15

Metalloproteinase enzymes, such as collagenases, stromelysins and gelatinases, may contribute to the onset or etiology of, or exacerbate disease states which are related to, connective tissue degradation and the like. For example, matrix metalloproteinases, such as collagenases, stromelysins and gelatinases, are thought to be involved in the tissue breakdown observed in rheumatoid arthritis; osteoarthritis; osteopenias (e.g., osteoporosis); periodontitis; gingivitis; corneal, epidermal and gastric ulceration; and tumour metastasis, invasion and growth; in neuroinflammatory disorders, such as myelin degradation (e.g., multiple sclerosis); and in angiogenesis dependent diseases, such as arthritic conditions; cancer; solid tumor growth; psoriasis; proliferative retinopathies; neovascular glaucoma; ocular tumours; angiofibromas; hemangiomas; nephritis; pulmonary inflammation; and restenosis.

"Leaving group" generally refers to groups readily
displaceable by a nucleophile, such as an amine, a thiol
30 or an alcohol nucleophile. Such leaving groups are well
known in the art. Examples of such leaving groups
include, but are not limited to, N-hydroxysuccinimide,
N-hydroxybenzotriazole, halides, triflates, tosylates
and the like. Preferred leaving groups are indicated
35 herein where appropriate.

"Protecting group" generally refers to groups well known in the art which are used to prevent selected reactive groups, such as carboxy, amino, hydroxy, mercapto and the like, from undergoing undesired reactions, such as nucleophilic, electrophilic, oxidation, reduction and the like. Preferred protecting groups are indicated herein where appropriate. Examples of amino protecting groups include, but are not limited to, aralkyl, substituted aralkyl, cycloalkenylalkyl and substituted cycloalkenyl alkyl, allyl, substituted allyl, acyl, alkoxycarbonyl, aralkoxycarbonyl, silyl and the like. Examples of aralkyl include, but are not limited to, benzyl, ortho-methylbenzyl, trityl and benzhydryl, which can be optionally substituted with halogen, alkyl, alkoxy, hydroxy, nitro, acylamino, acyl and the like, and salts, such as phosphonium and ammonium salts. Examples of aryl groups include phenyl, naphthyl, indanyl, anthracenyl, 9-(9-phenylfluorenyl), phenanthrenyl, durenyl and the like. Examples of cycloalkenylalkyl or substituted cycloalkenylalkyl radicals, preferably have 6-10 carbon atoms, include, but are not limited to, cyclohexenyl methyl and the like. Suitable acyl, alkoxycarbonyl and aralkoxycarbonyl groups include benzyloxycarbonyl, t-butoxycarbonyl, iso-butoxycarbonyl, benzoyl, substituted benzoyl, butyryl, acetyl, tri-fluoroacetyl, tri-chloro acetyl, phthaloyl and the like. A mixture of protecting groups can be used to protect the same amino group, such as a primary amino group can be protected by both an aralkyl group and an aralkoxycarbonyl group. Amino protecting groups can also form a heterocyclic ring with the nitrogen to which they are attached, for example, 1,2-bis(methylene)benzene, phthalimidyl, succinimidyl, maleimidyl and the like and where these heterocyclic groups can further include adjoining aryl and cycloalkyl rings. In addition, the heterocyclic groups can be mono-, di- or tri-substituted, such as

nitrophthalimidyl. Amino groups may also be protected against undesired reactions, such as oxidation, through the formation of an addition salt, such as hydrochloride, toluenesulfonic acid, trifluoroacetic acid and the like. Many of the amino protecting groups are also suitable for protecting carboxy, hydroxy and mercapto groups. For example, aralkyl groups. Alkyl groups are also suitable groups for protecting hydroxy and mercapto groups, such as tert-butyl.

10 Silyl protecting groups are silicon atoms optionally substituted by one or more alkyl, aryl and aralkyl groups. Suitable silyl protecting groups include, but are not limited to, trimethylsilyl, triethylsilyl, tri-isopropylsilyl, tert-butyl-
15 dimethylsilyl, dimethylphenylsilyl, 1,2-bis(dimethylsilyl)benzene, 1,2-bis(dimethylsilyl)ethane and diphenylmethylsilyl. Silylation of an amino groups provide mono- or di-silylamino groups. Silylation of aminoalcohol compounds can lead to a N,N,O-tri-silyl
20 derivative. Removal of the silyl function from a silyl ether function is readily accomplished by treatment with, for example, a metal hydroxide or ammonium fluoride reagent, either as a discrete reaction step or in situ during a reaction with the alcohol group.

25 Suitable silylating agents are, for example, trimethylsilyl chloride, tert-butyl-dimethylsilyl chloride, phenyldimethylsilyl chloride, diphenylmethylsilyl chloride or their combination products with imidazole or DMF. Methods for silylation of amines and
30 removal of silyl protecting groups are well known to those skilled in the art. Methods of preparation of these amine derivatives from corresponding amino acids, amino acid amides or amino acid esters are also well known to those skilled in the art of organic chemistry
35 including amino acid/amino acid ester or aminoalcohol chemistry.

Protecting groups are removed under conditions which will not affect the remaining portion of the molecule. These methods are well known in the art and include acid hydrolysis, hydrogenolysis and the like. A preferred method involves removal of a protecting group, such as removal of a benzyloxycarbonyl group by hydrogenolysis utilizing palladium on carbon in a suitable solvent system such as an alcohol, acetic acid, and the like or mixtures thereof. A t-butoxycarbonyl protecting group can be removed utilizing an inorganic or organic acid, such as HCl or trifluoroacetic acid, in a suitable solvent system, such as dioxane or methylene chloride. The resulting amino salt can readily be neutralized to yield the free amine. Carboxy protecting group, such as methyl, ethyl, benzyl, tert-butyl, 4-methoxyphenylmethyl and the like, can be removed under hydrolysis and hydrogenolysis conditions well known to those skilled in the art.

Procedures for preparing the compounds of this invention are set forth below. It should be noted that the general procedures are shown as it relates to preparation of compounds having unspecified stereochemistry. However, such procedures are generally applicable to those compounds of a specific stereochemistry, e.g., where the stereochemistry about a group is (S) or (R). In addition, the compounds having one stereochemistry (e.g., (R)) can often be utilized to produce those having opposite stereochemistry (i.e., (S)) using well-known methods, for example, by inversion.

Preparation of Compounds of Formula I

The compounds of the present invention represented by Formula I above can be prepared using various synthesis techniques, many of which are included by reference. In particular, compounds of the present

invention can be prepared following the general procedures discussed below.

A general synthesis useful for the preparation of the novel compounds of this invention is illustrated in Scheme I, which employs a convergent route to the azepine ring and larger ring systems. According to this method, the readily available Horner-Emmons reagent is reacted under standard conditions (see Wadsworth, Org. Reactions, 1977, 25, 73) with an aldehyde variably substituted by a silyl ether as well as additional substitution on the alkyl chain (R5, R6, R9, R10) to provide the α,β unsaturated ester. Deprotection of the silyl group, activation of the alcohol to provide a leaving group and intramolecular base catalyzed closure provides a key intermediate. Subsequent deprotection of the t-BOC group with dry HCl/Ethyl acetate (Gibson, J. Org. Chem., 1994, 59, 3216) or with TFA and

SCHEME I

- sulfonylation with a sulfonyl halide in the presence of a base, preferably a hindered amine base such as triethyl amine in a chlorinated solvent provides the substituted sulfonamide. The R group is a group that can be converted into an amino group using methods well known to those skilled in the art, such as benzyl amine, silyl protected benzyl amine, phthalimide, or other readily available nucleophilic amine equivalents. The protected primary amine is deprotected to the unsubstituted primary amine by methods known in the art for example hydrogenation in the presence of a metal catalyst. The primary amine is then functionalized to provide the ester derivatives of the final product. Methods for functionalization include sulfonylation as described above, treatment with isocyanates to prepare

ureas, treatment with acid chlorides or mixed anhydrides to provide amides, reductive aminations to provide amines, and chloroformates to provide carbamates (See Compendium of Synthetic Organic Methods, Wiley). These
5 adducts are treated with aqueous alkali bases such as LiOH to provide the free acid products when methyl or ethyl esters are used or TFA when the t-butyl ester is used as the ester component.

A second general synthesis useful for the
10 preparation of the novel compounds of this invention is illustrated in Scheme II, which employs a convergent route to the azepine ring.

The readily available aspartic, or glutamic acid derivative is protected and allylated as described
15 previously for an analog (see Baldwin, Tetrahedron, 1989, 45, 6309 and references cited therein). Mitsunobu reaction of the resulting sulfonamide (see Mitsunobu, Synthesis, 1981, 1) provides the bis olefin. Treatment of the resulting olefin with a metathesis reagent (see
20 Schuster, Angew. Chem. Int. Ed. Engl. 1997, 36, 2036) provides the cyclized olefin. Saponification, as known by one skilled in the art, followed by curtius rearrangement of the resultant acid under known conditions (Tetrahedron, 1974, 30, 2151) provides the desired
25 carbamates. The t-butyl acid protected carbamates can be deprotected with concentrated trifluoroacetic acid (TFA) to provide the final products. Additionally, by choosing the appropriate alcohol trapping agent for the Curtius rearrangement, for example, 4-methoxy benzyl
30 alcohol, the carbamate may be diferentially deprotected to the amine with dilute (3%) TFA in a chlorinated solvent to provide the t-butyl protected acid, amine salt. Sulfonylation, as described previously, or treatment with the appropriate alkylating or acylating
35 agent as known by one skilled in the art and deprotection of the t-butyl ester as described provides the compounds. Larger rings can be formed by using

homologues of allyl-iodide or hydroxy-allyl, such as 4-iodo-1-butene, 4-hydroxy-1-butene, 5-iodo-1-pentene, 5-hydroxy-1-pentene, 4-iodo-2-butene, 4-hydroxy-2-butene and the like.

5

SCHEME II

Intermediates from Scheme II can be used as starting materials for substituents R^5 , R^6 , R^9 and R^{10} . For example, the aspartic acid derivative can be alkylated with a variety of polysubstituted allyl iodides or triflates such as $CH_2=CH_2CHR^7R^{10}I$ followed by Mitsunobu reaction with allyl and homoallyl alcohols to provide intermediates for methathesis reaction. The compounds claimed may also be prepared by functionalization of the olefinic intermediates after

metathesis. For example, the olefin can be hydrogenated under standard conditions, preferably, Pd/C under an atmosphere of hydrogen in a solvent such as a alcohol, or ethyl acetate. The olefin can be hydroborated with a borane reagent, (see Brown, Borane Reagents, Academic Press, NY, 1988) preferably, BH_3 -DMS, and the subsequent borane complex oxidized with H_2O_2 to provide the alcohol or with cromium agents under standard conditions (see Hudlicky, Oxidations in Organic Chemistry, ACS mongraph 186, 1990), provides the ketone. The ketone can serve as a electrophil with wittig reagents, organometallic agents or can be reacted with aldehydes under basic or acidic conditions to undergo aldol condensations. The olefins can undergo allylic oxidation with chromium or preferably selenium reagents (see Rabjohn, Org. Reactions, 1976, 24, 261) as known in the art to provide allylic alcohols which activated as a leaving group and can be substituted with carbon, oxygen, nitrogen or sulphur nucleophiles as known in the art under neutral or basic conditions with or without palladium or lewis acid catalysis. Additional compounds can be prepared by treatment of the olefin with a aryl or alkenyl halide or triflate in the presence of a palladium catalyst to undergo a Heck reaction. (for an extensive reveiw of bond formation using palladium catalysis see Tsuji, Palladium Reagents and Catalysis, Wiley, 1995) The formed olefin can be funtionalized as described above to provide additional substitution. The olefin can be epoxidized with MCPBA or a related peroxide to for the epoxide that can be substituted in the presence or absence or a lewis acid with a reactive Carbon, nitrogen, oxygen or sulphur nucleophil as known in the art.

Alternatively, substituted urea derivatives can be prepared by reacting the isocyanate intermediate formed in the Curtius rearrangement by using an amine ($\text{HNR}^{31}\text{R}^{32}$) in place of the alcohol ($\text{R}^{30}\text{-OH}$) (Scheme III).

47

SCHEME III**SCHEME IV**

5

Further, the carbamate formed in Scheme II can be hydrolyzed in acid to the free amine (Scheme IV) which can then be derivatized, such as by alkylation,

reductive alkylation, sulfonylation, aminosulfonylation, acylated and the like, such as in Scheme V.

SCHEME V

5

It is apparent from the above description that no single general synthesis can be used in the preparation of all of the novel compounds of this invention, because some of the radicals, well known to those skilled in the art, will or may have the potential of interfering with, competing with or inhibiting the some of the reactions involved in the pathway. However, one skilled in the art is fully aware of appropriate point in the synthetic pathway when a radical may be introduced and when protecting groups can be used.

15

Sulfonyl halides can be prepared by the reaction of a suitable alkyl, aryl, heteroaryl, heterocyclyl and the like Grignard or lithium reagents with sulfuryl chloride, or sulfur dioxide followed by oxidation with a halogen, preferably chlorine. Alkyl, heteroaryl, heterocyclyl, aryl and the like Grignard or lithium reagents can be prepared from their corresponding halide (such as chloro

20

or bromo) compounds which are commercially available or readily prepared from commercially available starting materials using known methods in the art. Alternatively, mercaptans may be oxidized to sulfonyl chlorides using chlorine in the presence of water under carefully controlled conditions. Additionally, sulfonic acids may be converted into sulfonyl halides using reagents such as PCl_5 , SOCl_2 , ClC(O)C(O)Cl and the like, and also to anhydrides using suitable dehydrating reagents. The sulfonic acids are either commercially available or may be prepared using procedures well known in the art from commercially available starting materials. In place of the sulfonyl halides, sulfinyl halides or sulfenyl halides can be utilized to prepare compounds wherein the sulfonyl moiety is replaced by an sulfinyl or thio moiety, respectively. Arylsulfonic acids, benzo fused heterocyclyl sulfonic acids or heteroaryl sulfonic acids can be prepared by sulfonation of the aromatic ring by well known methods in the art, such as by reaction with sulfuric acid, SO_3 , SO_3 complexes, such as $\text{DMF(SO}_3\text{)}$, pyridine(SO_3), N,N-dimethylacetamide(SO_3), and the like. Preferably, such sulfonyl halides are prepared from such aromatic compounds by reaction with $\text{DMF(SO}_3\text{)}$ and SOCl_2 or ClC(O)C(O)Cl . The reactions may be performed stepwise or in a single pot.

Additional R1 substitution can be obtained by further reactions on the sulfonamide after reaction of the sulfonyl halide with the related amine. For instance, nitro substituted aryl or heteroaryl sulphonamides can be reduced to the aniline and substituted or converted to the diazonium salt and reacted further to provide the described compounds by methods known to one skilled in the art. Additional R1 substitutions can be obtained by reaction of fluorine, halogen, or trifluoromethanesulfonyloxy substituted aryl or heteroaryl or alkyl sulfonyl chlorides with the related amine followed by substitution of the reactive

intermediate with oxygen, nitrogen, sulfur or carbon nucleophile in the presence or absence of a transition metal catalyst such as palladium to provide the desired compounds. (For a monograph on the topic, see Miller, 5 Aromatic Nucleophilic Substitution, Elsevier, NY, 1968).

Alkyl sulfonic acids, aryl sulfonic acids, heterocyclyl sulfonic acids, heteroaryl sulfonic acids, alkylmercaptans, arylmercaptans, heterocyclylmercaptans, heteroarylmercaptans, alkylhalides, arylhalides, 10 heterocyclylhalides, heteroarylhalides, and the like are commercially available or can be readily prepared from starting materials commercially available using standard methods well known in the art.

Thioether derivatives can be converted into the 15 corresponding sulfone or sulfoxide by oxidizing the thioether derivative with a suitable oxidation agent in a suitable solvent. Suitable oxidation agents include, for example, hydrogen peroxide, sodium meta-perborate, oxone (potassium peroxy monosulfate), meta-chloroperoxy 20 benzoic acid, periodic acid and the like, including mixtures thereof. Suitable solvents include acetic acid (for sodium meta-perborate) and, for other peracids, ethers such as THF and dioxane, and acetonitrile, DMF and the like, including mixtures thereof.

25 The compounds of the invention may be produced in racemic or optically pure form. When a single enantiomer is prepared, these may be synthesized by beginning with optically pure starting materials, by resolution of a basic or acidic racemic intermediate 30 with the appropriate chiral acid or base respectively, as known to one skilled in the art, or by the addition of a chiral protecting group to the racemic intermediate or final product where the diastereomeric pair can be separated by chromatography or crystallization.

35 The chemical reactions described above are generally disclosed in terms of their broadest application to the preparation of the compounds of this

invention. Occasionally, the reactions may not be applicable as described to each compound included within the disclosed scope. The compounds for which this occurs will be readily recognized by those skilled in the art. In all such cases, either the reactions can be successfully performed by conventional modifications known to those skilled in the art, e.g., by appropriate protection of interfering groups, by changing to alternative conventional reagents, by routine modification of reaction conditions, and the like, or other reactions disclosed herein or otherwise conventional, will be applicable to the preparation of the corresponding compounds of this invention. In all preparative methods, all starting materials are known or readily prepared from known starting materials.

Prodrugs of the compounds of this invention are also contemplated by this invention. A prodrug is an active or inactive compound that is modified chemically through in vivo physiological action, such as hydrolysis, metabolism and the like, into a compound of this invention following administration of the prodrug to a patient. The suitability and techniques involved in making and using prodrugs are well known by those skilled in the art. For a general discussion of prodrugs involving esters see Svensson and Tunek Drug Metabolism Reviews 165 (1988) and Bundgaard Design of Prodrugs, Elsevier (1985). Examples of a masked carboxylate anion include a variety of esters, such as alkyl (for example, methyl, ethyl), cycloalkyl (for example, cyclohexyl), aralkyl (for example, benzyl, p-methoxybenzyl), and alkylcarbonyloxyalkyl (for example, pivaloyloxymethyl). Amines have been masked as arylcarbonyloxymethyl substituted derivatives which are cleaved by esterases in vivo releasing the free drug and formaldehyde (Bungard J. Med. Chem. 2503 (1989)).

Also, drugs containing an acidic NH group, such as imidazole, imide, indole and the like, have been masked with N-acyloxymethyl groups (Bundgaard Design of Prodrugs, Elsevier (1985)). Hydroxy groups have been
5 masked as esters and ethers. EP 039,051 (Sloan and Little, 4/11/81) discloses Mannich-base hydroxamic acid prodrugs, their preparation and use.

Without further elaboration, it is believed that one skilled in the art can, using the preceding
10 description, utilize the present invention to its fullest extent. The following preferred specific embodiments are, therefore, to be construed as merely illustrative, and not limitative of the remainder of the disclosure in any way whatsoever.

15 All reagents were used as received without purification. All proton and carbon NMR spectra were obtained on a Bruker nuclear magnetic resonance spectrometer.

The following Examples illustrate the preparation
20 of compounds of the present invention and intermediates useful in preparing the compounds of the present invention.

Example 13

The following assays are in vitro assays which were used to characterize the ability of compounds of this invention to inhibit collagenase and stromelysin: Human Neutrophil Collagenase Assay and Human Fibroblast Stromelysin Assay.

10 Human Neutrophil Collagenase Assay

Human neutrophil collagenase (HNC) activity is determined by using fluorogenic peptide substrate Dnp-Pro-b-Cyclohexyl-Ala-Gly-Cys(Me)-His-Ala-Lys-(N-methylantranilic acid)-NH₂. The N-terminus Dnp group and the C-terminus N-methyl-anthranilyl moiety (Nma) are fluorescence self-quenching until the peptide is cleaved at the Gly-Cys(me) bond. The fluorescence from the cleavage products is measured on a Bio-Tek Instrument FL500 fluorescence micro-plate reader (excitation at 360 nm, emission at 460 nm). The assay is performed in a 96-well plate (in duplicate), and the K_m = 51 nM for the substrate, and K_i = 722 nM for Actinonin have been determined. The test compounds (at 100, 33 & 10 mM) are compared for their inhibition of HNC activity on the substrate against the activity of Actinonin and K_i's were determined on selected compounds.

Human Fibroblast Stromelysin Assay

Human fibroblast stromelysin (HFS) activity is determined by using fluorogenic peptide substrate Dnp-Pro-b-Cyclohexyl-Ala-Gly-Cys(Me)-His-Ala-Lys-(N-methylantranilic acid)-NH₂. The N-terminus Dnp group and the C-terminus N-methyl-anthranilyl moiety (Nma) are fluorescence self-quenching until the peptide is cleaved at the Gly-Cys(me) bond. The fluorescence from the cleavage products is measured on a Bio-Tek Instrument FL500 fluorescence micro-plate reader (excitation at 360 nm, emission at 460 nm). The assay is performed in a 96-well plate (in duplicate), and the K_m = 51 nM for the substrate, and K_i = 722 nM for Actinonin (an inhibitor of enzyme activity; Sigma Chemical, St. Louis, MO; A6671) have been determined as the standard control. The test compounds (at 100, 33 & 10 mM) are compared for their inhibition of HFS activity on the substrate against the activity of Actinonin and K_i's were determined on selected compounds.

invasion and growth; in neuroinflammatory disorders, such as myelin degradation (e.g., multiple sclerosis); and in angiogenesis dependent diseases, such as arthritic conditions; cancer; solid tumor growth; psoriasis; proliferative retinopathies; neovascular glaucoma; ocular tumours; angiofibromas; hemangiomas; nephritis; pulmonary inflammation; and restenosis.

Pharmaceutical Compositions

10 This invention further relates to the use of a compound of this invention in the manufacture of a medicament for the prophylaxis and treatment, either acutely or chronically, of disease states in which HNC and/or HFS and/or gelatinases play a role.

15 This invention also relates to a pharmaceutical composition comprising a compound of this invention and a pharmaceutically acceptable carrier, and if desired other active ingredients. The compounds of this invention are administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. Therapeutically effective doses of the compounds of the present invention required to arrest the progress or prevent tissue damage associated with the disease are readily ascertained by one of ordinary skill in the art.

For the prophylaxis and treatment of disease states, the compounds of the present invention may be administered orally, parentally, or by inhalation spray, rectally, or topically in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants and vehicles. The term parenteral as used herein includes, subcutaneous, intravenous, intramuscular, intrasternal, infusion techniques or intraperitoneally.

35 The amount of active ingredient that may be combined with the carrier materials to produce a single

dosage form will vary depending upon the host treated and the particular mode of administration.

The dosage regimen for treating a disease state with the compounds of this invention and/or compositions of this invention is based on a variety of factors, including the type of disease, the age, weight, sex and medical condition of the patient, the severity of the condition, the route of administration, pharmacological considerations such as the activity, efficacy, pharmacokinetic and toxicology profiles of the particular compound employed, whether a drug delivery system is utilized and whether the compound is administered as part of a drug combination. Thus the dosage regimen may vary widely. Dosage levels of the order from about 0.01 mg to 80 mg per kilogram of body weight per day, preferably from about 0.5 mg to 30 mg/kg, more preferably from about 1 mg to 15 mg/kg are useful for all methods of use disclosed herein. The pharmaceutically active compounds of this invention can be processed in accordance with conventional methods of pharmacy to produce medicinal agents for administration to patients, mammals including humans.

For oral administration, the pharmaceutical composition may be in the form of, for example, a capsule, a tablet, a suspension, or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a given amount of the active ingredient. For example, these may contain an amount of active ingredient from about 1 to 250 mg, preferably from about 25 to 150 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors.

The compounds of this invention may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water. The daily parenteral dosage regimen will be from about 0.1 to

about 80 mg/kg of total body weight, preferably from about 0.5 to about 30 mg/kg, and more preferably from about 1 mg to 15 mg/kg.

Injectable preparations, for example, sterile
5 injectable aqueous or oleaginous suspensions may be formulated according to the known art using suitable dispersing or wetting agents and suspending agents. The sterile injectable preparation may also be a sterile injectable solution or suspension in a nontoxic
10 parenterally acceptable diluent or solvent, for example, as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are
15 conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

20 Suppositories for rectal administration of the drug can be prepared by mixing the drug with a suitable nonirritating excipient such as cocoa butter and polyethylene glycols which are solid at ordinary temperatures but liquid at the rectal temperature and
25 will therefore melt in the rectum and release the drug.

A suitable topical dose of compounds of this invention is 0.1 mg to 150 mg administered one to four, preferably two or three times daily. For topical administration, the active ingredient may comprise from
30 0.001% to 10% w/w, e.g. from 1% to 2% by weight of the formulation, although it may comprise as much as 10% w/w, but preferably not more than 5% w/w, and more preferably from 0.1% to 1% of the formulation. Formulations suitable for topical administration include
35 liquid or semi-liquid preparations suitable for penetration through the skin such as liniments, lotions,

ointments, creams, or pastes and drops suitable for administration to the eye, ear, or nose.

For administration, the compounds of this invention are ordinarily combined with one or more adjuvants appropriate for the indicated route of administration. The compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanolic acids, stearic acid, talc, magnesium stearate, sodium, magnesium oxide, sodium and calcium salts of phosphoric and sulphuric acids, acacia, gelatin, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, and tableted or encapsulated for conventional administration. Alternatively, the compounds of this invention may be dissolved in saline, water, polyethylene glycol, propylene glycol, ethanol, corn oil, peanut oil, cottonseed oil, sesame oil, benzyl alcohol, and/or various buffers. Other adjuvants and modes of administration are well known in the pharmaceutical art. The carrier or diluent may include time delay material, such as glyceryl monostearate or glyceryl distearate alone or with a wax, or other materials well known in the art.

The pharmaceutical compositions may be made up in a solid form including granules, powders or suppositories or in a liquid form such as solutions, suspensions, or emulsions. The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such as sterilization and/or may contain conventional adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers, buffers, etc.

Solid dosage forms for oral administration may include capsules, tablets, pills, powders, and granules. In such solid dosage forms, the active compound may be admixed with at least one inert diluent such as sucrose lactose or starch. Such dosage forms may also comprise, as in normal practice, additional substances other than inert diluents, e.g., lubricating agents such as

magnesium stearate. In the case of capsules, tablets, and pills, the dosage forms may also comprise buffering agents. Tablets and pills can additionally be prepared with enteric coatings.

5 Liquid dosage forms for oral administration may include pharmaceutically acceptable emulsions, solutions, suspensions, syrups, and elixirs containing inert diluents commonly used in the art, such as water. Such compositions may also comprise adjuvants, such as
10 wetting agents, emulsifying and suspending agents, and sweetening, flavoring, and perfuming agents.

Compounds of the present invention can possess one or more asymmetric carbon atoms and are thus capable of existing in the form of optical isomers as well as in
15 the form of racemic or nonracemic mixtures thereof. The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes, for example by formation of diastereoisomeric salts by treatment with an optically active acid or base.

20 Examples of appropriate acids are tartaric, diacetyltartaric, dibenzoyltartaric, ditoluoyltartaric and camphorsulfonic acid and then separation of the mixture of diastereoisomers by crystallization followed by liberation of the optically active bases from these
25 salts. A different process for separation of optical isomers involves the use of a chiral chromatography column optimally chosen to maximize the separation of the enantiomers. Still another available method involves synthesis of covalent diastereoisomeric
30 molecules by reacting compounds of Formula I with an optically pure acid in an activated form or an optically pure isocyanate. The synthesized diastereoisomers can be separated by conventional means such as chromatography, distillation, crystallization or
35 sublimation, and then hydrolyzed to deliver the enantiomerically pure compound. The optically active compounds of Formula I can likewise be obtained by

utilizing optically active starting materials. These isomers may be in the form of a free acid, a free base, an ester or a salt.

The compounds of the present invention can be used in the form of salts derived from inorganic or organic acids. These salts include but are not limited to the following: acetate, adipate, alginate, citrate, aspartate, benzoate, benzenesulfonate, bisulfate, butyrate, camphorate, camphorsulfonate, digluconate, cyclopentanepropionate, dodecylsulfate, ethanesulfonate, glucoheptanoate, glycerophosphate, hemisulfate, heptanoate, hexanoate, fumarate, hydrochloride, hydrobromide, hydroiodide, 2-hydroxy-ethanesulfonate, lactate, maleate, methanesulfonate, nicotinate, 2-naphthalenesulfonate, oxalate, palmoate, pectinate, persulfate, 3-phenylpropionate, picrate, pivalate, propionate, succinate, tartrate, thiocyanate, tosylate, mesylate and undecanoate. Also, the basic nitrogen-containing groups can be quaternized with such agents as lower alkyl halides, such as methyl, ethyl, propyl, and butyl chloride, bromides, and iodides; dialkyl sulfates like dimethyl, diethyl, dibutyl, and diamyl sulfates, long chain halides such as decyl, lauryl, myristyl and stearyl chlorides, bromides and iodides, aralkyl halides like benzyl and phenethyl bromides, and others. Water or oil-soluble or dispersible products are thereby obtained.

Examples of acids which may be employed to form pharmaceutically acceptable acid addition salts include such inorganic acids as hydrochloric acid, sulphuric acid and phosphoric acid and such organic acids as oxalic acid, maleic acid, succinic acid and citric acid.
