(54) Title: Modeling of Crop Growth for Desired Moisture Content of Targeted Livestock Feedstuffs for Determination of Harvest Windows Using Field-Level Diagnosis and Forecasting of Weather Conditions and Observations and User Input of Harvest Condition States

(57) Abstract: A modeling framework for evaluating the impact of weather conditions on farming and harvest operations applies real-time, field-level weather data and forecasts of meteorological and climatological conditions together with user-provided and/or observed feedback of a present state of a harvest-related condition to agronomic models and to generate a plurality of harvest advisory outputs for precision agriculture. A harvest advisory model simulates and predicts the impacts of this weather information and user-provided and/or observed feedback in one or more physical, empirical, or artificial intelligence models of precision agriculture to analyze crops, plants, soils, and resulting agricultural commodities, and provides harvest advisory outputs to a diagnostic support tool for users to enhance farming and harvest decision-making, whether by providing pre-, post-, or in-situ-harvest operations and crop analyses.

TITLE OF THE INVENTION

Modeling of Crop Growth for Desired Moisture Content of Targeted Livestock Feedstuff for Determination of Harvest Windows Using Field-Level Diagnosis and Forecasting of Weather Conditions and Observations and User Input of Harvest Condition States.

CROSS-REFERENCE TO RELATED PATENT APPLICATIONS

This patent application claims priority to, and is a continuation-in-part of, United States non-provisional application 14/603,383, filed on January 23, 2015, the contents of which are incorporated in their entirety herein. In accordance with 37 C.F.R. § 1.76, a claim of priority is included in an Application Data Sheet filed concurrently herewith.

INVENTORS

FIELD OF THE INVENTION

The present invention relates to harvest operations in precision agriculture. Specifically, the present invention relates to a system and method of applying real-time, field-level weather simulation and prediction to one or more agricultural models to generate a series of harvest advisory outputs in a tool for supporting farm operations management.

BACKGROUND OF THE INVENTION

Harvest operations for a variety of agricultural commodities are substantially influenced by environmental factors, such as the weather. While some weather conditions, such as precipitation, may create an obvious deterrent to harvest operations, more benign daily weather characteristics also play subtle yet significant roles. For example, many commodities require that the harvested product be at or below a product-dependent moisture threshold before they can be stably stored at ambient temperatures (at least without taking specific steps to
keep the product stable, such as the maintenance of a constant airflow through the product). On the other extreme, delaying harvest for too long can result in the crop becoming overly dry, potentially exposing seeds to damage during the threshing process, or removing permissible water weight from the product. Such an occurrence of delayed harvest may result in lower crop revenue, since payments are often based on mass. Similarly, crop temperature thresholds may be a major consideration for long-term storage of some crops, for example tuberous crops such as potatoes and sugar beets, where cold conditions are advantageous.

The harvest operation itself is also often sensitive to plant, product, and soil moisture and temperature levels. For instance, green plants, or even deceased plants with a heightened moisture level, often create difficulty for harvest operations that are based on the use of a threshing action to separate the seed (or other product) from the parent plant or stalk. This can result in both yield loss due to un-threshed seeds passing through and out of the harvester, and seed damage due to the repeated or harsh threshing action that may be required. Harvesting crops at a higher moisture content than is typical for long-term storage has short-term advantages, for example for livestock feed, however, yield loss may occur due to spoilage or mold if the grain moisture is too high while stored, or damage may occur to storage structures if excessive moisture seeps from the agricultural product. Additionally, yield or grain nutrient loss can result from overly dry plants or plant parts (such as a corn cob or corn husk), for example, when harvesting corn for silage, earlage, snaplage, for high-moisture corn grain, or for other types of livestock feed. Frozen or excessively wet soils can also inhibit harvest operations for various crops, depending upon the harvest mechanism for the particular crop. Each of the product, plant, and soil moisture and temperature therefore impact both the timing and viability of harvest operations, and all of these qualities are highly influenced by complex interactions between plant and soil characteristics and environmental conditions.

As global agricultural operations continue to grow in size, the practicality of in-situ monitoring of field conditions on a regular basis is becoming increasingly diminished. Further, the often substantial equipment and labor resources involved in harvest operations are not easily moved across significant distances in an effort to find fields with viable or more favorable harvest conditions. The ability to both diagnose and predict the viability of harvest operations in a potentially remote field is therefore of increasing importance to the management of modern farm
operations. Also, production agriculture is often a capital-intensive business with very thin relative profit margins. The ability to more effectively manage the logistics associated with deployment of a farm operation's equipment and human resources is therefore becoming increasingly critical to profitability and long-term viability of the farm itself.

In part because agricultural research globally is largely carried out by institutions with local or regional focus, agronomic models are often based on sample datasets that are limited in size and/or geographic representativeness, with less than ideal documentation of (or accommodation for) associated weather and environmental conditions. Because of this, there are very few models that can be picked up and applied to other locations and timeframes without a potentially substantial loss in model accuracy. Models for the same processes can often lead to diametrically opposed conclusions when applied at differing locations because of model shortcomings that are due to a lack of understanding of the extent to which localized influences impact the associated processes during the development of the model.

Existing solutions do not provide a sufficient framework for utilizing weather analysis and prediction to accurately diagnose field-level weather conditions for precision agriculture to overcome the challenges above. Accordingly, there is a strong need not found in the existing art for a system and method that provides an improved process for application of weather information in agronomic modeling to produce a better understanding of farm and harvest operations. There is also a need not found in the existing art for support tools designed to provide real-time assessments of weather conditions and the impact on crops, plants, soils, and resulting agricultural products to enable improvements in farm and harvest operations.

BRIEF SUMMARY OF THE INVENTION

It is therefore one objective of the present invention to provide a system and method of applying real-time assessments of weather conditions to precision agriculture models for enhancing harvest operations. It is another objective to combine real-time and location-tagged data communication in farm operations with such real-time assessments of weather conditions for generating harvest advisory information in precision agriculture. It is still another objective of the present invention to combine user-provided and/or observed feedback of a present state of
a harvest-related condition with real-time assessments of weather conditions for generating harvest advisory information in precision agriculture. It is yet another objective of the present invention to provide a diagnostic support tool for enhanced decision-making in harvest operations.

There are many other specific objectives of the present invention. One such objective is to provide a system and method of predicting dry-down of a crop over time, such as a mature small grain, coarse grain, oilseed crop, ears or other components of a corn plant, or an entire corn plant, for planning the timing of harvest operations. It is another such objective of the present invention to provide a system and method of predicting the time-varying unit costs, per percent moisture per unit of mass or volume, associated with fuel-based or forced-air mechanical drying of crops resulting from changing weather conditions and the characteristics of the drying facility. Yet another objective of the present invention is to provide a system and method of predicting the time-varying unit costs, per unit of mass or volume, associated with the combined impacts of time-varying grain or plant moisture levels of a crop to be harvested and the time-varying unit costs per percent moisture per unit of mass or volume of forced-air or fuel-based mechanical drying.

It is another objective to provide tools for assessing a risk of delayed harvest operations to achieve favorable crop moisture levels, for evaluating soil temperature and soil moisture in a given field to provide guidance as to when soil conditions are likely to inhibit harvest and post-harvest tillage operations due to soil being exceedingly wet or frozen, and for evaluating the impact of time-varying soil temperature in a given field for the timing of harvest operations as it pertains to the internal temperature of root-based crops and their long-term storage stability at those temperatures.

Other objectives of the present invention include providing systems and methods for predicting the day-by-day and intraday windows of opportunity for harvest operations owing to time-varying threshability, chopping, or other harvest-related operations as a result of interactions between a standing crop and atmospheric and soil conditions, to aid in more immediate planning of harvest operations; predicting the dry-down of hay (alfalfa, etc.) and other cuttings over time for planning the timing or windows of opportunity of cutting, windrow, silageing, or bailing operations; and assisting in decision-making for application of
a desiccant to affect a desired harvest window.

The present invention is a system and method of evaluating, diagnosing, and predicting various agronomic conditions attendant to farming activities in an advisory model configured to simulate and predict the impact of weather conditions on harvest operations. The present invention applies real-time, field-level data representative of assessments of localized weather conditions, together with real-time and location-tagged communication of data of various types and content, and long-range climatological and/or meteorological forecasting, to one or more physical, empirical, or artificial intelligence models of precision agriculture to analyze crops, plants, soils, and resulting agricultural commodities, and generate a plurality of harvest advisory outputs. Such outputs are provided either directly to farmers, to third parties, or in a harvest advisory tool based on the advisory model for supporting precision agricultural operations.

Through application of the harvest advisory modeling paradigms discussed herein, the prospects for providing improved guidance relating to farm and harvest operations has the potential to be very substantial in the field of precision agriculture. For example, diagnosing and predicting the in-field dry-down of agricultural commodities or other harvestable products, the efficiency of fuel-based and/or forced-air grain drying activities, the associations between plant moisture and atmospheric conditions, and the soil temperature and moisture profiles all provide significant value-added benefit. Recent parallel advances in weather analysis and prediction, and in the availability of mechanisms for facilitating real-time and location-tagged data communication in farm operations, have created an enticing set of possible new applications for addressing the problems described above, and others. The application of both in-situ (though not necessarily in or near a given field) and remotely-sensed weather information, in combination with scientific and computational advances in the integration of data collected by these disparate weather observing systems, permit the diagnosis of field-level weather conditions with accuracy that greatly improve upon that obtained with the deployment of a basic weather station to each and every field.

Further, advances in the understanding of the interactions between the land surface and the overlying atmosphere, combined with other improvements to the physics of meteorological weather models, and the ever-increasing computational power available to operate these models, enable a level of both
short-term and long-term accuracy and locality to weather forecasts that has not been previously attainable.

The present invention also applies time- and location-tagged feedback and observations on current and recent characteristics representing measurements of various crop states, such as moisture and temperature, to the one or more physical, empirical, or artificial intelligence models of precision agriculture. Such feedback and observations provide an enhanced collection of data along with the associated weather conditions and other relevant information to build more comprehensive datasets that are used to make far-reaching improvements to associated physical models for diagnosing and predicting underlying harvest-related conditions. Artificial intelligence is also incorporated to this more comprehensive dataset to draw automatic associations between available external data and the harvest-related condition to yield further models for simulating harvest conditions. Artificial intelligence in the present invention is also retrained as more and more data are accumulated, and the results may be tested against independent data in an effort to find the most reliable model. Such a model framework implicitly yields information as to the importance of related factors through the resulting weighting systems between inputs, subcomponents within the artificial intelligence layer, and the model output(s). Together, this feedback and observations, and physical, empirical, and artificial intelligence modeling paradigms discussed herein significantly enhance the analysis of crops, plants, soils, and resulting agricultural commodities within the present invention to generate harvest advisory outputs and improved guidance for farm and harvest operations.

Other objects, embodiments, features and advantages of the present invention will become apparent from the following description of the embodiments, taken together with the accompanying drawings, which illustrate, by way of example, the principles of the invention.

BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWINGS

The accompanying drawings, which are incorporated in and constitute a part of this specification, illustrate several embodiments of the invention and together with the description, serve to explain the principles of the invention.

FIG. 1 is a systemic diagram of a harvest advisory model and support tool for according to the present invention; and
FIG. 2 is a block diagram of information flow and steps performed within a harvest advisory model and support tool according to the present invention.

DETAILED DESCRIPTION OF THE INVENTION

In the following description of the present invention reference is made to the exemplary embodiments illustrating the principles of the present invention and how it is practiced. Other embodiments will be utilized to practice the present invention and structural and functional changes will be made thereto without departing from the scope of the present invention.

FIG. 1 is a system diagram of a harvest advisory model 100 for evaluating, diagnosing, and predicting various agronomic conditions that have an impact on farm and harvest operations, according to one embodiment of the present invention. The harvest advisory model 100 is performed within one or more systems and/or methods that includes several components, each of which define distinct activities required to apply real-time, field-level data representative of assessments of localized weather conditions, together with real-time and location-tagged communication of data of various types and content, and long-range climatological and/or meteorological forecasting to analyze crops, plants, soils, and agricultural products, to generate a plurality of harvest condition advisory outputs, and enable a harvest advisory tool 200 configured to provide diagnostic support to farm and harvest operations.

The harvest advisory model 100 ingests, or receives, input data 102 that includes weather and location specifications 110, such as meteorological data 111, real-time, field-level weather data 112, observed weather data 113 that has occurred, for example, during a current growing season, and extended-range weather and climatological forecast information 114. The weather and location specifications 110 may also include other types of real-time and location-tagged data 115, such as for example GPS data 116, and data captured from orbiting satellites or remotely powered vehicles that when processed provide details at a field-level resolution, such as remotely-sensed satellite imagery data 117 and remotely-captured drone imagery data 118. The input data 102 may further include crop and plant specifications 120 such as for example the type, variety and relative maturity of the crop 121, and other planting, chemical application, and harvest data 122, such as for example the date that a field was planted with seed, the population of planted seeds per specified area, when a field was sprayed for
example with a pesticide, desiccant, other chemical, the type and amount of chemical applied, and anticipated temporal harvest data such as an expected harvest date or harvest window. The crop and plant specifications 120 may also include the desired crop temperature 123, crop moisture 124, seed moisture 125, facility storage dimensions and specifications 126, and airflow characteristics for a stored crop 127. Additional information may include planting information such as plant depth 128 and row width 129.

The input data 102 may also include field and soil specifications 140, which may further include data such as for example the soil type 141 in which a crop was planted, and attributes such as soil temperature 142, soil moisture 143, current and/or forecasted soil conditions 144, overall soil profile 145, levels of vegetative debris 146 existing at the time of planting, and nutrient levels 147 present.

The input data 102 may also include physical, empirical, or observed agricultural data 130, such as for example sampled crop moisture content 131. This may include data such as samples and/or observations of actual grain or plant moisture taken from a planted field at one or more times, and the associated dry-down of the grain or plant in a particular field over time. Other examples of such data 130 include data regarding temporal harvestability windows 132 for a particular crop at a particular location over some recent period of time, or for various crops at various locations, over time. This may include, for example, temporal windows of threshability of a seed-based crop over some recent period of time, temporal windows of choppability of a plant-based crop over some recent period of time, temporal windows of cut-windrow-bail operations for crops such as hay at a particular location over some recent period of time, and temporal windows of mature growth stages, desiccant efficacy, and harvestability for a particular desiccant for particular crop at a particular location over some recent period of time.

The physical, empirical, or observed agricultural data 130 may further include descriptive metadata reflecting actual performance, realization, or implementation of one or more of crops, plants, fields, soils, and facilities. This metadata may include crop and seed metadata 133 such as the relative maturity and dry-down characteristics of the variety, pest and disease susceptibility or resistance, whether a crop is irrigated or non-irrigated, and type and origin of seeds (for example, genetically modified or non-genetically modified, and company
source). Such metadata may also include soils metadata such as information relating to previous crop grown on or in the soil, tillage practice, soil composition, presence of surface and/or subsurface drainage, nutrient composition, rate of degradation, rate of water movement in both a lateral and vertical direction, presence of materials such as salts in soil strata, and facility metadata such as metadata relating to type characteristics, for example whether the facility is a forced-air drying facility or a fuel-based mechanical grain drying facility or an open-air-based holding facility or a silo, and their associated resources and costs.

All of this input data is ingested into the harvest advisory model 100 via a data ingest module 171 as shown in the system diagram of FIG. 1. The harvest advisory model 100 ingests this input data 102 and applies it to one or more precision agriculture (agronomic) models 160 which may include artificial intelligence-derived precision agriculture models, to produce output data 180. The output data 180 of the harvest advisory model 100 is represented a harvest condition output profile 181 that is provided to a harvest advisory tool 200 that can be used to predict, simulate, and forecast harvest conditions 270 as discussed further herein.

The input data 102 is applied to the one or more precision agriculture models 160 in a plurality of data processing modules 170 within a computing environment 150 that also includes one or more processors 152 and a plurality of software and hardware components. The one or more processors 152 and plurality of software and hardware components are configured to execute program instructions to perform the functions of the harvest advisory model 100 described herein, and embodied in the one or more data processing modules 170.

The plurality of data processing modules 170 include, in addition to the data ingest module 171, a physical and empirical models module 172, and an artificial intelligence module 173 configured to apply a layer of artificial intelligence to the harvest advisory model 100 to develop relationships between input data 102 and outputs from other precision agriculture models to perform and improve the assessments, diagnoses, simulations, forecasts, and predictions that form the harvest condition output profile 182. The plurality of data processing modules 170 also includes a harvest condition prediction module 177 configured to generate the harvest condition outputs 270.

The physical and empirical models module 172 enables application of the
input data 102 to the one or more precision agriculture models 160. Such models 
160 include crop, soil, plant, and other modeling paradigms, such as for example 
phenological models that include general crop-specific and crop variety-specific 
models, a common example being growing degree day (GDD) models. These models 
160 also include soil models such as the EPIC, APEX, and ICBM soil models, and 
land surface models such as the NOAH, Mosaic, and VIC models. Other models 
contemplated within the scope of the present invention include crop-specific, site- 
specific, and attribute-specific physical models, such as models for simulating 
temperature, moisture, wetness, in-field crop dry-down, plant-atmosphere vapor 
diffusion, plant rewetting associated with precipitation, and deterministic and 
stochastic grain or plant drying models that parameterize the unique drying 
characteristics of a specific crop to be dried based on characteristics of the drying 
process and statistical models, and models for analyzing storage characteristics of 
crops, seeds, soils, and storage facilities. It is contemplated that the input data 102 
may be applied to existing precision agriculture models, as well as customized 
models for specific harvest conditions 270, for example simulation of expected dry-
down of grain or plant in the particular field, grain and plant moisture levels, and 
temperature and moisture content of a root-based crop over time, and other 
simulations, predictions, and forecasts as noted herein.

The harvest condition output profile 182, as noted above, is output data 
180 of the harvest advisory model 100. Once the harvest advisory model 100 has 
generated the harvest condition output profile 182, the present invention applies 
the harvest condition output profile 182 to develop the harvest advisory tool 200 for 
analyzing many types of information in harvest operations. The harvest condition 
output profile 182 provides estimates, for example, of standing crop dry-down 
rates, anticipated harvest dates and suitability, fuel consumption optimizers for 
forced-air drying, indicators of plant 'toughness' for anticipating harvest windows, 
and possible loss of field workability due to the formation of frost in the soils prior 
to post-harvest tillage.

The crop and plant specifications 120 of the input data 102 may also include 
specifications regarding a livestock feedstuff 300, and desired moisture contents for 
such livestock feedstuff 300 depending on post-harvest storage characteristics 310. 
The present invention may therefore include applying this additional data to the 
one or more precision agriculture (agronomic) models 160 for determining a harvest 
condition for producing a targeted livestock feedstuff 300 at desired moisture
Livestock feedstuff 300 may include any harvested crop that is suitable for consumption as animal feed. The present invention contemplates that the harvest advisory model 100 and harvest advisory tool 200 can be configured to analyze and assess moisture content and other characteristics of feedstuff 300 for any type of animal to aid in the timing of harvest operations so as to optimize storage conditions. The harvest advisory model 100 and harvest advisory tool 200 may therefore generate a harvest condition output profile that can be used to provide information to a user related to dry-down of a crop to be harvested, such as one or more harvest opportunity windows for livestock feedstuff 300, and related advisories.

For example, the present invention may generate an output that includes an advisory comprising a risk from harvesting targeted livestock feedstuff 300 at a moisture content that is higher than the desired moisture content. Such a risk advisory may constitute an assessment of damage to a storage structure, an assessment of a loss of feedstuff nutrient levels due to runoff and seepage in the storage structure, and an assessment of water supply contamination.

Similarly, the present invention may generate an output that includes an advisory comprising a risk from harvesting targeted livestock feedstuff 300 at a moisture content that is higher than the desired moisture content. Such a risk advisory may include a recommendation of a packing factor, an assessment of palatability and digestability by the type of animal consuming the feedstuff 300, and an assessment of feedstuff sugar content.

Many other advisories and recommendations related to harvest of crops for livestock feedstuff 300 and for achieving desired moisture contents are possible and within the scope of the present invention. For example, the harvest advisory model 100 and harvest advisory tool 200 may be configured to generate a recommendation to growers and/or landowners regarding an amount or type of artificial precipitation to irrigate a field for harvest of a crop during the one or more harvest opportunity windows, and/or to achieve the desired moisture content. Similarly, the present invention may be configured to generate a recommendation to growers and/or landowners regarding an amount of fertilizer or other crop or soil treatment to apply to a field for harvest of a crop during the one or more harvest opportunity windows, and/or to achieve the desired moisture content.
A targeted livestock feedstuff 300 may include a bovine feedstuff for which opportunity windows 185 for harvest at a desired moisture content are important considerations, depending at least in part on the type of crop, the method of storage, and the type of cattle consuming the feedstuff 300. For example, different breeds of cattle may require different feedstuff considerations. Additionally, the desired cattle use - dairy, beef, etc. - may also require different feedstuff considerations.

Corn is a one example of an agricultural that is commonly grown to produce feedstuff 300 for livestock, such as cattle. A corn crop may be harvested as silage, earlage, snaplage, and high-moisture corn, for example, depending on the harvesting technique applied to a field and often the type of farming equipment used for harvesting the corn crop. Corn silage refers to a harvest of the whole corn plant, instead of just the grain or kernel. Earlage refers to a harvest of the corn grain/kernel, as well as cobs, husks, shanks, or a portion of the stalk, and is generally higher in energy content than corn silage. Earlage may also refer to a type of harvest with an all-crop header raised to a height at which the ear and stalk material about the shank is harvested.

High-moisture corn refers to kernel and cob material that is harvested with a combine which is set to return the grain and a portion of the ground cob to the hopper. High-moisture corn is similar in energy and protein content to dry corn, and tends to ferment faster in the rumen of ruminant livestock such as cattle. Snaplage refers to harvest of earlage of the corn crop and some other portion of the plant. Snaplage is earlage or silage that is harvested with equipment such as a forage harvester equipped with a corn snapper header, so that only the ear and a portion of the ear shank is removed and chopped.

Post-harvest storage characteristics 310 may include storage in a plurality of different structures or using different storage methods. For example, livestock feedstuff 300 may be stored in silos of many different configurations, such as in upright tower silos, oxygen-limiting silos, bunker or pile silos, and bag silos. Each of these structures has differing characteristics for storage, airflow, packing factor, and drying of feedstuff 300 stored therein that affect the quality of the harvested material and its subsequent use as a livestock feedstuff 300.

Moisture contents for corn that has been harvested for animal consumption, such as bovine feedstuff 300, varies depending on many different factors. These
factors include the type of harvest, the type of machinery or equipment used for the harvest, and/or the type of storage structure. For example, moisture of content of corn silage is typically between 65% and 70% whole plant moisture if the harvested feedstuff is to be stored in a bunker silo or pile. If it is to be stored in an upright silo, the moisture content should be between 63% and 70% whole plant moisture. Moisture content should be between 63% to 67% for storage in a bag silo, and 55% to 60% for storage in an oxygen-limiting silo.

Because of its higher energy content in comparison with silage, moisture content for earlage is typically between 26% and 40% whole plant moisture if the harvested feedstuff 300 is to be stored in a bunker silo or pile, an upright silo, or a bag silo. For storage in an oxygen-limiting silo, the desired moisture content should be between 26% and 36% whole plant moisture. Moisture content for high-moisture corn is typically between 24% and 35% moisture if the harvested feedstuff is to be stored in a bunker silo or pile, an upright silo, or a bag silo. For storage in an oxygen-limiting silo, the desired moisture content should be between 24% and 32% moisture.

FIG. 2 is a block diagram of information flow and steps performed within the harvest advisory model 100 and harvest advisory tool 200 for supporting users 300. In the present invention, the model 100 is initialized 210 by receiving various input data 102, such as weather and location specifications 110. Crop and plant specifications 120 may also be applied at this phase. The harvest advisory model 100 uses this information to develop predictions of expected weather conditions 230 using one or more weather modeling paradigms. Additional input data 102 related to specific harvest conditions 270 to be modeled may then be applied, such as plant, seed, soil, field and facility data, livestock feedstuff type, and any type of metadata. The present invention may utilize one or more predictive data models 175 for generating predictions or forecasts 220 relating to such additional input data 102, depending on the type of harvest condition 270.

The expected weather conditions 230, and additional input data 102, are then applied in step 240 to one or more precision agriculture models 160. Output from such models 160 may also be further applied to develop 242 artificial intelligence models for further analysis of the harvest condition 270, as discussed further herein. The present invention performs an initial evaluation 250 of the harvest condition 270, and may ingest input data 102 representing further
observations to perform modifications 260 of the initial evaluation. The present invention then produces the harvest condition output profile 182 and provides this to the harvest advisory tool 200, for use by one or more users 300 or for further distribution or processing in an API module 176.

As noted above, the harvest advisory model 100 includes a layer of artificial intelligence that may be applied to develop relationships between input data 102 and outputs from others of the precision agriculture models to perform the simulations, forecasts, diagnoses, and predictions represented in the harvest condition output profile 182. The present invention contemplates that these relationships may be developed in a variety of different ways. For example, the artificial intelligence module 173 is configured to adjust to input data 102 that includes observations provided from fields that are local or even distributed across a region. Other data applied to the artificial intelligence module 173 includes, as noted above, output from other precision agriculture models, and it is further contemplated that the original datasets for such models may be collected from institutions around the world and analyzed within the present invention. Regardless, observations may be either quantitative (e.g. grain moisture level as tested) or qualitative (e.g. the plant material became harvestable or unharvestable at a given time and location, whether or not because of environmental factors). Such information can be analyzed with respect to both recent and current weather and soil conditions, and the corresponding agronomic model outputs, to make appropriate adjustments to the unaltered agronomic model output that would otherwise be provided to the user. This information can also be used to provide updated guidance to other users in similar circumstances (with respect to locale, crop, etc.).

The artificial intelligence module 173 uses associated weather conditions, agronomic and other agricultural model outputs, environmental considerations, crop characteristics, and other relevant data, together with empirical observations where applicable, to build a more comprehensive dataset that can be used to make far-reaching improvements to (or even replacements for) the associated physical models for diagnosing and predicting the underlying harvest-related condition. For instance, the artificial intelligence layer can be applied to an adequately-sized dataset to draw automatic associations between the available external data and the harvest-related condition, effectively yielding a "black box" model for simulating the condition. As more and more data are accumulated, the data can be sub-sampled,
the artificial intelligence layer retrained, and the results tested against independent data in an effort to find the most reliable model. Further, such a model implicitly yields information as to the importance of related factors through the resulting weighting systems between inputs, subcomponents within the artificial intelligence layer, and the model output(s). This information may be used to identify which factors are particularly important or unimportant in the associated process, and thus help to target ways of improving the model over time.

The present invention contemplates that many different types of artificial intelligence may be employed within the scope thereof, and therefore, the artificial intelligence module 173 may include one or more of such types of artificial intelligence. The artificial intelligence module 173 may apply techniques including, but not limited to, k-nearest neighbor (KNN), logistic regression, support vector machines or networks (SVM), and one or more neural networks.

The use of artificial intelligence in the harvest advisory model 100 of the present invention enhances the utility of physical and empirical models by automatically and heuristically constructing appropriate relationships, mathematical or otherwise, relative to the complex interactions between growing and maturing plants, the environment in which they reside, the underlying processes and characteristics, and the observational input data made available to the system. For example, where predictive factors known to be related to a particular outcome are known and measured along with the actual outcomes in real-world situations, artificial intelligence techniques are used to 'train' or construct a model that relates the more readily-available predictors to the ultimate outcomes, without any specific a priori knowledge as to the form of those relationships.

The present invention adopts a combined approach for simulating the relationships between predictive data and eventual outcomes. In the harvest advisory model 100, the general nature of the relationships can be quantified with one or more physical models and/or with artificial intelligence models, which are then applied to a combination of the predictive data, historical data, metadata, and other physical model outputs to better simulate the ultimate outcomes. This approach permits the better-understood portions of the problem at hand to be modeled using a physical or empirical model, while permitting the less well understood portions of the problem to be automatically modeled based on the
relationships implicit in the data provided to the system. In additional embodiments, with sufficient input data and output reliability and accuracy, the physical models may be entirely supplanted by the use of artificial intelligence model(s). Alternatively, the artificial intelligence layer need not be employed in the system to produce the desired output information.

The proliferation of devices for communicating data both collected and required during harvests provides the opportunity to address many issues with obtaining reliable, centralized datasets for modeling harvest activities. For example, issues arise because, although key predictive factors or ground truths are routinely measured in production agriculture, they are rarely reported into a centralized repository of data that could be used to develop models that simulate the relevant relationships. Further, the mere act of reporting and collecting this data does not in itself provide the ability to develop models based on the data. In one embodiment of the present invention, past, present, and predicted weather data for any location globally are constructed through combined application of one or more of in-situ weather observations, remotely-sensed weather observations, and meteorological analysis and prediction models. These data are made available via an API-based system for obtaining weather data for any given location and timeframe. Likewise, global, national, and regional databases of soil and land-cover characteristics are also made available via an API system, making these potentially predictive parameters readily available for association with any harvest-related observations that might become available. These data, along with user-provided crop metadata, can be used to diagnose and predict the growth and maturation of a crop to be harvested, with or without the aforementioned systems and methods including whether or not the processes are performed on a mobile device. Using a field data collection device, such as a smartphone or tablet, observations of conditions impacting harvest operations can be provided in near real-time. These observations may include grain or plant moisture samples (whether from a trial harvest operation or manual sampling), crop harvestability metrics, field accessibility metrics, or any number of other characteristics of the crop or field that may impact the crop's behaviors or its harvest operations. Additionally, through combined application of locational information available from the device, and crop or field metadata relating to the aforementioned observations that might be collected through an application accessible on the device, data on additional predictive factors can be collected and associated with each observation. When combined with
automatically-collected weather, soil, and other environmental data, these data can
be used as the basis for automatically building artificial intelligence models that
either simulate the future expected states of the harvest-impacting conditions
directly, or that act to provide corrective adjustments to the outputs of one or more
physical models for simulating the underlying processes.

The systems and methods of the present invention therefore provide the
opportunity to substantially advance the state of the art in terms of planning and
managing harvest operations with the use of combinations of physical and
empirical models with artificial intelligence. It is further notable however that many
types and sources of input data 100 allow for user-based and/ or locality-based
biases in the observations and predictive data that are available to develop the
artificial intelligence modeling paradigms contemplated herein. Some of these
biases may represent differences in perception (where subjective feedback is
accepted), while others may be due to biases in the instrument(s) used to collect
more quantitative observations, and even others may be due to variability in factors
associated with the crop or farm operation that are outside of the realm of what is
being collected in terms of metadata (for instance, the design of the particular
harvesting equipment used can impact both harvestability and field-accessibility
for a given operation). Because of this, the present invention contemplates
development of both generalized artificial intelligence models, using all available
data and metadata, and localized or user-specific artificial intelligence models
tailored to analyze, for example: a particular location, user, crop, operation, soil
type, and seed variety. These highly-localized or-personalized models may yield
information that is more closely-tailored to the particular location or user than that
provided from original data.

As noted above, the harvest advisory model 100 ingests many different types
of weather information for application to the modeling approaches discussed above.
This includes real-time, historical, and forecasted field-level data representative of
assessments of localized weather conditions, and may include long-range
climatological and/ or meteorological forecasting, in one or more predictive weather
models 174.

Such real-time, field-level data representative of assessments of localized
weather conditions may be produced by many different sources of meteorological
data to provide one or more of observed weather data and current field-level
weather data, and predicted weather data, for example as data that is complementary to the data assimilation systems and forecasting systems noted below. Such additional sources of weather data may include data from both in-situ and remotely-sensed observation platforms. For example, numerical weather prediction models (NWP) and/or surface networks may be combined with data from weather radars and satellites to reconstruct the current weather conditions on any particular area to be analyzed. There are numerous industry NWP models available, and any such models may be used as sources of meteorological data in the present invention. Examples of NWP models at least include RUC (Rapid Update Cycle), WRF (Weather Research and Forecasting Model), GFS (Global Forecast System) (as noted above), and GEM (Global Environmental Model). Meteorological data is received in real-time, and may come from several different NWP sources, such as from the European Centre for Medium-Range Weather Forecasting (ECMWF), Meteorological Services of Canada's (MSC) Canadian Meteorological Centre (CMC), as well as the National Oceanic and Atmospheric Administration's (NOAA) Environmental Modeling Center (EMC), and many others. Additionally, internally or privately-generated "mesoscale" NWP models developed from data collected from real-time feeds to global and localized observation resources may also be utilized. Such mesoscale numerical weather prediction models may be specialized in forecasting weather with more local detail than the models operated at government centers, and therefore contain smaller-scale data collections than other NWP models used. These mesoscale models are very useful in characterizing how weather conditions may vary over small distances and over small increments of time. The present invention may be configured to ingest data from all types of NWP models, regardless of whether publicly, privately, or internally provided or developed.

Long-range climatological and/or meteorological forecasting may be generated by, in one aspect of the present invention, dynamical extended range weather forecast models generated from known methods for inter-seasonal to inter-annual climate prediction, which have evolved into a combination of deterministic and statistical modeling schemes that permit the capture of long-term low-frequency features. Such forecasting often requires global analyses for the specification of observed initial and boundary conditions, the use of sophisticated numerical weather prediction models, a statistical treatment of the model results, and a verification of the forecast results as a feedback into forecast refinement.
In one embodiment of the present invention, providing long-range climatological and/or meteorological forecasting may involve the use of two data assimilation systems and two forecasting systems. The two data assimilation systems may be used to provide historic and current atmospheric and land surface initial conditions and also global ocean temperatures. For example, the two forecast systems may incorporate the U.S. National Centers for Environmental Predictions (NCEP) Global Forecast System (GFS) for atmospheric predictions and the Geophysical Fluid Dynamics Laboratory Modular Ocean Model to provide sea-surface temperature predictions. Software and data supporting the above are publicly available from the NCEP.

The present invention contemplates that one or more predictive weather models 174 may be incorporated to develop expected weather conditions 230 as in FIG. 2. Such models may be executed at any desirable time interval, such as daily or hourly, to provide a complete global dataset for use in initializing the subsequent model run, and to be used to supply localized values for harvest projections for individual crop locations.

Another type of input data 102 contemplated within the scope of the present invention is image data, such as field-level processed remotely-sensed imagery in the form of remotely-sensed satellite imagery data 117 and remotely-captured drone imagery data 118, which may be ingested to provide additional support for an assessment of crop and soil states and yield metrics in the harvest advisory model 100. One source of image data representing this remotely-sensed imagery is satellite systems, such as fine temporal resolution low-earth orbit satellites that provide a minimum of three spectral bands. Another source is unmanned or remotely-piloted vehicles such as those commonly referred to as "drones". Other sources are also contemplated, such as for example manned aerial reconnaissance, lower temporal frequency earth resources satellite such as LANDSAT and MODIS, ground-based robots, and sensors mounted on field and farm equipment. Regardless of the source, this image information is field-navigated to provide users with the most recent high-resolution depiction of a field to be or being harvested. Image data may be delivered on a web or application-based device configured for use with the harvest advisory tool 200, and additional tools may be provided for spatially navigating the image data and overlaying a variety of weather data elements.
Regardless of the source, the field-level remotely-sensed raw or image data may be used by the harvest advisory model 100 to map the crop field and generate a time-series profile of harvest activity. It is contemplated that remotely-sensed satellite imagery data 117 and remotely-captured drone imagery data 118 may be analyzed prior to or in concert with application to the one or more modeling paradigms discussed herein. The remotely-sensed satellite imagery data 117 and remotely-captured drone imagery data 118 may be analyzed using a normalized difference vegetative index (NDVI) that provides the user with an evaluation of plant health, biomass, nutrient content and moisture or wetness content. Other approaches may also be employed for such analysis, such as: Modified Chlorophyll Absorption Ratio Index/ Optimized Soil-Adjusted Vegetation Index (OSAVI), Triangular Chlorophyll Index/ OSAVI, Moderate Resolution Imaging Spectrometer Terrestrial Chlorophyll Index/ Improved Soil-Adjusted Vegetation Index (MSAVI), and Red-Edge Model/MSAVI.

The harvest advisory model 100 may further include additional sources of data, such as image-based data from systems such as video cameras, and data generated from one or more vehicle-based sensing systems, including those systems coupled to computing systems configured on harvesting equipment, or those systems configured to gather weather data from mobile devices present within vehicles, such as the mobile telephony devices and tablet computers as noted above. Crowd-sourced observational data may also be provided from farmers using mobile telephony devices or tablet computers using software tools such as mobile applications, and from other sources such as social media feeds. Meteorologist input may be still a further source of data. The data collected or used need not be in image format.

Visible adaptation of the output of any of the modeling paradigms employed within the harvest advisory model 100 and harvest advisory tool 200 to user-provided feedback data helps to foster a productive and ongoing feedback loop between the user 300 and the harvest advisory model 100 over time. While adding an artificial intelligence layer to the overall modeling system leads to output that is generally responsive to user feedback on the whole, it is possible that even the output of the artificial intelligence model (or artificial intelligence layer functioning together with a physical model) may differ from real-world observations. The present invention therefore contemplates, in another embodiment, an extra layer of forced-adaptation software for adjusting output to ensure responsiveness to
feedback data and enforce the belief that data being provided is actually being used to automatically improve the corresponding model over time. Since even a model based on artificial intelligence cannot be reasonably forced to return an outcome that is consistent with what is observed, even after that observation has been included in the pool of data that was used to develop the model in the first place, a forced-adaptation layer that varies according to the nature of the problem and model(s) to which it resides is applied so that information provided to the user going forward is well-matched to the information the user has provided. For example, it is entirely possible that feedback and observational data provided by two different users, for seemingly identical situations from the perspective of the data the system has available, will conflict, even to the extent of potentially being diametrically opposed. Applied to the same adaptive learning model, the present invention may produce an indeterminate outcome because of the conflicting feedback, or even a conflicting outcome to what the user has reported. The forced adaptation layer is therefore an additional module atop the artificial intelligence layer that provides an appropriate albeit brute-force adjustment to system output to ensure that it is consistent with the feedback and observational data the user has provided for the appropriate timeframe (if one exists), so as to provide the perception of responsiveness to the user and encourage the provision of further feedback and observational data.

The present invention contemplates that many applications of the harvest advisory model 100 are used to provide specific output information for supporting farming and harvesting operations. In one such application, the harvest condition output profile 182 provides a pre-harvest prediction of in-field dry-down of a mature small grain, coarse grain, or oilseed crop over time, but crop type need not be limited to this. For example, root-based crops may be considered for either in-field crop dry-down or crop moisture acquisition. This prediction is provided via the harvest advisory tool 200 and is used for planning the timing of pre-harvest, harvest, and post-harvest operations for such crops.

The harvest advisory tool 200 provides this prediction in one or more approaches. In one such approach, the harvest advisory model 100 leverages weather prediction models to predict weather conditions that impact the rate of drying or wetting of a root-based crop or the grain associated with a mature small grain, coarse grain, oilseed crop, ears or other components of a corn plant, or an entire corn plant in a particular field. A physical model is also applied to simulate
the expected dry-down of the grain or plant in the particular field, based on the combination of crop and field characteristics and the expected weather conditions. This is accomplished by receiving one or more samples of actual grain or plant moisture from the field at one or more times, and modifying, based on the differences between simulated and sampled moisture content at the corresponding times, the prediction of the expected dry-down of the grain or plant in the particular field over time.

It should be noted that where the present invention is configured to determine a harvest condition for producing a targeted livestock feedstuff 300 at desired moisture contents, the sampled crop moisture content 131 is used at least in part to accurately sample moisture content of the mixture of plant materials, such as in corn silage and corn earlage. There are many ways to collect observations and data representing such sampled moisture content 131, including for example the use of an oven or microwave to dry the mixture, along with a scale to weigh it before and after. In other cases, growers may observe particular target or specific growth stages that in turn result in known or estimated plant moisture levels. For example, a "black layer" growth stage would roughly equal 65% plant moisture, while other vegetative and reproductive growth stages have their own estimates of moisture. The present invention may therefore associate predictive crop growth models with actual, sampled crop growth moisture to generate a predicted harvest condition.

In another approach, a prediction of weather conditions that impact the rate of drying or wetting of a root-based crop or the grain associated with a mature small grain, coarse grain, oilseed crop, ears or other components of a corn plant, or an entire corn plant in a particular field is formed using crop metadata, and one or more samples of actual grain or plant moisture from one or more fields at one or more times. The weather conditions, crop metadata, and root, grain, or plant moisture samples from one or more fields and one or more crops are applied to automatically develop an in-field root, grain, or plant dry-down model based on artificial intelligence. The harvest advisory model 100 then applies the artificial intelligence-based model to diagnose or predict the in-field dry-down of grain or plants with similar characteristics in any field at any chosen time.

In another application, the harvest condition output profile 182 provides a prediction of the time-varying unit costs (per percent moisture per unit of mass or
volume) associated with fuel-based or forced-air mechanical drying of grain or plant matter resulting from changing weather conditions and the characteristics of a grain drying facility. This prediction is provided via the harvest advisory tool 200 for evaluating the impact of time-varying weather conditions on the unit costs of forced-air or fuel-based drying.

In this application, the harvest advisory model 100 leverages weather prediction models to predict weather conditions that impact the energy requirements associated with at least one of forced-air and fuel-based mechanical grain or plant matter drying. This is accomplished by receiving metadata (whether past, present, or future) regarding the characteristics of at least one of forced-air and fuel-based mechanical grain or plant matter drying facility and their associated resources, and applying the predicted weather data and facility metadata in at least one of an empirical, physical, and artificial intelligence model to predict the time-varying cost of at least one of forced-air and fuel-based grain or plant matter drying. Factors that may impact the cost of forced-air or fuel-based drying include the atmospheric temperature and moisture content, the temperature of the grain or plant matter itself (often reflective of the ambient temperature at the time of harvest), the moisture of the grain or plant matter, the amount of airflow with respect to a measurement of area or volume, cost of the energy used to drive the airflow, and the energy efficiency of the facility itself. In the process of drying heat is necessary to evaporate moisture from the grain or plant matter and a flow of air is needed to carry away the evaporated moisture. There are two basic mechanisms involved in the drying process; the migration of moisture from the interior of an individual grain to the surface, and the evaporation of moisture from the surface to the surrounding air. The rate of drying is determined by the moisture content and the temperature of the grain or plant matter and the temperature, the (relative) humidity and the velocity of the air in contact with the grain or plant matter. Likewise, facility design, such as continuous-flow dryers, batch dryers, tower dryers, and the like can impact the ultimate drying costs by 50% or more.

In yet another application, the harvest condition output profile 182 provides a prediction of the time-varying unit costs (per unit of mass or volume) associated with the combined impacts of time-varying grain or plant moisture levels of the crop to be harvested, and the time-varying unit costs (per percent moisture per unit of mass or volume) of forced-air or fuel-based mechanical drying. This prediction is provided via harvest advisory tool 200 for evaluating the costs associated with in-
field vs. facility-based drying of an agricultural commodity requiring sufficiently low moisture levels for stable long-term storage or appropriate moisture levels for stable winter or short- or long-term storage.

In this application, the harvest advisory model 100 predicts the in-field dry-down of the grain or plant associated with a crop in a particular field using one or more physically-based and/or or artificial intelligence models to simulate the combined impacts of weather conditions, crop characteristics, and field characteristics on grain or plant moisture levels. The harvest advisory model 100 then uses predicted weather data to predict metadata associated with one or more of forced-air and fuel-based mechanical grain or plant matter drying facilities, and analyzes relationships that quantify the process of grain or plant matter drying, the per-unit, time-varying cost of drying the grain or plant matter (cost, per percentage point of moisture, per unit of grain or plant matter mass or volume). Then, using the predicted in-field grain or plant dry-down and the predicted cost of one or more of forced-air and fuel-based grain or plant matter drying, the effective time-varying overall cost of forced-air and/or fuel-based grain or plant matter drying (cost per unit of grain or plant matter mass or volume) is predicted.

Another application of the present invention includes aiding in the assessment of the expected costs of forced-air or fuel-based mechanical drying of a crop owing to early harvest, relative to the potential costs of crop losses due to adverse weather conditions and the susceptibility of the in-field crop to weather and other causes of yield loss, such as mold or spoilage. In this application, the harvest condition output profile 182 provides an assessment of the trade-offs associated with delaying harvest operations to achieve a more appealing crop moisture level verses the risks associated with leaving the crop exposed in a field. The present invention performs this assessment by applying predictions of the in-field grain or plant dry-down and the time-varying cost of at least one of forced-air and fuel-based grain or plant matter drying to predict the effective overall time-varying cost of mechanical forced-air or fuel-based grain or plant matter drying (cost, per unit of grain or plant matter mass or volume). It then predicts, using crop characteristics and predicted weather data, the time-varying potential for crop yield losses owing to adverse weather conditions, and provides time-varying comparative data on the costs of at least one of forced-air and fuel-based drying associated with earlier harvest of the crop, versus the risks associated with yield losses associated with adverse weather conditions that may be experienced prior to harvest of the
crop.

The present invention may also be configured to diagnose and predict the soil temperature and moisture profiles in a given field to provide guidance as to when soils in that field are likely to become exceedingly wet or frozen, thereby inhibiting harvest and post-harvest tillage operations. In this application, the harvest condition output profile 182 provides an assessment of the trade-offs associated with delaying harvest operations to achieve a more appealing crop moisture level verses the risks associated with leaving the crop exposed in a field. The present invention performs this assessment by applying predictions of the in-field grain or plant dry-down and the time-varying cost of at least one of forced-air and fuel-based grain or plant matter drying to predict the effective overall time-varying cost of mechanical forced-air or fuel-based grain or plant matter drying (cost, per unit of grain or plant matter mass or volume). In parallel it also predicts, using crop characteristics, soil data, and predicted weather data, the time-varying likelihood of at least one of excess moisture or frost developing within the soil profile, and provides time-varying comparative data on the costs of forced-air or fuel-based drying associated with earlier harvest of the crop, versus the risks associated with excessive moisture or frost developing within the soil profile prior to the time when at least one of harvest operations and post-harvest tillage operations can be completed.

In another application, the harvest condition output profile 182 enables a diagnosis and prediction of the impacts of time-varying soil temperature profile in a given field as it pertains to the internal temperature of root-based crops and their long-term storage stability at those temperatures. This is provided via harvest advisory tool 200 for aiding in the timing of harvest operations so as to optimize storage conditions.

The present invention provides this diagnosis and prediction in one or more approaches. In one approach, the harvest advisory model 100 leverages at least one of weather prediction models, land surface, and soil models to predict the time varying temperature and moisture content of a root-based crop intended to be harvested. Utilizing predicted weather conditions, the present invention then predicts, using the crop temperature and moisture, and airflow characteristics of the storage pile or facility, the stability of the crop for long-term storage.

In another approach, the present invention collects data on crop
temperature and moisture, storage dimensions, and airflow characteristics for a stored crop, over time. It then compares this crop storage data against at least one of time-varying weather data and outputs of models for simulating crop moisture and temperature characteristics in the corresponding times and locations, for the corresponding crops, to develop artificial intelligence models for relating these crop storage characteristics to the more readily-available weather data and outputs of models for simulating crop moisture and temperature characteristics. Using the airflow characteristics of the storage pile or facility, and the artificial intelligence model and at least one of forecast weather data and forecast outputs of models for simulating crop temperature and moisture characteristics, the present invention then provides a forecast of the likely windows of harvestability on the current and future days and the potential for crop stability for long-term storage.

In another application, the harvest condition output profile 182 enables prediction of the day-by-day windows of opportunity for harvest operations owing to time-varying threshability or choppability as a result of interactions between a standing or windrowed crop and atmospheric and soil conditions. The present invention provides this prediction to aid in more immediate planning of harvest operations in one or more approaches. In one approach, the harvest advisory model 100 predicts the daily window of harvest opportunity due to the impact of plant wetness on crop threshability or choppability by collecting data on temporal windows of harvestability for a particular crop at a particular location over some recent period of time, and comparing this harvestability data against at least one of time-varying weather data and outputs of models for simulating plant wetness characteristics in the crop in order to identify relationships between these external data and the reported harvestability data. The harvest advisory model 100 then provides, based on these identified relationships and the at least one of time-varying weather forecast data and forecast outputs of models for simulating plant wetness characteristics, a forecast of the likely windows of harvestability on the current and future days.

In another approach, the present invention predicts the daily window of harvest opportunity due to the impact of plant wetness on crop threshability or choppability by collecting data on windows of harvestability for various crops at various locations, over time, and comparing this harvestability data against at least one of time-varying weather data and outputs of models for simulating plant wetness characteristics in the corresponding times and locations, for the
corresponding crops, in order to develop artificial intelligence models for relating these windows of harvestability to the more readily-available weather data and outputs of models for simulating plant wetness characteristics. The harvest advisory model 100 then provides, using the artificial intelligence model and at least one of forecast weather data and forecast outputs of models for simulating plant wetness characteristics, a forecast of the likely windows of harvestability on the current and future days.

The present invention may also be configured for an application in which the harvest condition output profile 182 enables prediction of the dry-down of cutting crops such as hay (and others, for example alfalfa) over time. The harvest advisory tool 200 uses this output of the harvest advisory model 100 for planning the timing of, or predicting windows of opportunity for, cutting, windrowing, silageing, or bailing operations for hay fields.

The present invention performs this collecting of data on temporal windows of cut-windrow-bail during consecutive and disjoint operations for hay at a particular location over some recent period of time, and compares this operational data against at least one of time-varying weather data and outputs of models for simulating plant wetness characteristics in the hay in order to identify relationships between these external data and the reported operational data. The harvest advisory model 100 then provides, based on these identified relationships and the at least one of time-varying weather forecast data and forecast outputs of models for simulating plant wetness characteristics, a forecast of the likely windows of, for example, cut-windrow-bail operations on the current and future days.

Additionally, the present invention may also be configured for an application in which the harvest condition output profile 182 provides assistance with the decision to apply a desiccant to affect a desired harvest window. The harvest advisory tool 200 uses this output of the harvest advisory model 100 in one or more approaches. In one such approach, the present invention collects data on temporal windows of mature growth stages, and desiccant efficacy and harvestability for a particular desiccant for particular crop at a particular location over some recent period of time. It then compares crop growth stage, desiccant, and harvestability data against at least one of time-varying weather data and outputs of models for simulating plant wetness and seed moisture characteristics in the crop.
in order to identify relationships between these external data and the reported crop growth stage, desiccant, and harvestability data. The present invention then provides, based on these identified relationships and the at least one of time-varying weather forecast data and forecast outputs of models for simulating plant wetness and seed moisture characteristics, a forecast of the likely windows of desiccant efficacy, and subsequently the crop moisture, on the current and future days.

In another approach, the harvest advisory model 100 collects data on temporal windows of mature growth stages, desiccant efficacy, and harvestability for a particular desiccant for a particular crop at a particular location over some recent period of time, and compares crop growth stage, desiccant, and harvestability data against at least one of time-varying weather data and outputs of models for simulating plant wetness and seed moisture characteristics in the crop in order to develop artificial intelligence models relating these external data and the reported crop growth stage, desiccant, and harvestability data. The harvest advisory tool 200 then provides, using the artificial intelligence model and at least one of time-varying weather forecast data and forecast outputs of models for simulating plant wetness and seed moisture characteristics, a forecast of the likely windows of desiccant efficacy, and subsequently the crop moisture, on the current and future days.

The execution of the harvest advisory model 100 prior to, during, or following harvest activities, addresses multiple factors that can be used by farmers to improve and enhance management of harvest operations. The harvest advisory tool 200 provides farmers with many different types of harvest-related information, such as evaluations, predictions, forecast, and diagnoses of harvest conditions 270. As noted above, this harvest-related information may include estimates of standing crop dry-down rates, anticipated harvest dates and suitability, fuel consumption optimizers for forced-air drying, indicators of plant 'toughness' for anticipating harvest windows, and possible loss of field workability due to the formation of frost in the soils prior to post-harvest tillage.

One specific example of such harvest-related information include predictions of expected in-field, pre-harvest dry-down 183 of a mature small grain, coarse grain, oilseed crop, ears of a corn plant, or an entire corn plant over time, so that users 300 can plan the timing of a harvest operation. Another example is a
prediction of time-varying unit costs associated with at least one of fuel-based or forced-air mechanical drying 184 of grain or plant matter resulting from changing weather conditions and characteristics of the grain or plant matter drying facility, for post-harvest crop storage. Yet another example is an assessment of expected costs of forced-air or fuel-based mechanical drying of a crop owing to early harvest relative to the potential costs of crop losses due to adverse weather conditions and the susceptibility of the in-field crop to weather and other causes of yield loss. Still another example is a diagnosis and prediction of soil temperature and moisture profiles in a given field, to provide guidance as to when soils in that field are likely to become exceedingly wet or frozen, thereby inhibiting harvest and post-harvest tillage operations. A further example is a diagnosis and prediction of the impacts of a time-varying soil temperature profile in a given field as it pertains to the internal temperature of root-based crops and their long-term storage stability at those temperatures, thereby aiding in the timing of harvest operations so as to optimize storage conditions. Still a further example is prediction of harvest opportunity windows 184, such as the daily window of harvest opportunity due to the impact of plant wetness on crop threshability or choppability, and the timing or windows of opportunity of cutting, windrowing, silageing, or bailing operations with regard to dry-down of hay (alfalfa et al.) cutting over time. Additional examples involve a determination of whether to apply a desiccant 186 to affect a desired harvest window, and a determination of field workability loss 187.

The harvest advisory tool 200 contemplates that output data 180 may be generated for visual representation of the information contained, for example on a graphical user interface. With the harvest advisory tool 200, users may be able to configure settings for, and view various aspects of, the harvest advisory model 100 using a display on such graphical user interfaces, and/or via web-based or application-based modules. Tools and pull-down menus on such a display (or in web-based or application-based modules) may also be provided to customize the type and nature of the input data 102 applied to the various modeling paradigms of the harvest advisory model 100, as well as the output data 180 provided in the harvest condition output profile 182. Examples of this include the tactile and/or haptic notifications of changes in the harvest conditions discussed herein. Other types of notifications may include those provided via applications resident on mobile telephony, tablet, or wearable devices are also possible, such as for example a voice-based output generated to verbally notify farmers of possible disease or pest
risk.

As noted above, the output data 180 of the harvest advisory model 100 may be used to generate a plurality of advisory services 190 in one or more application programming interface (API) modules 176. These advisory services 190 provide enhanced decision-making support to harvest operations in precision agricultural production.

These advisory services 190 are driven by the generation of the harvest condition output profile 182 that results in the harvest action reporting and harvest summary reporting aspects of the output data 180. Each of these advisory services 190 enriches the utilization and application of the augmented crop growth model 100.

One such advisory service 190 is a current and historical weather reporting service 192. Site-specific weather information is an important element of field recordkeeping in agricultural production. Using the field geo-positional information provided for the harvest advisory modeling, current and historical weather for the field location may be provided as an advisory service for specific geographical locations.

A soil modeling service 194 is another advisory service 190 contemplated within the scope of the present invention. One API module 176 applies the harvest condition output profile 182 and output data 180 to a sophisticated soil model to generate information that provides a better understanding of current and future soil conditions relative to historical soil conditions at harvest times. Such a soil model supports the use of existing soil properties e.g., organic matter, soil type, etc., tillage practices, presence of tile drainage, and irrigation history, along with the advanced short-, medium-, or long-range weather forecasting. This coupling of modeled soil characteristics with advanced weather forecasting information at harvest times provides a valuable tool for indicating crop potential. The output of an API module 176 generating this soil modeling service 194 may be further configured to provide a detailed past-through-future analysis of soil characteristics impacting harvest conditions, such as soil temperature and moisture assessments, including freeze and thaw information, the amount of water 'throughput', runoff or ponding of soils, and an important interpretation of workability of the soils.

Another advisory service 190 is soil conditions forecasting service 196. The
soil modeling service 194 can be used with prediction of expected weather conditions to provide an estimate of future soil conditions at harvest times in this advisory service 190. Using the weather and location specifications 110, a forecast of soil temperature and moisture conditions for the specified field location can generated. Such a forecast in this service 196 enables anticipation of periods of suitable soil conditions for field operations, including workability, particularly those after periods of rainfall.

Another advisory service 190 as an output 180 of the harvest advisory model 100 is a harvest alerts service 198. The importance of information provided to production agriculture in the present invention dictates a necessity for an effective and direct method of conveying information. The harvest alerts service 198 may utilize a ‘push’ technology for immediate and direct dissemination of information provided as output data 180 from the harvest advisory model 100. The API module 176 that generates this service may be configured to so that as the time for conducting a harvest operation nears, users may receive alerts of important combinations of weather conditions, risk factors, and decision-support aides for the purposes of managing and timing harvest operations. This is supported by user-specified elements including alert parameters, location(s), lead time(s), time(s) of day, and the particular device(s) to receive the alerts. For example, a custom harvesting operation may integrate their work orders with such an alerting system in order to optimize the logistics of their operation by avoiding costly weather-related delays to harvest operations, through either spatial or temporal reassignment of equipment and related resources.

As noted above, the present invention may in one embodiment is configured to diagnosis and prediction of the impacts of a time-varying soil temperature profile in a given field as it pertains to the internal temperature of root-based crops and their long-term storage stability at those temperatures. Such a model aids in the timing of harvest operations so as to optimize crop storage conditions.

Such an embodiment is performed in a system and method of evaluating a timing of harvest operations and crop storage conditions, comprising in which a profile of long-term storability of an agricultural commodity is developed with a harvest advisory model. The harvest advisory model in this embodiment predicts expected weather conditions relative to a timing of harvest operations and crop storage conditions by applying weather information including recent and current
field-level weather data and extended-range weather forecast data, and field-specific information including location data representing a field where an agricultural commodity is planted to one or more predictive numerical weather models. The harvest advisory model forecasts harvestability windows over a specified period of time and crop stability for long-term storage, by simulating the expected weather conditions, crop-specific information for an agricultural commodity to be harvested, and the field-specific information in an agricultural model of one or more physical and empirical characteristics of crop moisture and crop temperature for harvestability of crops at corresponding times and locations. The agricultural model comprises at least one of a crop-specific growing degree day model, a soil model, a land surface model. Also, an artificial intelligence model may be developed to simulate crop storage characteristics from the expected weather conditions, one or more sampled observations from a planted field, and crop storage facility data by building a comprehensive dataset for the agricultural model of one or more physical and empirical characteristics of crop moisture and crop temperature for harvestability of crops at corresponding times and locations.

The systems and methods of the present invention may be implemented in many different computing environments. For example, they may be implemented in conjunction with a special purpose computer, a programmed microprocessor or microcontroller and peripheral integrated circuit element(s), an ASIC or other integrated circuit, a digital signal processor, electronic or logic circuitry such as discrete element circuit, a programmable logic device or gate array such as a PLD, PLA, FPGA, PAL, and any comparable means. In general, any means of implementing the methodology illustrated herein can be used to implement the various aspects of the present invention. Exemplary hardware that can be used for the present invention includes computers, handheld devices, telephones (e.g., cellular, Internet enabled, digital, analog, hybrids, and others), and other such hardware. Some of these devices include processors (e.g., a single or multiple microprocessors), memory, nonvolatile storage, input devices, and output devices. Furthermore, alternative software implementations including, but not limited to, distributed processing, parallel processing, or virtual machine processing can also be configured to perform the methods described herein.

The systems and methods of the present invention may also be partially implemented in software that can be stored on a storage medium, executed on programmed general-purpose computer with the cooperation of a controller and
memory, a special purpose computer, a microprocessor, or the like. In these instances, the systems and methods of this invention can be implemented as a program embedded on a mobile device or personal computer through such mediums as an applet, JAVA.RTM or CGI script, as a resource residing on one or more servers or computer workstations, as a routine embedded in a dedicated measurement system, system component, or the like. The system can also be implemented by physically incorporating the system and/or method into a software and/or hardware system.

Additionally, the data processing functions disclosed herein may be performed by one or more program instructions stored in or executed by such memory, either transitory or non-transitory, and further may be performed by one or more modules configured to carry out those program instructions. Modules are intended to refer to any known or later developed hardware, software, firmware, artificial intelligence, fuzzy logic, expert system or combination of hardware and software that is capable of performing the data processing functionality described herein.

The foregoing descriptions of embodiments of the present invention have been presented for the purposes of illustration and description. It is not intended to be exhaustive or to limit the invention to the precise forms disclosed. Accordingly, many alterations, modifications and variations are possible in light of the above teachings, may be made by those having ordinary skill in the art without departing from the spirit and scope of the invention. It is therefore intended that the scope of the invention be limited not by this detailed description. For example, notwithstanding the fact that the elements of a claim are set forth below in a certain combination, it must be expressly understood that the invention includes other combinations of fewer, more or different elements, which are disclosed in above even when not initially claimed in such combinations.

The words used in this specification to describe the invention and its various embodiments are to be understood not only in the sense of their commonly defined meanings, but to include by special definition in this specification structure, material or acts beyond the scope of the commonly defined meanings. Thus if an element can be understood in the context of this specification as including more than one meaning, then its use in a claim must be understood as being generic to all possible meanings supported by the specification and by the word itself.
The definitions of the words or elements of the following claims are, therefore, defined in this specification to include not only the combination of elements which are literally set forth, but all equivalent structure, material or acts for performing substantially the same function in substantially the same way to obtain substantially the same result. In this sense it is therefore contemplated that an equivalent substitution of two or more elements may be made for any one of the elements in the claims below or that a single element may be substituted for two or more elements in a claim. Although elements may be described above as acting in certain combinations and even initially claimed as such, it is to be expressly understood that one or more elements from a claimed combination can in some cases be excised from the combination and that the claimed combination may be directed to a sub-combination or variation of a sub-combination.

Insubstantial changes from the claimed subject matter as viewed by a person with ordinary skill in the art, now known or later devised, are expressly contemplated as being equivalently within the scope of the claims. Therefore, obvious substitutions now or later known to one with ordinary skill in the art are defined to be within the scope of the defined elements.

The claims are thus to be understood to include what is specifically illustrated and described above, what is conceptually equivalent, what can be obviously substituted and also what essentially incorporates the essential idea of the invention.
IN THE CLAIMS:

1. A method comprising:

   ingesting, as input data, weather information and crop-specific information for an agricultural commodity to be harvested, the weather information including at least one of current field-level weather data and extended-range weather data, and the crop-specific information including crop type data, planting data, and targeted livestock feedstuff data that includes storage characteristics for the targeted livestock feedstuff;

   modeling the input data in a plurality of data processing modules within a computing environment in which the plurality of data processing modules are executed in conjunction with, and performed on, at least one computer processor, the data processing modules configured to profile crop growth for the agricultural commodity, by

   1) predicting expected weather conditions at a specific location impacting moisture content of the agricultural commodity during crop growth,

   2) aggregating the expected weather conditions with the crop-specific information into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the agricultural commodity configured to simulate the moisture content of the agricultural commodity at one or more crop growth stages, and

   3) identifying differences in the simulation of the moisture content with additional data representing sampled observations at or near the specific location at corresponding times, and modifying the simulation of the moisture content on the differences between the simulated moisture content and the additional data to predict a harvest condition for producing the targeted livestock feedstuff; and

   generating, as output data, a harvest condition output profile representing the predicted harvest condition.
2. The method of claim 1, further comprising applying the harvest output condition profile to a decision support tool configured to provide one or more advisories of the predicted harvest condition to a user, wherein the predicted harvest condition represents a number of days that the agricultural commodity will be at an appropriate crop growth stage for producing the targeted livestock feedstuff at a desired moisture content for storage of the targeted livestock feedstuff according to the storage characteristics.

3. The method of claim 2, wherein the decision support tool generates an advisory of one or more temporal harvest opportunity windows for the targeted livestock feedstuff at the desired moisture content.

4. The method of claim 2, wherein the decision support tool generates a risk advisory of a risk from harvesting targeted livestock feedstuff at a moisture content that exceeds the desired moisture content, the risk advisory including one or more of damage to a storage structure, loss of feedstuff nutrient levels due to runoff and seepage in the storage structure, and water supply contamination.

5. The method of claim 2, wherein the decision support tool generates a risk advisory of a risk from harvesting targeted livestock feedstuff at a lesser moisture content than the desired moisture content, the risk advisory including one or more of a packing factor, a digestability, and a sugar content of the targeted livestock feedstuff.

6. The method of claim 1, wherein the defined storage characteristics include information for maintaining the targeted livestock feedstuff in different post-harvest storage structures, the different post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.

7. The method of claim 1, wherein the modeling further comprises applying the weather information to one or more predictive numerical weather models to generate the prediction of expected weather conditions.

8. The method of claim 1, further comprising ingesting the additional data representing sampled observations at or near the specific location at corresponding times, the additional data including physical, empirical or observed agricultural information, wherein the physical, empirical or observed agricultural information and field and soil information includes at least one of sampled crop moisture content, sampled soil temperature, sampled soil moisture content, and current
and/or forecasted soil conditions.

9. The method of claim 1, wherein the agricultural model of one or more physical and empirical characteristics impacting harvest operations of the agricultural commodity includes at least one of a crop-specific growth model, a soil model, and a land surface model.

10. The method of claim 1, further comprising applying the expected weather conditions and the additional data representing sampled observations at or near the specific location at corresponding times to automatically develop an artificial intelligence model configured to analyze a specific harvest condition model by building a comprehensive harvest condition dataset for the agricultural model of one or more physical and empirical characteristics impacting harvest operations of the agricultural commodity, and applying the artificial intelligence model to predict the harvest condition to produce the targeted livestock feedstuff.

11. The method of claim 1, wherein the targeted livestock feedstuff is a bovine feedstuff includes one or more of corn silage, corn earlage, corn snaplage, and high-moisture corn.

12. A system comprising:

a computing environment including at least one computer-readable storage medium having program instructions stored therein and a computer processor operable to execute the program instructions to profile crop growth for an agricultural commodity in a harvest advisory model within a plurality of data processing modules, the plurality of data processing modules including:

a weather modeling module configured to diagnose and predict expected weather conditions at a specific location impacting moisture content of the agricultural commodity during crop growth by applying weather information including current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

one or more modules configured to 1) aggregate the expected weather conditions with crop-specific information comprised of crop type data, planting data, and targeted livestock feedstuff data that includes storage characteristics for the targeted livestock feedstuff into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the agricultural
commodity, 2) simulate the moisture content of the agricultural commodity at one or more crop growth stages, and 3) compare additional data representing sampled one or more observations of actual moisture content at or near the specific location at corresponding times with the simulation of the moisture content to modify the simulation based on identified differences between the otherwise simulated moisture content and the one or more sampled observations of actual moisture content; and

a harvest condition prediction module configured to predict a harvest condition for producing the targeted livestock feedstuff in a harvest output condition profile for planning a timing of harvest operations and storage of the harvested livestock feedstuff.

13. The system of claim 12, wherein the predicted harvest condition includes a number of days that the agricultural commodity will be at an appropriate crop growth stage for producing the targeted livestock feedstuff at a desired moisture content for storage of the targeted livestock feedstuff according to the storage characteristics.

14. The system of claim 13, wherein the harvest output condition profile is applied to a diagnostic support tool configured to provide one or more advisories to a user.

15. The system of claim 14, wherein the decision support tool generates an advisory of one or more temporal harvest opportunity windows for the targeted livestock feedstuff at the desired moisture content.

16. The system of claim 14, wherein the decision support tool generates a risk advisory of a risk from harvesting livestock bovine feedstuff at a moisture content that exceeds the desired moisture content, the risk advisory including one or more of damage to a storage structure, loss of feedstuff nutrient levels due to runoff and seepage in the storage structure, and water supply contamination.

17. The system of claim 14, wherein the decision support tool generates a risk advisory of a risk from harvesting targeted livestock feedstuff at a lesser moisture content than the desired moisture content, the risk advisory including one or more of a packing factor, a digestability, and a sugar content of the targeted livestock feedstuff.
18. The system of claim 12, wherein the defined storage characteristics include information for maintaining the targeted livestock feedstuff in different post-harvest storage structures, the different post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.

19. The system of claim 8, wherein the additional data representing sampled observations at or near the specific location at corresponding times includes physical, empirical or observed agricultural information and field and soil information, wherein the physical, empirical or observed agricultural information and field and soil information includes at least one of sampled crop moisture content, sampled soil temperature, sampled soil moisture content, and current and/or forecasted soil conditions.

20. The method of claim 12, wherein the targeted livestock feedstuff is a bovine feedstuff that includes one or more of corn silage, corn earlage, corn snaplage, and high-moisture corn.

21. A method of evaluating agricultural conditions to support harvest operations and storage of livestock feedstuff, comprising:

within a computing environment comprised of a computer processor and at least one computer-readable storage medium operably coupled to the computer processor and having program instructions stored therein, the computer processor being operable to execute the program instructions to profile crop growth of an agricultural commodity to be harvested in a harvest advisory model configured to perform the steps of:

forecasting weather conditions impacting moisture content of the agricultural commodity during crop growth in a specific location, by applying weather information comprised of current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

simulating the moisture content of the agricultural commodity at one or more crop growth stages by applying the forecasted weather conditions and crop-specific information comprised of crop type data, planting data, and targeted livestock feedstuff data that includes storage characteristics for a targeted livestock feedstuff to an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the agricultural commodity, the agricultural model comprising at least one of a crop-specific growth model, a soil model, and a land
surface model; and

adjusting the simulation of the moisture content of the agricultural commodity at one or more crop growth stages using at least one of 1) differences between the simulated moisture content and additional data representing sampled observations of actual moisture content at or near the specific location at corresponding times, and 2) one or more artificial intelligence models automatically developed to analyze the moisture content of the agricultural commodity at one or more crop growth stages from a comprehensive harvest condition dataset for the agricultural model of the one or more physical and empirical characteristics impacting harvest operations of the agricultural commodity,

to generate a prediction of the number of days that the agricultural commodity will be at an appropriate crop growth stage for producing the targeted livestock feedstuff at a desired moisture content for storage of the targeted livestock feedstuff according to the storage characteristics.

22. The method of claim 21, further comprising generating a harvest output condition profile representing the prediction, and applying the harvest output condition profile to a diagnostic support tool configured to provide one or more advisories based on the prediction to a user performing harvest operations.

23. The method of claim 22, wherein the decision support tool generates an advisory of one or more temporal harvest opportunity windows for the targeted livestock feedstuff at the desired moisture content.

24. The method of claim 22, wherein the decision support tool generates a risk advisory of a risk from harvesting targeted livestock feedstuff at a moisture content that exceeds the desired moisture content, the risk advisory including one or more of damage to a storage structure, loss of feedstuff nutrient levels due to runoff and seepage in the storage structure, and water supply contamination.

25. The method of claim 22, wherein the decision support tool generates a risk advisory of a risk from harvesting targeted livestock feedstuff at a lesser moisture content than the desired moisture content, the risk advisory including one or more of a packing factor, a digestability, and a sugar content of the targeted livestock feedstuff.

26. The method of claim 21, wherein the defined storage characteristics include
information for maintaining the targeted livestock feedstuff in different post-harvest storage structures, the different post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.

27. The method of claim 21, wherein the additional data representing sampled observations at or near the specific location at corresponding times is comprised of physical, empirical or observed agricultural information and field and soil information that includes at least one of sampled crop moisture content, sampled soil temperature, sampled soil moisture content, and current and/or forecasted soil conditions.

28. The method of claim 21, wherein the targeted livestock feedstuff is a bovine feedstuff includes one or more of corn silage, corn earlage, corn snaplage, and high-moisture corn.

29. A method comprising:

ingesting, as input data, weather information and crop-specific information for a corn crop to be harvested, the weather information including at least one of current field-level weather data and extended-range weather data, and the crop-specific information at least including planting data and bovine feedstuff data that includes a desired moisture content of between 55% and 70% whole plant moisture for a bovine feedstuff comprised of corn silage to be stored in one or more post-harvest storage structures, the one or more post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo;

modeling the input data in a plurality of data processing modules within a computing environment in which the plurality of data processing modules are executed in conjunction with, and performed on, at least one computer processor, the data processing modules configured to profile crop growth for a harvest of the corn silage at the desired moisture content, by

1) predicting expected weather conditions at a specific location impacting a moisture content of the corn crop during crop growth,

2) aggregating the expected weather conditions with the crop-specific information into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop configured to simulate the moisture content of the corn crop at one or more crop growth stages, and
3) identifying differences in the simulation of the moisture content with additional data representing crop growth stage observations in a planted field at or near the specific location at corresponding times, and adapting the simulation of the moisture content to the crop growth stage observations to predict a harvest condition to produce bovine feedstuff having the desired moisture content from the corn silage; and

generating, as output data, a harvest condition output profile representing the predicted harvest condition.

30. A system comprising:

a computing environment including at least one computer-readable storage medium having program instructions stored therein and a computer processor operable to execute the program instructions to profile crop growth for a harvest of corn silage at a desired moisture content in a harvest advisory model within a plurality of data processing modules, the plurality of data processing modules including:

a weather modeling module configured to diagnose and predict expected weather conditions at a specific location impacting a moisture content of a corn crop during crop growth by applying weather information including current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

one or more modules configured to 1) aggregate the expected weather conditions with crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 55% and 70% whole plant moisture for a bovine feedstuff composed of the corn silage to be stored in one or more post-harvest storage structures, into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, 2) simulate the moisture content of the corn crop at one or more crop growth stages, and 3) compare additional data representing moisture content from one or more crop growth stage observations in a planted field at or near the specific location at corresponding times with the simulation of the moisture content to adapt the simulation to the one or more crop growth stage observations; and

a harvest condition prediction module configured to predict one or more harvest opportunity windows to produce bovine feedstuff having the desired moisture content
content from the corn silage in a harvest output condition profile for planning a timing of harvest operations and storage of the corn silage.

31. A method of evaluating agricultural conditions to support harvest operations and storage of a bovine feedstuff, comprising:

within a computing environment comprised of a computer processor and at least one computer-readable storage medium operably coupled to the computer processor and having program instructions stored therein, the computer processor being operable to execute the program instructions to profile crop growth for a harvest of corn silage at a desired moisture content in a harvest advisory model configured to perform the steps of:

forecasting weather conditions impacting moisture content during crop growth of a corn crop to be harvested in a specific location, by applying weather information comprised of current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

simulating the moisture content of the corn crop at one or more crop growth stages by applying the forecasted weather conditions and crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 55% and 70% whole plant moisture for a bovine feedstuff comprised of corn silage to be stored in one or more post-harvest storage structures, to an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, the agricultural model comprising at least one of a crop-specific growth model, a soil model, and a land surface model; and

associating the simulated moisture content with plant moisture from one or more crop growth stage observations using at least one of 1) differences between the simulated moisture content and additional data representing the plant moisture from the one or more crop growth stage observations in a planted field at or near the specific location at corresponding times, and 2) one or more artificial intelligence models automatically developed to analyze the moisture content of the corn crop at one or more crop growth stages from a comprehensive harvest condition dataset for the agricultural model of the one or more physical and empirical characteristics impacting harvest operations of the corn crop, to generate a prediction of one or more harvest opportunity windows to achieve the
desired moisture content of the corn silage for storage in one or more of an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.

32. A method comprising:

ingesting, as input data, weather information and crop-specific information for a corn crop to be harvested, the weather information including at least one of current field-level weather data and extended-range weather data, and the crop-specific information at least including planting data and bovine feedstuff data that includes a desired moisture content of between 26% and 40% whole plant moisture for a bovine feedstuff comprised of corn earlage to be stored in one or more post-harvest storage structures, the one or more post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo;

modeling the input data in a plurality of data processing modules within a computing environment in which the plurality of data processing modules are executed in conjunction with, and performed on, at least one computer processor, the data processing modules configured to profile crop growth for a harvest of the corn earlage at the desired moisture content, by

1) predicting expected weather conditions at a specific location impacting a moisture content of the corn crop during crop growth,

2) aggregating the expected weather conditions with the crop-specific information into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop configured to simulate the moisture content of the corn crop at one or more crop growth stages, and

3) identifying differences in the simulation of the moisture content with additional data representing crop growth stage observations in a planted field at or near the specific location at corresponding times, and adapting the simulation of the moisture content to the crop growth stage observations to predict a harvest condition to produce bovine feedstuff having the desired moisture content from the corn earlage; and

generating, as output data, a harvest condition output profile representing the predicted harvest condition.

33. A system comprising:
a computing environment including at least one computer-readable storage medium having program instructions stored therein and a computer processor operable to execute the program instructions to profile crop growth for a harvest of corn earlage at a desired moisture content in a harvest advisory model within a plurality of data processing modules, the plurality of data processing modules including:

a weather modeling module configured to diagnose and predict expected weather conditions at a specific location impacting a moisture content of a corn crop during crop growth by applying weather information including current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

one or more modules configured to 1) aggregate the expected weather conditions with crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 26% and 40% whole plant moisture for a bovine feedstuff composed of the corn earlage to be stored in one or more post-harvest storage structures, into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, 2) simulate the moisture content of the corn crop at one or more crop growth stages, and 3) compare additional data representing moisture content from one or more crop growth observations in a planted field at or near the specific location at corresponding times with the simulation of the moisture content to adapt the simulation to the one or more crop growth stage observations; and

a harvest condition prediction module configured to predict one or more harvest opportunity windows to produce bovine feedstuff having the desired moisture content from the corn earlage in a harvest output condition profile for planning a timing of harvest operations and storage of the corn earlage.

34. A method of evaluating agricultural conditions to support harvest operations and storage of a bovine feedstuff, comprising:

within a computing environment comprised of a computer processor and at least one computer-readable storage medium operably coupled to the computer processor and having program instructions stored therein, the computer processor being operable to execute the program instructions to profile crop growth for a harvest of corn earlage at a desired moisture content in a harvest advisory model
configured to perform the steps of:

forecasting weather conditions impacting moisture content during crop growth of a corn crop to be harvested in a specific location, by applying weather information comprised of current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

simulating the moisture content of the corn crop at one or more crop growth stages by applying the forecasted weather conditions and crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 26% and 40% of whole plant moisture for a bovine feedstuff comprised of corn earlage to be stored in one or more post-harvest storage structures, to an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, the agricultural model comprising at least one of a crop-specific growth model, a soil model, and a land surface model; and

associating the simulated moisture content with plant moisture from one or more crop growth stage observations using at least one of 1) differences between the simulated moisture content and additional data representing the plant moisture from the one or more crop growth stage observations in a planted field at or near the specific location at corresponding times, and 2) one or more artificial intelligence models automatically developed to analyze the moisture content of the corn crop at one or more crop growth stages from a comprehensive harvest condition dataset for the agricultural model of the one or more physical and empirical characteristics impacting harvest operations of the corn crop,

to generate a prediction of one or more harvest opportunity windows to achieve the desired moisture content of the corn earlage for storage in one or more of an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.

35. A method comprising:

ingesting, as input data, weather information and crop-specific information for a corn crop to be harvested, the weather information including at least one of current field-level weather data and extended-range weather data, and the crop-specific information at least including planting data and bovine feedstuff data that includes a desired moisture content of between 25% and 35% moisture for a bovine feedstuff comprised of high-moisture corn to be stored in one or more post-harvest storage
structures, the one or more post-harvest storage structures including an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo;

modeling the input data in a plurality of data processing modules within a computing environment in which the plurality of data processing modules are executed in conjunction with, and performed on, at least one computer processor, the data processing modules configured to profile crop growth for a harvest of the high-moisture corn at the desired moisture content, by

1) predicting expected weather conditions at a specific location impacting a moisture content of the corn crop during crop growth,

2) aggregating the expected weather conditions with the crop-specific information into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop configured to simulate the moisture content of the corn crop at one or more crop growth stages, and

3) identifying differences in the simulation of the moisture content with additional data representing sampled observations at or near the specific location at corresponding times, and modifying the simulation of the moisture content on the differences between the simulated moisture content and the additional data to predict a harvest condition to produce bovine feedstuff having the desired moisture content from the high-moisture corn; and

generating, as output data, a harvest condition output profile representing the predicted harvest condition.

36. A system comprising:

a computing environment including at least one computer-readable storage medium having program instructions stored therein and a computer processor operable to execute the program instructions to profile crop growth for a harvest of high-moisture corn at a desired moisture content in a harvest advisory model within a plurality of data processing modules, the plurality of data processing modules including:

a weather modeling module configured to diagnose and predict expected weather conditions at a specific location impacting a moisture content of a corn crop during
crop growth by applying weather information including current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

one or more modules configured to 1) aggregate the expected weather conditions with crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 24% and 35% moisture for a bovine feedstuff composed of the high-moisture corn to be stored in one or more post-harvest storage structures, into an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, 2) simulate the moisture content of the corn crop at one or more crop growth stages, and 3) compare additional data representing sampled one or more observations of actual moisture content at or near the specific location at corresponding times with the simulation of the moisture content to modify the simulation based on identified differences between the otherwise simulated moisture content and the one or more sampled observations of actual moisture content; and

a harvest condition prediction module configured to predict one or more harvest opportunity windows to produce bovine feedstuff having the desired moisture content from the high-moisture corn in a harvest output condition profile for planning a timing of harvest operations and storage of the high-moisture corn.

37. A method of evaluating agricultural conditions to support harvest operations and storage of a bovine feedstuff, comprising:

within a computing environment comprised of a computer processor and at least one computer-readable storage medium operably coupled to the computer processor and having program instructions stored therein, the computer processor being operable to execute the program instructions to profile crop growth for a harvest of high-moisture corn at a desired moisture content in a harvest advisory model configured to perform the steps of:

forecasting weather conditions impacting moisture content during crop growth of a corn crop to be harvested in a specific location, by applying weather information comprised of current field-level weather data and extended-range weather data to one or more predictive numerical weather models;

simulating the moisture content of the corn crop at one or more crop growth stages
by applying the forecasted weather conditions and crop-specific information comprised at least of planting data and bovine feedstuff data that includes a desired moisture content of between 24% and 35% moisture for a bovine feedstuff comprised of high-moisture corn to be stored in one or more post-harvest storage structures, to an agricultural model of one or more physical and empirical characteristics impacting harvest operations of the corn crop, the agricultural model comprising at least one of a crop-specific growth model, a soil model, and a land surface model; and

adjusting the simulation of the moisture content of the corn crop at one or more crop growth stages using at least one of 1) differences between the simulated moisture content and additional data representing sampled observations of actual moisture content at or near the specific location at corresponding times, and 2) one or more artificial intelligence models automatically developed to analyze the moisture content of the corn crop at one or more crop growth stages from a comprehensive harvest condition dataset for the agricultural model of the one or more physical and empirical characteristics impacting harvest operations of the corn crop,

to generate a prediction of one or more harvest opportunity windows to achieve the desired moisture content of the high-moisture corn for storage in one or more of an upright tower silo, a bunker silo, a bag silo, and an oxygen-limiting silo.
INTERNATIONAL SEARCH REPORT

A. CLASSIFICATION OF SUBJECT MATTER

IPC (2016.01) G06F 19/00, G06F 15/18, G06Q 10/06, G06Q 50/02

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC (2016.01) G06F 19/00, G06F 15/18, G06Q 10/06, G06Q 50/02

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

Databases consulted: Esp@cenet, Google Patents, FamPat database

C. DOCUMENTS CONSIDERED TO BE RELEVANT

<table>
<thead>
<tr>
<th>Category*</th>
<th>Citation of document, with indication, where appropriate, of the relevant passages</th>
<th>Relevant to claim No.</th>
</tr>
</thead>
</table>

Further documents are listed in the continuation of Box C. See patent family annex.

* Special categories of cited documents:
  "A" document defining the general state of the art which is not considered to be of particular relevance
  "E" earlier application or patent but published on or after the international filing date
  "L" document which may throw doubts on priority claim(s) or which is \( \neq \) to establish the publication date of another citation or of a subsequent invention
  "O" document referring to an oral disclosure, use, exhibition or other means
  "P" document published prior to the international filing date but later than the priority date claimed

"I" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art

"&" document member of the same patent family

Date of the actual completion of the international search 05 May 2016

Date of mailing of the international search report 08 May 2016
