METHODS OF USE

RELATED APPLICATIONS
This application claims the benefit of U.S. Provisional Patent Application No. 61/416,718, filed November 23, 2010, which specification is hereby incorporated here in by reference in its entirety.

FIELD OF THE INVENTION
The invention relates generally to pharmaceutically active compounds, pharmaceutical compositions and methods of use thereof, to treat beta-secretase mediated diseases and conditions, including, without limitation, Alzheimer's disease, plaque formation and related central nervous system (CNS) disorders.

BACKGROUND OF THE INVENTION
Alzheimer's disease (AD) affects greater than 12 million aging people worldwide, and importantly, the number affected continues to grow. AD accounts for the majority of dementia clinically diagnosed after the age of 60. AD is generally characterized by the progressive decline of memory, reasoning, judgement and orientation. As the disease progresses, motor, sensory, and vocal abilities are affected until there is global impairment of multiple cognitive functions. The loss of cognitive function occurs gradually, typically leading to a diminished cognition of self, family and friends. Patients with severe cognitive impairment and/or diagnosed as end-stage AD are generally bedridden, incontinent, and dependent on custodial care. The AD patient eventually dies in about nine to ten years, on average, after initial diagnosis. Due to the incapacitating, generally humiliating and ultimately fatal effects of AD, there is a need to effectively treat AD upon diagnosis.

AD is characterized by two major physiological changes in the brain. The first change, beta amyloid plaque formation, supports the "amyloid cascade hypothesis" which conveys the thought that AD is caused by the formation of characteristic beta amyloid peptide (A-beta), or A-beta fragments thereof, deposits in the brain (commonly referred to as beta amyloid "plaques" or "plaque deposits") and in cerebral blood vessels (beta amyloid angiopathy). A wealth of evidence suggests that beta-amyloid and accompanying
amyloid plaque formation is central to the pathophysiology of AD and is likely to play an early role in this intractable neurodegenerative disorder. The second change in AD is the formation of intraneuronal tangles, consisting of an aggregate form of the protein tau. Besides being found in patients with AD, intraneuronal tangles are also found in other dementia-inducing disorders. Joachim et al., *Ab. Dis. Assoc. Dis.*, 6:7-34 (1992).

Several lines of evidence indicate that progressive cerebral deposition of A-beta plays a seminal role in the pathogenesis of AD and can precede cognitive symptoms by years or even decades. Selkoe, *Neuron*, 6:487 (1991). Release of A-beta from neuronal cells grown in culture and the presence of A-beta in cerebrospinal fluid (CSF) of both normal individuals and AD patients has been demonstrated. Seubert et al., *Nature*, 359:325-327 (1992). Autopsies of AD patients have revealed large numbers of lesions comprising these 2 factors in areas of the human brain believed to be important for memory and cognition.

Smaller numbers of these lesions in a more restricted anatomical distribution are found in the brains of most aged humans who do not have clinical AD. Amyloid containing plaques and vascular amyloid angiopathy were also found in the brains of individuals with Down's Syndrome, Hereditary Cerebral Hemorrhage with Amyloidosis of the Dutch-type (HCHWA-D), and other neurodegenerative disorders.

It has been hypothesized that A-beta formation is a causative precursor or factor in the development of AD. More specifically, deposition of A-beta in areas of the brain responsible for cognitive factors is believed to be a major factor in the development of AD. Beta amyloid plaques are primarily composed of amyloid beta peptide (A-beta peptide). A-beta peptide is derived from the proteolytic cleavage of a large transmembrane amyloid precursor protein (APP), and is a peptide ranging in about 39-42 amino acid residues. A-beta 42 (42 amino acids long) is thought to be the major component of these plaque deposits in the brains of Alzheimer's Disease patients. Citron, *Trends in Pharmacological Sciences*, 25(2):92-97 (2004).

Similar plaques appear in some variants of Lewy body dementia and in inclusion body myositis, a muscle disease. Aβ also forms aggregates coating cerebral blood vessels in cerebral amyloid angiopathy. These plaques are composed of a tangle of regularly ordered fibrillar aggregates called amyloid fibers, a protein fold shared by other peptides such as prions associated with protein misfolding diseases. Research on laboratory rats suggest that the two-molecule, soluble form of the peptide is a causative agent in the development of Alzheimer's and that the two-molecule form is the smallest synaptotox

Several aspartyl proteases, including beta-secretase and gamma-secretase, are thought to be involved in the processing or cleavage of APP, resulting in the formation of A-beta peptide. Beta secretase (BACE, also commonly referred to as memapsin) is thought to first cleave APP to generate two fragments: (1) a first N-terminus fragment (beta APP) and (2) a second C-99 fragment, which is subsequently cleaved by gamma secretase to generate the A-beta peptide. APP has also found to be cleaved by alpha-secretase to produce alpha-sAPP, a secreted form of APP that does not result in beta-amyloid plaque formation. This alternate pathway precludes the formation of A-beta peptide. A description of the proteolytic processing fragments of APP is found, for example, in U.S. Patent Nos. 5,441,870, 5,712,130 and 5,942,400.

BACE is an aspartyl protease enzyme comprising 501 amino acids and responsible for processing APP at the beta-secretase specific cleavage site. BACE is present in two forms, BACE 1 and BACE 2, designated as such depending upon the specific cleavage site of APP. Beta secretase is described in Sinha et al., *Nature*, 402:537-554 (1999) (p510) and PCT application WO 2000/17369. It has been proposed that A-beta peptide accumulates as a result of APP processing by BACE. Moreover, in vivo processing of APP at the beta secretase cleavage site is thought to be a rate-limiting step in A-beta production. Sabbagh, M. et al., *Alz. Dis. Rev.* 3:1-19 (1997). Thus, inhibition of the BACE enzyme activity is desirable for the treatment of AD.

Studies have shown that the inhibition of BACE may be linked to the treatment of AD. The BACE enzyme is essential for the generation of beta-amyloid or A-beta. BACE knockout mice do not produce beta-amyloid and are free from Alzheimer’s associated pathologies including neuronal loss and certain memory deficits. Cole, S.L., Vassar, R., *Molecular Degeneration* 2:22, 2007. When crossed with transgenic mice that over express APP, the progeny of BACE deficient mice show reduced amounts of A-beta in brain extracts as compared with control animals (Luo et al., *Nature Neuroscience*, 4:23 1-232 (2001)). The fact that BACE initiates the formation of beta-amyloid, and the observation that BACE levels are elevated in this disease provide direct and compelling reasons to develop therapies directed at BACE inhibition thus reducing beta-amyloid and its associated toxicities. To this end, inhibition of beta secretase activity and a corresponding reduction of A-beta in the brain should provide a therapeutic method for treating AD and other beta amyloid or plaque related disorders.
Consequently, the approach of regulating or reducing the formation of A-beta peptide formation and deposition as a potential treatment for AD has received tremendous attention and belief from both researchers and investors alike. A small molecule gamma-secretase inhibitor, LY450139 ("Semagacestat"), an A-beta lowering agent, is in phase II and Phase III clinical trials for the treatment of Alzheimer's Disease. The pharmacokinetics of semagacestat in plasma, as well as the plasma and cerebral spinal fluid (CSF) A-Beta peptide levels as pharmacodynamic responses to semagacestat administration were evaluated in healthy human subjects in single and multiple doses, and pharmacokinetic and pharmacodynamic changes were also assessed in mild to moderate AD patients in two (2) clinical trials (Expert Opin. Pharmacother. (2009), 10 (10); Clin. Neuropharmacol. 2007; 30 (pgs 317-325); and Neurology, 2006, 66 (pgs 602-624)).

The lysosomal aspartic protease Cathepsin D (CatD) is ubiquitously expressed in eukaryotic organisms. CatD activity is essential to accomplish the acid-dependent extensive or partial proteolysis of protein substrates within endosomal and lysosomal compartments therein delivered via endocytosis, phagocytosis or autophagocytosis. CatD may also act at physiological pH on small-size substrates in the cytosol and in the extracellular milieu. Mouse and fruit fly CatD knock-out models have highlighted the multi-pathophysiological roles of CatD in tissue homeostasis and organ development.

Inhibition of protein Cathepsin D has been implicated in undesirable side effects. For instance, the inhibition of Cathepsin D is believed to be linked to adverse retinal development and retinal atrophy. Particularly, in mice it was found that cathepsin D is
essential for the metabolic maintenance of retinal photoreceptor cells and that its deficiency induces apoptosis of the cells, while the loss of INL neurons is mediated by NO from microglial cells. However, in the very same mice, it was also found that no atrophic change was detected in the retina of mice deficient in cathepsin B or L. *Mol. Cell. Neurosci.*, 2003, Feb 22(2):146-161. Further, Animal models of cathepsin D (CatD) deficiency are characterized by a progressive and relentless neurodegenerative phenotype similar to that observed in Neuronal Ceroid Lipofuscinoses (NCL), a group of pediatric neurodegenerative diseases known collectively as Batten Disease. It has been shown that the targeted deletion of the pro-apoptotic molecule Bax prevents apoptotic markers but not neuron death and neurodegeneration induced by CatD deficiency, which suggests that alterations in the macroautophagy-lysosomal degradation pathway can mediate neuron death in NCL/Batten Disease in the absence of apoptosis. *Autophagy*, 2007, Sept-Oct;3(5):474-476. Finally, an adverse effect of the inhibition of Cat D is evident from the data presented in *PLoS One*, 2011; 6(7):e21908, published 7-1-2011. The authors of the *PLoS One* paper found that knock-down of cathepsin D affects the retinal pigment epithelium, impairs swim-bladder ontogenesis and causes premature death in zebrafish. The main phenotypic alterations produced by CatD knock-down in zebrafish were: 1. abnormal development of the eye and of retinal pigment epithelium; 2. absence of the swim-bladder; 3. skin hyper-pigmentation; 4. reduced growth and premature death. Rescue experiments confirmed the involvement of CatD in the developmental processes leading to these phenotypic alterations.

Moreover, such toxicity findings thought to be related to the inhibition of CatD has played a role in the termination of a human Bace-mediated Alzheimer's Disease clinical trial. Eli Lilly terminated a phase I clinical trial of LY 281 1376 after rat toxicology studies showed that a higher compound dose given for three months ravaged the pigment epithelium of the rat's eye. The retinal layer had inclusions and extensive damage. Lilly ended the Ph I dosing and brought people in for eye assessments, which did not show any abnormalities. (Alzheimer's Research Forum News, 3-31-2011 reporting on Martin Citron's presentation at the AD/PD Conference 3-2011 in Barcelona, Spain)

Hence, it is desirable to provide compounds which modulate the activity of BACE while not suffering from the undesirable retinal side effects possibly due to intervention in the CatD pathway or due to the reduction and/or direct inhibition of the cathepsin D protein.

DEFINITIONS
The following definitions should assist in understanding the invention.
The term "comprising" is meant to be open ended, i.e., all encompassing and non-limiting. It may be used herein synonymously with "having." Comprising is intended to include each and every indicated or recited component or element(s) while not excluding any other components or elements.

The terms "L is absent" and "W is absent" is intended to mean that these variables do not exist in the generic formula, i.e., they are merely a bond connecting the two structural moieties as illustrated in the Formulas. For example, the compounds of Formula I wherein W is absent are compounds of Formula II, described herein. Similarly, the term "L is absent" is intended to mean that variable R⁷ is attached directly to the core of the compound, as illustrated, for instance, in Formulas I-A and II-A.

The term "Cₐ₋ₚalkyl", when used either alone or within other terms such as "haloalkyl" and "alkylamino", embraces linear or branched radicals having a to β number of carbon atoms (such as Cl-Clo; Cl-C₆; or Cl-C⁴). Unless otherwise specified, one or more carbon atoms of the "alkyl" radical may be substituted, such as with a cycloalkyl moiety. Examples of "alkyl" radicals include methyl, cyclopropylmethyl, cyclobutylmethyl, cyclopentylmethyl, ethyl, cyclopropylethyl, cyclobutylethyl, cyclopentylethyl, n-propyl, isopropyl, n-butyl, cyclopropylbutyl, isobutyl, sec-butyl, tert-butyl, pentyl, isoamyl, hexyl and the like.

The term "Cₐ₋ₚalkenyl", when used alone or in combination, embraces linear or branched radicals having at least one carbon-carbon double bond in a moiety having a number of carbon atoms in the range from α and β. Included within alkenyl radicals are "lower alkenyl" radicals having two to about six carbon atoms and, for example, those radicals having two to about four carbon atoms. Examples of alkenyl radicals include, without limitation, ethenyl, propenyl, allyl, propenyl, butenyl and 4-methylbutenyl. The terms "alkenyl" and "lower alkenyl", embrace radicals having "cis" and "trans" orientations, or alternatively, "E" and "Z" orientations, as appreciated by those of ordinary skill in the art.

The term "Cₐ₋ₚalkynyl", when used alone or in combination, denotes linear or branched radicals having at least one carbon-carbon triple bond in a moiety having α number of carbon atoms in the range from α and β. Examples of alkynyl radicals include "lower alkynyl" radicals having two to about six carbon atoms and, for example, lower alkynyl radicals having two to about four carbon atoms. Examples of such radicals include, without limitation, ethynyl, propynyl (propargyl), butynyl, and the like.
The term "Cβ-α-alkyl", "Cβ-α-alkenyl" and "Cβ-α-alkynyl", when used with other terms such as " wherein 1, 2 or 3 carbon atoms of said Cβ-α-alkyl, Cβ-α-alkenyl or Cβ-α-alkynyl is optionally replaced with a heteroatom selected from O, S, S(0), S(0)2 and N" embraces linear or branched radicals wherein one or more of the carbon atoms may be replaced with a heteroatom. Examples of such "alkyl" radicals include -O-methyl, -O-ethyl, -CH2-CH2-CH2-o-CH2 CH2, -CH2-CH2-S-CH2 and the like. Accordingly, such radicals also include radicals encompassed by -OR7 where R7 may be defined as a Cβ-α-alkyl. Examples of such "alkenyl" radicals include -NH-CH2 CH=CH2, -S-(CH2)3 CH2, -CH2-CH2-S-CH3 and the like. Similar examples exist for such "alkynyl" radicals, as appreciated by those skilled in the art.

The term "Cβ-α-palkoxy" or "-OCβ-α-palkyl" when used alone or in combination, embraces linear or branched oxygen-containing alkyl radicals each having a to β number of carbon atoms (such as Ci-C10). The terms "alkoxy" and "alkoxyl", when used alone or in combination, embraces linear or branched oxygen-containing radicals each having alkyl and substituted alkyl portions of one or more carbon atoms. Examples of such radicals include methoxy, ethoxy, propoxy, butoxy, tert-butoxy and neopentoxy. Alkoxyl radicals may be further substituted with one or more halo atoms, such as fluoro, chloro or bromo, to provide "haloalkoxy" radicals or with other substitution. Examples of such radicals include fluoromethoxy, chloromethoxy, trifluoromethoxy, trifluoroethoxy, fluoroethoxy and fluoropropoxy.

The term "aryl", when used alone or in combination, means a carbocyclic aromatic moiety containing one, two or even three rings wherein such rings may be attached together in a fused manner. Every ring of an "aryl" multi-ring system need not be aromatic, and the ring(s) fused to the aromatic ring may be partially or fully unsaturated and include one or more heteroatoms selected from nitrogen, oxygen and sulfur. Thus, the term "aryl" embraces aromatic radicals such as phenyl, naphthyl, indenyl, tetrahydronaphthyl, dihydrobenzofuranyl, anthracenyl, indanyl, benzodioxazinyl, and the like. The "aryl" group may be substituted, such as with 1 to 5 substituents including lower alkyl, hydroxyl, halo, haloalkyl, nitro, cyano, alkoxy and lower alkylamino, and the like. Phenyl substituted with -0-CH2-0 or -0-CH2-CH2-0 forms an aryl benzodioxolyl substituent.
The term "C_α-p-cycloalkyl", also referred to herein as "carbocyclic", when used alone or in combination, denotes a partially or fully saturated ring radical having a number of carbon atoms in the range from α and β. The "cycloalkyl" may contain one ("monocyclic"), two ("bicyclic") or even three ("tricyclic") rings wherein such rings may be attached together in a fused manner and each formed from carbon atoms. Examples of saturated carbocyclic radicals include saturated 3 to 6-membered monocyclic groups such as cyclopropane, cyclobutane, cyclopentane and cyclohexane. Cycloalkyls may be substituted as described herein.

The terms "ring" and "ring system" refer to a ring comprising the delineated number of atoms, the atoms being carbon or, where indicated, a heteroatom such as nitrogen, oxygen or sulfur. Where the number of atoms is not delineated, such as a "monocyclic ring system" or a "bicyclic ring system", the numbers of atoms are 3-8 for a monocyclic and 6-12 for a bicyclic ring. The ring itself, as well as any substituents thereon, may be attached at any atom that allows a stable compound to be formed. The term "nonaromatic" ring or ring system refers to the fact that at least one, but not necessarily all, rings in a bicyclic or tricyclic ring system is nonaromatic.

The terms "partially or fully saturated or unsaturated" and "saturated or partially or fully unsaturated" with respect to each individual ring, refer to the ring either as fully aromatic (fully unsaturated), partially aromatic (or partially saturated) or fully saturated (containing no double or triple bonds therein). If not specified as such, then it is contemplated that each ring (monocyclic) in a ring system (if bicyclic or tricyclic) may either be fully aromatic, partially aromatic or fully saturated, and optionally substituted with up to 5 substituents. The ring moiety or ring system may contain one ("monocyclic"), two ("bicyclic") or even three ("tricyclic") rings wherein such rings are attached together in a fused manner. Every ring of a "heteroaryl" ring system need not be aromatic, and the ring(s) fused thereto (to the heteroaromatic ring) may be partially or fully saturated and optionally include one or more heteroatoms selected from nitrogen, oxygen and sulfur. The term "heteroary1" does not include rings having ring members of -0-0-, -O-S- or -S-S-.

Where the number of atoms is not delineated, such as a "monocyclic ring system" or a "bicyclic ring system", the numbers of atoms are 3-8 for a monocyclic and 6-12 for a bicyclic ring. The
ring or ring system may contain substituents thereon, attached at any atom that allows a
stable compound to be formed. A bicyclic ring is intended to include fused ring systems as
well as spiro-fused rings. This phrase encompasses carbocyclics, heterocyclics, aryl and
heteroaryl rings.

-NHC(=O)- and -C(=O)N(CH₃)- and -N(CH₃)C(=O)-.

The term "Formula I" includes any sub formulas, such as Formulas II and III.
Similar with Formulas II and III, in that they include sub-formulas where described.

The term "pharmacologically-acceptable" when used with reference to a
compound of Formulas I-III is intended to refer to a form of the compound that is safe for
administration. For example, a salt form, a solvate, a hydrate, a prodrug or derivative
form of a compound of Formulas I-III, which has been approved for mammalian use, via
oral ingestion or other routes of administration, by a governing body or regulatory
agency, such as the Food and Drug Administration (FDA) of the United States, is
pharmacologically acceptable.
Included in the compounds of Formulas I-III are the pharmaceutically acceptable salt forms of the free-base compounds. The term "pharmaceutically-acceptable salts" embraces salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. As appreciated by those of ordinary skill in the art, salts may be formed from ionic associations, charge-charge interactions, covalent bonding, complexation, coordination, etc. The nature of the salt is not critical, provided that it is pharmaceutically acceptable.

Suitable pharmaceutically acceptable acid addition salts of compounds of Formulas I-III may be prepared from an inorganic acid or from an organic acid. Examples of such inorganic acids are hydrochloric, hydrobromic, hydroiodic, hydrofluoric, nitric, carbonic, sulfuric and phosphoric acid. Appropriate organic acids may be selected from aliphatic, cycloaliphatic, aromatic, aryloaliphatic, heterocyclic, carboxylic and sulfonic classes of organic acids, examples of which include, without limitation, formic, acetic, adipic, butyric, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, ascorbic, glucuronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic, anthranilic, mesylic, 4-hydroxybenzoic, phenylacetic, mandelic, embonic (pamoic), methanesulfonic, ethanesulfonic, ethanedisulfonic, benzenesulfonic, pantothenic, 2-hydroxyethanesulfonic, toluenesulfonic, sulfanilic, cyclohexylaminosulfonic, camphoric, camphorsulfonic, digluconic, cyclopentanepropionic, dodecylsulfonic, glucoheptanoic, glycerophosphonic, heptanoic, hexanoic, 2-hydroxy-ethanesulfonic, nicotinic, 2-naphthalenesulfonic, oxalic, palmoic, pectinic, persulfuric, 2-phenylpropionic, picric, pivalic propionic, succinic, thiocyanic, undecanoic, stearic, algenic, β-hydroxybutyric, salicylic, galactaric and galacturonic acid. iodides; dialkyl sulfates like dimethyl, diethyl, dibutyl, and diamyl sulfates, long chain halides such as decyl, lauryl, myristyl and stearyl chlorides, bromides and iodides, aralkyl halides like benzyl and phenethyl bromides, and others. Water or oil-soluble or dispersible products are thereby obtained.

Additional examples of such salts can be found in Berge et al., J. Pharm. Sci., 66:1 (1977). Conventional methods may be used to form the salts. For example, a phosphate salt of a compound of the invention may be made by combining the desired compound free base in a desired solvent, or combination of solvents, with phosphoric acid in a desired stoichiometric amount, at a desired temperature, typically under heat (depending upon the boiling point of the solvent). The salt can be precipitated upon cooling (slow or fast) and may crystallize (i.e., if crystalline in nature), as appreciated by those of ordinary skill in the art. Further, hemi-, mono-, di, tri- and poly-salt forms of the compounds of the present invention are also contemplated herein. Similarly, hemi-, mono-, di, tri- and poly-hydrated forms of the compounds, salts and derivatives thereof, are also contemplated herein.

The term "pharmacuetically-acceptable derivative" as used herein, denotes a derivative which is pharmaceutically acceptable.

The compound(s) of Formulas I-III may be used to treat a subject by administering the compound(s) as a pharmaceutical composition. To this end, the compound(s) can be combined with one or more excipients, including without limitation, carriers, diluents or adjuvants to form a suitable composition, which is described in more detail herein.

The term "excipient", as used herein, denotes any pharmaceutically acceptable additive, carrier, adjuvant, or other suitable ingredient, other than the active pharmaceutical ingredient (API), which is typically included for formulation and/or administration purposes. "Diluent" and "adjuvant" are defined hereinafter.

Prophylactic treatment generally constitutes either preventing the onset of disorders altogether or delaying the onset of a pre-clinically evident stage of disorders in individuals.

The phrase "effective dosage amount" is intended to quantify the amount of each agent, which will achieve the goal of improvement in disorder severity and the frequency of incidence over treatment of each agent by itself, while avoiding adverse side effects
typically associated with alternative therapies. Accordingly, this term is not limited to a single dose, but may comprise multiple dosages required to bring about a therapeutic or prophylactic response in the subject. For example, "effective dosage amount" is not limited to a single capsule or tablet, but may include more than one capsule or tablet, which is the dose prescribed by a qualified physician or medical care giver to the subject.

The term "leaving group" (also denoted as "LG") generally refers to groups that are displaceable by a nucleophile. Such leaving groups are known in the art. Scheme 1
Scheme 1 describes a exemplary method for preparing racemic compounds 5 of Formulas I and II, wherein W is absent. Beginning with compound 1, one of ordinary skill in the art may convert the methoxy group to the corresponding hydroxyl via conventional O-demethylation techniques, such as use of BBr₃, as described herein, under suitable conditions, to afford compound 2. The alcohol-bromide 2 may be derivatized with desired aromatic R⁷ groups using conventional Suzuki coupling methods via coupling at the site of the bromide, or Suzuki-like aromatic-halogen exchange reactions, which reactions generally employ a boronic acid moiety, a palladium catalyst reagent and a base. Other aryl/heteroaryl coupling methods, including Stille and the like under appropriate conditions, may also be employed to provide compounds 3. The hydroxyl group of compound 3 can be activated into a suitable leaving group ("LG" in scheme 1), such as a triflate, as described in the examples herein, or other suitable O-linked leaving group. The leaving group of intermediate 4 can then be reacted with a desired aromatic boronic acid to install the desired R² group, as shown in scheme 1, to afford the desired compounds 5 of Formula I and II.

Alternatively, the hydroxyl group of intermediate 2 may be functionlized with the desired O-linked R² group via a base assisted coupling reaction, as discussed herein, to provide the corresponding bromo-xanthene-R² intermediate (not shown). The bromide of this intermediate may then be converted to the corresponding compounds 5 using the conditions discussed above.

The boronic ester intermediates utilized in steps 2 and/or 4 may be prepared by methods described in the following references: (1) PCT Int. Patent Appl. No. WO 2005073 189, titled "Preparation of fused heteroaryl derivatives as p38 kinase inhibitors" or (2) PCT Int. Patent Appl. No. WO 20060941 87, titled "Preparation of phthalazine, aza- and diaza-phthalazine compounds as protein kinase, especially p38 kinase, inhibitors for
treating inflammation and related conditions". Also, desired boronic acids may be purchased commercially from vendor catalogs, or specially made by the vendor or by persons of ordinary skill in the art.

The Suzuki method is a reaction using a borane reagent, such as a boronic acid 7 or ester such as a dioxaborolane (see pages 82-84 herein), and a suitable leaving group containing reagent, such as the xanthene 4 or bromo-xanthene 2 (halogens, including bromides and chlorides are suitable halogen leaving groups "LG"). As appreciated to one of ordinary skill in the art, Suzuki reactions also utilize a palladium catalyst. Suitable palladium catalysts include, without limitation, Pd(PPh₃)₄, Pd(OAc)₂ or Pd(dppf)Cl₂. Where LG is a halide, the halide may be an iodide, a bromide or chloride. Chloro-pyridyl rings (where A¹ = N) undergo Suzuki reactions in the presence of Pd catalysts. Other LGs are also suitable. For example, Suzuki couplings are known to occur with a sulfonate, such as trifluoromethanesulfonate, as the leaving group.

The Suzuki reaction conditions may vary. For example, Suzuki reactions are generally run in the presence of a suitable base such as a carbonate base, bicarbonate or an acetate base, in a suitable solvent such as toluene, acetonitrile, DMF or an aqueous-organic solvent combination or a biphasic system of solvents. Further, the reaction may require heat depending upon the particular bromide 2 and/or boronic acid or ester 7 (see pgs 82-84), as appreciated by those skilled in the art. In addition, where the bromide is an aromatic moiety, such as phenyl, the reaction may be complete in a short period of time with heat.

Other coupling methods are known. For example metal catalized coupling chemistry, such Stille, Kumada, Negishi coupling methods, and the like, may be employed to the xanthene cores 2 and/or 4 to prepare desired cyclic products 5. In addition, compounds may possess groups which may need to be protected (and later deprotected), such as a free amino group, to carry out effective coupling reactions to install either R² or R⁷ groups to afford the final desired compounds 5, as appreciated by persons of ordinary skill in the art.
Desired compounds 7 of Formulas I, II and III, and sub-formulas thereof, wherein the \( R^2 \) group is \(-\text{OR}^{10}\) may be made as generally described in Scheme 2. As shown, \( R^7 \)-hydroxy intermediate 6 can be functionalized as desired, such as by alkylation as shown, by reaction with an alkyl halide 12 in the presence of a suitable base, such as cesium carbonate, in suitable solvents to afford the finally desired product 7.

"LG" in this instance is a "leaving group" which may be a halide such as an iodide, bromide, chloride or fluoride. LG may also be a non-halide moiety such as an alkylsulfonate or other known groups which generally form an electrophilic species (\( \text{E}^+ \)). Coupling reactions generally occur more readily in one or a combination of solvents and a base. Suitable solvents include, without limitation, generally non-nucleophilic, anhydrous solvents such as toluene, \( \text{CH}_2\text{Cl}_2 \), THF, DMF, \( \text{N,N} \)-dimethylacetamide and the like. The solvent may range in polarity, as appreciated by those skilled in the art. Suitable bases include, for example, tertiary amine bases such as DIEA, TEA, carbonate bases such as \( \text{Na}_2\text{CO}_3 \), \( \text{K}_2\text{CO}_3 \), \( \text{CS}_2\text{CO}_3 \), hydrides such as NaH, KH and the like, alkoxides such as \( \text{NaOCH}_3 \), and the like. The base itself may also serve as a solvent. These coupling reactions are generally fast and conversion occurs typically in ambient conditions. However, depending upon the particular substrate, such reactions may require heat, as appreciated by those skilled in the art.
Desired compounds 12 of Formulas I and III where \( W = \text{CH}_2 \), and sub-Formulas thereof, may be prepared in a manner similar to that described in the Examples hereunder as shown in Scheme 3. Beginning with ketone 6, one of ordinary skill in the art may convert the ketone group to the corresponding spiro-dihydro-pyrimidinone-ylidine carbamate 9 via the techniques described in Example 10. The BOC-protected amine group of intermediate 9 may be deprotected by conventional methods, such as by acid (TFA for instance) to provide the free amino intermediate 10. Alternatively, compounds 9 may be functionalized at the desired \( R^7 \) and/or \( R^2 \) positions in Formulas I and III, using Suzuki or Suzuki-like conditions as described herein, in scheme 1 and in the Examples, to afford protected compounds 12 (not shown), which then may be treated with a suitable acid, such as TFA to afford the acid salt (or free base) of compounds 12.

Intermediate 10 may successively be taken through Suzuki coupling reactions, or Suzuki-like aromatic-halogen exchange reactions including Stille and the like, under appropriate conditions, to provide final compounds 12.
Desired compounds 17 of Formulas I-III, and sub-formulas thereof wherein L is an amine or an amide linker to desired R^7 groups may be made as generally described in Scheme 4. As shown, desired R^7 amines may be coupled directed to the bromide intermediate 14 using XPhos in the presence of a suitable palladium catalyst under suitable conditions to afford desired products 15.

Similarly, compound 14 can be transformed into the corresponding amine 16 using conditions like those described in scheme 1 hereinabove. Compound 16 may then be reacted with a desired acid in the presence of conventional amide coupling conditions to afford desired compound 17. Alternatively the R^7-acid may be converted to the corresponding acid-halide, such as a reactive acid-chloride using oxalyl chloride under suitable conditions, and reacted with the amine 16 in the presence of a suitable base and solvent to afford product 17.

**Synthesis of 7-Bromo-3-methoxy-5H-chromeno[2,3-b]pyridin-5-one**

**Step 1**: A three neck 3-L RBF equipped with an overhead stirred was charged with 6-fluoropyridin-3-ylboronic acid (105 g, 745 mmol) and 1L of THF. The mixture was cooled to 0 °C and NaOH 6N (373 mL, 2235 mmol) was added. To the resulting mixture was added hydrogen peroxide 30% (126 mL, 4098 mmol), dropwise via an addition funnel over the course of 30 minutes. After stirring at 0 °C for 2 hours the mixture was
removed from the ice bath and maintained at RT for 30 minutes. The reaction was acidified to pH 7 with 6 N HCl (ca. 300 mL) and diluted with 500 mL of ether. The aqueous layer was extracted with ether (2 x 1 L) and the combined organic layers were washed with water (1.5 L) then brine before being dried over sodium sulfate. Filtration and concentration provided a white solid that was dried on high vac overnight to provide 6-fluoropyridin-3-ol.

Step 2: To a solution of 6-fluoropyridin-3-ol (75 g, 663 mmol) in DMF (265 mL, 663 mmol) were added potassium carbonate (59.7 g, 995 mmol) and iodomethane (108 g, 763 mmol). The resulting slurry was heated at 100 °C for 3 hours. The reaction was diluted with water (1000 mL) and poured into a separatory funnel containing diethyl ether (1000 mL). The layers were separated and the aqueous layer was extracted with diethyl ether (4 x 500 mL). The combined organic layers were washed with water and then brine, dried over sodium sulfate, filtered and concentrated in vacuo to provide a yellow oil. This oil was diluted with 500 mL of DCM and concentrated to provide a yellow oil with a large amount of an off white precipitate. The mixture was filtered and the derived solid was washed well with DCM. The filtrate was concentrate to provide a mixture consisting of a yellow oil and an off white solid. The oil was taken up in 100 mL of ether and flashed through a plug of silica gel with 10:1 hexanes:ether to provide 2-fluoro-5-methoxypyridine as a yellow oil.

Step 3: To a solution of DIPA (54.0 mL, 385 mmol) in THF (1101 mL, 385 mmol) at -60 °C was added BuLi, 2.5 M in hexanes (154 mL, 385 mmol) over 5 minutes such that the internal temperature was maintained below -60 °C. After stirring for 45 minutes at -65 °C a solution of 2-fluoro-5-methoxypyridine (49 g, 385 mmol) in 200 mL of THF was added over the course of 2 minutes maintaining an internal temperature < -65 °C. The reaction was stirred at -70 °C for 1.5 hours then reaction was poured into a 3 L flask containing 1200 g of crushed dry ice. The reaction was allowed to warm to 0 °C and then poured into 1000 mL of water. The organics were removed under reduced pressure and the aqueous layer was acidified with 1100 mL of 2 N HCl. stirred for an additional 5 minutes at room temperature. Added 2-fluoro-5-
methoxynicotinic acid (30 g, 175 mmol) portionwise over 10 minutes and heated the
resulting slurry at 140 °C. After cooling to RT the mixture was then poured onto 1 kg of
ice and was quenched with acetic acid (50.2 mL, 877 mmol) and then 75 mL of 6 N HC1.
Stirred vigorously for 1 hour, leading to the formation of a red slurry containing a very
fine white precipitate. The slurry was filtered to provide 2-(4-bromophenoxy)-5-
methoxynicotinic acid.

Step 5: A 2 L RBF charged with polyphosphoric acid (115% H3PO4) (300 g, 89 mmol)
was heated to 140 °C at which point 2-(4-bromophenoxy)-5-methoxynicotinic acid (29 g,

140 °C. After heating for 2.5 hours the solution was cooled to 100 °C and then poured
onto 1 kg of ice, leading to the formation of a yellow taffy mixture. The slurry was
vigorously stirred for 1 hour leading to the formation of a fine white precipitate.
Filtration of this mixture proceeded slowly to provide an off-white solid. This solid was
washed well with DCM. The filtrate, which contained the desired product, was washed
with brine and concentrated to provide 7-bromo-3-methoxy-5H-chromeno[2,3-b]pyridin-

The residue was purified by flash chromatography on silica gel to afford 2-amino-2′-(2-fluoropyridin-3-yl)-7′-hydroxy-1-methylspiro[imidazole-4,9′-xanthen]-5(1H)-one.

Step 3: To a suspension of 2-amino-2′-(2-fluoropyridin-3-yl)-7′-hydroxy-1-methylspiro[imidazole-4,9′-xanthen]-5(1H)-one (131 mg, 0.348 mmol) in DCM (3 mL) triethylamine (97 µL, 0.697 mmol) and 1,1,1-trifluoro-N-phenyl-N-(trifluoromethylsulfonyl) methanesulfonamide (187 mg, 0.523 mmol) were added and the mixture was stirred for 4 hrs. Additional TEA (100 mkL) and N-phenyl triflimide (150 mg) were added and the mixture was stirred for an additional 2 hrs until consumption of the starting material. The reaction mixture was diluted with DCM and quenched with NaHCO₃ (5 mL). The organic layer was filtered through celite and concentrated to afford 2-amino-2′-(2-fluoropyridin-3-yl)-1-methyl-5-oxo-1,5-dihydrospiro[imidazole-4,9′-xanthene]-7′-yl trifluoromethanesulfonate, which was used without further purification.

The material was recovered from the column with 2 M ammonia in MeOH, concentrated and purified by reverse phase HPLC (Gilson, 15-90% MeCN in 0.1% aq. TFA). The pure fractions were combined, concentrated and lyophilized overnight to give 2-amino-2′-(3,6-dihydro-2H-pyran-4-yl)-7′-(2-fluoropyridin-3-yl)-1-methylspiro[imidazole-4,9′-xanthene]-5(1H)-one as the 2,2,2-trifluoroacetate (TFA) salt.

A 10 ml resealable tube was charged with 2-amino-2'-bromo-7'-methoxy-1-methylspiro[imidazole-4,9'-xanthen]-5(H)-one (234 mg, 0.603 mmol) (Intermediate B, example 6), (+)-sodium L-ascorbate (11.94 mg, 0.060 mmol), sodium azide (118 mg, 1.808 mmol) and copper(I) iodide (22.96 mg, 0.121 mmol). Ethanol (2.1 ml), water (0.9 ml) and trans-N,N’-dimethyl-1,2-cyclohexanediadimine (0.029 ml, 0.181 mmol) were added, and the vial was sealed and heated at 85 °C for 18 hrs. The reaction mixture was
diluted with EtOAc (5 ml) and washed 3 times with water then with brine and concentrated. The residue was diluted with 3 ml THF and 1 ml water and treated with trimethylphosphine (1.0M solution in THF) (0.603 ml, 0.603 mmol), and stirred for 20 min at RT. LCMS 116872-50-8 of the reaction mixture revealed complete conversion of the azide to the aniline (peak at 1.12 min, M+H = 325). The mixture was concentrated in vacuo, diluted with water and extracted with EtOAc. The organic layer was washed with brine and concentrated. The residue was redissolved in 3 ml EtOAc, 5-chloro-2-pyridinecarboxylic acid (95 mg, 0.603 mmol) and triethylamine (0.252 ml, 1.808 mmol) were added and the mixture was cooled in ice-water bath. 1-Propanephosphonic acid cyclic anhydride (T3P) (50 wt. % solution in ethyl acetate) (0.718 ml, 1.206 mmol) was added dropwise. The bath was removed and the mixture was stirred at RT for 30 min, then quenched by addition of sat. NaHCO₃. The organic layer was washed twice with water, brine and concentrated. The residue was purified by column chromatography on 25 g PuriFlash column using 10-100% DCM/MeOH/NH₄OH (90:10:1) in DCM to afford N-(2-amino-2'-methoxy-1-methyl-5-oxo-1,5-dihydrospiro[imidazole-4,9'-xanthen]-7'-yl)-5-chloropicolinamide as off white solid. Found M+H = 464.

wherein R² is as defined herein, to make a compound of Formula II.

As can be appreciated by the skilled artisan, the above synthetic schemes and representative examples are not intended to comprise a comprehensive list of all means by which the compounds described and claimed in this application may be synthesized. Further methods will be evident to those of ordinary skill in the art. Additionally, the various synthetic steps described above may be performed in an alternate sequence or order to give the desired compounds.

For example, in these procedures, the steps may be preceded, or followed, by additional protection/deprotection steps as necessary. Particularly, if one or more
functional groups, for example carboxy, hydroxy, amino, or mercapto groups, are or need to be protected in preparing the compounds of the invention, because they are not intended to take part in a specific reaction or chemical transformation, various known conventional protecting groups may be used. For example, protecting groups typically utilized in the synthesis of natural and synthetic compounds, including peptides, nucleic acids, derivatives thereof and sugars, having multiple reactive centers, chiral centers and other sites potentially susceptible to the reaction reagents and/or conditions, may be used.

Salts, including pharmaceutically acceptable salts, of a compound of the invention having a salt-forming group may be prepared in a conventional manner or manner known to persons skilled in the art. For example, acid addition salts of compounds of the invention may be obtained by treatment with an acid or with a suitable anion exchange reagent. A salt with two acid molecules (for example a dihalogenide) may also be converted into a salt with one acid molecule per compound (for example a monohalogenide); this may be done by heating to a melt, or for example by heating as a solid under a high vacuum at elevated temperature, for example from 50 °C to 170 °C, one molecule of the acid being expelled per molecule of the compound.

Acid salts can usually be converted to free-base compounds, e.g. by treating the salt with suitable basic agents, for example with alkali metal carbonates, alkali metal hydrogen carbonates, or alkali metal hydroxides, typically potassium carbonate or sodium hydroxide. Exemplary and suitable salts, and their preparation, are described herein in the Definition section of the application.
All synthetic procedures described herein can be carried out under known reaction conditions, advantageously under those described herein, either in the absence or in the presence (usually) of solvents or diluents. As appreciated by those of ordinary skill in the art, the solvents should be inert with respect to, and should be able to dissolve, the starting materials and other reagents used. Solvents should be able to partially or wholly solubilize the reactants in the absence or presence of catalysts, condensing agents or neutralizing agents, for example ion exchangers, typically cation exchangers for example in the H⁺ form. The ability of the solvent to allow and/or influence the progress or rate of the reaction is generally dependant on the type and properties of the solvent(s), the reaction conditions including temperature, pressure, atmospheric conditions such as in an inert atmosphere under argon or nitrogen, and concentration, and of the reactants themselves.

Suitable solvents for conducting reactions to synthesize compounds of the invention include, without limitation, water; esters, including lower alkyl-lower alkanoates, e.g., EtOAc; ethers including aliphatic ethers, e.g., Et₂O and ethylene glycol dimethylether or cyclic ethers, e.g., THF; liquid aromatic hydrocarbons, including benzene, toluene and xylene; alcohols, including MeOH, EtOH, 1-propanol, IPOH, n- and t-butanol; nitriles including CH₃CN; halogenated hydrocarbons, including CH₂Cl₂, CHCl₃ and CCl₄; acid amides including DMF; sulfoxides, including DMSO; bases, including heterocyclic nitrogen bases, e.g. pyridine; carboxylic acids, including lower alkanecarboxylic acids, e.g., AcOH; inorganic acids including HCl, HBr, HF, H₂SO₄ and the like; carboxylic acid anhydrides, including lower alkane acid anhydrides, e.g., acetic anhydride; cyclic, linear, or branched hydrocarbons, including cyclohexane, hexane, pentane, isopentane and the like, and mixtures of these solvents, such as purely organic solvent combinations, or water-containing solvent combinations e.g., aqueous solutions. These solvents and solvent mixtures may also be used in "working-up" the reaction as well as in processing the reaction and/or isolating the reaction product(s), such as in chromatography.

Purification methods are known in the art and include, for example, crystallization, chromatography (liquid and gas phase, and the like), extraction, distillation, trituration, reverse phase HPLC and the like. Reactions conditions such as temperature, duration, pressure, and atmosphere (inert gas, ambient) are known in the art and may be adjusted as appropriate for the reaction.
The invention further encompasses "intermediate" compounds, including structures produced from the synthetic procedures described, whether isolated or generated in-situ and not isolated, prior to obtaining the finally desired compound. Structures resulting from carrying out steps from a transient starting material, structures resulting from divergence from the described method(s) at any stage, and structures forming starting materials under the reaction conditions are all "intermediates" included in the invention. Further, structures produced by using starting materials in the form of a reactive derivative or salt, or produced by a compound obtainable by means of the process according to the invention and structures resulting from processing the compounds of the invention in situ are also within the scope of the invention.

The invention also provides new starting materials and/or intermediates, as well as processes for the preparation thereof. In select embodiments, such starting materials are used and reaction conditions so selected as to obtain the desired compound(s).

Starting materials of the invention, are either known, commercially available, or can be synthesized in analogy to or according to methods that are known in the art. Many starting materials may be prepared according to known processes and, in particular, can be prepared using processes described in the examples. In synthesizing starting materials, functional groups may be protected with suitable protecting groups when necessary. Protecting groups, their introduction and removal are described above.

Compounds of the present invention can possess, in general, one or more asymmetric carbon atoms and are thus capable of existing in the form of optical isomers as well as in the form of racemic or non-racemic mixtures thereof. While shown without respect to stereochemistry in Formulas I-III, the present invention includes such optical isomers and diastereomers, as well as the racemic and resolved, enantiomerically pure R and S stereoisomers, as well as other mixtures of R and S stereoisomers and pharmaceutically acceptable salts thereof.

The optical isomers can be obtained by resolution of the racemic mixtures according to conventional processes, e.g., by formation of diastereoisomeric salts, by treatment with an optically active acid or base. Examples of appropriate acids are tartaric, diacetyltartaric, dibenzoyletartaric, ditoluoyltartaric, and camphorsulfonic acid and then separation of the mixture of diastereoisomers by crystallization followed by liberation of the optically active bases from these salts. A different process for separation of optical isomers involves the use of a chiral chromatography column optimally chosen to maximize the separation of the enantiomers. Still another available method involves
synthesis of covalent diastereoisomeric molecules by reacting compounds of the invention with an optically pure acid in an activated form or an optically pure isocyanate. The synthesized diastereoisomers can be separated by conventional means such as chromatography, distillation, crystallization or sublimation, and then hydrolyzed to deliver the enantiomerically pure compound. The optically active compounds of the invention can likewise be obtained by using optically active starting materials. These isomers may be in the form of a free acid, a free base, an ester or a salt. All such isomeric forms of such compounds are expressly included in the present invention.

The compounds of the invention may also be represented in multiple tautomeric forms. Tautomers often exist in equilibrium with each other, and interconvert under environmental and physiological conditions. The compounds of the invention may also occur in cis- or trans- or E- or Z- double bond isomeric forms. The invention expressly includes all tautomeric forms of the compounds described herein.

All crystal forms of the compounds described herein are expressly included in the present invention.

The present invention also includes isotopically-labeled compounds, which are identical to those recited herein, but for the fact that one or more atoms are replaced by an atom having an atomic mass or mass number different from the atomic mass or mass number usually found in nature. Examples of isotopes that can be incorporated into compounds of the invention include isotopes of hydrogen, carbon, nitrogen, oxygen, phosphorous, fluorine and chlorine, such as ²H (deuterium), ³H (tritium), ¹³C, ¹⁴C, ¹⁵N, ¹⁶O, ¹⁷O, ³¹P, ³²P, ³⁵S, ¹⁸F, and ³⁶Cl.

Compounds of the present invention that contain the aforementioned isotopes and/or other isotopes of other atoms are within the scope of this invention. Certain isotopically-labeled compounds of the present invention, for example those into which radioactive isotopes such as ³H and ¹⁴C are incorporated, are useful in drug and/or substrate tissue distribution assays. Deuterated (²H), Tritiated (³H) and carbon-14, i.e., ¹⁴C, isotopes are particularly preferred for their ease of preparation and detection. Further, substitution with heavier isotopes such as deuterium, i.e., ²H, can afford certain therapeutic advantages resulting from greater metabolic stability, for example increased in vivo half-life or reduced dosage requirements and, hence, may be preferred in some circumstances. Isotopically labeled compounds of this invention can generally be prepared by substituting a readily available isotopically labeled reagent for a non-isotopically labeled reagent.
BILOGICAL EVALUATION

The compounds of the invention may be modified by appending appropriate functionalities to enhance selective biological properties. The pharmacokinetic and pharmacodynamic properties of a compound relate, directly and indirectly, to the ability of the compound to be effective for its intended use.

Although the pharmacological properties of the compounds of the invention (Formulas I-III) vary with structural change, in general, activity possessed by compounds of Formulas I-III may be demonstrated both in vitro as well as in vivo. The following exemplified pharmacological assays have been carried out with the compounds according to the invention, to assess and characterize the compound’s ability to modulate BACE activity and to regulate the cleavage of amyloid beta precursor protein, thereby reducing or inhibiting the production of amyloid beta.

In Vitro Enzymatic BACE FRET (fluorescence resonance energy transfer) Assay (Enzyme Assay data in the Example Table I)

The assay buffer used in this screen is 0.05 M acetate, pH 4.2, 10% DMSO final, 100 uM genapol (which is a nonionic detergent, below its Critical Micelle Concentration). The Beta Secretase enzyme (0.2nM) is pre-incubated for one hour with inhibitors, typically in about 1uL of DMSO according to a serial dilution, are added thereto. This assay is effectively started by the addition of FRET substrate (50nM) and the combination is incubated for one hour. The FRET assay is terminated with by addition of Tris buffer, which raises the pH to neutrality, and the fluorescence is determined. The FRET substrate is a peptide with commercially available fluorophore and quencher, on opposite sides of the BACE cleavage site. Proteolytic cleavage of the FRET substrate releases quenching of fluorescence (excitation 488 nm and emission 425 nm).

Where available, the in-vitro BACE FRET enzyme data for each of the Examples is provided in Table I. Data key for the in-vitro BACE FRET assay is as follows:

"+" means the compound example has an IC_{50} value of = to or > 1.0 uM;

"++" means the compound example has an IC_{50} value in the range from 100 nM-1.0 uM (<1.0 uM to = or > 100 nM);

"+++" means the compound example has an IC_{50} value in the range from 25 nM-100 nM (<100 nM to = or >25 nM); and

"++++" means the compound example has an IC_{50} value in the range less than 25 nM (< 0.1 uM).
In Vitro BACE cell-based assay

The cell-based assay measures inhibition or reduction of Αβ40 in conditioned medium of test compound treated cells expressing amyloid precursor protein.

Cells stably expressing Amyloid Precursor Protein (APP) were plated at a density of 40K cells/well in 96 well plates (Costar). The cells were cultivated for 24 hours at 37 °C and 5% CO2 in DMEM supplemented with 10% FBS. The test compounds were then added to cells in 10-point dose response concentrations with the starting concentration being either 100 μM or 10 μM. The compounds were diluted from stock solutions in DMSO and the final DMSO concentration of the test compounds on cells was 0.1%. After 24 h of incubation with the test compounds the supernatant conditioned media was collected and the Αβ40 levels were determined using a sandwich ELISA. The IC50 of the compound was calculated from the percent of control or percent inhibition of Αβ40 as a function of the concentration of the test compound.

The sandwich ELISA to detect Αβ40 was performed in 96 well microtiter plates, which were pre-treated with goat anti-rabbit IgG (Pierce). The capture and detecting antibody pair that were used to detect Αβ40 from cell supematants were affinity purified pAb40 (Biosource) and biotinylated 6E10 (Signet Labs Inc.), respectively. The optimal concentration for the pAb40 antibody was 3 μg/ml in Superblock/TBS (Pierce) that was supplemented with 0.05% Tween 20 (Sigma). Optimal concentration for the detection antibody 6E10-biotinylated was 0.5 μg/ml in Superblock/TBS (Pierce) that had been supplemented with 2% normal goat serum and 2% normal mouse serum.

Cellular supematants were incubated with the capture antibody for 3 h at 4 °C, followed by 3 wash steps in TBS-tween (0.05%). The detecting antibody incubation was for 2 h at 4 °C, again followed by the wash steps as described previously. The final readout of the ELISA is Time-Resolved Fluorescence (counts per minute) using Delfia reagents Streptavidin-Europium and Enhancement solutions (Perkin Elmer) and the Victor 2 multilabel counter (Perkin Elmer).

Where available, the in-vitro BACE cell based data for each of the Examples is provided in Table 1. Data key for the in-vitro BACE cell based assay is as follows:

"+" means the compound example has an IC50 value of = to or > 1.0 uM;

"++" means the compound example has an IC50 value in the range from 100 nM-1.0 uM (<1.0 uM to = or > 100 nM);

**In Vitro Enzymatic Cathepsin D (Cat D) FRET (fluorescence resonance energy transfer) Assay**

Recombinant Cat D was expressed in CHO cells. The assay buffer for CathepsinD is 0.05 M citrate pH 3.5, 10% DMSO final, 5 mM CHAPS. The Cat D enzyme (9 nM) is pre-incubated for one hour with inhibitors, typically in about 1uL of DMSO according to a serial dilution, is added thereto. The assays are effectively started by the addition of different FRET substrates (20 nM for Cat D) and the combination is incubated for one hour. The FRET assay is terminated with by addition of Tris buffer, which raises the pH to neutrality, and the fluorescence is determined. The FRET substrate is a peptide with commercially available fluorophore and quencher, on opposite sides of the BACE cleavage site. The Cat D substrate peptide sequence is based on sequence #1 of Table 1 from Gulnik et al. FEBS Letters v413 p379-384 1997. Proteolytic cleavage of the FRET substrate releases quenching of fluorescence (Cat D excitation 500 nm and emission 580 nm).

Alternatively, a Cat D assay may also be run according to the procedure described in the article, Characterization of new fluorogenic substrates for the rapid and sensitive assay of cathepsin E and cathepsin D, J. Biochem., 125:1137, 1999. In addition, the cathepsin D and cathepsin E assays are described in PCT publication WO2011069934. This WIPO publication describes BACE inhibitor compounds having an amide linker connecting two aromatic groups with extremely poor cathepsin D and/or cathepsin E inhibitory activity (see Table 2).

Where available, the in-vitro Cat D FRET assay data for each of the Examples, conducted by the first procedure, is provided. For example, the compound of example 40 has a Cat D IC₅₀ value of 7.4aM. As shown by the high micromolar Cat D data (very poorly active or inactive against cat D), the compounds of the present invention possess the unexpected property of little to no ability to inhibit the activity of Cat D. It was surprisingly found that incorporation of a linker "L" between the core of the compounds and the R² group has conferred a significantly reduced, poor or no potency on the protein Cat D. Thus, with this surprising selectivity profile, the compounds of the present
invention are believed to minimize, reduce or completely eliminate any risk of retinal atrophy and abnormal development of the eye and of the retinal pigmented epithelium as it relates to the normal function and activity of Cat D.

**In vivo Inhibition of Beta-Secretase**

Several animal models, including mouse, rat, dog, and monkey, may be used to screen for inhibition of beta-secretase activity in vivo following administration of a test compound sample. Animals used in this invention can be wild type, transgenic, or gene knockout animals. For example, the Tg2576 mouse model, prepared and conducted as described in Hsiao et al., 1996, *Science* 27A, 99-102, and other non-transgenic or gene knockout animals are useful to analyze in vivo inhibition of Amyloid beta peptide (Abeta) production in the presence of inhibitory test compounds. Generally, 2 to 18 month old Tg2576 mice, gene knockout mice or non-transgenic animals are administered test compounds formulated in vehicles, such as cyclodextran, phosphate buffers, hydroxypropyl methylcellulose or other suitable vehicles. One to twenty-four hours following the administration of compound, animals are sacrificed, and brains as well as cerebrospinal fluid (CSF) and plasma are removed for analysis of A-beta levels and drug or test compound concentrations (Dovey et al., 2001, *Journal of Neurochemistry*, 76,173-181)

Beginning at time 0, animals are administered by oral gavage, or other means of delivery such as intravenous injection, an inhibitory test compound of up to 100 mg/kg in a standard, conventional formulation, such as 2% hydroxypropyl methylcellulose, 1% Tween80. A separate group of animals receive 2% hydroxypropyl methylcellulose, 1% Tween80 alone, containing no test compound, and serve as a vehicle-control group. At the end of the test period, animals are sacrificed and brain tissues, plasma or cerebrospinal fluid are collected. Brains are either homogenized in 10 volumes (w/v) of 0.2% diethylamine (DEA) in 50 mM NaCl (Best et al., 2005, *Journal of Pharmacology and Experimental Therapeutics*, 313, 902-908), or in 10 volumes of 0.5% TritonX-100 in Tris-buffered saline (pH at about 7.6). Homogenates are centrifuged at 355,000g, 4°C for 30 minutes. CSF or brain supernatants are then analyzed for the presence of A-beta peptide by specific sandwich ELISA assays based on ECL (Electrochemiluminescence) technology. For example, rat Abeta40 is measured using biotinylated-4G8 (Signet) as a capture antibody and Fab40 (an in-house antibody specific to the C-terminal of Abeta40) as a detection antibody. For example, 4 hours after administration of 30 mg/kg oral dose of the test compound in 2% hydroxypropyl methylcellulose, 1% Tween80 (pH2.2) to
200g male Sprague Dawley rats, amyloid beta peptide levels are measured for reduction by X% and Y% in cerebrospinal fluid and brain, respectively, when compared to the levels measured in the vehicle-treated or control mice.

Actual vehicles used: Oral: 2% HPMC, 1% Tween80, pH 2.2
IV: 5% EtOH, 45% Propylene glycol in 5% Dextrose

The compounds of the invention may be shown to reduce the formation and/or deposition of amyloid beta peptide in the cerebrospinal fluid (CSF) as well as in the brain of a mouse or rat at both 10mpk (mpk = mg compound per kg animal) and 30mpk dosing concentrations after 4hrs.

INDICATIONS

For more than a decade, BACE1 has been a prime target for designing drugs to prevent or treat AD. However, development of such agents has turned out to be extremely
challenging, with major hurdles in cell penetration, oral bioavailability/metabolic clearance, and brain access.

Bapineuzamab, a monoclonal amino-terminus specific anti-amyloid antibody is presently in Phase III clinical trials for the treatment of AD. Alzheimer's Research & Therapy, 1:2, 2009. Each of the known genetic causes of AD is linked to A-beta. Dementia, Down's Syndrome to APP over-production, are all believed to be linked to the deposition of A-beta on the brain. With methods for identifying brain amyloid deposition, positron emission scanning (PET) and CSF measurements of Ab42, identification of AD suffering individuals needing treatment is becoming easier and more common. It is firmly believed that by reducing the formation of A-beta, one can begin to pre-treat AD. Vassar et al, Journal of Neuroscience, 29 (41):12787 - 12794, 2009. One published pathway for treatment of AD is inhibition of beta-secretase. Tirrell, Bloomberg News, The Boston Globe, 1-7-2010.

The US biotech company CoMentis is developing an orally bioavailable small molecule CTS-21 166, a highly potent, highly selective and efficacious brain-penetrating beta -secretase inhibitor. CoMentis successfully completed a Phase I study of CTS-21 166 in healthy volunteers in 2008. Results indicated that CTS-21 166 was safe, well-tolerated and pharmacodynamically active at all dose levels. All clinical subjects administered CTS-21 166 showed area-under-curve (AUC) reduction in plasma A-Beta40 reductions ranging from 40-75%. Because of the urgent need for AD treatment, Phase II studies for CTS-21 166 are planned, or ongoing, for AD patients. In preclinical studies, CTS-21 166 exhibits excellent efficacy, selectivity, brain penetration and pharmacologic activity.

Using a fragment-based chemistry strategy, Eli Lilly and company generated LY2811376 [(5)-4-(2,4-difluoro-5 -pyrimidin-5 -yl-phenyl)-4-methyl-5 ,6-dihydro-4//-][1,3]thiazin-2-ylamine], an orally available non-peptidic BACE1 inhibitor that produces profound Aβ-lowering effects in animals. The biomarker changes obtained in preclinical animal models translate into man at doses of LY281 1376 that were safe and well tolerated in healthy volunteers (US Ph 1 Clinical trial - www.clinicaltrials.gov). Prominent and long-lasting Aβ reductions in lumbar CSF were measured after oral dosing of 30 or 90 mg of LY281 1376. This represents the first translation of BACE1-driven biomarker changes in CNS from preclinical animal models to man. Because of toxicology findings identified in longer-term preclinical studies, this compound is no longer progressing in clinical development. However, BACE1 remains a viable target because the adverse effects reported here were recapitulated in LY281 1376-treated BACE1 KO
mice and thus are unrelated to BACE1 inhibition. The magnitude and duration of central Aβ reduction obtainable with BACE1 inhibition positions this protease as a tractable small-molecule target through which to test the amyloid hypothesis in man. Neuroscience, 31(46):16507-16515, 2011

The compounds of the invention have been shown to modulate, and specifically inhibit the activity of the beta-secretase enzyme, thereby reducing the A-beta peptide fragments. Accordingly, compounds of the invention are useful for, but not limited to, the prevention or treatment of beta-secretase related diseases, including Alzheimer's disease. The compounds of the invention have the ability to modulate the activity of beta secretase enzyme, thereby regulating the production of amyloid beta (Abeta peptide) and reducing the formation and deposition of Abeta peptide in both the cerebral spinal fluid as well as in the brain, resulting in a decrease of amyloid plaque on the brain. In one embodiment of the invention, there is provided a method of treating a disorder related to a beta-secretase enzyme in a subject, the method comprising administering to the subject an effective dosage amount of a compound of Formulas I, II, III, and sub-formulae thereof. In another embodiment, there is provided a method of reducing production of amyloid beta, and of reducing plaque formation on the brain. In another embodiment, there is provided a method for the treatment, prevention or amelioration of a disease or disorder characterized by the elevated beta-amyloid deposits or beta-amyloid levels in a subject, the method comprising administering to the subject a therapeutically effective amount of a compound according to any of Formulas I - III. In yet another embodiment, the invention provides a method of treating Alzheimer's disease, cognitive impairment including mild, moderate and/or severe, Down's Syndrome, cognitive decline, senile dementia, cerebral amyloid angiopathy or a neurodegenerative disorder.

Accordingly, the compounds of the invention would be useful in therapy as CNS agents in treating neurological disorders and related conditions in subjects.

FORMULATIONS AND METHOD OF USE

Treatment of diseases and disorders herein is intended to also include therapeutic administration of a compound of the invention, or a pharmaceutical salt thereof, or a pharmaceutical composition of either to a subject (i.e., an animal, preferably a mammal, most preferably a human) which may be in need of preventative treatment, such as, for example, for pain, inflammation and the like. Treatment also encompasses prophylactic administration of a compound of the invention, or a pharmaceutical salt thereof, or a pharmaceutical composition of either to a subject (i.e., an animal, preferably a mammal, most preferably a human). Generally, the subject is initially diagnosed by a licensed physician and/or authorized medical practitioner, and a regimen for prophylactic and/or therapeutic treatment via administration of the compound(s) or compositions of the invention is suggested, recommended or prescribed.

The amount of compound(s) which is/are administered and the dosage regimen for treating neurological disorders and beta-secretase mediated diseases with the compounds and/or compositions of this invention depends on a variety of factors, including the age, weight, sex and medical condition of the subject, the type of disease, the severity of the disease, the route and frequency of administration, and the particular compound employed. Thus, the dosage regimen may vary widely, but can be determined routinely using standard methods. A daily dose of about 0.01 to 500 mg/kg, advantageously between about 0.01 and about 50 mg/kg, more advantageously about 0.01 and about 30 mg/kg, and even more advantageously between about 0.1 and about 10 mg/kg body weight may be appropriate, and should be useful for all methods of use disclosed herein. The daily dose can be administered in one to four doses per day.

While it may be possible to administer a compound of the invention alone, in the methods described, the compound administered normally will be present as an active ingredient in a pharmaceutical composition. Thus, in another embodiment of the invention, there is provided a pharmaceutical composition comprising a compound of this invention in combination with a pharmaceutically acceptable excipient, which includes diluents, carriers, adjuvants and the like (collectively referred to herein as "excipient"
materials) as described herein, and, if desired, other active ingredients. A pharmaceutical composition of the invention may comprise an "effective amount" of a compound of the invention or an "effective dosage amount" of a compound of the invention. An "effective dosage amount" of a compound of the invention includes an amount less than, equal to or greater than an effective amount of the compound. For example, a pharmaceutical composition in which two or more unit dosages, such as in tablets, capsules and the like, are required to administer an effective amount of the compound, or alternatively, a multi-dose pharmaceutical composition, such as powders, liquids and the like, in which an effective amount of the compound is administered by administering a portion of the composition.

The compound(s) of the present invention may be administered by any suitable route, preferably in the form of a pharmaceutical composition adapted to such a route, and in a dose effective for the treatment intended. The compounds and compositions of the present invention may, for example, be administered orally, mucosally, topically, rectally, pulmonarily such as by inhalation spray, or parentally including intravascularly, intravenously, intraperitoneally, subcutaneously, intramuscularly intratermally and infusion techniques, in dosage unit formulations containing conventional pharmaceutically acceptable carriers, adjuvants, and vehicles.

For oral administration, the pharmaceutical composition may be in the form of, for example, a tablet, capsule, suspension or liquid. The pharmaceutical composition is preferably made in the form of a dosage unit containing a particular amount of the active ingredient. Examples of such dosage units are tablets or capsules. For example, these may contain an amount of active ingredient from about 1 to 2000 mg, advantageously from about 1 to 500 mg, and typically from about 5 to 150 mg. A suitable daily dose for a human or other mammal may vary widely depending on the condition of the patient and other factors, but, once again, can be determined using routine methods and practices.

For therapeutic purposes, the active compounds of this invention are ordinarily combined with one or more adjuvants or other "excipients" appropriate to the indicated route of administration. If orally administered on a per dose basis, the compounds may be admixed with lactose, sucrose, starch powder, cellulose esters of alkanoic acids, cellulose alkyl esters, talc, stearic acid, magnesium stearate, magnesium oxide, sodium and calcium salts of phosphoric and sulfuric acids, gelatin, acacia gum, sodium alginate, polyvinylpyrrolidone, and/or polyvinyl alcohol, to form the final formulation. For example, the active compound(s) and excipient(s) may be tableted or encapsulated by
known and accepted methods for convenient administration. Examples of suitable formulations include, without limitation, pills, tablets, soft and hard-shell gel capsules, troches, orally-dissolvable forms and delayed or controlled-release formulations thereof. Particularly, capsule or tablet formulations may contain one or more controlled-release agents, such as hydroxypropylmethyl cellulose, as a dispersion with the active compound(s).

Formulations for parenteral administration may be in the form of aqueous or non-aqueous isotonic sterile injection solutions or suspensions. These solutions and suspensions may be prepared from sterile powders or granules using one or more of the carriers or diluents mentioned for use in the formulations for oral administration or by using other suitable dispersing or wetting agents and suspending agents. The compounds may be dissolved in water, polyethylene glycol, propylene glycol, ethanol, corn oil, cottonseed oil, peanut oil, sesame oil, benzyl alcohol, sodium chloride, tragacanth gum, and/or various buffers. Other adjuvants and modes of administration are well and widely known in the pharmaceutical art. The active ingredient may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water, or with cyclodextrin (ie. Captisol), cosolvent solubilization (ie. propylene glycol) or micellar solubilization (ie. Tween 80).

The sterile injectable preparation may also be a sterile injectable solution or suspension in a non-toxic parenterally acceptable diluent or solvent, for example as a solution in 1,3-butanediol. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution, and isotonic sodium chloride solution. In addition, sterile, fixed oils are conventionally employed as a solvent or suspending medium. For this purpose any bland fixed oil may be employed, including synthetic mono- or diglycerides. In addition, fatty acids such as oleic acid find use in the preparation of injectables.

The active ingredient may also be administered by injection as a composition with suitable carriers including saline, dextrose, or water. The daily parenteral dosage regimen will be from about 0.1 to about 30 mg/kg of total body weight, and preferably from about 0.1 to about 10 mg/kg.

For pulmonary administration, the pharmaceutical composition may be administered in the form of an aerosol or with an inhaler including dry powder aerosol.

The pharmaceutical compositions may be subjected to conventional pharmaceutical operations such as sterilization and/or may contain conventional
adjuvants, such as preservatives, stabilizers, wetting agents, emulsifiers, buffers etc. Tablets and pills can additionally be prepared with enteric coatings. Such compositions may also comprise adjuvants, such as wetting, sweetening, flavoring, and perfuming agents. Accordingly, in yet another embodiment of the present invention, there is provided a method of manufacturing a medicament, the method comprising combining an amount of a compound according to Formulas I-III with a pharmaceutically acceptable carrier to manufacture the medicament.

In yet another embodiment, the invention provides a method of manufacturing a medicament for the treatment of Alzheimer’s disease, the method comprising combining an amount of a compound according to Formulas I-III with a pharmaceutically acceptable carrier to manufacture the medicament.

COMBINATIONS

While the compounds of the invention can be dosed or administered as the sole active pharmaceutical agent, they can also be used in combination with one or more compounds of the invention or in conjunction with other agents. When administered as a combination, the therapeutic agents can be formulated as separate compositions that are administered simultaneously or sequentially at different times, or the therapeutic agents can be given as a single composition.

The phrase "co-therapy" (or "combination-therapy"), in defining use of a compound of the present invention and another pharmaceutical agent, is intended to embrace administration of each agent in a sequential manner in a regimen that will provide beneficial effects of the drug combination, and is intended as well to embrace co-administration of these agents in a substantially simultaneous manner, such as in a single capsule having a fixed ratio of these active agents or in multiple, separate capsules for each agent.

Specifically, the administration of compounds of the present invention may be in conjunction with additional therapies known to those skilled in the art in the prevention or treatment of beta-secretase, gamma-secretase and/or other reagents known in influence the formation and/or deposition of amyloid beta, otherwise responsible for the formation of plaque on the brain.

If formulated as a fixed dose, such combination products employ the compounds of this invention within the accepted dosage ranges. Compounds of Formulas I, II and III may also be administered sequentially with other known medicinal agents. The invention
is not limited in the sequence of administration; compounds of the invention may be administered either prior to, simultaneous with or after administration of the known anti-inflammatory agent.

The foregoing description is merely illustrative of the invention and is not intended to limit the invention to the disclosed compounds, compositions and methods. Variations and changes, which are obvious to one skilled in the art, are intended to be within the scope and nature of the invention, as defined in the appended claims. From the foregoing description, one skilled in the art can easily ascertain the essential characteristics of this invention, and without departing from the spirit and scope thereof, can make various changes and modifications of the invention to adapt it to various usages and conditions. All patents and other publications recited herein are hereby incorporated by reference in their entireties.
