planarity of the upper electrode 105 across the interior cavity 102, and the weight of the upper electrode 105 is not so great as to deform other components that will bear the weight of the upper electrode 105. In the embodiment where the upper electrode 105 is defined as a copper plate, an exemplary upper electrode 105 thickness can vary from about 0.125 inch to about 1 inch. In one particular embodiment, the upper electrode 105 is defined as a copper plate of 0.25 inch thickness.

Also, a size of the upper electrode 105 is defined such that the upper electrode 105 substantially covers a majority of the interior cavity 102 horizontal cross-section area when the upper electrode 105 is positioned in a substantially level orientation within the interior cavity 102. In one embodiment, the upper electrode 105 is sized such that the periphery of the upper electrode 105 extends to within 1 inch to 3 inches of the chamber 101 when the upper electrode is centered within the

interior cavity **102** in a substantially horizontal, i.e., level, orientation. Also, in one embodiment, the upper electrode **105** is sized to extend beyond a periphery of a part **111** to be measured by at least twice the vertical thickness of the part **111**.

The upper electrode **105** is electrically connected to the chamber **101** by way of peripheral connections **107**, thereby placing the upper electrode **105** at the same ground potential as the chamber **101**. The peripheral connections **107** are defined to provide a substantially uniform grounding of the upper electrode **105** to the chamber **101** around the periphery of the upper electrode **105**. In one embodiment, the peripheral connections **107** are defined by flexible sheets of copper foil. In this embodiment, a solid sheet of flexible copper foil is defined to have a length substantially equivalent to the length of a side of the upper electrode **105**. In this embodiment, the flexible copper foil is electrically connected to the upper electrode along the entire length of the edge of the upper electrode **105**. Also in this embodiment, the flexible copper foil is electrically connected to the chamber **101** wall proximate to the entire length of the edge of the upper electrode **105**. Thus, with an upper electrode **105** defined as a plate having four edges, four flexible copper foil strips are used to respectively connect the four edges of the upper electrode **105** to the chamber **101** wall.

The upper electrode **105** is also defined to be moved vertically within the chamber **101**, as indicated by arrow **104**. FIG. 2A is an illustration showing the chamber **101** configured to enable vertical movement of the upper electrode **105**, in accordance with one embodiment of the present invention. In the embodiment of FIG. 2A, three vertical positioning devices **207A-207C** are provided at the top of the chamber **101**. Each of the vertical position devices **207A-207C** is defined to enable vertical position control of a respective lifting member **203A-203C**. Each lifting member **203A-203C** is defined to have a lifting rod with a disk attached to its lower end. Three guide structures **201A-201C** are connected to the top surface of the upper electrode **105**. Each guide structure **201A-201C** is defined to receive a respective lifting member **203A-203C**. More specifically, each guide structure **201A-201C** is defined to receive the disk of the lifting member **203A-203C** within an internal vertical guide region. Each guide structure **201A-201C** is also defined to include a top having an access sized to allow movement of the lifting rod therethrough without allowing movement of the disk of the lifting rod therethrough. Thus, each lifting member **203A-203C** is defined to be moved in a vertical direction **205A-205C** by its respective vertical positioning device **207A-207C**.

The disk portion of each lifting member **203A-203C** within each guide structure **201A-201C** is defined to engage the underside of the top of the guide structure **201A-201C** so as to enable vertical positioning of the upper electrode **105** by way of the lifting members **203A-203C** and guide structures **201A-201C**. Additionally, in one embodiment, each of the vertical positioning devices **207A-207C** includes a vertical position indicator that provides a measure of the vertical position of the lifting member **203A-203C**, which in turn provides a measure of the vertical position of the upper electrode **105** in the vicinity of the lifting member **203A-203C**. In one embodiment, the vertical position indicators of the vertical positioning devices **207A-207C** provide a vertical position measurement to the nearest one-thousandth of an inch.

In addition to providing vertical elevation control of the upper electrode **105**, the three vertical positioning devices **207A-207C** are positioned on the top of the chamber **101** to also enable horizontal leveling control of the upper electrode

105 in all directions. FIG. 2B is an illustration showing a top view of the chamber **101** depicting the relative placement of the three vertical positioning devices **207A-207C**, in accordance with one embodiment of the present invention. An outline **206** of the periphery of the upper electrode **105** is shown in FIG. 2B. Based on the placement of the three vertical positioning devices **207A-207C**, it should be appreciated that through independent control of the vertical positioning devices **207A-207C** the horizontal leveling of the upper electrode **105** can be controlled.

As discussed in more detail below, during operation of the chamber **101** the upper electrode **105** is lowered so as to rest upon a top surface of a part **111** to be measured. FIG. 2C is an illustration showing the upper electrode **105** lowered so as to rest upon a top surface of a part **111**, in accordance with one embodiment of the present invention. To ensure that the upper electrode **105** is allowed to completely rest on top of the part **111**, the guide structures **201A-201C** are defined to allow the lifting members **203A-203C** to be lowered such that their disk members disengage from the top of the guide structures **201A-201C**, thereby allowing the upper electrode **105** to rest freely on top of the part **111**, as indicated by the gaps **213A-213C** between the lifting member **203A-203C** disks and the top of the guide structures **201A-201C**. It should be appreciated that in this embodiment the contact force between the upper electrode **105** and the part **111** is defined by the weight of the upper electrode **105**. Also, it should be understood that the horizontal area size of the grounded upper electrode **105** can remain the same regardless of the size of the part **111** to be measured within the chamber **101**.

While the vertical positioning devices **207A-207C** and corresponding lifting members **203A-203B** and guide structures **201A-201C** represent one embodiment for controlling the vertical elevation and horizontal level of the upper electrode **105** within the chamber **101**, it should be appreciated that variations of this embodiment can also be used for controlling the vertical elevation and horizontal level of the upper electrode **105**. For example, other embodiments can include additional mechanics, such as gears and motors, not explicitly identified herein. Also, other embodiments can include electronic devices, such as motors and sensors, not explicitly identified herein. Also, other embodiments can include data acquisition and control interfaces to enable computer control and monitoring of the various vertical positioning devices **207A-207C**, and thereby of the upper electrode **105**. Furthermore, it should be appreciated that the peripheral connections **107** are defined to allow the upper electrode **105** to remain electrically connected to the chamber **101** wall as the vertical elevation and horizontal level of the upper electrode **105** is adjusted. In the embodiment where the peripheral connections **107** are defined by sheets of flexible copper foil, the sheets of flexible copper foil are of sufficient size accommodate a full range of vertical movement of the upper electrode **105**, within the interior cavity **102** of the chamber **101**.

With reference back to FIG. 1, the hot electrode **109** represents a lower electrode within the chamber **101** with respect to the upper electrode **105**. The hot electrode **109** is defined to support the part **111** to be measured. The hot electrode **109** is electrically connected to an RF rod **113** through which RF power is conducted to the hot electrode **109** from the RF components within the electrical components housing **103**. Both the hot electrode **109** and the RF rod **113** are defined to be electrically isolated from the chamber **101**. The hot electrode **109** is positioned within the interior cavity **102** to be far enough away from the grounded chamber **101** walls so as to avoid obscuring a capacitance of the part **111** by the capacitance between the hot electrode **109** and the chamber **101**. In

one embodiment, the hot electrode **109** is sized as small as possible, but not smaller than the part size **111**, so as to minimize the capacitance between the hot electrode **109** and the grounded chamber **101**. Both the hot electrode **109** and the RF rod **113** are defined by an electrically conductive material of low electrical resistance, such as copper. The hot electrode **109** is defined to have a vertical thickness sufficient to enable manufacture of the hot electrode **109** without distortion, and to enable support of the combined weight of the part **111** and upper electrode **105** without distortion. In various embodiments, the hot electrode **109** can be defined to have a vertical thickness within a range extending from about 0.125 inch to about 2 inches. In one embodiment, the hot electrode **109** is defined to have a vertical thickness, when disposed within the chamber **101**, of about 0.75 inch.

Also, in one embodiment, the hot electrode **109** can be configured to include alignment features to facilitate proper alignment of the part **111** on the hot electrode **109**. In one embodiment, proper alignment of the part **111** on the hot electrode **109** is achieved when the part **111** is substantially centered on the top surface of the hot electrode **109**. In one embodiment, such as that shown in FIG. 2A, the hot electrode **109** is supported by an electrically insulated support plate **209**. In one embodiment, a number of alignment pins are provided in the insulated support plate **209** to enable accurate positioning and alignment of the part **111** on the hot electrode **109**. In various embodiments, the support plate **209** can be defined by essentially any type of electrical insulating material. In one embodiment, the support plate **209** is formed from a plastic material. Also, in one embodiment, such as that shown in FIG. 2A, the support plate **209** is further separated from the grounded chamber **101** by a electrically insulated stand **211**. In one embodiment the stand **211** is defined by the same material as the support plate **209**. In one embodiment, the support plate **209** is defined as a solid plastic disk having an opening in the center through which the RF rod **113** can pass to connect with the hot electrode **109**. Also, in this embodiment, the stand **211** is defined as a solid plastic right circular cylinder.

It should be appreciated that the hot electrode **109** is defined to be an interchangeable component of the apparatus **100**. Because the sizes of the various parts **111** to be measured will vary, it follows that the size of the hot electrode **109** will also vary. While the size of the hot electrode **109** does not have to exactly match every part **111** to be measured, it is likely that the various parts **111** to be measured will vary sufficiently in size so as to necessitate use of different sized hot electrodes **109**. Also, the particular configuration and characteristics of a part **111** to be measured may require use of a hot electrode **109** that is customized in size and shape. For example, if the part **111** includes one or more embedded parts of conductive material, the hot electrode **109** may need to be defined to support the part **111** while also avoiding positioning of the hot electrode **109** beneath the embedded conductive material within the part **111**. For instance, if the hot electrode **109** is positioned beneath the embedded conductive material, the embedded conductive material may provide for increased electrical communication between the hot electrode **109** and the upper electrode **105** at the location of the embedded conductive material, which would not be representative of the part **111** as a whole. Because the part **111** to be measured can be of essentially any size and configuration and can include any arrangement of embedded conductive materials, it should be appreciated that the hot electrode **109** can be defined to have essentially any size and configuration as necessary to accommodate the particular characteristics of the part **111** to be measured.

FIG. 5A is an illustration showing an exemplary hot electrode **109A** configured to accommodate a ring-shaped part **111A** including embedded conductive material, in accordance with one embodiment of the present invention. The embedded conductive material is positioned within the ring-shaped part **111A** at locations **501**. The hot electrode **109A** is defined to have a spoked-shape to allow the hot electrode **109A** to support the part **111A** while simultaneously avoiding placement of the part's embedded conductive material above the hot electrode **109A**. Specifically, the hot electrode **109A** is defined to be absent at locations **503** below the embedded conductive material locations **501**. It should be appreciated that in the same manner that the exemplary hot electrode **109A** is specifically configured for the part **111A**, other hot electrodes **109** can be specifically configured for other parts **111**.

FIG. 5B is a flowchart of a method for configuring the hot electrode **109** for use with a particular part **111**, in accordance with one embodiment of the present invention. The method includes an operation **510** for defining a plate of electrically conductive material, such as copper, to have an outer perimeter defined to substantially match an outer perimeter of the part **111**. In one embodiment, the part is a dielectric part including a number of embedded conductive materials. The method also includes an operation **512** for identifying the location of each embedded conductive material within the part **111**. In an operation **514**, the identified location of each embedded conductive material within the part is projected upon the plate with the outer perimeters of the part and the plate substantially aligned. Then, in an operation **516**, portions of the plate defining the hot electrode are removed at the locations corresponding to the embedded conductive material locations projected thereon. The size of each removed portion of the hot electrode plate is sufficient to ensure that the hot electrode **109** is not located below the embedded conductive material within the part **111** when the outer perimeters of the part **111** and hot electrode plate **109** are aligned. To the extent possible, operation **516** is performed to ensure that the hot electrode **109** remains a single, contiguous component.

With reference back to FIG. 1, the electrical components housing **103** is defined to house a number of electrical components for conveying the RF power to the RF rod **113** and enabling control of the resonance frequency of the apparatus **100**. As a grounded structure, the electrical components housing **103** is also defined to provide RF shielding. The electrical components housing **103** includes a connector **129** to which an RF signal generator **125** is connected via a conductor **133**. An RF voltmeter **127** is also connected to the connector **129** via a conductor **135**. The electrical components housing **103** also includes a connector **131** to which the RF voltmeter **127** is connected via a conductor **137**. In one embodiment, the connectors **129** and **131** are defined as BNC connectors.

The electrical components housing **103** also includes a conductor plate **115** of low electrical resistance material, such as copper, through which the RF power is to be transmitted. The connector **129** is connected through a capacitor **117** to the conductor plate **115** to enable the RF power transmitted from the RF signal generator **125** to be conveyed to the conductor plate **115**. The conductor plate **115** is also electrically connected to the connector **131** to enable electrical connection of the RF voltmeter **127** to the conductor plate **115**. The electrical components housing **103** further includes an inductor **119**, a capacitor **121**, and a variable capacitor **123**, each of which is electrically connected between the conductor plate **115** and the grounded chamber **101** bottom. In one embodiment, multiple capacitors can be electrically connected between the

conductor plate **115** and the grounded chamber **101** bottom to provide an equivalent of the single capacitor **121**, as depicted in FIG. 1.

In one embodiment, the capacitor **121** (or its multiple capacitor equivalent) is used to support the conductor plate **115** in a position so as to be electrically separated from the grounded electrical components housing **103**, thereby avoiding a short between the conductor plate **115** and the electrical components housing **103**. In another embodiment, electrically insulating support brackets can be used to support the conductor plate **115** off of the electrical components housing **103**. Additionally, the RF rod **113** is electrically connected to the conductor plate **115** to enable transmission of the RF power from the conductor plate **115** to the hot electrode **109**. The variable capacitor **123** can be adjusted to set the resonance frequency of the apparatus **100**. For example the variable capacitor **123** can be set so that the resonance frequency of the apparatus **100** is substantially equivalent to the operational frequency of the RF power to be used in the plasma process to which the part **111** is to be exposed.

The chamber **101** can be configured in a number of ways with regard to providing access for placement of the part **111** on the hot electrode **109** and removal of the part **111** from the hot electrode **109**. FIG. 3A is an illustration showing a hinged version of the chamber **101**, in accordance with one embodiment of the present invention. In the hinged version, the chamber **101** is defined by an upper chamber portion **101A** and a lower chamber portion **101B**. A hinge **303** is provided to enable opening of the upper chamber portion **101A** with respect to the lower chamber portion **101B**. FIG. 3B is an illustration showing the hinged version of the chamber in an open state, in accordance with one embodiment of the present invention. In the open state, the part **111** can be easily placed on the hot electrode **109** and retrieved from the hot electrode **109**. Also, in the open state, the hot electrode **109** can be accessed for replacement. Also, the hinged version of the chamber utilizes an RF gasket **301** between the upper chamber portion **101A** and the lower chamber portion **101B**. The RF gasket **301** is defined to provide a uniform electrical connection between the upper chamber portion **101A** and the lower chamber portion **101B** around the entire periphery of the chamber, so as to ensure that a uniform ground potential exists around the entire periphery of the chamber at the interface between the upper chamber portion **101A** and the lower chamber portion **101B**. The RF gasket **301** is defined to provide an amount of flexibility to accommodate variations in the interface between the upper and lower chamber portions **101A/101B**, thereby ensuring full electrical contact between the upper and lower chamber portions **101A/101B** around the periphery of the chamber.

FIG. 4A is an illustration showing a closed version of the chamber **101C** having an access door **401**, in accordance with another embodiment of the present invention. The access door **401** is defined to be removed from the chamber **101C** to enable access to the interior of the chamber **101C** for placement and retrieval of the of the part **111** and for changing the hot electrode **109**. FIG. 4B is an illustration showing a closed version of the chamber **101C** with the access door **401** removed, in accordance with another embodiment of the present invention. In various embodiments, the access door **401** can be secured to the chamber **101C** in a number of ways, such as through fasteners or clamps. It should be appreciated, however, that regardless of the technique used to secure the access door **401** to the chamber **101C**, the access door **401** should be secured so as to establish a substantially uniform ground potential between the interface of the access door **401** and the chamber **101C**.

In one embodiment, the apparatus **100** is defined to operate at natural atmospheric and room temperature conditions. However, in another embodiment, the apparatus **100** is defined to provide a controlled environment within the chamber **101** interior cavity **102** during operation of the apparatus **100**. The controlled environment can include a controlled atmosphere and temperature within the chamber **101** interior cavity **102**. In one embodiment, the atmospheric conditions (such as gas content, moisture level, pressure, etc.) and temperature within the chamber **101** interior cavity **102** is controlled to substantially emulate atmospheric conditions and temperature to which the part **111** will be exposed during operation of the plasma processing system within which the part **111** will be deployed. It should be appreciated that in this embodiment, a number of gas input and output ports can be disposed within the chamber **101** so as to enable supply and removal of various gas mixtures to/from the chamber **101** interior cavity **102**. Also, it should be appreciated that in this embodiment a number of support systems can be plumbed to the number of gas input and output ports. These support systems can include gas supply systems, pressurization systems, vacuum systems, gas heating and/or cooling systems, etc., as necessary to establish the appropriate controlled atmospheric conditions and temperature with the chamber **101** interior cavity **102**.

Determining Capacitance and Dielectric Constant of Part

FIG. 6 is an illustration depicting capacitances between the hot electrode **109**/RF rod **113** and the grounded upper electrode **105**/chamber **101** when the exemplary part **111** is disposed between the upper electrode **105** and the hot electrode **109**, in accordance with one embodiment of the present invention. As shown in FIG. 6, the capacitance between the upper electrode **105** and the hot electrode **109** is defined by the capacitance (C_{part}) of the part **111** and the capacitance (C_{st1}) between the hot electrode **109** and the portions of the upper electrode **105** outside of the contact region between the part **111** and the upper electrode **105**. Also, a capacitance (C_{st2}) exists between the RF rod **113** and the chamber **101** bottom. It should be understood that the capacitances (C_{st1}) and (C_{st2}) are functions of the separation distance ($Y1$) between the upper electrode **105** and the hot electrode **109**. Also, the capacitance (C_{part}) is a function of the dielectric constant of the part (k_{part}). Because the capacitances (C_{part}), (C_{st1}), and (C_{st2}) represent parallel capacitances, the total capacitance ($C_{total_with_part}$) between the hot electrode **109**/RF rod **113** and the grounded upper electrode **105**/chamber **101** is defined as a sum of the capacitances (C_{part}), (C_{st1}), and (C_{st2}), as shown in Equation 1.

$$(C_{total_with_part})=(C_{part}\{k_{part}\})+(C_{st1}\{Y1\})+(C_{st2}\{Y1\}) \quad \text{Equation 1}$$

FIG. 7 is an illustration depicting capacitances between the hot electrode **109**/RF rod **113** and the grounded upper electrode **105**/chamber **101** when there is no part disposed between the upper electrode **105** and the hot electrode **109**, in accordance with one embodiment of the present invention. As shown in FIG. 7, the capacitance between the upper electrode **105** and the hot electrode **109** is defined by the capacitance (C_{st3}) of the atmosphere within the chamber **101** interior cavity. Also, as in FIG. 6, the capacitance (C_{st2}) exists between the RF rod **113** and the chamber **101** bottom. It should be understood that the capacitances (C_{st3}) and (C_{st2}) in FIG. 7 are functions of the separation distance ($Y2$) between the upper electrode **105** and the hot electrode **109**. Because the capacitances (C_{st3}) and (C_{st2}) represent parallel capacitances, the total capacitance ($C_{total_without_part}$) between the hot electrode **109**/RF rod **113** and the grounded upper elec-

11

trode **105**/chamber **101** is defined as a sum of the capacitances (C_{st3}) and (C_{st2}), as shown in Equation 2.

$$(C_{total_without_part})=(C_{st3}\{Y2\})+(C_{st2}\{Y2\}) \quad \text{Equation 2}$$

In the configuration of FIG. 6, with the upper electrode **105** resting on top of the part **111** positioned in a substantially centered manner on top of the hot electrode **109**, the variable capacitor **123** can be adjusted to achieve a particular resonance frequency of the apparatus **100**. Because dielectric properties of the part **111** are frequency dependent, in one embodiment, the resonance frequency of the apparatus **100** is set to the operating frequency of the RF power that is to be used in the plasma process to which the part **111** will be exposed when deployed in the plasma processing system. Thus, the apparatus **100** according to the configuration of FIG. 6 with the part **111** present in the chamber **101** will have a particular resonance frequency.

With reference to the configuration of FIG. 7 with the part absent, it should be understood that the resonance frequency of the RF power will change as the distance (Y2) between the upper electrode **105** and the hot electrode **109** is changed. In the configuration of FIG. 7, the variable capacitor **123** and RF signal generator **125** are maintained at their respective settings as applied in the configuration of FIG. 6 with the part **111** present in the chamber **101**. Under these conditions, the upper electrode **105** in the configuration of FIG. 7 (without the part present) can be lowered toward the hot electrode **109** until the resonance frequency of the apparatus **100** according to the configuration of FIG. 7 substantially matches the resonance frequency of the apparatus **100** according to the configuration of FIG. 6 (with the part **111** present). When the upper electrode **105** is lowered to cause the substantial matching between the resonance frequencies of the configurations of FIGS. 6 and 7, the total capacitance ($C_{total_with_part}$) of configuration 6 will be substantially equivalent to the total capacitance ($C_{total_without_part}$) of configuration 7. In this situation, Equations 1 and 2 can be set equal to each other as shown in Equation 3.

$$(C_{part}\{k_{part}\})+(C_{st1}\{Y1\})+(C_{st2}\{Y1\})=(C_{total_without_part}) \quad \text{Equation 3}$$

The right side of Equation 3, ($C_{total_without_part}$) at the resonance frequency, can be measured directly by connecting a capacitance meter between the RF rod **113** and the upper electrode **105**, with the RF rod **113** disconnected from the conductor plate **115** and the upper electrode **105** maintained at the vertical elevation corresponding to the resonance frequency when the part is absent. Also, the capacitance ($C_{st1}\{Y1\}$) between the hot electrode **109** and the portions of the upper electrode **105** outside of the contact region between the part **111** and the upper electrode **105** in the configuration of FIG. 6 can be simulated. Also, the capacitance ($C_{st2}\{Y1\}$) between the RF rod **113** and the chamber **101** bottom in the configuration of FIG. 6 can be simulated. In one embodiment, the capacitances ($C_{st1}\{Y1\}$) and ($C_{st2}\{Y1\}$) are simulated through a finite element model analysis of the configuration of FIG. 6. With the capacitances ($C_{total_without_part}$), ($C_{st1}\{Y1\}$), and ($C_{st2}\{Y1\}$) known, the capacitance of the part ($C_{part}\{k_{part}\}$) can be calculated, as shown in Equation 4.

$$(C_{part}\{k_{part}\})=(C_{total_without_part})-(C_{st1}\{Y1\})-(C_{st2}\{Y1\}) \quad \text{Equation 4}$$

Once the capacitance of the part ($C_{part}\{k_{part}\}$) is calculated, the dielectric constant of the part (k_{part}) can be determined based on the calculated capacitance of the part ($C_{part}\{k_{part}\}$). In one embodiment, the capacitance of the part (C_{part}), as disposed between the upper electrode **105** and the hot electrode **109**, is simulated for a number of different

12

assumed part dielectric constant (k_{part}) values, so as to enable generation of a curve of part capacitance (C_{part}) versus part dielectric constant (k_{part}). FIG. 8 is an illustration showing an exemplary curve **801** of part capacitance (C_{part}) versus part dielectric constant (k_{part}). Because the part capacitance (C_{part}) is a linear function of the part dielectric constant (k_{part}), the curve of part capacitance (C_{part}) versus part dielectric constant (k_{part}) will generally be a well-fit line, as illustrated by the curve **801** in FIG. 8. In one embodiment, the simulation of the part capacitance (C_{part}) for the number of different assumed part dielectric constant (k_{part}) values is performed through a finite element model analysis of the part **111** disposed between the upper electrode **105** and hot electrode **109**. However, in another embodiment, if the geometric configurations of the part **111**, the upper electrode **105**, and the hot electrode **109** are sufficiently simple, the part capacitance (C_{part}) for the number of different assumed part dielectric constant (k_{part}) values may be determined analytically. Using the generated curve of part capacitance (C_{part}) versus part dielectric constant (k_{part}), and the actual capacitance of the part (C_{part}) as calculated using Equation 4, the actual dielectric constant of the part (k_{part}) can be determined.

As discussed above, to determine the total capacitance ($C_{total_without_part}$) at the resonance frequency, it is necessary to know the relationship between the total capacitance ($C_{total_without_part}$) and the separation distance between the upper electrode **105** and the hot electrode **109**. FIG. 9 is an illustration showing a flowchart of a method for calibrating the relationship between the total capacitance ($C_{total_without_part}$) and the separation distance between the upper electrode **105** and the hot electrode **109**, in accordance with one embodiment of the present invention. In an operation **901**, the RF rod **113** is disconnected from the conductor plate **115** and from any other electrical connection within the electrical components housing **103**. In an operation **903**, a capacitance meter is connected between the RF rod **113** and the upper electrode **105**. In an operation **905**, using the capacitance meter, the capacitance between the RF rod **113** and grounded upper electrode **105** is measured and recorded for a number of vertical separation distances between the upper electrode **105** and the hot electrode **109**. In one embodiment, operation **905** is performed by positioning the upper electrode **105** at a number of vertical separation distances from the hot electrode **109** extending from 0.05 inch to 1.2 inch, in increments of 0.05 inch. In the operation **905**, at each vertical separation distance between the upper electrode **105** and the hot electrode **109**, the upper electrode **105** is maintained in a substantially level horizontal orientation so as to be substantially parallel to the hot electrode **109**. The method further includes an operation **907** for generating a capacitance calibration curve for the chamber **101** by plotting the capacitance versus vertical separation distance between the upper electrode **105** and the hot electrode **109** using the data measured in operation **905**. The capacitance calibration curve for the chamber **101** can be repeatedly used to determine the total capacitance ($C_{total_without_part}$) at the resonance frequency once the vertical elevation of the upper electrode **105** at the resonance frequency (without the part present) is determined.

FIG. 10 is an illustration showing a method for determining a capacitance of a part (C_{part}), in accordance with one embodiment of the present invention. The method of FIG. 10 is a representation of the procedure as described above. The method includes an operation **1001** for placing a part to be measured on the hot electrode **109** within the chamber **101**, and for lowering the upper electrode **105** to rest on top of the part. In one embodiment, alignment pins are used to enable precise positioning and alignment of the part on the hot elec-

13

trode 109. In an operation 1003, the RF signal generator 125 is operated to transmit RF power to the hot electrode 109. In an operation 1005, the variable capacitor 123 is adjusted to achieve the resonance frequency, i.e., peak frequency, of the RF power. In one embodiment, the resonance frequency corresponds to a peak gain between the connector 129 and the connector 131 of the electrical components housing 103. In this embodiment, the RF voltmeter 127 can be monitored to identify when the variable capacitor 123 setting corresponds to the peak gain between the connectors 129 and 131, and thereby corresponds to the resonance frequency of the apparatus 100.

The method further includes an operation 1007 for turning off the RF signal generator 125 and removing the part from the chamber. In an operation 1009, the RF signal generator 125 is operated to transmit RF power to the hot electrode 109 with the part absent. In the operation 1009, the variable capacitor 123 is maintained at the setting determined in operation 1005. In an operation 1011, the upper electrode 105 is lowered until the resonance frequency determined in operation 1005 is achieved with the part absent. In one embodiment, the RF voltmeter 127 can be monitored to identify when the upper electrode 105 elevation causes the peak gain between the connectors 129 and 131 to be reached, and thereby causes the resonance frequency to be achieved. The vertical separation distance between the upper electrode 105 and the hot electrode 109 at the resonance frequency with the part absent is called the resonant upper electrode 105 separation.

Once the resonant upper electrode 105 separation is determined, an operation 1013 is performed to determine the total capacitance ($C_{total_without_part}$) at the resonance frequency based on the resonant upper electrode 105 separation. In one embodiment, the capacitance calibration curve for the chamber 101, as generated in the method of FIG. 9, is used to determine the total capacitance ($C_{total_without_part}$) at the resonance frequency in operation 1013.

The method further includes an operation 1015 for simulating both the capacitance ($C_{sr1}\{Y1\}$) between the hot electrode 109 and the portions of the upper electrode 105 outside of the contact region between the part 111 and the upper electrode 105, and the capacitance ($C_{sr2}\{Y1\}$) between the RF rod 113 and the chamber 101 bottom. As previously mentioned, in one embodiment, the capacitances ($C_{sr1}\{Y1\}$) and ($C_{sr2}\{Y1\}$) can be simulated through a finite element model analysis. An operation 1017 is then performed to calculate the capacitance of the part (C_{part}) as being equal to the total capacitance ($C_{total_without_part}$) determined in operation 1013 minus the capacitances ($C_{sr1}\{Y1\}$) and ($C_{sr2}\{Y1\}$) simulated in the operation 1015.

FIG. 11 is an illustration showing a flowchart of a method for determining the dielectric constant of the part (k_{part}), in accordance with one embodiment of the present invention. In an operation 1101, the capacitance of the part (C_{part}) is simulated and recorded for a number of assumed part dielectric constant (k_{part}) values. In an operation 1103, a capacitance versus dielectric constant curve, such as the example shown in FIG. 8, is generated for the part based on the simulated data from operation 1101. In an operation 1105, the capacitance versus dielectric constant curve of operation 1103 is used to determine the dielectric constant of the part (k_{part}) that corresponds to the capacitance of the part (C_{part}) as determined in the method of FIG. 10.

Determining Loss Tangent of Part

FIG. 12 is an illustration showing a flowchart of a method for determining a loss tangent of a part, in accordance with one embodiment of the present invention. The method

14

includes an operation 1201 for placing a part to be measured on the hot electrode 109 within the chamber 101, and for lowering the upper electrode 105 to rest on top of the part. In an operation 1203, the RF signal generator 125 is operated to transmit RF power to the hot electrode 109. In an operation 1205, the variable capacitor 123 is adjusted to achieve the resonance frequency, i.e., peak frequency, of the RF power. In one embodiment, the resonance frequency corresponds to a peak gain between the connectors 129 and 131 of the electrical components housing 103. In this embodiment, the RF voltmeter 127 can be monitored to identify when the variable capacitor 123 setting corresponds to the peak gain between the connectors 129 and 131, and thereby corresponds to the resonance frequency of the apparatus 100.

The method continues with an operation 1207 in which the RF signal generator 125 is controlled to sweep the frequency of the RF power over a range bounding the resonance frequency achieved in operation 1205, while using the RF voltmeter 127 to measure and record the gain of the apparatus 100 between the connections 129 and 131 at a number of frequencies within the frequency sweep range. In one embodiment, the frequency range covered by the frequency sweep of operation 1207 is defined to include a 3 dB variation in gain of the apparatus 100 on each side of the peak gain corresponding to the resonance frequency. The method further includes an operation 1209 for fitting a mathematical model of the gain of the apparatus 100 to the gain versus frequency data measured in operation 1207, wherein the fitting of operation 1209 provides a value for the total capacitance of the apparatus 100 with the part therein ($C_{total_with_part}$) and a value for the total resistance of the apparatus 100 with the part therein ($R_{total_with_part}$). The fitting of operation 1209 is further described below with regard to FIGS. 13-14 and Equation 5.

FIG. 13 is an illustration showing an equivalent electrical circuit representation 1300 of the apparatus 100 with the part 111 disposed between the upper electrode 105 and hot electrode 109, as depicted in FIG. 1, in accordance with one embodiment of the present invention. A node 1313 corresponds to the connector 129 of the electrical components housing 103. A node 1315 corresponds to the connector 131 of the electrical components housing 103. The RF voltmeter 127 connected to connectors 129 and 131 is capable of measuring a gain of the apparatus 100 as defined by $|V_{out}/V_{in}|$. With regard to FIG. 1, the equivalent electrical circuit 1300 includes a capacitance (C_s) 1301 representing the capacitor 117, an inductance (L) 1303 and resistance (R_L) 1305 representing the inductor 119, a capacitance (C) 1307 representing the total capacitance of the apparatus 100, a resistance (R_X) 1309 representing the total resistance of the apparatus 100, and a ground potential 1311. It should be understood that the capacitance (C) 1307 represents the combination of the capacitors 121 and 123, the capacitance between the RF rod 113/hot electrode 109 and chamber 101/upper electrode 105, and the capacitance of the part 111 if present.

Equation 5 defines the gain of the apparatus 100 as a function of the electrical components within the equivalent electrical circuit 1300 of FIG. 13. In Equation 5, (f) is the frequency of the RF power corresponding to the gain, (C) is the total capacitance of the apparatus 100, and (R_X) is the total resistance of the apparatus 100. In Equation 5, the parameters (C_s), (L), (R_L) are known from the electrical components within the electrical components housing 103. Therefore, in Equation 5, the parameters (C) and (R_X) represent the unknown parameters.

$$\text{Gain} = \left| \frac{1}{\left(\frac{i}{2C_s f \pi} + \frac{1}{2iC f \pi + \frac{1}{2f i \pi L + R_L} + \frac{1}{R_X}} \right)} \right|$$

In the operation 1209, Equation 5 is fit to the gain versus frequency data measured in operation 1207 with the part present in the apparatus 100, thereby yielding a value for the total capacitance of the apparatus 100 with the part therein, i.e., $(C)=(C_{total_with_part})$ and a value for the total resistance of the apparatus 100 with the part therein, i.e., $(R_X)=(R_{total_with_part})$. FIG. 14 is an illustration showing an exemplary fitting of Equation 5 in accordance with operation 1209, based on gain versus frequency data measured and recorded in the frequency sweep of operation 1207. In one embodiment, a multivariate regression technique is used to fit Equation 5 to the measured gain versus frequency data in operation 1209. Also, in one embodiment, a confidence interval for each of the unknown parameters (C) and (R_X) is estimated by Monte Carlo simulation.

The method of FIG. 12 continues with an operation 1211 for turning off the RF signal generator 125 and removing the part from the chamber. In an operation 1213, the RF signal generator 125 is operated to transmit RF power to the hot electrode 109 with the part absent. In the operation 1213, the variable capacitor 123 is maintained at the setting determined in operation 1205. In an operation 1215, the upper electrode 105 is lowered until the resonance frequency determined in operation 1205 is achieved with the part absent. In one embodiment, the RF voltmeter 127 can be monitored to identify when the upper electrode 105 elevation causes the peak gain between the connectors 129 and 131 to be reached, and thereby causes the resonance frequency to be achieved. As previously mentioned, the vertical separation distance between the upper electrode 105 and the hot electrode 109 at the resonance frequency with the part absent is called the resonant upper electrode 105 separation.

The method continues with an operation 1217 in which the RF signal generator 125 is controlled to sweep the frequency of the RF power over a range bounding the resonance frequency achieved in operation 1215, while using the RF voltmeter 127 to measure and record the gain of the apparatus 100 between the connections 129 and 131 at a number of frequencies within the frequency sweep range. In one embodiment, the frequency range covered by the frequency sweep of operation 1217 is defined to include a 3 dB variation in gain of the apparatus 100 on each side of the peak gain corresponding to the resonance frequency. The method further includes an operation 1219 for fitting a mathematical model of the gain of the apparatus 100, i.e., Equation 5, to the gain versus frequency data measured in operation 1217. The fitting of operation 1219 provides a value for the total capacitance of the apparatus 100 with the part absent, i.e., $(C)=(C_{total_without_part})$, and a value for the total resistance of the apparatus 100 with the part absent $(R_X)=(R_{total_without_part})$. As previously mentioned, a multivariate regression technique can be used to fit Equation 5 to the measured gain versus frequency data in operation 1219. Also, in one embodiment, a confidence interval for each of the unknown parameters (C) and (R_X) is estimated by Monte Carlo simulation.

The method continues with an operation 1221 for calculating the resistance of the part (R_{part}) based on the total resistance of the apparatus 100 with the part therein $(R_{total_with_part})$, as determined in operation 1209, and the

Equation 5

total resistance of the apparatus 100 with the part absent $(R_{total_without_part})$, as determined in operation 1219. More specifically, the resistance of the part (R_{part}) is determined using Equation 6.

$$\frac{1}{R_{part}} = \frac{1}{R_{total_without_part}} - \frac{1}{R_{total_with_part}} \Rightarrow R_{part} = \frac{(R_{total_with_part})(R_{total_without_part})}{R_{total_with_part} - R_{total_without_part}}$$

The method then includes an operation 1223 for calculating the loss tangent of the part based on the resistance of the part (R_{part}) , as determined in operation 1221, the capacitance of the part (C_{part}) , as determined in the method of FIG. 10, and the resonance frequency, i.e., peak frequency, corresponding to operations 1205 and 1215. More specifically, the loss tangent of the part is determined using Equation 7.

$$\text{Loss Tangent of Part} = \frac{1}{(\text{Resonance Frequency})(R_{part})(C_{part})}$$

Based on the foregoing, it should be appreciated that the apparatus 100 and the associated methods (FIGS. 5B, 9, 10, 11, and 12) provide for measurement of the dielectric properties of actual full-size parts to be deployed in a plasma processing system. Also, the apparatus 100 and associated methods provide for measurement of the dielectric properties of parts at the actual operating frequency of the RF power to which the part will be exposed during plasma processing operations. Furthermore, the apparatus 100 and associated methods provide for measurement of the dielectric properties of parts under simulated atmospheric conditions and temperatures to which the part will be exposed during plasma processing operations. Additionally, the apparatus 100 and associated methods have been demonstrated to provide a loss tangent measurement repeatability having standard deviation of less than 1.24E-5.

In one embodiment, the dielectric properties of the full-size part determined through use of the apparatus 100, such as the dielectric constant value and the loss tangent value, can be attached to the full-size part. In one embodiment, the determined dielectric constant and loss tangent values are embossed on the full-size part. For example, FIG. 5A shows an example of dielectric constant and loss tangent values embossed on the part 111A. In another embodiment, a tag is affixed to the full-size part to display the determined dielectric constant and loss tangent values. Additionally, the determined dielectric constant and loss tangent values of the full-size part can be stored on a computer readable medium, which can be supplied in conjunction with the full-size part.

With the above embodiments in mind, it should be understood that the invention can employ various computer-implemented operations involving data stored in computer systems. These operations are those requiring physical manipulation of physical quantities. Usually, though not necessarily, these quantities take the form of electrical or mag-

netic signals capable of being stored, transferred, combined, compared and otherwise manipulated. Further, the manipulations performed are often referred to in terms such as producing, identifying, determining, or comparing. Any of the operations described herein may be directed, controlled, or performed by a computer system. The computer system can be specially constructed for the required purpose, or the computer system can be a general-purpose computer selectively activated or configured by a computer program stored in the computer.

A computer program can be defined to control and monitor the apparatus 100 and perform the calculations associated with measuring the dielectric properties of a part utilizing the apparatus 100. Such a computer program can be defined to provide a graphical user interface (GUI) for enabling a user to control the apparatus 100, monitor a state of the apparatus 100, view data acquired by the apparatus 100, control calculations based on the data acquired by the apparatus 100, and view and record data/results generated through operation of the apparatus 100. Such a computer program can be embodied as computer readable code on a computer readable medium. The computer readable medium is any data storage device that can store data, which can be thereafter be read by a computer system. Examples of the computer readable medium include hard drives, network attached storage (NAS), read-only memory, random-access memory, CD-ROMs, CD-Rs, CD-RWs, magnetic tapes and other optical and non-optical data storage devices.

While this invention has been described in terms of several embodiments, it will be appreciated that those skilled in the art upon reading the preceding specifications and studying the drawings will realize various alterations, additions, permutations and equivalents thereof. Therefore, it is intended that the present invention includes all such alterations, additions, permutations, and equivalents as fall within the true spirit and scope of the invention.

What is claimed is:

1. A method for defining an electrode for use in measuring dielectric properties of a part, comprising:

forming a plate of electrically conductive material to have an outer perimeter defined to substantially match an outer perimeter of the part, wherein the part is a dielectric part including a number of embedded conductive material items, wherein the plate has a top surface and a bottom surface;

identifying a location of each embedded conductive material item within the part;

projecting the identified location of each embedded conductive material item within the part upon either the top surface of the plate or the bottom surface of the plate with the outer perimeters of the part and the plate substantially aligned; and

removing a portion of the plate at each embedded conductive material item location as projected upon the plate, wherein the portion of the plate that is removed extends through an entire vertical thickness of the plate from the top surface of the plate to the bottom surface of the plate.

2. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein a size of each removed portion of the plate is sufficient to ensure that the plate is not located below the embedded conductive material item within the part when the part is positioned upon the top surface of the plate with the outer perimeters of the part and the plate substantially aligned.

3. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein removing the portion of the plate at each embedded conductive material item location is performed such that the plate remains a single contiguous component.

4. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein the plate is formed from copper metal.

5. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein a vertical thickness of the plate from the top surface of the plate to the bottom surface of the plate is within a range extending from about 0.125 inch to about 2 inches.

6. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, further comprising:

forming a number of alignment features within the plate to facilitate alignment of the part on the top surface of the plate.

7. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, further comprising:

forming a number of fastening devices within the plate to enable securing of the plate to a support rod within an apparatus for measuring dielectric properties of the part.

8. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein the top surface of the plate is substantially flat.

9. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, wherein a vertical thickness of the plate from the top surface of the plate to the bottom surface of the plate is about 0.75 inch.

10. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, further comprising:

disposing the plate of electrically conductive material on an electrically insulating support plate.

11. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 10, wherein the electrically insulating support plate is defined to support the plate of electrically conductive material in a substantially horizontal orientation.

12. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 10, wherein the electrically insulating support plate is formed from a plastic material.

13. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 10, further comprising:

disposing the electrically insulating support plate on an electrically insulated stand.

14. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 10, wherein the electrically insulated stand is formed of a same material as the electrically insulating support plate.

15. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 14, wherein the electrically insulated stand is formed as a right circular cylinder.

16. A method for defining an electrode for use in measuring dielectric properties of a part as recited in claim 1, further comprising:

connecting the plate of electrically conductive material to a radiofrequency power transmission rod.
