Abstract

The invention relates to a method for diagnosing a kidney disease state. The method comprises the steps of administering to a patient a composition comprising a conjugate or complex of the general formula V-L-D where the group V comprises a vitamin receptor binding ligand that binds to kidney proximal tubule cells and the group D comprises a diagnostic marker, and diagnosing the kidney disease state. The invention also relates to a method for treating a kidney disease state. The method comprises the steps of administering to a patient suffering from the disease state an effective amount of a composition comprising a conjugate or complex of the general formula V-L-D where the group V comprises a vitamin receptor binding ligand that binds to kidney proximal tubule cells and the group D comprises an antigen, a cytotoxin, or a cell growth inhibitor, and eliminating the disease state.

CROSS REFERENCE TO RELATED APPLICATIONS

[0001] This application claims priority to U.S. Provisional Patent Application Ser. No. 60/901,778, filed on Feb. 16, 2007, the entire disclosure of which is hereby incorporated by reference.

FIELD OF THE INVENTION

[0002] This invention relates to methods and compositions for treating and diagnosing kidney disease states. More particularly, ligands that bind to receptors overexpressed on proximal tubule cells are complexed with a diagnostic marker for use in diagnosis or to an antigen, a cytotoxin, or a cell growth inhibitor for use in the treatment of kidney disease states.

BACKGROUND

[0003] Diseases affecting kidney function are prevalent. For example, polycystic kidney disease (PKD) is a prevalent inherited disease. Adult PKD is an autosomal dominant disorder affecting approximately 600,000 people in the United States and 12.5 million worldwide. Infants can also present with autosomal recessive PKD which is rapidly developing and which can lead to renal insufficiency in the neonate. PKD and other kidney disease states (e.g., Dent’s disease and nephrocytosis) affect and manifest abnormal growth of kidney proximal tubule cells. PKD results in the proliferation of kidney epithelial cells and the formation of PKD renal cysts. The kidneys can become enlarged and symptoms including pain, bleeding, and kidney stones can occur. Associated problems include liver cysts, abdominal aneurysm, intracranial aneurysm, and renal insufficiency. It has been suggested that cellular processes associated with signal transduction, transcriptional regulation, and cell-cycle control are involved in cyst formation in PKD.

[0004] The folate receptor is a 38 KD GPI-anchored protein that binds the vitamin folic acid with high affinity (<1 nM). Following receptor binding, rapid endocytosis delivers a substantial fraction of the vitamins into the cell, where they are unloaded in an endosomal compartment at low pH. Importantly, covalent conjugation of small molecules, proteins, and even liposomes to folic acid does not block the vitamin’s ability to bind the folate receptor, and therefore, folate-drug conjugates can readily be delivered to and can enter cells by receptor-mediated endocytosis. Because most cells use an unrelated reduced folate carrier to acquire the necessary folic acid, expression of the folate receptor is restricted to a few cell types, and normal tissues typically express low or nondetectable levels of the folate receptor. Folate receptors are overexpressed in proximal tubule cells.

[0005] The invention is based on the manifestation of abnormal proliferation of kidney proximal tubule cells in PKD and other kidney disease states that exhibit abnormal proximal tubule cell proliferation. These kidney disease states can be treated with ligands that bind to receptors overexpressed on proximal tubule cells wherein the ligands are complexed with an antigen, a cytotoxin, or a cell growth inhibitor for use in the treatment of the kidney disease states. These kidney disease states, including PKD, can also be diagnosed by using ligands that bind to receptors overexpressed on proximal tubule cells wherein the ligands are complexed with a diagnostic marker.

SUMMARY

[0006] In one embodiment, a method for diagnosing a kidney disease state is provided. The method comprises the steps of administering to a patient a composition comprising a conjugate or complex of the general formula V-L-D, where the group V comprises a vitamin receptor binding ligand that binds to kidney cells and the group D comprises a diagnostic marker, and diagnosing the kidney disease state.

[0007] In another embodiment, V comprises a folate receptor binding ligand or V comprises a folate receptor binding antibody or antibody fragment. In yet another embodiment, the marker can comprise a metal chelating moiety, or a fluorescent chromophore. In another illustrative embodiment, the disease state is selected from the group consisting of polycystic kidney disease, Dent’s disease, nephrocytosis, and Heymann nephritis.

[0008] In another embodiment, a method for treating a kidney disease state is provided. The method comprises the steps of administering to a patient suffering from the disease state an effective amount of a composition comprising a conjugate or complex of the general formula V-L-D wherein the group V comprises a vitamin receptor binding ligand that binds to kidney cells and the group D comprises an antigen, a cytotoxin, or a cell growth inhibitor, and eliminating the disease state.

[0009] In another embodiment, V comprises a folate receptor binding ligand or an antibody or antibody fragment that binds to the folate receptor. In another illustrative aspect, group D comprises an antigen, a cytotoxin, or a cell growth inhibitor. In yet another embodiment, the cell growth inhibitor is selected from the group consisting of epidermal growth factor receptor kinase inhibitors, inhibitors of the mTOR pathway, DNA alkylators, microtubule inhibitors, cell cycle inhibitors, and protein synthesis inhibitors. In another embodiment, the disease state is selected from the group consisting of polycystic kidney disease, Dent’s disease, nephrocytosis, and Heymann nephritis.

BRIEF DESCRIPTION OF THE DRAWINGS

[0010] FIG. 1 shows HIC analysis of folate receptor expression in polycystic kidney disease tissues using a monoclonal antibody directed to the folate receptor for staining. The upper left panel shows normal human kidney tissue and the remainder of the panels show staining of cysts in polycystic kidney disease tissues using the anti-folate receptor monoclonal antibody.

[0011] FIG. 2 shows HIC analysis of folate receptor expression in polycystic kidney disease tissues using a polyclonal antibody directed to the folate receptor for staining. The upper left panel shows normal mouse kidney tissue and the remainder of the panels show staining of cysts in polycystic kidney disease tissues using the anti-folate receptor polyclonal antibody.

[0012] FIG. 3 shows the structure of EC0371, a folate-rapamycin conjugate.

[0013] FIG. 4 shows an affinity assay comparing the relative affinities of folic acid (circles; 1.0) and EC0371 (triangles; 0.5) for the folate receptor.
FIG. 5 shows the effect of rapamycin and EC0371 on the viability of KB cells at various free rapamycin and conjugated rapamycin (EC0371) concentrations. The leftmost panels show untreated cells. The panels in the second column from the left show control cells treated with DMSO (diluent). The panels in the third column from the left show cells treated with 2, 10, or 50 nM rapamycin. The panels in the rightmost column show cells treated with 2, 10, or 50 nM EC0371. Neither rapamycin nor EC0371 is cytoxic after 24 hours of treatment.

FIG. 6 shows the effects of rapamycin and EC0371 on P-S6 immunostaining in KB cells after 16 hours of incubation with rapamycin or EC0371. P-S6 is a phosphorylation target of m-TOR and the antibody used is phospho-specific. The leftmost panels show untreated cells. The panels in the middle column show cells treated with 2, 10, or 50 nM rapamycin. The panels in the rightmost column show cells treated with 2, 10, or 50 nM EC0371. Rapamycin and EC0371 inhibit P-S6 immunostaining (i.e., phosphorylation of P-S6 through the m-TOR pathway).

FIG. 7 shows an immunoblot using a phospho-specific antibody. The left panel shows phosphorylation of ribosomal S6 and S-6 kinase (T389) in untreated cells and cells treated with DMSO (diluent). The right panel shows that rapamycin (2, 10, and 50 nM) and EC0371 (folute-rapamycin; 2, 10, and 50 nM) abolish or greatly reduce phosphorylation of ribosomal S6 and S-6 kinase (T389) which are phosphorylation targets in the m-TOR pathway.

FIG. 8 shows the therapeutic effect of EC0371 on the in vivo development of polycystic kidney disease in the bpk-mutant mouse model. The leftmost kidney is from a wildtype mouse. The middle kidney is from a bpk mutant mouse not treated with EC0371. The rightmost kidney is from a bpk mutant mouse treated with EC0371 showing that EC0371 greatly reduces kidney size.

FIG. 9 shows the effect on one-kidney weight of EC0371 treatment in multiple bpk mutant mice (rightmost group of symbols). EC0371-treated bpk mice exhibit a significant decrease in one-kidney weight as a percentage of total body weight relative to untreated bpk mice.

FIG. 10 shows the effect of two-kidney weight of EC0371 treatment in multiple bpk mutant mice (rightmost group of symbols). EC0371-treated bpk mice exhibit a significant decrease in two-kidney weight as a percentage of total body weight relative to untreated bpk mice.

DETAILED DESCRIPTION

Methods are provided for treating and diagnosing kidney disease states. Exemplary disease states include PKD, Dent’s disease, nephrocytosis, Heymann nephritis, and other diseases manifested by abnormal proliferation of proximal tubule cells of the kidney. PKD’s include, but are not limited to, autosomal dominant (adult) polycystic kidney disease and autosomal recessive (childhood) polycystic kidney disease. These disease states are characterized by abnormal proliferation of kidney proximal tubule cells. Such disease states can be diagnosed by contacting kidney proximal tubule cells with a composition comprising a conjugate of the general formula V-L-D wherein the group V comprises a ligand that binds to the kidney proximal tubule cells, and the group D comprises an antigen, a cytotoxin, or a cell growth inhibitor, and eliminating the disease state.

As used herein, the terms “eliminated” and “eliminating” in reference to the disease state, mean reducing the symptoms or eliminating the symptoms of the disease state or preventing the progression or the reoccurrence of disease.

As used herein, the term “elimination” of the proximal tubule cell population causing the disease state that expresses the ligand receptor means that this cell population is killed or is completely or partially removed or inactivated which reduces the pathogenic characteristics of the disease state being treated.

The kidney disease states characterized by abnormal proliferation of proximal tubule cells can be treated in accordance with the methods disclosed herein by administering an effective amount of a composition V-L-D wherein V comprises a ligand that binds to proximal tubule cells and wherein the group D comprises an antigen, a cytotoxin, or a cell growth inhibitor. Such targeting conjugates, when administered to a patient suffering from a kidney disease state manifested by abnormal proximal tubule cell proliferation, work to concentrate and associate the conjugated cytotoxin, antigen, or cell growth inhibitor with the population of proximal tubule cells to kill the cells or alter cell function. The conjugate is typically administered parenterally, but can be delivered by any suitable method of administration (e.g., orally), as a composition comprising the conjugate and a pharmaceutically acceptable carrier therefor. Conjugate administration is typically continued until symptoms of the disease state are reduced or eliminated, or administration is continued after this time to prevent progression or reappearance of the disease.

For diagnosis the typical method of administration of the conjugates is parenteral administration, but any suitable method can be used. In this embodiment, kidney disease states can be diagnosed by administering parenterally to a patient a composition comprising a conjugate or complex of the general formula V-L-D where the group V comprises a ligand that binds to proximal tubule cells and the group D comprises a diagnostic marker, and diagnosing the disease state.

In one embodiment, for example, the diagnostic marker (e.g., a reporter molecule) can comprise a radioactively labeled compound such as a chelating moiety and an element that is a radionuclide, for example a metal cation that is a radionuclide. In another embodiment, the radionuclide is selected from the group consisting of technetium, gallium, indium, and a positron emitting radionuclide (PET imaging agent). In another embodiment, the diagnostic marker can comprise a fluorescent chromophore such as, for example, fluorescein, rhodamine, Texas Red, phycoerythrin, Oregon Green, AlexaFluor 488 (Molecular Probes, Eugene, Oreg.), Cy3, Cy5, Cy7, and the like. Imaging agents are described in U.S. Pat. No. 7,128,893 and in U.S. Patent Publ. No. 20070094343, each incorporated herein by reference.

Diagnosis typically occurs before treatment. However, in the diagnostic methods described herein, the term “diagnosis” can also mean monitoring of the disease state before, during, or after treatment to determine the progression of the disease state. The monitoring can occur before, during, or after treatment, or combinations thereof, to determine the efficacy of therapy, or to predict future episodes of disease.
The diagnostic method can be any suitable method known in the art, including imaging methods, such as intravital imaging. [0027] The method disclosed herein can be used for both human clinical medicine and veterinary applications. Thus, the patient or animal afflicted with the kidney disease state and in need of diagnosis or therapy can be a human, or in the case of veterinary applications, can be a laboratory, agricultural, domestic or wild animal. In embodiments where the conjugates are administered to the patient or animal, the conjugates can be administered parenterally to the animal or patient suffering from the kidney disease state, for example, intradermally, subcutaneously, intramuscularly, intraperitoneally, or intravenously. Alternatively, the conjugates can be administered to the animal or patient by other medically useful procedures and effective doses can be administered in standard or prolonged release dosage forms, such as a slow pump. The therapeutic method described herein can be used alone or in combination with other therapeutic methods recognized for the treatment of kidney disease states. [0028] In the ligand conjugates of the general formula V-L-D, the group V is a ligand that binds to proximal tubule cells when the conjugates are used to diagnose or treat kidney disease states. Any of a wide number of binding ligands can be employed. Acceptable ligands include, for example, folate receptor binding ligands, and analogous thereof, and antibodies or antibody fragments capable of recognizing and binding to surface moieties expressed on proximal tubule cells, in particular when these cells proliferate abnormally. In one embodiment, the binding ligand is folic acid, a folic acid analog, or another folate receptor binding molecule. In another embodiment the binding ligand is a specific monoclonal or polyclonal antibody or an Fab or an scFv (i.e., a single chain variable region) fragment of an antibody capable of binding to receptors overexpressed on proximal tubule cells, for example, when these cells proliferate abnormally. [0029] In one embodiment, the binding ligand can be folic acid, a folic acid analog, or another folate receptor-binding molecule. Analogs of folate that can be used include folinic acid, pteroylglutamic acid, and folate receptor-binding pteridines such as tetrahydropterin, dihydrofolates, tetrahydrofolates, and their deaza and deideaza analogs. The terms “deaza” and “deideaza” analogs refers to the art recognized analogs having a carbon atom substituted for one or more nitrogen atoms in the naturally occurring folic acid structure. For example, the deaza analogs include the 1-deaza, 3-deaza, 5-deaza, 8-deaza, and 10-deaza analogs. The deideaza analogs include, for example, 1,5 deida, 5,10-deida, 8,10-deida, and 5,8 deida analogs. The foregoing folic acid analogs are conventionally termed “folates,” reflecting their capacity to bind to folate receptors. Other folate receptor-binding analogs include aminopterin, amethopterin (methotrexate), N^10^-methylfolate, 2-deamino-hydroxyfolate, deaza analogs such as 1-deazafolate or 3-deazafolate, and 3',5'-dichloro-4-amo-4-deoxy-N^10^-methylpteroyl-glutamic acid (dichloromethotrexate). [0030] In another embodiment, other vitamins can be used as the binding ligand. The vitamins that can be used in accordance with the methods described herein include niacin, pantothenic acid, folic acid, riboflavin, thiamine, biotin, vitamin B12, vitamins A, D, E and K, other related vitamin molecules, analogs, and derivatives thereof, and combinations thereof. [0031] In other embodiments, the binding ligand can be any ligand that binds to a receptor expressed or overexpressed on proximal tubule cells, in particular when they proliferate abnormally (e.g., EGF, KGF, or leptin). In another embodiment, the binding ligand can be any ligand that binds to a receptor expressed or overexpressed on proximal tubule cells proliferating abnormally and involved in a kidney disease state. [0032] The targeted conjugates used for diagnosing or treating disease states mediated by proximal tubule cells proliferating abnormally have the formula V-L-D, wherein V is a ligand capable of binding to the proximal tubule cells, and the group D comprises a diagnostic marker or an antigen (such as an immunogen), cytoxin, or a cell growth inhibitor. In such conjugates wherein the group V is folic acid, a folic acid analog, or another folic acid receptor binding ligand, these conjugates are described in detail in U.S. Pat. No. 5,688,488, the specification of which is incorporated herein by reference. That patent, as well as related U.S. Pat. Nos. 5,416,016 and 5,108,921, and related U.S. patent application Ser. No. 10/765,336, each incorporated herein by reference, describe methods and examples for preparing conjugates useful in accordance with the methods described herein. The present targeted diagnostic and therapeutic agents can be prepared and used following general protocols described in those earlier patents and patent applications, and by the protocols described herein. [0033] In accordance with another embodiment, there is provided a method of treating kidney disease states by administering to a patient suffering from such disease state an effective amount of a composition comprising a conjugate of the general formula V-L-D wherein V is as defined above and the group D comprises a cytoxin, an antigen (i.e., a compound administered to a patient for the purpose of eliciting an immune response in vivo), or a cell growth inhibitor. The group V can be any of the ligands described above. Examples of cytoxic moieties useful for forming conjugates for use in accordance with the methods described herein include art-recognized chemotherapeutic agents such as antimetabolites, methotrexate, busulfin, carboptatin, chlorambucil, cisplatin and other platinum compounds, plant alkaloids, hydroxyurea, teniposide, and bleomycin, MEK kinase inhibitors, MAP kinase pathway inhibitors, PI-3-kinase inhibitors, NFkB pathway inhibitors, pro-apoptotic agents, apoptosis-inducing agents, proteins such as pokeweed, saporin, somoradin, and gelonin, didemnin B, verrucarvin A, geldanamycin, toxins, and the like. Such cytoxic compounds can be directly conjugated to the targeting ligand, for example, folate or another folate receptor-binding ligand, or they can be formulated in liposomes or other small particles which themselves can be targeted to proximal tubule cells by pendent targeting ligands V non-covalently or covalently linked to one or more liposome components. [0034] In another embodiment, the group D comprises a cell growth inhibitor, and the inhibitor can be covalently linked to the targeting ligand V, for example, a folate receptor-binding ligand or a proximal tubule cell-binding antibody or antibody fragment (i.e., an antibody to a receptor overexpressed on proximal tubule cells that are proliferating abnormally). The ligand can be linked directly, or the ligand can be encapsulated in a liposome which is itself targeted to the proximal tubule cells by pendent targeting ligands V covalently or non-covalently linked to one or more liposome components. Cell growth inhibitors can be selected from the group consisting of epidermal growth factor receptor kinase inhibitors and other kinase inhibitors (e.g. rapamycin and
other inhibitors of the mTOR pathway, r-roscovitine and other cyclin-dependent kinase inhibitors), DNA alkylators (e.g., nitrogen mustards (e.g., cyclophosphamide), ethyleneamines, alkyl sulfonates, nitrosoureas, and triazine derivatives), microtubule inhibitors (e.g., taxotere, paclitaxel, docetaxel (and other taxols), vincristine, vinblastine, colcemid, and colchicine), cell cycle inhibitors (e.g., cytochrome arabinoside, purine analogs, and pyrimidine analogs), and protein synthesis inhibitors (e.g., proteosine inhibitors). In one embodiment, rapamycin (RAPAMUNE®, Wyeth Pharmaceuticals, Inc., Madison, N.J.) is the cell growth inhibitor. Rapamycin is described in Shillingford, et al., *PNAS* 103:5466-5471 (2006), incorporated herein by reference. In another embodiment, more than one of these drugs can be conjugated to a ligand, such as folate, to form, for example, a dual-drug conjugate.

**[0035]** In another embodiment, conjugates V-L-D where D is an antigen or a cell growth inhibitor can be administered in combination with a cytotoxic compound. The cytotoxic compounds listed above are among the compounds suitable for this purpose.

**[0036]** In one embodiment, conjugates are described herein, and such conjugates may be used in the treatment methods described herein. Illustratively, the conjugates have the general formula

\[ V-L-D \]

where V is a folate receptor binding ligand, L is an optional linker, and D is a cell growth inhibitor, an antigen, or a cytotoxin.

**[0037]** In one embodiment, the folate receptor binding ligand is folate or an analog of folate, or alternatively a derivative of either folate or an analog thereof. As used herein, the term "folate" or "folates" may refer to folate itself, or such analogs and derivatives of folate. However, it is to be understood that other folate receptor binding ligands in addition to folates are contemplated herein. Illustratively, such folate receptor binding ligands include any compound capable of specific or selective binding to folate receptors, especially those receptors present on the surface of cells.

**[0038]** In another embodiment, the optional linker is absent, and the conjugate is formed by directly attaching the folate receptor binding ligand to the cell-growth inhibitor, a cytotoxin, or an antigen. In another embodiment, the optional linker is present and is a divalent chemical fragment comprising a chain of carbon, nitrogen, oxygen, silicon, sulfur, and phosphorus. It is to be understood that the foregoing atoms may be arranged in any chemically meaningful way. In one variation, peroxide bonds, i.e. \(-O=O-\), do not form part of the linker. Generally, the linker is formed from the foregoing atoms by arranging those atoms to form functional groups, including but not limited to, alkylene, cyclic alkylene, arylene, ether, amino, hydroxyamine, oxime, hydrazine, hydrazono, thio, disulfide, carbonyl, carboxyl, carbamoyl, thiocarbonyl, thiocarboxyl, thiocarbamoyl, xanthyl, silyl, phosphonyl, phosphonyl, phosphate, and like groups that may be linked together to construct the linker. It is appreciated that each of these fragments may also be independently substituted.

**[0039]** In another embodiment, the drug is a cell-growth inhibitor. Illustrative of such cell-growth inhibitors are epidermal growth factor (EGF) receptor kinase inhibitors. Furthermore illustrative of such cell-growth inhibitor are DNA alkylators, microtubule inhibitors, cell cycle inhibitors, and protein synthesis inhibitors.

**[0040]** In another illustrative embodiment, such cell growth inhibitors are compounds that inhibit the mammalian target of rapamycin, also referred to as mTOR. mTOR is a serine/threonine protein kinase that has been reported to regulate cell growth, cell proliferation, cell motility, cell survival, protein synthesis, and transcription (see generally, Bevers et al., "Curcin inhibits the mammalian target of rapamycin-mediated signaling pathways in cancer cells," *International Journal of Cancer*, 119(4):757-764 (2006); Hay & Sonenberg N "Upstream and downstream of mTOR," *Genes & Development*, 18(16):1926-45 (2004)). mTOR has been shown to function as the catalytic subunit of two distinct molecular complexes in cells. mTOR Complex 1 (mTORC1) is composed of mTOR, regulatory associated protein of mTOR (Raptor), and mammalian LST8/G-protein flb-subunit like protein (mLST8/Gflb). This complex possesses the classic features of mTOR by functioning as a nutrient/energy/redox sensor and controlling protein synthesis. mTOR Complex 2 (mTORC2) is composed of mTOR, rapamycin-insensitive companion of mTOR (Rictor), Gflb, and mammalian stress-activated protein kinase interacting protein 1 (mSIN1). mTORC2 has been shown to function as an important regulator of the cytoskeleton through its stimulation of V-actin stress fibers, paxillin, RhoA, Rac1, Cdc42, and protein kinase C alpha (PKCα). In addition, mTORC2 has also been reported to be a "PKD2."
which is independently selected in each occurrence, and q is an integer such as 1, 2, 3, 4, or 5. Illustratively, R', R², and/or R'² independently correspond to, but are not limited to, hydrogen or the side chains present on naturally occurring amino acids, such as methyl, benzyl, hydroxymethyl, thiomethyl, carbonyl, carbamoylmethyl, guanidinopropyl, and the like, and derivatives and protected derivatives thereof. The above described formula includes all stereoisomeric variations. It is further appreciated that water solubilizing amino acids may be included in the linker to facilitate uptake and transport of the conjugates described herein. For example, the amino acids may be selected from asparagine, aspartic acid, cysteine, glutamic acid, lysine, glutamine, arginine, serine, ornithine, threonine, and the like.

[0043] In another illustrative embodiment, the bivalent linker (L) comprises one or more spacer linkers, heteroatom linkers, and releasable (i.e., cleavable) linkers, and combinations thereof, in any order. The term “releasable linker” as used herein generally refers to a linker that includes at least one bond that can be broken under physiological conditions (e.g., a pH-labile, acid-labile, oxidatively-labile, enzyme-labile bond, and the like). It is appreciated that such physiological conditions resulting in bond breaking include standard chemical hydrolysis reactions that occur, for example, at physiological pH, or as a result of compartmentalization into a cellular organelle such as an endosome having a lower pH than cytosolic pH.

[0044] It is also understood that a cleavable bond can connect two adjacent atoms within the releasable linker and/or connect other linkers or V and/or D, as described herein, at either or both ends of the releasable linker. In the case where a cleavable bond connects two adjacent atoms within the releasable linker, following breakage of the bond, the releasable linker is broken into two or more fragments. Alternatively, in the case where a cleavable bond is between the releasable linker and another moiety, such as an heteroatom linker, a spacer linker, another releasable linker, the drug, or analog or derivative thereof, or the vitamin, or analog or derivative thereof, following breakage of the bond, the releasable linker is separated from the other moiety.

[0045] The lability of the cleavable bond can be adjusted by, for example, substitutional changes at or near the cleavable bond, such as including alpha branching adjacent to a cleavable disulfide bond, increasing the hydrophobicity of substituents on silicon in a moiety having silicon-oxygen bond that may be hydrolyzed, homologating alkoxy groups that form part of a ketal or acetal that may be hydrolyzed, and the like.

[0046] In one embodiment, the present invention provides a vitamin receptor binding drug delivery conjugate. The drug delivery conjugate comprises a vitamin receptor binding moiety, bivalent linker (L,) and a drug. The vitamin receptor binding moiety is a vitamin, or an analog or a derivative thereof, capable of binding to vitamin receptors, and the drug (antigen, cytokotoxin, or cell growth inhibitor) includes analogs or derivatives thereof exhibiting drug activity. The vitamin, or the analog or the derivative thereof, is covalently attached to the bivalent linker (L), and the drug, or the analog or the derivative thereof, is also covalently attached to the bivalent linker (L). The bivalent linker (L) comprises one or more spacer linkers, releasable linkers, and heteroatom linkers, and combinations thereof, in any order. For example, the heteroatom linker can be nitrogen, and the releasable linker and the heteroatom linker can be taken together to form a divalent radical comprising alkylenearzidin-1-yl, alkylencycarbonylaziridin-1-yl, carboxalylkylaziridin-1-yl, alkylensulfonoylaziridin-1-yl, sulfonoylalkylaziridin-1-yl, or alkylensulfonofluoraziridin-1-yl, wherein each of the releasable linkers is optionally substituted with a substituent X¹, as defined below. Alternatively, the heteroatom linkers can be nitrogen, oxygen, sulfur, and the formulae —(NH₂NHR) —, —SO₂—, —(SO₃)₂—, and —N(R²) —, wherein R¹, R², and R³ are each independently selected from hydrogen, alkyl, aryl, arylalkyl, substituted aryl, substituted arylalkyl, heteroaryl, substituted heteroaryl, and alkoxyalkyl.

In another embodiment, the heteroatom linker can be oxygen, the spacer linker can be 1-alkyleneusuccinimide-3-yl, optionally substituted with a substituent X¹, as defined below, and the releasable linker can be methylene, 1-alkoxyalkylene, 1-alkoxyycycloalkylene, 1-alkoxyalkylenecarbonyl, 1-alkoxyycycloalkylenecarbonyl, wherein each of the releasable linkers is optionally substituted with a substituent X¹, as defined below, and wherein the spacer linker and the releasable linker are each bonded to the heteroatom linker to form a succinimide-1-ylalkyl acetal or ketal.

[0047] The spacer linker can be carbonyl, thionocarbonyl, alkylene, cycloalkylene, alkylenecycloalkyl, alkylencycarbonyl, cycloalkylenecarbonyl, carbonylalkylcarbonyl, 1-alkylenesuccinimide-3-yl, 1-(carbonylalkyl)succinimide-3-yl, alkylensulfonoylalkylenecarbonyl, alkylenesulfonofluoraziridin-1-yl, alkylsulfonofluoraziridin-1-yl, carbonylalkyltetrahydro-2H-pyran, carboxyalkyltetrahydrofuranyl, 1-(carbonylalkyltetrahydro-2H-pyran) succinimide-3-yl, and 1-(carbonylalkyltetrahydrofuranyl)succinimide-3-yl, wherein each of the spacer linkers is optionally substituted with a substituent X¹, as defined below. In this embodiment, the heteroatom linker can be nitrogen, and the spacer linkers can be alkylencycarbonyl, cycloalkylenecarbonyl, carbonylalkylcarbonyl, 1-(carbonylalkyl)succinimide-3-yl, wherein each of the spacer linkers is optionally substituted with a substituent X¹, as defined below, and the spacer linker is bonded to the nitrogen to form an amide. Alternatively, the heteroatom linker can be sulfur, and the spacer linkers can be alkylencycarbonyl, cycloalkylenecarbonyl, carbonylalkylcarbonyl, 1-(carbonylalkyl)succinimide-3-yl, wherein each of the spacer linkers is optionally substituted with carboxy, and the spacer linker is bonded to the sulfur to form a thiol. In another embodiment, the heteroatom linker can be sulfur, and the spacer linkers can be 1-alkylsulfonoylalkylsuccinimide-3-yl, and 1-(carbonylalkyl)succinimide-3-yl, and the spacer linker is bonded to the sulfur to form a succinimide-3-ythiol.

[0048] In an alternative to the above-described embodiments, the heteroatom linker can be nitrogen, and the releasable linker and the heteroatom linker can be taken together to form a divalent radical comprising alkylenearzidin-1-yl, carbonylalkylsulfonoylalkylaziridin-1-yl, sulfonylalkylaziridin-1-yl, sulfonylalkylaziridin-1-yl, wherein each of the releasable linkers is optionally substituted with a substituent X¹, as defined below. In this alternative embodiment, the spacer linkers can be carbonyl, thionocarbonyl, alkylenecarbonyl, cycloalkylenecarbonyl, carbonylalkylcarbonyl, 1-(carbonylalkyl)succinimide-3-yl, wherein each of the spacer linkers is optionally substituted with a substituent X¹, as defined below, and wherein the spacer linker is bonded to the releasable linker to form an aziridine amide.

[0049] The substituents X¹ can be alkyl, alkoxy, alkoxycarbonyl, hydroxy, hydroxalkyl, amino, aminoalkyl, alkylnitroalkyl, dialkylaminioalkyl, halo, haloalkyl, sulphonylalkyl, alkyliodoalkyl, aryl, substituted aryl, arylalkyl, substituted arylalkyl, heteroaryl, substituted heteroaryl, carboxy, car-
boxyalkyl, alkyl carboxylate, alkyl alkanoate, guanidinoalkyl, R'=carbonyl, R''-carbonylalkyl, R''-acylaminooalkyl, wherein R' and R'' are each independently selected from amino acids, amino acid derivatives, and peptides, and wherein R' and R'' are each independently selected from amino acids, amino acid derivatives, and peptides. In this embodiment the heteroatom linker can be nitrogen, and the substituent X² and the heteroatom linker can be taken together with the spacer linker to which they are bound to form an heterocycle.

[0050] The releasable linkers can be methylene, 1-alkoxyalkylene, 1-alkoxyalkylidene, 1-alkoxyalkylidenecarbonyl, 1-alkoxyalkylocyloalkylidenecarbonyl, carbonylarylcarbonyl, carbonyl[(carboxyaryl)carbonyl], carbonyl[(bis(carboxyaryl)carbonyl], carbonyl, haloalkylene carbonyl, alkylene(dialkylsilyl), alkylene(alkylarylsilyl), alkylene(diaryl)silyl], (diaryl)silyl]aryl, oxy-carbonylalkyl, oxy-carbonyloxyalkyl, sulfonyloxyl, oxy-sulfonyloxyalkyl, iminoalkyldenyl, carbonylalkylideniminyln, iminocycloalkyldenyl, carbonylcycloalkyldeniminyln, alkylenethio, alkylenearythio, and carbonylalkyldithio, wherein each of the releasable linkers is optionally substituted with a substituent X², as defined below.

[0051] In the preceding embodiment, the heteroatom linker can be oxygen, and the releasable linkers can be methylene, 1-alkoxyalkylene, 1-alkoxyalkylidene, 1-alkoxyalkylidenecarbonyl, and 1-alkoxyalkylocyloalkylidenecarbonyl, wherein each of the releasable linkers is optionally substituted with a substituent X² or oxygen, as defined below, and the releasable linker is bonded to the oxygen to form an acetyl or ketal. Alternatively, the heteroatom linker can be methylene, wherein the methylene is substituted with an optionally-substituted aryl, and the releasable linker is bonded to the oxygen to form an acetyl or ketal. Further, the heteroatom linker can be oxygen, and the releasable linker can be sulfonylalkyl, and the releasable linker is bonded to the oxygen to form an alkylsulfonate.

[0052] In another embodiment of the above releasable linker embodiment, the heteroatom linker can be nitrogen, and the releasable linkers can be iminocycloalkyldenyl, carbonylalkyldeniminyln, iminocycloalkyldenyl, and carbonylcycloalkyldeniminyln, wherein each of the releasable linkers is optionally substituted with a substituent X², as defined below, and the releasable linker is bonded to the nitrogen to form an hydrazine. In an alternate configuration, the hydrazine may be acylated with a carboxylic acid derivative, an orthoformate derivative, or a carbamoyl derivative to form various acylhydrazine releasable linkers.

[0053] Alternatively, the heteroatom linker can be oxygen, and the releasable linkers can be alkylene(dialkylsilyl), alkylene(alkylarylsilyl), alkylene(diaryl)silyl], (diaryl)silyl]aryl, (alkylarylsilyl)]aryl, and (diaryl)silyl]aryl, wherein each of the releasable linkers is optionally substituted with a substituent X², as defined below, and the releasable linker is bonded to the oxygen to form a silanil.

[0054] In the above releasable linker embodiment, the drug can include a nitrogen atom, the heteroatom linker can be nitrogen, and the releasable linkers can be carbonylarylcarbonyl, carbonyl[(carboxyaryl)carbonyl], carbonyl[(bis(carboxyaryl)carbonyl], and the releasable linker can be bonded to the heteroatom linker to form an amide, and also bonded to the drug oxygen to form an ester.

[0055] In the above releasable linker embodiment, the drug can include an oxygen atom, the heteroatom linker can be nitrogen, and the releasable linkers can be carbonylarylcarbonyl, carbonyl[(carboxyaryl)carbonyl], carbonyl[(bis(carboxyaryl)carbonyl], and the releasable linker can be bonded to the heteroatom linker nitrogen to form an amide, and also bonded to the drug oxygen to form an ester.

[0056] The substituents X² can be alkyl, alkoxy, alkoxyalkyl, hydroxy, hydroxylalkyl, amino, aminalkyl, alkylaminoalkyl, dialkylaminoalkyl, halo, haloalkyl, sulfhydrylalkyl, alkylthioalkyl, aryl, substituted aryl, arylalkyl, substituted aralkyl, heteroaryl, substituted heteroaryl, carboxyalkyl, alkyl carboxylate, alkyl alkanoate, guanidinoalkyl, R'-carbonyl, R''-carbonylalkyl, R''-acylaminooalkyl, and R''-acylaminoalkyl, wherein R' and R'' are each independently selected from amino acids, amino acid derivatives, and peptides, and wherein R' and R'' are each independently selected from amino acids, amino acid derivatives, and peptides. In this embodiment the heteroatom linker can be nitrogen, and the substituent X² and the heteroatom linker can be taken together with the releasable linker to which they are bound to form an heterocycle.

[0057] The heterocycles can be pyrrolidines, piperidines, oxazolidines, isoxazolidines, thiazolidines, isothiazolidines, pyrrolidinones, piperidinones, oxazolidinones, isoxazolidinones, thiazolidinones, isothiazolidinones, and succinimides.

[0058] The drug can include a nitrogen atom, and the releasable linker can be haloalkylene carbonyl, optionally substituted with a substituent X², and the releasable linker is bonded to the drug nitrogen to form an amide.

[0059] The drug can include an oxygen atom, and the releasable linker can be haloalkylene carbonyl, optionally substituted with a substituent X², and the releasable linker is bonded to the drug oxygen to form an ester.

[0060] The drug can include a double-bonded nitrogen atom, and in this embodiment, the releasable linkers can be alkylene carbonylamine and 1-(alkylene carbonylamine)acetic acid-3-yl, and the releasable linker can be bonded to the drug nitrogen to form an hydrazine.

[0061] The drug can include a sulfur atom, and in this embodiment, the releasable linkers can be alkylenetio and carbonylalkyldithio, and the releasable linker can be bonded to the drug sulfur to form a disulfide.

[0062] The term “aryl” as used herein refers to an aromatic mono or polycyclic ring of carbon atoms, such as phenyl, naphthyl, and the like.

[0063] The term “heteroaryl” as used herein refers to an aromatic mono or polycyclic ring of carbon atoms and at least one heteroatom selected from nitrogen, oxygen, and sulfur, such as pyridinyl, pyrimidinyl, indolyl, benzoxazolyl, and the like.

[0064] The term “substituted aryl” or “substituted heteroaryl” as used herein refers to aryl or heteroaryl substituted with one or more substituents selected, such as halo, hydroxy, amino, alkyl or dialkylamino, alkoxy, alkylsulfonfyl, cyano, nitro, and the like.

[0065] In addition, the following linkers are contemplated. It is understood that these linkers may be combined with each other and other space, heteroatom and releasable links to prepare the conjugates described herein. Illustrative linkers, and combinations of spacer and heteroatom linkers include:
Illustrative linkers, and combinations of releasable and heteroatom linkers include:
Illustrative folate receptor binding ligands include folic acid, folinic acid, pteropolyglutamic acid, and folate receptor-binding pteridines such as tetrahydropterins, dihydrofolates, tetrahydrofolates, and their deaza and dideaza analogs. The terms “deaza” and “dideaza” analogs refer to the art-recognized analogs having a carbon atom substituted for one or two nitrogen atoms in the naturally occurring folic acid structure, or analog or derivative thereof. For example, the deaza analogs include the 1-deaza, 3-deaza, 5-deaza, and 10-deaza analogs of folate. The dideaza analogs include, for example, 1,5-dideaza, 5,10-dideaza, 8,10-dideaza, and 5,8-dideaza analogs of folate. Other folates useful as complex forming ligands for this invention are the folate receptor-binding analogs aminopterin, amethopterin (methotrexate), N^10^-methylfolate, 2-deamino-hydroxyfolate, deaza analogs such as 1-deazamethopterin or 3-deazamethopterin, and 3,5-dichloro-4-amino-4-deoxy-N^10^-methylpteroylglutamic acid (dichloromethotrexate). The foregoing folate acid analogs and/or derivatives are conventionally termed “folate” or “folates,” reflecting their ability to bind with folate-receptors, and such ligands when conjugated with exogenous molecules are effective to enhance transmembrane transport, such as via folate-mediated endocytosis as described herein. Other suitable ligands capable of binding to folate receptors to initiate receptor-mediated endocytic transport of the complex include anti-idiotypic antibodies to the folate receptor. An exogenous molecule in complex with an anti-idiotypic antibody to a folate receptor is used to trigger transmembrane transport of the complex in accordance with the present invention.

Generally, any manner of forming a conjugate between the bivalent linker (L) and the folate receptor-binding ligand, or between the bivalent linker (L) and the cell-growth inhibitor, antigen, or cytotoxin, or analog or derivative thereof, including any intervening heterostom linkers, may be used. The conjugate may be formed by direct conjugation of any of these molecules, for example, through hydrogen, ionic, or covalent bonds. Covalent bonding can occur, for example, through the formation of amide, ester, disulfide, or imino bonds between acid, aldehyde, hydroxyl, amino, sulhydryl, hydrazo, and like groups, such as those described herein.

The spacer and/or releasable linker (i.e., cleavable linker) can be any biocompatible linker. The cleavable linker can be, for example, a linker susceptible to cleavage under reducing or oxidizing conditions present in or on cells, a pH-sensitive linker that may be an acid-labile or base-labile linker, or a linker that is cleavable by biochemical or metabolic processes, such as an enzyme-labile linker. Generally, the spacer and/or releasable linker comprises about 1 to about 50 atoms in length, more typically about 2 to about 20 carbon atoms. It is appreciated that lower molecular weight linkers (i.e., those having an approximate molecular weight of about 30 to about 300) may be employed. Precursors to such linkers are selected to have suitably reactive groups at the points of attachment, such as nucleophilic or electrophilic functional groups, or both, optionally in a protected form with a readily cleavable protecting group to facilitate their use in synthesis of the intermediate species.
In another illustrative embodiment, the conjugate is a compound of the following formula:

[0069] wherein:

[R] is \( \text{O-C-} \text{O, C-R}^7 \text{R}^9 \);  
[R\(^7\)] is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, \( \text{-(CR}^{13}_1 \text{R}^{13}_2 \text{)} \);  
[R\(^9\)] is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, triphenylmethyl, benzyl, alkoxyalkyl of 2-7 carbon atoms, chloroethyl, or tetrahydropyranyl; \( R^8 \) and \( R^9 \) are taken together to form \( X \);

[0073] \( X \) is 2-phenyl-1,3,2-dioxaborinan-5-yl or 2-phenyl-1,3,2-dioxaborinan-4-yl, wherein the phenyl may be optionally substituted;

[0074] \( R^{12} \) and \( R^{13} \) are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, trifluoromethyl, or \( -\text{F} \);

[0075] \( L \) is as defined herein.

[0077] In another illustrative embodiment, the conjugate is a compound of the following formula:
wherein \( R \) in each instance is the same or different and is independently selected from the group consisting of alkyl of 1-6 carbon atoms, phenyl and benzyl, and \( L \) is as defined herein.

In another illustrative embodiment, the conjugate is a compound of the following formula:

\[
\text{OMe} \quad \text{w} \quad \text{OH} \quad \text{N} \quad \text{Na} \quad \text{H} \quad \text{Sa} \quad \text{Apr. 29, 2010}
\]

where \( L \) is as defined herein, and \( L \) is connected to the rapamycin or analog or derivative thereof at either of \((O^*)\), and the other of \((O^*)\) is substituted with \( R \), wherein \( R \) is hydrogen or

\[
(R^* - W - R^*_b) \quad ;
\]

\( W \) is a linking group;

\( R^* \) is selected from the group consisting of carbonyl, 

\[
-\text{S(O)}- \quad , \quad -\text{S(O)}_2- \quad , \quad -\text{P(O)}_2- \quad , \quad -\text{P(O)(CH)}_3- \quad ,
\]

\[
-\text{C(S)}- \quad , \quad -\text{CH}_2\text{C(O)}- ;
\]

\( R^* \) is selected from the group consisting of carbonyl, 

\[
-\text{NH}- \quad , \quad -\text{S}- \quad , \quad -\text{CH}_2- \quad , \quad -\text{O}- ;
\]

\( n=1-5 \).

In another illustrative embodiment, the conjugate is a compound of the following formula:

\[
\text{CO}_2\text{H} \quad \text{O} \quad \text{NH} \quad \text{als} \quad \text{N} \quad \text{N} \quad \text{NH}_2
\]

where \( L \) is as defined herein, and \( L \) is connected to the rapamycin or analog or derivative thereof at either of \((O^*)\), and the other of \((O^*)\) is substituted with \( R \), wherein \( R \) is hydrogen, thioalkyl of 1-6 carbon atoms, arylalkyl of 7-10 carbon atoms, hydroxyalkyl of 1-6 carbon atoms, dihydroxyalkyl of 1-6 carbon atoms, alkoxyalkyl of 2-12 carbon atoms, hydroxyalkoxyalkyl of 2-12 carbon atoms, acexyalkyl of 3-12 carbon atoms, aminoalkyl of 1-6 carbon atoms, alkylaminoalkyl of 1-6 carbon atoms per alkyl group, dialkylaminoalkyl of 1-6 carbon atoms per alkyl group, alkoxy carbonylaminoalkyl of 3-12 carbon atoms, acylaminoalkyl of 3-12 carbon atoms, alkenyl of 2-7 carbon atoms, aryl sulfamidoalkyl having 1-6 carbon atoms in the alkyl group, hydroxyalkylallyl of 4-9 carbon atoms, dihydroxyalkylallyl of 4-9 carbon atoms, or dioxolanylallyl.
In another illustrative embodiment, the conjugate is a compound of the following formula:

where L is as defined herein, and L is connected to the rapamycin or analog or derivative thereof at either of (O*), and the other of (O*) is substituted with R, wherein R is hydrogen or —CO(CR'R')_n(CR'R')_m(CR'R')_n; where

R^3 and R^4 are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, trifluoromethyl, or F; R^5 and R^6 are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR'R')_nOR, CF_3, or CO_2R'; R^7 is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR'R')_nOR, CF_3, or CO_2R';

R^8 and R^9 are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR'R')_nOR, CF_3, F, or CO_2R';

R^{10} is hydrogen or COCH_2SCH_2CH_2(OCH_2CH_2)_nOCH_3;

R^{11} is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, or phenylalkyl of 7-10 carbon atoms;

b=0-6; d=0-6; f=0-6; and n=5-450.

In another illustrative embodiment, the conjugate is a compound of the following formula:
where \( L \) is as defined herein, and \( L \) is connected to the rapamycin or analog or derivative thereof at either of \( (O^*) \), and the other of \( (O^*) \) is substituted with \( R \), wherein \( R \) is hydrogen or \(-\text{CO}(\text{CR}^3\text{R}^4),(\text{CR}^3\text{R}^5)\text{CR}^7\text{R}^8; \) where

1. \( R^3 \) and \( R^4 \) are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, trifluoromethyl, or F;
2. \( R^5 \) and \( R^6 \) are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, \((\text{CR}^7\text{R}^8)\text{OH}, \text{CF}_3, \text{F}, \text{or CO}_2\text{R}^{11};
3. \( R^7 \) is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, \((\text{CR}^7\text{R}^8)\text{OH}, \text{CF}_3, \text{F}, \text{or CO}_2\text{R}^{11};
4. \( R^8 \) and \( R^9 \) are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, \((\text{CR}^7\text{R}^8)\text{OH}, \text{CF}_3, \text{F}, \text{or CO}_2\text{R}^{11};

[0096] \( R^{11} \) is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, or phenylalkyl of 7-10 carbon atoms;

[0097] In one aspect of each of the foregoing, \( L \) includes an amino acid or a peptide. In another aspect of each of the foregoing, \( L \) includes amino acids selected from cysteine, aspartic acid, glutamic acid, arginine, and lysine. It is to be understood that either enantiomer of such amino acids may be included in such illustrative linkers in each instance. In another aspect of each of the foregoing, \( L \) includes a releasable linker. In one variation, the releasable linker comprises a disulfide bond. In another variation, the releasable linker comprises a carbonate.

[0098] In another illustrative embodiment, the conjugate is a compound of the following formula:
In another illustrative embodiment, the conjugate is a compound of the following formula:

where L is as defined herein, and L is connected to the rapamycin or analog or derivative thereof at either of (O*). In one aspect, L includes an amino acid or a peptide. In another aspect, L includes amino acids selected from cysteine, aspartic acid, glutamic acid, arginine, and lysine. It is to be understood that either enantiomer of such amino acids may be included in such illustrative linkers in each instance. In another aspect, L includes a releasable linker. In one variation, the releasable linker comprises a disulfide bond. In another variation, the releasable linker comprises a carbonate.

In another illustrative embodiment, the conjugate is a compound of the following formula:
where L is as defined herein. In one aspect, L includes an amino acid or a peptide. In another aspect, L includes amino acids selected from cysteine, aspartic acid, glutamic acid, arginine, and lysine. It is to be understood that either enantiomer of such amino acids may be included in such illustrative linkers in each instance.

In another illustrative embodiment, the conjugate is a compound of the following formula (EC0371; see also FIG. 3):

The compounds described herein may be prepared by general organic synthetic reactions, such as those described in U.S. patent application Ser. No. 10/765,336, the disclosure of which is incorporated herein by reference.

Briefly, the following chemical transformations are described for preparing the compounds described herein.

**General amide and ester formation.** For example, where the heteroatom linker is a nitrogen atom, and the terminal functional group present on the spacer linker or the releasable linker is a carbonyl group, the required amide group can be obtained by coupling reactions or acylation reactions of the corresponding carboxylic acid or derivative, where L is a suitably-selected leaving group such as halo, triflate, pentfluorophenoxy, trimethylsilyloxy, succinimide-N-oxyl, and the like, and an amine, as illustrated in Scheme 1.

Coupling reagents include DCC, EDC, RRDQ, CGI, HBTU, TBTU, HOBT/DCC, HOBT/EDC, BOP-Cl, PyBOP, PyBroP, and the like. Alternatively, the parent acid can be converted into an activated carbonyl derivative, such as
an acid chloride, a N-hydroxsuccinimidyl ester, a pentafluorophenyl ester, and the like. The amide-forming reaction can also be conducted in the presence of a base, such as triethylamine, disopropylethylamine, N,N-dimethyl-4-aminopyridine, and the like. Suitable solvents for forming amides described herein include CH₂Cl₂, CHCl₃, THF, DMF, DMSO, acetonitrile, EtOAc, and the like. Illustratively, the amides can be prepared at temperatures in the range from about −15°C to about 80°C, or from about 0°C to about 45°C. Amides can be formed from, for example, nitrogen-containing aziridine rings, carbohydrates, and α-halogenated carboxylic acids. Illustrative carboxylic acid derivatives useful for forming amides include compounds having the formulae:

and the like, where n is an integer such as 1, 2, 3, or 4.

Similarly, where the heteroatom linker is an oxygen atom and the terminal functional group present on the spacer linker or the releasable linker is a carbonyl group, the required ester group can be obtained by coupling reactions of the corresponding carboxylic acid or derivative, and an alcohol.

Coupling reagents include DCC, EDC, CDI, BOP, PyBOP, isopropenyl chloroformate, EEDQ, DEAD, PPh₃, and the like. Solvents include CH₂Cl₂, CHCl₃, THF, DMF, DMSO, acetonitrile, EtOAc, and the like. Bases include triethylamine, disopropyl-ethylamine, and N,N-dimethyl-4-aminopyridine. Alternatively, the parent acid can be converted into an activated carboxyl derivative, such as an acid chloride, a N-hydroxsuccinimidyl ester, a pentafluorophenyl ester, and the like.

General ketal and acetal formation. Furthermore, where the heteroatom linker is an oxygen atom, and the functional group present on the spacer linker or the releasable linker is 1-siloxyalkyl, the required acetal or ketal group can be formed by ketal and acetal forming reactions of the corresponding alcohol and an enol ether, as illustrated in Scheme 2.

Solvants include alcohols, CH₂Cl₂, CHCl₃, THF, diethylene, DMF, DMSO, acetonitrile, EtOAc, and the like. The formation of such acetals and ketals can be accomplished with an acid catalyst. Where the heteroatom linker comprises two oxygen atoms, and the releasable linker is methylene, optionally substituted with a group X₂ as described herein, the required symmetrical acetal or ketal group can be illustratively formed by acetal and ketal forming reactions from the corresponding alcohols and an aldehyde or ketone, as illustrated in Scheme 3.

Alternatively, where the methylene is substituted with an optionally-substituted aryl group, the required acetal or ketal may be prepared stepwise, where L is a suitably selected Leaving group such as halo, trifluoroacetoxy, triflate, and the like, as illustrated in Scheme 4. The process illustrated in Scheme 4 is a conventional preparation, and generally follows the procedure reviewed by R. R. Schmidt et al., Chem. Rev., 2000, 100, 4423-42, the disclosure of which is incorporated herein by reference.

The resulting arylalkyl ether is treated with an oxidizing agent, such as DDQ, and the like, to generate an intermediate oxonium ion that is subsequently treated with another alcohol to generate the acetal or ketal.

General succinimide formation. Furthermore, where the heteroatom linker is, for example, a nitrogen, oxygen, or sulfur atom, and the functional group present on the spacer linker or the releasable linker is a succinimide derivative, the resulting carbon-heteroatom bond can be formed by a Michael addition of the corresponding amine, alcohol, or thiol, and a maleimide derivative, where X is the heteroatom linker, as illustrated in Scheme 5.

Solvants for performing the Michael addition include THF, EtOAc, CH₂Cl₂, DMF, DMSO, H₂O and the like. The formation of such Michael adducts can be accomplished with the addition of equimolar amounts of bases, such as triethylamine, Hüning’s base or by adjusting the pH of water solutions to 6.0-7.4. It is appreciated that when the heteroatom linker is an oxygen or nitrogen atom, reaction conditions may be adjusted to facilitate the Michael addition, such as, for example, by using higher reaction temperatures, adding catalysts, using more polar solvents, such as DMF, DMSO, and the like, and activating the maleimide with silylating reagents.
[0114] General silyloxy formation. Furthermore, where the heteroatom linker is an oxygen atom, and the functional group present on the spacer linker or the releasable linker is a silyl derivative, the required silyloxy group may be formed by reacting the corresponding silyl derivative, and an alcohol, where L is a suitably selected leaving group such as halo, trifluoroacetoxy, triflate, and the like, as illustrated in Scheme 6.

[0115] Silyl derivatives include properly functionalized silyl derivatives such as vinylsulfonylalkyl diaryl, or diaryl, or alkyl aryl silyl chloride. Instead of a vinylsulfonylalkyl group, a β-chlorothioethanesulfonofluoride precursor may be used. Any aprotic and anhydrous solvent and any nitrogen-containing base may serve as a reaction medium. The temperature range employed in this transformation may vary between -78°C and 80°C.

[0116] General hydrazone formation. Furthermore, where the heteroatom linker is a nitrogen atom, and the functional group present on the spacer linker or the releasable linker is an iminyl derivative, the required hydrazone group can be formed by reacting the corresponding aldehyde or ketone, and a hydrazine or acylhydrazine derivative, as illustrated in Scheme 7, equations (1) and (2) respectively.

[0117] Solvents that can be used include THF, EtOA, CH₂Cl₂, CHCl₃, CCl₄, DMF, DMSO, and the like. The temperature range employed in this transformation may vary between 0°C and 80°C. Any acidic catalyst such as a mineral acid, H₂CCOOH, F₂CCOOH, p-TsOH.H₂O, pyridinium p-toluene sulfonate, and the like can be used. In the case of the acyhydrazone in equation (2), the acyhydrazone may be prepared by initially acylating hydrazine with a suitable carboxylic acid or derivative, as generally described above in Scheme 1, and subsequently reacting the acyhydrazone with the corresponding aldehyde or ketone to form the acyhydrazone. Alternatively, the hydrazone functionality may be initially formed by reacting hydrazine with the corresponding aldehyde or ketone. The resulting hydrazone may subsequently be acylated with a suitable carboxylic acid or derivative, as generally described above in Scheme 1.

[0118] General disulfide formation. Furthermore, where the heteroatom linker is a sulfur atom, and the functional group present on the releasable linker is an alkylene thiol derivative, the required disulfide group can be formed by reacting the corresponding alkyl or aryl sulfonofluoride derivative, of the corresponding heteroarylsulfonyl derivative such as a pyrid-2-yldithioalkyl derivative, and the like, with an alkylene thiol derivative, as illustrated in Scheme 8.

[0119] Solvents that can be used are THF, EtOA, CH₂Cl₂, CHCl₃, CCl₄, DMF, DMSO, and the like. The temperature range employed in this transformation may vary between 0°C and 80°C. The required alkyl or aryl sulfonofluoride derivative may be prepared using art-recognized protocols, and also according to the method of Rasanghae and Fuchs, *Synth. Commun.* 18(3), 227-32 (1988), the disclosure of which is incorporated herein by reference. Other methods of preparing unsymmetrical dialkyldisulfides are based on a transthiolation of unsymmetrical heteroarylidalkyl disulfides, such as 2-thiopyridin-1-yl, 3-nitro-2-thiopyridin-1-yl, and like disulfides, with alkyl thiol, as described in WO 88/01622, European Patent Application No. 0116208A1, and U.S. Pat. No. 4,691,024, the disclosures of which are incorporated herein by reference.

[0120] General carbonate formation. Furthermore, where the heteroatom linker is an oxygen atom, and the functional group present on the spacer linker or the releasable linker is an alkoxy carbonyl derivative, the required carbonate group can be formed by reacting the corresponding hydroxy-substituted compound with an activated alkoxy carbonyl derivative where L is a suitable leaving group, as illustrated in Scheme 9.

[0121] Solvents that can be used are THF, EtOA, CH₂Cl₂, CHCl₃, CCl₄, DMF, DMSO, and the like. The temperature range employed in this transformation may vary between 0°C
C. and 80°C. Any basic catalyst such as an inorganic base, an amine base, a polymer bound base, and the like can be used to facilitate the reaction.

**[0122]** General semicarbazone formation. Furthermore, where the heteroatom linker is a nitrogen atom, and the functional group present on one spacer linker or the releasable linker is an iminyl derivative, and the functional group present on the other spacer linker or the other releasable linker is an alkylamino or arylaminocarbonyl derivative, the required semicarbazone group can be formed by reacting the corresponding aldehyde or ketone, and a semicarbazide derivative, as illustrated in Scheme 10.

![Scheme 10](image)

**[0123]** Solvents that can be used are THF, EtOAc, CH₂Cl₂, CHCl₃, CCl₄, DMF, DMSO, MeOH and the like. The temperature range employed in this transformation may vary between 0°C and 80°C. Any acidic catalyst such as a mineral acid, H₂COOH, F₂CCOOH, p-TsOH·H₂O, pyridinium p-toluene sulfonate, and the like can be used. In addition, in forming the semicarbazone, the hydrazone functionality may be initially formed by reacting hydrazine with the corresponding aldehyde or ketone. The resulting hydrazone may subsequently be acylated with an isocyanate or a carbamoyl derivative, such as a carbamoyl halide, to form the semicarbazone. Alternatively, the corresponding semicarbazide may be formed by reacting hydrazine with an isocyanate or carbamoyl derivative, such as a carbamoyl halide to form a semicarbazide. Subsequently, the semicarbazide may be reacted with the corresponding aldehyde or ketone to form the semicarbazone.

**[0124]** General sulfonate formation. Furthermore, where the heteroatom linker is an oxygen atom, and the functional group present on the spacer linker or the releasable linker is sulfonyl derivative, the required sulfonate group can be formed by reacting the corresponding hydroxy-substituted compound with an activated sulfonyl derivative where L is a suitable leaving group such as halo, and the like, as illustrated in Scheme 11.

![Scheme 11](image)

**[0125]** Solvents that can be used are THF, EtOAc, CH₂Cl₂, CHCl₃, CCl₄, and the like. The temperature range employed in this transformation may vary between 0°C and 80°C. Any basic catalyst such as an inorganic base, an amine base, a polymer bound base, and the like can be used to facilitate the reaction.

**[0126]** General formation of folate-peptides. The folate-containing peptide fragment Pte-Glu-(AA)ₙ-NH(CHR₂)CO₂H (3) is prepared by a polymer-supported sequential approach using standard methods, such as the Fmoc-strategy on an acid-sensitive Fmoc-AA-Wang resin (1), as shown in Scheme 12.

![Scheme 12](image)
In this illustrative embodiment of the processes described herein, R is Fmoc, R₂ is the desired appropriately-protected amino acid side chain, and DIPEA is diisopropylethylamine. Standard coupling procedures, such as PyBOP and others described herein or known in the art are used, where the coupling agent is illustratively applied as the activating reagent to ensure efficient coupling. Fmoc protecting groups are removed after each coupling step under standard conditions, such as upon treatment with piperidine, tetrabutylammonium fluoride (TBAF), and the like. Appropriately protected amino acid building-blocks, such as Fmoc-Glu(tBut), N°-TFA-Pte-OH, and the like, are used, as described in Scheme 12, and represented in step (b) by Fmoc-AA-OH. Thus, AA refers to any amino acid starting material that is appropriately protected. It is to be understood that the amino acid as used herein is intended to refer to any reagent having both an amine and a carboxylic acid functional group separated by one or more carbons, and includes the naturally occurring alpha and beta amino acids, as well as amino acid derivatives and analogs of these amino acids. In particular, amino acids having side chains that are protected, such as protected serine, threonine, cysteine, aspartate, and the like may also be used in the folate-peptide synthesis described herein. Further, gamma, delta, or longer homologous amino acids may also be included as starting materials in the folate-peptide synthesis described herein. Further, amino acid analogs having homologous side chains, or alternate branching structures, such as norleucine, isovaline, β-methyl threonine, β-methyl cysteine, β,β-dimethyl cysteine, and the like, may also be included as starting materials in the folate-peptide synthesis described herein.

The coupling sequence (steps (a) & (b)) involving Fmoc-AA-OH is performed “n” times to prepare solid-support peptide 2, where n is an integer and may equal 0 to about 100. Following the last coupling step, the remaining Fmoc group is removed (step (a)), and the peptide is sequentially coupled to a glutamate derivative (step (c)), deprotected, and coupled to TFA-protected pteroic acid (step (d)). Subsequently, the peptide is cleaved from the polymeric support upon treatment with trifluoroacetic acid, ethanedithiol, and trisopropylsilane (step (e)). These reaction conditions result in the simultaneous removal of the t-Bu, t-Boc, and Trt protecting groups that may form part of the appropriately-protected amino acid side chain. The TFA protecting group is removed upon treatment with base (step (O)) to provide the folate-containing peptidyl fragment 3.

In another method of treatment embodiment, the group D in the targeted conjugate V-L-D, comprises an antigen (i.e., a compound that is administered for the purpose of eliciting an immune response in vivo), the ligand-antigen conjugates being effective to “label” the population of proximal tubule cells responsible for disease pathogenesis in the patient suffering from the kidney disease for specific elimination by an endogenous immune response or by co-administered antibodies. The use of ligand-antigen conjugates in the method of treatment described herein works to enhance an immune response-mediated elimination of the proximal tubule cells proliferating abnormally that overexpress the ligand receptor. Such elimination can be effected through an endogenous immune response or by a passive immune response effectuated by co-administered antibodies.

The methods of treatment involving the use of ligand-antigen conjugates are described in U.S. patent application Ser. Nos. 09/822,379, 10/138,275, and PCT Application Serial No. PCT/US04/014097, each incorporated herein by reference.

The endogenous immune response can include a humoral response, a cell-mediated immune response, and any other immune response endogenous to the host animal, including complement-mediated cell lysis, antibody-dependent cell-mediated cytotoxicity (ADCC), antibody opsonization leading to phagocytosis, clustering of receptors upon antibody binding resulting in signaling of apoptosis, antiproliferation, or differentiation, and direct immune cell recognition of the delivered antigen (e.g., a hapten). It is also contemplated that the endogenous immune response may employ the secretion of cytokines that regulate such processes as the multiplication, differentiation, and migration of immune cells. The endogenous immune response may include the participation of such immune cell types as B cells, T cells, including helper and cytotoxic T cells, macrophages, natural killer cells, neutrophils, LAK cells, and the like.

The humoral response can be a response induced by such processes as normally scheduled vaccination, or active immunization with a natural antigen or an unnatural antigen or hapten, e.g., fluorescein isothiocyanate (FITC) or dinitrophenyl (DNP), with the unnatural antigen inducing a novel immunity. Active immunization involves multiple injections of the unnatural antigen or hapten scheduled outside of a normal vaccination regimen to induce the novel immunity. The humoral response may also result from an innate immunity where the host animal has a natural preexisting immunity, such as an immunity to α-galactosyl groups.
[0133] Alternatively, a passive immunity may be established by administering antibodies to the host animal such as natural antibodies collected from serum or monoclonal antibodies that may or may not be genetically engineered antibodies, including humanized antibodies. The utilization of a particular amount of an antibody reagent to develop a passive immunity, and the use of a ligand-antigen conjugate wherein the passively administered antibodies are directed against the antigen, would provide the advantage of a standard set of reagents to be used in cases where a patient’s preexisting antibody titer to potential antigens is not therapeutically useful. The passively administered antibodies may be “co-administered” with the ligand-antigen conjugate, and co-administration is defined as administration of antibodies at a time prior to, at the same time as, or at a time following administration of the ligand-antigen conjugate.

[0134] The preexisting antibodies, induced antibodies, or passively administered antibodies will be redirected to the proximal tubule cells proliferating abnormally by binding of the ligand-antigen conjugates to the proximal tubule cell populations overexpressing the receptor for the ligand, and such pathogenic cells are killed or eliminated or reduced in number by complement-mediated lysis, ADCC, antibody-dependent phagocytosis, or antibody clustering of receptors. The cytotoxic process may also involve other types of immune responses, such as cell-mediated immunity.

[0135] Acceptable antigens for use in preparing the conjugates used in the method of treatment described herein are antigens that are capable of eliciting antibody production in a patient or animal or that have previously elicited antibody production in a patient or animal, resulting in a preexisting immunity, or that constitute part of the innate immune system. Alternatively, antibodies directed against the antigen may be administered to the patient or animal to establish a passive immunity. Suitable antigens for use in the invention include antigens or antigenic peptides against which a preexisting immunity has developed via normally scheduled vaccinations or prior natural exposure to such agents such as polio virus, tetanus, typhus, rubella, measles, mumps, pertussis, tuberculosis and influenza antigens, and α-galactosyl groups. In such cases, the ligand-antigen conjugates will be used to redirect a previously acquired humoral or cellular immunity to a population of proximal tubule cells proliferating abnormally in the patient or animal for elimination of the proximal tubule cells or reduction in number or inactivation, completely or partially.

[0136] Other suitable immunogens include antigens or antigenic peptides to which the host animal has developed a novel immunity through immunization against an unnatural antigen or hapten, for example, fluorescein isothiocyanate (FITC) or dinitrophenyl, and antigens against which an innate immunity exists, for example, super antigens and muramyl dipeptide.

[0137] The proximal tubule cell-binding ligands and antigens, cytotoxic agents, and cell growth inhibitors, or diagnostic markers, as the case may be, in forming conjugates for use in accordance with the methods described herein can be conjugated by using any art-recognized method for forming a complex. This can include covalent, ionic, or hydrogen bonding of the ligand V to the group D compound, either directly or indirectly via a linking group such as a divalent linker. The conjugate is typically formed by covalent bonding of the ligand to the targeted entity through the formation of amide, ester or imino bonds between acid, aldehyde, hydroxy, amino, or hydrazo groups on the respective components of the complex or, for example, by the formation of disulfide bonds. Methods of linking binding ligands to antigens, cytotoxic agents, or cell growth inhibitors, or diagnostic markers are described in U.S. patent application Ser. Nos. 10/765,336 and 60/590,580, each incorporated herein by reference.

[0138] Alternatively, as mentioned above, the ligand complex can be one comprising a liposome wherein the targeted entity (that is, the diagnostic marker, or the antigen, cytotoxic agent or cell growth inhibitor) is contained within a liposome which is itself covalently linked to the binding ligand. Other nanoparticles, dendrimers, derivatizable polymers or copolymers that can be linked to therapeutic or diagnostic markers useful in the treatment and diagnosis of kidney disease states can also be used in targeted conjugates.

[0139] In one embodiment of the invention the ligand is folic acid, an analog of folic acid, or any other folate receptor binding molecule, and the folate ligand is conjugated to the targeted entity by a procedure that utilizes trifluoroacetic anhydride to prepare γ-esters of folic acid via a pteroyl azide intermediate. This procedure results in the synthesis of a folate ligand, conjugated to the targeted entity only through the γ-carboxy group of the glutamic acid groups of folate. Alternatively, folic acid analogs can be coupled through the α-carboxy moiety of the glutamic acid group or both the α and γ carboxylic acid entities.

[0140] The therapeutic methods described herein can be used to slow the progress of disease completely or partially. Alternatively, the therapeutic methods described herein can eliminate or prevent reoccurrence of the disease state.

[0141] The conjugates used in accordance with the methods described herein of the formula V-L-D are used in one aspect to formulate therapeutic or diagnostic compositions, for administration to a patient or animal, wherein the compositions comprise effective amounts of the conjugate and an acceptable carrier therefor. Typically such compositions are formulated for parenteral use. The amount of the conjugate effective for use in accordance with the methods described herein depends on many parameters, including the nature of the disease being treated or diagnosed, the molecular weight of the conjugate, its route of administration and its tissue distribution, and the possibility of co-usage of other therapeutic or diagnostic agents. The effective amount to be administered to a patient or animal is typically based on body surface area, patient weight and physician assessment of patient condition. An effective amount can range from about 1 mg/kg to about 1 mg/kg, more typically from about 1 μg/kg to about 500 μg/kg, and most typically from about 1 μg/kg to about 100 μg/kg.

[0142] Any effective regimen for administering the ligand conjugates can be used. For example, the ligand conjugates can be administered as single doses, or they can be divided and administered as a multiple-dose daily regimen. Further, a staggered regimen, for example, one to three days per week can be used as an alternative to daily treatment, and such an intermittent or staggered daily regimen is considered to be equivalent to every day treatment and within the scope of this disclosure. In one embodiment, the patient or animal is treated with multiple injections of the ligand conjugate wherein the targeted entity is an antigen or a cytotoxic agent or a cell growth inhibitor to eliminate the population of patho-
genic proximal tubule cells. In one embodiment, the patient or animal is treated, for example, injected multiple times with the ligand conjugate at, for example, 12-72 hour intervals or at 48-72 hour intervals. Additional injections of the ligand conjugate can be administered to the patient or animal at intervals of days or months after the initial injections, and the additional injections prevent recurrence of disease. Alternatively, the ligand conjugates may be administered prophylactically to prevent the occurrence of disease in patients or animals known to be disposed to development of kidney disease states. In one embodiment, more than one type of ligand conjugate can be used, for example, the patient or animal may be pre-immunized with fluorescein isothiocyanate and dinitrophenyl and subsequently treated with fluorescein isothiocyanate and dinitrophenyl linked to the same or different targeting ligands in a co-dosing protocol.

Example 2

Synthesis of Folate-Cysteine

[0146] Standard Fmoc peptide chemistry can be used to synthesize folate-cysteine with the cysteine attached to the γ-COOH of folic acid. The sequence Cys-Glu-Pteroic acid (Folate-Cys) will be constructed by Fmoc chemistry with HBTU and N-hydroxybenzotriazole as the activating agents along with diisopropylethylamine as the base and 20% piperidine in dimethylformamide (DMF) for deprotection of the Fmoc groups. An α-t-Boc-protected N-α-Fmoc-L-glutamic acid will be linked to a trityl-protected Cys linked to a 2-Chlorotryptil resin. N unforeoacetylpteroic acid was then attached to the γ-COOH of Glu. The Folate-Cys was cleaved from the resin using a 92.5% trifluoroacetic acid-2.5% water-2.5% trisopropylsilane-2.5% ethanedithiol solution. Diethyl ether will be used to precipitate the product, and the precipitate was collected by centrifugation. The product will be washed twice with diethyl ether and dried under vacuum overnight. To remove the N unforeoacetyl protecting group, the product will be dissolved in 10% ammonium hydroxide solution and stirred for 30 min at room temperature. The solution will be kept under a stream of nitrogen the entire time in order to prevent the cysteine from forming disulfides. After 30 minutes, hydrochloric acid will be added to the solution until the compound precipitates. The product will be collected by centrifugation and lyophilized. The product will be analyzed and confirmed by mass spectroscopic analysis.

Example 3

Synthesis of Folate-R-Phycocerythin

[0147] Folate-phycocerythin will be synthesized by following a procedure published by Kennedy M. D. et al. in Pharmaceutical Research, Vol. 20(5); 2003. Briefly, a 10-fold excess of folate-cysteine will be added to a solution of R-phycoerythrin pyridyl disulfide (Sigma, St. Louis, Mo.) in phosphate buffered saline (PBS), pH 7.4. The solution will be allowed to react overnight at 4°C. and the labeled protein (Mr ~260 kDa) will be purified by gel filtration chromatography using a G-15 desalting column. The folate labelling will be confirmed by fluorescence microscopy of M109 cells incubated with folate-phycocerythin in the presence and absence of 100-fold excess of folic acid. After a 1-h incubation and 3 cells washes with PBS, the treated cells will be intensely fluorescent, while the sample in the presence of excess folic acid will show little cellular fluorescence.
Example 4
Synthesis of Folate-Fluorescein

Folate-EDA-FITC
MW 888.90

Example 5
Liposome Preparation

[0149] Liposomes will be prepared following methods by Leamon et al. in Bioconjugate Chemistry 2003, 14, 738-747. Briefly, lipids and cholesterol will be purchased from Avanti Polar Lipids (Alabaster, Ala.). Folate-targeted liposomes will consist of 40 mole % cholesterol, either 4 mole % or 6 mole % polyethylene glycol (Mr–2000)-derivatized phosphatidylethanolamine (PEG2000-PE, Nektar AI., Huntsville, Ala.), either 0.03 mole % or 0.1 mole % folate-cysteine-PEG3400-PE and the remaining mole % will be composed of egg phosphatidylcholine. Non-targeted liposomes will be prepared identically with the absence of folate-cysteine-PEG3400-PE. Lipids in chloroform will be dried to a thin film by rotary evaporation and then rehydrated in PBS containing the drug. Rehydration will be accomplished by vigorous vortexing followed by 10 cycles of freezing and thawing. Liposomes will be extruded 10 times through a 50 nm pore size polycarbonate membrane using a high-pressure extruder (Lipex Biomembranes, Vancouver, Canada).

Example 6
Synthesis of Folate-Saporin

[0150] The protein saporin will be purchased from Sigma (St. Louis, Mo.). Folate-saporin will be prepared following folate-protein conjugation methods published by Leamon and Low in The Journal of Biological Chemistry 1992, 267 (35); 24966-24971. Briefly, folic acid will be dissolved in DMSO and incubated with a 5 fold molar excess of 1-ethyl-3-(3-dimethylaminopropyl)carbodiimide for 30 minutes at room temperature. The saporin will be dissolved in 100 mM KH₂PO₄, 100 mM boric acid, pH 8.5. A 10-fold molar excess of the “activated” vitamin will be added to the protein solution and the labeling reaction was allowed to proceed for 4 hours.

Example 7
Synthesis of Folate-Peptides

[0151] Generally, the reagents shown in the following table were used in the preparation of this example and other examples:

<table>
<thead>
<tr>

</table>

[0152] The coupling step was performed as follows: In a peptide synthesis vessel add the resin, add the amino acid solution, DIPEA, and PyBOP. Bubble argon for 1 hr. and wash 3x with DMF and IPA. Use 20% piperidine in DMF for Fmoc deprotection, 3x (10 min), before each amino acid coupling. Continue to complete all 6 coupling steps. At the end wash the resin with 2% hydrazine in DMF 3x (5 min) to cleave TFA protecting group on Pteroic acid.

[0153] Cleave the peptide analog from the resin using the following reagent, 92.5% (50 mL) TFA, 2.5% (1.34 mL) H₂O, 2.5% (1.34 mL) Triisopropylsilane, 2.5% (1.34 mL) ethanedithiol, the cleavage step was performed as follows:
Add 25 ml cleavage reagent and bubble for 1.5 hr, drain, and wash 3x with remaining reagent. Evaporate to about 5 mL and precipitate in ethyl ether. Centrifuge and dry. Purification was performed as follows: Column—Waters NovoPak C18 300x 19 mm; Buffer A=10 mM Ammonium Acetate, pH 5; B=ACN; 1% B to 20% B in 40 min to 350 mg (64%); HPLC-RT 10.307 min, 100% pure, 1H NMR spectrum consistent with the assigned structure, and MS (ES+)

Example 8
Synthesis of Folate-γ-Asp-Arg-Asp-Asp-Cys

According to the general procedure of the prior example and Scheme 12, Wang resin bound 4-methoxytrityl (MTT)-protected Cys-NH₂ was reacted according to the following sequence: 1) a. Fmoc-Asp(OrBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 2) a. Fmoc-Asp(OrBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 3) a. Fmoc-Arg(Pbf)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 4) a. Fmoc-Asp(OrBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 5) a. Fmoc-Glu(OrBu), PyBOP, DIPEA; b. 20% Piperidine/DMF; 6) N₁⁰-TFA-pterogenic acid, PyBOP, DIPEA. The MTT, tBu, and Pbf protecting groups were removed with aqueous NH₂OH at pH=9.3. Selected ¹H NMR (D₂O) δ (ppm) 8.68 (s, 1H, FAH-7), 7.57 (d, 2H, J=8.4 Hz, FA H-12 &16), 6.67 (d, 2H, J=9 Hz, FA H-13 & 15), 4.40-4.75 (m, 5H), 4.35 (m, 2H), 4.16 (m, 1H), 3.02 (m, 2H), 2.55-2.95 (m, 81H), 2.42 (m, 2H), 2.00-2.30 (m, 2H), 1.55-1.90 (m, 2H), 1.48 (m, 2H); MS (ESI, m⁺H⁺) 1046.

Example 9
Synthesis of Folate-γ-Asp-Asp-Asp-(β-NH₂-Ala)-Cys

[0154] [0155]

[0156]
According to the general procedure of the prior example and Scheme 12, Wang resin bound 4-methoxytrityl (MTT)-protected Cys-NH₂ was reacted according to the following sequence: 1) a. Fmoc-β-aminoalanine(NH-MTT)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 2) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 3) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 4) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 5) a. Fmoc-Glu(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 6) N¹⁰-TFA-pterioic acid, PyBOP, DIPEA. The MTT, tBu, and TFA protecting groups were removed with a. 2% hydrazine/DMF; b. TFA/H₂O/TIPS/EDT (92.5:2.5:2.5:2.5).

Example 10

Synthesis of Folate-α-Asp-Arg-Asp-Asp-Cys

According to the general procedure of the prior example and Scheme 12, Wang resin bound MTT-protected Cys-NH₂ was reacted according to the following sequence: 1) a. Fmoc-β-aminoalanine(NH-MTT)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 2) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 3) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 4) a. Fmoc-Asp(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 5) a. Fmoc-Glu(OTBu)-OH, PyBOP, DIPEA; b. 20% Piperidine/DMF; 6) N¹⁰-TFA-pterioic acid, PyBOP, DIPEA. The MTT, tBu, and Pbf protecting groups were removed with TFA/H₂O/TIPS/EDT (92.5:2.5:2.5:2.5), and the TFA protecting group was removed with aqueous NH₂OH at pH=9.3. The ¹H NMR spectrum was consistent with the assigned structure.

Example 11

Synthesis of Folate-γ-D-Asp-D-Arg-D-Asp-D-Asp-D-Cys

According to the general procedure of the prior example and Scheme 12, Wang resin bound MTT-protected D-Cys-NH₂ was reacted according to the following sequence:
Example 12

Example 14

Immunofluorescence

The ability of folate-conjugated rapamycin to inhibit the mTOR pathway was tested in KB cells using...
immunostaining for P-S6 as a marker (see FIG. 6). The immunostaining procedure was performed according to the following protocol:

1. Aspirate media from cells and immediately add 1 ml/well of 10% neutral-buffered formalin (NBF) to each well.
2. Fix cells for 15 minutes at room temp with gentle orbital shaking.
3. Aspirate NBF from cells and wash briefly with 2 changes (1 ml/well) of 1xPBS.
4. Aspirate PBS and add 1 ml of quench solution and quench for 10 minutes at room temperature with gentle orbital shaking.
5. Aspirate quench and wash briefly with 2 changes (1 ml/well) of 1xPBS.
6. Aspirate PBS and add 1 ml/well cell block/permeabilization (CBP) solution and incubate for 30 minutes at 37°C.
7. Prepare P-S6 (S235/6)/β-tubulin antibody solution by diluting antibody 1:200 in CBP solution (for 12 coverslips make 1194 ul CBP+6 ul P-S6 and β-tubulin). Mix thoroughly.
8. Remove the lid from the cell culture dish and place in a humidified chamber. Cut paraffin to the size of the lid and press firmly on to the lid.
9. Using a pair of needle-nose tweezers transfer a coverslip, cell-side up, to its corresponding well position on the lid. Pipet 150 µl of P-S6/β-tubulin antibody solution onto the coverslip. Repeat for all remaining coverslips.
10. Close the lid and incubate overnight at 4°C.
11. The following day, make 100 ml cell wash (CW) solution.
12. Pipet 1 ml CW solution into each well of a fresh 12-well plate. Using two pairs of tweezers, one placed on the back of the coverslip, carefully pick up the coverslip and place back in the corresponding well.
13. Incubate for 5 minutes with gentle orbital shaking. Aspirate and repeat wash 2x.
14. During washes, dilute fluorescent-conjugated anti-rabbit FITC and anti-mouse TXR secondary antibodies 1:200 in CBP. Centrifuge 10 minutes at 4°C, 13,000 rpm, to remove aggregates.
15. After washing, repeat steps 8 and 9 with diluted fluorescent-conjugated secondary antibody solution. Incubate for 1 hour at 37°C.
17. Rinse 1x with 1xPBS.
18. Aspirate and wash 2x3 minutes with 1xPBS+0.1% Triton-X 100 with gentle orbital shaking.
19. Aspirate and rinse 2x with 1xPBS.
20. Aspirate and add 1 ml of 10% NBF to post-fix secondary antibodies. Incubate for 10 minutes at room temperature with gentle orbital shaking.
21. Aspirate and wash 1x5 minutes with 1xPBS.
22. Aspirate and add 1 ml of 1xPBS+DAP(1 mg/ml stock, 1:50,000 dilution). Incubate for 5-10 minutes.
23. Thaw Prolong Gold mounting medium. Dispense two drops on a slide. Using needle-nose tweezers remove individual coverslips, wipe excess solution from backside and place on top of mounting medium, cell-side down. Gently squeeze out any air bubbles with the opposite end of the tweezers.

25. Allow mounting medium to harden for at least 1 hour, preferably overnight. View slides under a suitable microscope equipped for fluorescence. Store slides at -20°C.

Example 15
Folate Receptor Immunohistochemistry

Immunohistochemistry was performed as described in PCT Publ. No. WO/2006/105141, incorporated herein by reference. As shown in FIGS. 1 and 2, monoclonal and polyclonal antibodies to the folate receptor stain cysts in polycystic kidney disease tissues indicating folate receptor overexpression in the cells that form PKD cysts (see also Table 1 below).

Example 16
Relative Affinity Assay

Binding assays were run to determine the relative affinities of EC0371 and folic acid at the folate receptor. KB cells were incubated for 1 hour at 37°C with 100 nM 3H-folic acid in the presence and absence of increasing competitor concentrations. As shown in FIG. 4 (error bars represent 1 standard deviation (n=3)), the relative affinity of EC0371 at the folate receptor is 0.5 compared to a relative affinity of 1.0 for folic acid.

Example 17
Cell Viability

Cell viability was examined in KB cells following incubation for 16 hours in Rapamycin (2, 10, and 50 nM), EC0371 (2, 10, and 50 nM), DMSO (diluent), and media alone (FIG. 5). At 24 hours, neither rapamycin nor EC0371 was found to be cytotoxic at any of the concentrations tested.

Example 18
P-S6 and P-S6K Immunoblots

Folate-rapamycin was found to be highly effective in inhibiting mTOR in cultured cells. Folate receptor-positive KB cells were treated with either unconjugated rapamycin (2, 10, or 50 nM) or folate-rapamycin (2, 10, or 50 nM) for 16
hours. The activity of mTOR was determined by immunoblotting using phospho-specific antibodies against P-S6 and P-S6K (FIG. 7).

Example 19

Therapeutic Effects of EC0371 In Vivo

[0192] The therapeutic effect of EC0371 (folate-conjugated rapamycin) was tested on in vivo development of polycystic kidney disease in the bpk-mutant mouse model. Bpk-mutant mice develop polycystic kidney disease (PKD) starting at embryogenesis due to a point mutation in the gene encoding bicucullin C. All nephron segments are affected, and most bpk-mutant mice die between postnatal days 24-30 due to severely enlarged cystic kidneys and renal failure.

[0193] All mice were genotyped by PCR prior to treatment. Wildtype (Wt) and bpk-mutant (bpk) mice were then segregated into the following three groups: no treatment (n=5 Wt, 2 bpk); vehicle treatment (n=5 Wt, 3 bpk); and EC0371 treatment (n=4 Wt, 4 bpk).

[0194] EC0371 was prepared by reconstitution in sterile PBS to a concentration of 1 mM, then diluted 1:5 for a final concentration of 0.2 mM (2 nmol/ul). Mice were injected (i.p.)daily with either EC0371 (3 μmol/kg), vehicle (PBS), or received no injection, from postnatal day 7 to day 21. On day 21, whole body weight was recorded and blood was collected. Mice were then sacrificed and the kidneys, liver, spleen, and thymus were removed and weighed. EC0371 treatment of bpk-mutant mice was found to significantly improve the PKD phenotype as measured by kidney size (FIG. 8), and proportion of kidney(s) to whole body weight (FIGS. 9 and 10).

1. A method for diagnosing a kidney disease state, said method comprising the steps of:
   administering to a patient a composition comprising a conjugate or complex of the general formula

   V-L-D

   where the group V comprises a vitamin receptor binding ligand that binds to kidney cells and the group D comprises a cell growth inhibitor.

2-11. (canceled)

12. A method for treating a kidney disease state, said method comprising the steps of:
   administering to a patient suffering from the disease state an effective amount of a composition comprising a conjugate or complex of the general formula

   V-L-D

   where the group V comprises a vitamin receptor binding ligand that binds to kidney cells and the group D comprises an antigen, a cytotoxin, or a cell growth inhibitor; and
   eliminating the disease state.

13. The method of claim 12 wherein V comprises a folate.

14. (canceled)

15. The method of claim 12 wherein the group D comprises an antigen.

16. The method of claim 13 wherein the group D comprises an antigen.

17. The method of claim 12 wherein the group D comprises a cytotoxin.

18. The method of claim 17 wherein the group D further comprises a liposome.

19. The method of claim 13 wherein the group D comprises a cytotoxin.

20. The method of claim 19 wherein the group D further comprises a liposome.

21. The method of claim 12 wherein the group D comprises a cell growth inhibitor.

22-23. (canceled)

24. The method of claim 13 wherein the group D comprises a cell growth inhibitor.

25-26. (canceled)

27. The method of claim 21 wherein the cell growth inhibitor is rapamycin.

28. The method of claim 24 wherein the cell growth inhibitor is rapamycin.

29. A compound of the formula V-L-D, wherein V is a folate receptor binding ligand, L is an optional linker, and D is a cell-growth inhibitor.

30. The compound of claim 29 wherein V-L-D has the following formula:
where L is as defined herein, and L is connected to the rapamycin or analog or derivative thereof at either of (O<sup>α</sup>), and the other of (O<sup>α</sup>) is substituted with R, wherein R is hydrogen or —CO(CR<sup>3</sup>R<sup>4</sup>)<sub>0</sub>(CR<sup>3</sup>R<sup>4</sup>)<sub>2</sub>CR<sup>3</sup>R<sup>4</sup>R; where
R<sup>3</sup> and R<sup>4</sup> are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, trifluoromethyl, or F;
R<sup>2</sup> and R<sup>6</sup> are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR<sup>3</sup>R<sup>4</sup>)<sub>0</sub>OH, CF<sub>3</sub>, F, or CO<sub>2</sub>R<sub>11</sub>.
R<sup>7</sup> is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR<sup>3</sup>R<sup>4</sup>)<sub><sub>0</sub>H, CF<sub>3</sub>, F, or CO<sub>2</sub>R<sub>11</sub>;
R<sup>8</sup> and R<sup>9</sup> are each, independently, hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, (CR<sup>3</sup>R<sup>4</sup>)<sub>0</sub>OH, CF<sub>3</sub>, F, or CO<sub>2</sub>R<sub>11</sub>.
R<sup>10</sup> is hydrogen, alkyl of 1-6 carbon atoms, alkenyl of 2-7 carbon atoms, alkynyl of 2-7 carbon atoms, or phenylalkyl of 7-10 carbon atoms;
b=0-6; d=0-6; and f=0-6.

31. (canceled)

32. The compound of claim 29 wherein the cell growth inhibitor is an epidermal growth factor receptor kinase inhibitor.

33. The compound of claim 29 wherein the cell growth inhibitor is an inhibitor of mTOR.

34. The compound of claim 29 wherein the cell growth inhibitor is a rapamycin.

35. The compound of claim 29 wherein the folate receptor binding ligand is a folate.

36. The compound of claim 29 wherein the linker is a peptide comprising one or more amino acids selected from the group consisting of cysteine, aspartic acid, and arginine, where the amino acid can be either the D or the L configuration in each instance.
