UNITED STATES PATENT OFFICE.

CARL HOFFMANN, OF SCHWEIDNITZ, GERMANY.

CURTAIN-PROTECTOR.

SPECIFICATION forming part of Letters Patent No. 747,709, dated December 22, 1903.

Application filed February 21, 1903. Serial No. 144,365. (No model.)

To all whom it may concern:

Be it known that I, CARL HOFFMANN, a subject of the German Emperor, residing at Schweidnitz, Germany, have invented certain new and useful Improvements in Curtain-Protectors, of which the following is a specification.

This invention relates to certain improvements in what I term "curtain-protectors," having for its object to prevent the curtain becoming torn or otherwise damaged.

Said invention consists of the combination and arrangements of parts, substantially as hereinafter more fully disclosed, and specifically pointed out by the claims.

In the accompanying drawings, illustrating the preferred embodiment of my invention, Figure 1 is a front elevation. Fig. 2 is a view at right angles therewith. Fig. 3 is a transverse section taken on the line of the spring securing or retaining device hereinafter described. Fig. 4 is a view showing my device in position upon a window.

It will be understood that I do not limit myself to details, as they may be changed as circumstances suggest without departing from the spirit of my invention.

In carrying out my invention I preferably employ a plate or bracket *f*, adapted to be applied to either a door-frame or the cross-rail of a window by suitable fastenings, said plate or bracket having a vertical or longitudinal socket therein to receive a slide or bar *b* for the retention of said bar. Said bar has a series of notches or cavities, one series being arranged in each side thereof to permit of the engagement therewith and retention at the required point of adjustment of said bar, of a stud or catch *l*, secured to the upper end of a spring *h*, the opposite end of said spring being secured in said bracket or plate, the outer end of said stud or catch having a projecting portion accessible for its actuation by the finger of the operator in effecting the adjustment of said bar, as may be desired. To the upper end of the bar *b* is pivoted or hinged an arm *a*, adapted to be adjusted or moved within an arc of one hundred and eighty degrees, as required in the at-

tachment or application of the device or plate *f* to the right or left hand side of the window or door frame, as in applying the same for protecting the curtain, as circumstances may require. Said arm carries, preferably, a roll *c* for engagement with the curtain, the pivoted end of said arm having an arcuate stop or plate *e*, conforming to the corresponding surface of a boss formed upon the bar *b*, to limit the movement of said arm within the prescribed limits of adjustment, said stop engaging at either extremity the bar *b* laterally of said boss. By means of this arrangement it will be seen that the bar *b*, with its arm *a* and roll *c*, is adapted to be applied either to the cross-rail of a window or to the vertical lateral portion of a door-frame, as may be required, said arm *a* being permitted to stand either in alinement with the bar *b* or at right angles thereto and, as above noted, to permit said roll, with its arm, to be swung to the right or to the left for the purpose heretofore stated. Generally it is only necessary to move the arm *a*, with its roll, through an arc of ninety degrees instead of moving it as previously stated in effecting the afore-said adjustment thereof.

Having thus described my invention, what I claim as new, and desire to secure by Letters Patent, is—

1. A device of the character described, comprising a sliding bar having pivoted or hinged to one end an arm carrying a bearing or roll and adapted to be moved in a suitable radius in applying the same for use, said arm having an arcuate stop for prescribing the movement of said arm.

2. A device of the character described, comprising a plate having a spring catch or stud, a sliding bar arranged in said plate or socket and adapted to be engaged by said spring catch or stud, said bar having a pivoted or hinged arm at one end, provided with a roll or bearing, and adapted to be moved in a suitable radius, in applying the same for use.

3. A device of the character described, comprising a bar having a series of notches or cavities in opposite sides thereof, a plate or socket adapted to be attached to a suitable

support and equipped with a spring-pressed
stud or catch adapted to engage any one of
said notches, said bar having at one end a
pivoted or hinged arm provided with a roll
5 or bearing adapted to be moved in a suitable
radius in applying the same for use, said arm
having an arcuate or segmental stop con-
forming to the corresponding surface of a

boss upon said bar to prescribe the movement
of said arm. 10

In testimony whereof I have hereunto set
my hand in the presence of two witnesses.

CARL HOFFMANN.
