(57) **Abrégé/Abstract:**

Compositions disclosed herein, and methods of use thereof included those for inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell therapy, wherein the subjects are administered compositions comprising apoptotic cells or apoptotic cell supernatants. In certain instances compositions and methods of use thereof disclosed herein do not reduce the efficacy of the CAR T-cell cancer therapy. Disclosed herein are also compositions and methods of use thereof for decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm comprising administration of a composition comprising apoptotic cells or an apoptotic cell supernatant.

(54) Title: COMBINATION IMMUNE THERAPY AND CYTOKINE CONTROL THERAPY FOR CANCER TREATMENT

CAR + APOPTOTIC CELLS/SUPERNATANT(using patient's own cells)

FIGURE 2B

(57) **Abstract:** Compositions disclosed herein, and methods of use thereof included those for inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell therapy, wherein the subjects are administered compositions comprising apoptotic cells or apoptotic cell supernatants. In certain instances compositions and methods of use thereof disclosed herein do not reduce the efficacy of the CAR T-cell cancer therapy. Disclosed herein are also compositions and methods of use thereof for decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm comprising administration of a composition comprising apoptotic cells or an apoptotic cell supernatant.

WO 2017/141243 A1

COMBINATION IMMUNE THERAPY AND CYTOKINE CONTROL THERAPY FOR CANCER TREATMENT

FIELD OF INTEREST

5 [0001] Disclosed herein are compositions and methods thereof for maintaining or increasing the proliferation rate of chimeric antigen receptor-expressing T-cells during CAR T-cell cancer therapy. Further, disclosed herein are compositions and methods thereof for increasing the efficacy of chimeric antigen receptor T-cell cancer therapy, wherein the incidence of a subject experiencing cytokine release syndrome or a cytokine storm is reduced or inhibited. Methods disclosed herein
10 include those comprising administration of CAR T-cells and an additional agent comprising apoptotic cells, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

BACKGROUND

15 [0002] While standard treatments for cancer are surgery, chemotherapy, and radiation therapy, improved methods, such as targeted immunological therapies, are currently being developed and tested. One promising technique uses adoptive cell transfer (ACT), in which immune cells are modified to recognize and attack their tumors. One example of ACT is when a patient's own cytotoxic T-cells, or a donor's, are engineered to express a chimeric antigen receptor (CAR T-cells)
20 targeted to a tumor specific antigen expressed on the surface of the tumor cells. These CAR T-cells are then cytotoxic only to cells expressing the tumor specific antigen. Clinical trials have shown that CAR T-cell therapy has great potential in controlling advanced acute lymphoblastic leukemia (ALL) and lymphoma, among others.

[0003] However, some patients given CAR T-cell therapy and other immune therapies experience a
25 dangerous and sometimes life-threatening side effect called cytokine release syndrome (CRS) or cytokine storm, in which the infused, activated T-cells produce a systemic inflammatory response in which there is a rapid and massive release of cytokines into the bloodstream, leading to dangerously low blood pressure, high fever and shivering.

[0004] In severe cases of CRS, patients experience a cytokine storm (a.k.a. cytokine cascade or
30 hypercytokinemia), in which there is a positive feedback loop between cytokines and white blood cells with highly elevated levels of cytokines. This can lead to potentially life-threatening complications including cardiac dysfunction, adult respiratory distress syndrome, neurologic toxicity, renal and/or hepatic failure, pulmonary edema and disseminated intravascular coagulation.

[0005] For example, six patients in a recent phase I trial who were administered the monoclonal

antibody TGN1412, which binds to the CD28 receptor on T-cells, exhibited severe cases of cytokine storm and multi-organ failure. This happened despite the fact that the TGN1412 dose was 500-times lower than that found to be safe in animals (St. Clair EW: The calm after the cytokine storm: Lessons from the TGN1412 trial. J Clin Invest 118: 1344-1347, 2008).

5 [0006] Chimeric antigen receptor (CAR)–modified T cells with specificity against CD19 have demonstrated dramatic promise against highly refractory hematologic malignancies. Clinical responses with complete remission rates as high as 90% have been reported in children and adults with relapsed/refractory acute lymphoblastic leukemia (ALL). However, very significant toxicity has been observed and as many as 30% of subject administered CAR-T cells develop severe forms
10 of CRS and possibly related neurotoxicity. CRS is occurring due to large secretion of pro-inflammatory cytokines mainly from macrophages/monocytes, and resembles macrophage activating syndrome and hemophagocytosis, which is in response to CAR-T secreting interferon-gamma (IFN- γ) and possibly additional cytokines.

[0007] To date, corticosteroids, biological therapies such as anti-IL6 therapies and anti-
15 inflammatory drugs are being evaluated to control cytokine release syndrome in patients administered CAR T-cell therapy. However, steroids may affect CAR T-cells' activity and/or proliferation and put the patients in danger of sepsis and opportunistic infections. Anti-inflammatory drugs may not be effective in controlling cytokine release syndromes or cytokine storms, because the cytokine storm includes a very large number of cytokines while there is limited ability to infuse
20 patients with anti-inflammatory drugs. Novel strategies are needed to control cytokine release syndromes, and especially cytokine storms, in order to realize the potential of CAR T-cell therapy.

[0008] Cytokine storms are also a problem after other infectious and non-infectious stimuli. In a cytokine storm, numerous proinflammatory cytokines, such as interleukin-1 (IL-1), IL-6, interferon-gamma (IFN- γ), and tumor necrosis factor- α (TNF α), are released, resulting in hypotension,
25 hemorrhage, and, ultimately, multiorgan failure. In addition, IFN- γ also excited macrophages, which in turn may secrete vast quantities of pro-inflammatory cytokines including IL-6 and TNF- α .

[0009] CRS is the most common potentially severe toxicity associated with CAR T cells, but it occurs with other therapies that engage T cells to kill cancer cells, including bispecific T-cell-engaging (BiTE) antibodies such as blinatumomab, and even in non-T cell therapies such as rituxan.
30 Nevertheless, occurrence in 80–100% of patients is unique to CAR T cells, where 30% of patients with ALL have a severe form of toxicity that can be fatal in some patients.

[0010] The relatively high death rate in young people, with presumably healthy immune systems, in the 1918 H1N1 influenza pandemic and the more recent bird flu H5N1 infection are attributed to cytokine storms. This syndrome has been also known to occur in advanced or terminal cases of

severe acute respiratory syndrome (SARS), Epstein-Barr virus-associated hemophagocytic lymphohistiocytosis, gram-negative sepsis, malaria and numerous other infectious diseases, including Ebola infection. Cytokine storm may also stem from non-infectious causes, such as acute pancreatitis, severe burns or trauma, or acute respiratory distress syndrome.

5 [0011] Neurotoxicity, which could be regarded separately or as part of the syndrome, includes mental status changes, reversible delirium, and seizure-like activity. Patients may develop a gradual progression of confusion, word-finding difficulty, and aphasia, and ultimately become obtunded. In three cases, these neurologic complications required intubation and mechanical ventilation for airway protection. Patients with neurologic complications were evaluated with CT and MRI of the
10 brain, which did not depict changes apart from possible leukoencephalopathy in some cases, as well as electroencephalograms (EEGs) and lumbar punctures. The EEGs confirmed seizure-like activity, which resolved after antiepileptic treatment. Analysis of cerebrospinal fluid (CSF) obtained by lumbar puncture in three patients at the time of overt neurologic complications revealed lymphocytosis, which, by further qPCR analyses, was found to be composed of, at least in part,
15 CAR T cells.

[0012] Despite the high rate of occurrence of CRS after CAR-T cell infusion, relatively little is understood about the underlying biology of the syndrome. The condition resembles hemophagocytic lymphohistiocytosis (HLH) and macrophage activating syndrome (MAS), and is associated with marked elevations of cytokines and chemokines.

20 [0013] Currently, few modalities are used to treat CRS. Tocilizumab is an IL-6 receptor antagonist that is used to treat rheumatologic disorders. It was used to treat CRS-related toxicities in clinical trials, and is now widely used off-label for toxicity following CAR T-cell infusions. Tocilizumab may lessen or abrogate CRS-related toxicities following CAR T-cell infusions. Uncontrolled studies suggest that treating ALL patients, complete remissions still occur when they receive tocilizumab to
25 treat CRS caused by CAR T cells. However, some concern remains that tocilizumab might subtly impair the depth or duration of anti-malignancy responses caused by CAR T cells as formal studies of the impact of tocilizumab on anti-malignancy outcomes have not been performed. In addition, most published experience with tocilizumab is with ALL. Tocilizumab might impair the efficacy of CAR T cells against lymphoma or other malignancies even if it does not impair the activity of CAR
30 T cells against ALL.

[0014] There is a general consensus that if CRS has not improved with initial tocilizumab administration, an additional dose of tocilizumab should be given, or another immunosuppressive agent such as corticosteroids should be considered. Others give tocilizumab when specific hemodynamic and organ function thresholds are crossed, rather than for a certain grade of CRS. It is

suggested that tocilizumab should not be administered for neurologic toxicity because of concerns about its ability to cross the blood brain barrier, and experience in an admittedly very small number of patients that tocilizumab did not ameliorate neurologic toxicity.

[0015] Systemic corticosteroids have been used effectively to abrogate CRS related toxicities, with some evidence that corticosteroids may inhibit CAR T-cell persistence and anti-malignancy efficacy, as reported previously in ALL patients following anti-CD19 CAR T-cell infusion. For this reason, corticosteroid therapy has been reserved for use following failure of tocilizumab to ameliorate CRS. Other immunosuppressive agents that have been used or considered in CRS management include siltuximab, etanercept, infliximab, and anakinra. Due to paucity of data, no one second-line agent has been recommended over another.

[0016] CAR T cells can cause additional, less significant toxicity by several mechanisms. If the tumor-associated antigen to which the CAR is targeted is expressed on normal tissues, those tissues may be damaged, as is the case with normal B cells being depleted by anti-CD19 CAR T cells. CAR T cells may damage normal tissues by unexpectedly cross-reacting with a protein that is not expressed on tumor cells. Acute anaphylaxis and tumor lysis syndrome (TLS) have occurred following infusion of CAR T cells; however, these toxicities are by far less frequent in comparison to CRS.

[0017] In addition to factors that affect the safety of CAR T-cell therapy, multiple other factors affect CAR T-cell efficacy. Efficacy may be dependent on a number of factors including persistence and survival of the genetically modified CAR T-cells, cell dose-as the final steady-state number of cells appears to be patient specific, and loss or down-regulation of expression of targeted antigens.

[0018] Novel strategies are therefore needed, which maintain or increase the efficacy of CAR T-cell therapies while at the same time controlling safety issues including cytokine release syndrome and especially cytokine storms. Further, there is a need to develop *in vitro* and *in-vivo* models of CRS with and without CAR-modified T cells. Disclosed herein are *in vitro* and *in vivo* models of CRS in which the effects of early apoptotic cell populations were tested for their effectiveness on cytokine release and CAR T-cell toxicity.

SUMMARY

[0019] In one aspect, disclosed herein is a method of maintaining or increasing the proliferation rate of chimeric antigen receptor-expressing T-cells (CAR T-cell) during CAR T-cell cancer therapy, the method comprising the step of administering a composition comprising apoptotic cells or an apoptotic cell supernatant to a subject undergoing CAR T-cell therapy, and wherein said proliferation rate is maintained or increased in the subject compared with a subject undergoing CAR

T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.

[0020] In a related aspect, the method does not reduce or inhibit the efficacy of said CAR T-cell cancer therapy. In another related aspect the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject not administered said apoptotic cells or said apoptotic cell supernatant.

[0021] In a related aspect, said apoptotic cells comprise apoptotic cells in an early-apoptotic state. In another related aspect, said apoptotic cells are autologous to the subject being treated by said CAR T-cell therapy or are pooled third-party donor cells.

[0022] In a related aspect, administration of said composition comprising said apoptotic cells or said apoptotic cell supernatant occurs prior to, concurrent with, or following the CAR T-cell therapy. In another related aspect, administration of said apoptotic cells or said apoptotic supernatant occurs prior to, concurrent with, or following the CAR T-cell therapy.

[0023] In a related aspect, the apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with the apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant. In another related aspect, the white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.

[0024] In a related aspect, the method maintains or increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.

[0025] In one aspect, disclosed herein is a method of increasing the efficacy of chimeric antigen receptor T-cell (CAR T-cell) cancer therapy, the method comprising the step of administering CAR T-cells and an additional agent selected from the group comprising apoptotic cells, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said efficacy said CAR T-cells is increased in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said additional agent. In a related aspect, the level of production of at least one pro-inflammatory cytokine is reduced compared with the level of said pro-inflammatory cytokine in a subject received CAR T-cell cancer therapy and not administered a composition comprising said agent. In another related aspect, the pro-inflammatory cytokine comprises IL-6.

[0026] In a related aspect, when apoptotic cells or an apoptotic cell supernatant is administered, said method maintains or increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic

cell supernatant. In another related aspect, the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject not administered said additional agent.

[0027] In a related aspect, CAR T-cells and said additional agent or any combination thereof are comprised in a single composition. In another related aspect, said CAR T-cell and said additional agent or any combination thereof, are comprised in at least two compositions. In another related aspect, wherein said additional agent or any combination of agents thereof, is comprised in a composition not including said CAR T-cells, the administration of said composition comprising said agent or agents occurs prior to, concurrent with, or following administration of said CAR T-cells.

[0028] In a related aspect said apoptotic cells comprise apoptotic cells in an early-apoptotic state. In another related aspect, said apoptotic cells are autologous to a subject being treated by said CAR T-cell therapy or are pooled third-party donor cells. In another aspect, the administration of said composition comprising said agent occurs prior to, concurrent with, or following administration of said CAR T-cells.

[0029] In a related aspect, said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with the apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant. In another related aspect, the provided white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.

[0030] In one aspect, disclosed herein is a method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cell) and an additional agent, said additional agent comprising apoptotic cells, apoptotic supernatants or a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said method treats, prevents, inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.

[0031] In a related aspect, said method has increased efficacy treating, preventing, inhibiting, reducing the incidence of, ameliorating or alleviating said cancer or said tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.

[0032] In another related aspect, the level of production of at least one pro-inflammatory cytokine is reduced compared with the level of said pro-inflammatory cytokine in a subject administered said CAR T-cells and not administered a composition comprising said agent. In another related aspect, said pro-inflammatory cytokine comprises IL-6. In another related aspect, said additional agent

comprises apoptotic cells or an apoptotic cell supernatant, said method maintains or increases the levels of IL-2 in the subject compared with a subject administered said CAR T-cells and not administered said apoptotic cells or said apoptotic cell supernatant.

[0033] In another related aspect, said CAR T-cells and said additional agent or any combination thereof are comprised in a single composition. In yet another related aspect, said CAR T-cells and said additional agent or any combination thereof are comprised in at least two compositions. In another related aspect, wherein said additional agent or any combination of agents thereof, is comprised in a composition not including said CAR T-cells, the administration of said composition comprising said agent or agents occurs prior to, concurrent with, or following administration of said CAR T-cells.

[0034] In a related aspect, the administration of said additional agent occurs prior to, concurrent with, or following the administration of said CAR T-cells. In another related aspect, said apoptotic cells comprise apoptotic cells in an early-apoptotic state. In another related aspect, said apoptotic cells are autologous to said subject or are pooled third-party donor cells.

[0035] In a related aspect, said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with the apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant. In another related aspect, the provided white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.

BRIEF DESCRIPTION OF THE DRAWINGS

[0036] The subject matter disclosed herein is particularly pointed out and distinctly claimed in the concluding portion of the specification. The compositions and methods disclosed herein, however, both as to organization and method of operation, together with objects, features, and advantages thereof, may best be understood by reference to the following detailed description when read with the accompanying drawings.

[0037] **Figure 1.** Flow chart presenting the steps during one embodiment of a manufacturing process of an early apoptotic cell populations, wherein anti-coagulants were included in the process.

[0038] **Figures 2A-2B.** Schematic showing standard CAR T-cell therapy (**Figure 2A**) and embodiments of a method of safe and efficacious CAR T-cell cancer therapy in a patient using patients' own cells (autologous) (**Figure 2B**) to produce apoptotic cells or an apoptotic cell supernatant.

[0043] **Figure 7.** Apoptotic Cells do not abrogate T4⁺ CAR-T cells anti-tumor activity. Results are based on a cytotoxicity assay, wherein a monolayer of SKOV3-luc cells were cultured either with
10 non-transduced T cells or with T4⁺CAR-T cells in the presence of a vehicle (Hartmann solution), or apoptotic cells (ApoCell), or a supernatant of apoptotic cells (ApoSup), or supernatant of co-culture of apoptotic cells and monocytes/macrophages (ApoMon Sup).

[0044] **Figure 8.** Il-6, secreted at high levels during CAR-T cytotoxicity, is down-regulated by
15 apoptotic cells or ApoCell supernatant (ApoSup), or apoptotic cells and monocyte/macrophage co-culture (ApoMon Sup).

The results shown here demonstrate the effect of co-culture of SKOV3-luc and human monocytes/macrophages were exposed to apoptotic cells (ApoCell), or ApoCell supernatant (ApoSup), or apoptotic cells and monocyte/macrophage co-culture (ApoMon Sup) in the presence of cancer and CAR-19,

20 [0045] **Figures 9A – 9J.** Apoptotic cells prevent cytokine storm in *in vitro* model of cytokine storm induced in LPS-Sterile model of macrophage activation syndrome in a cancer environment. **Figure 9A** shows the reduction of LPS induced IL-10 levels in the macrophage activation syndrome model in the presence of cancer following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:8 and 1:16, at two time periods (6 hours and 24 hours). **Figure 9B** shows the reduction of
25 LPS induced IL-6 levels in the macrophage activation syndrome model following administration of Apocells in the presence of cancer and CAR-19, at a macrophage/monocyte:Apocell ratio of 1:8 and 1:16, at two time periods (6 hours and 24 hours). **Figure 9C** shows the reduction of LPS induced MIP-1 α levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:8
30 and 1:16, at two time periods (6 hours and 24 hours). **Figure 9D** shows the reduction of LPS induced IL-8 levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:8 and 1:16, at two time periods (6 hours and 24 hours). **Figure 9E** shows the reduction of LPS induced TNF- α levels in the macrophage activation syndrome model in the presence of cancer and CAR-19,

following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:8 and 1:16, at TWO time periods (6 hours and 24 hours). **Figure 9F** shows the reduction of LPS induced MIP-1 β levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:4, 1:8, 1:16, 1:32, and 1:64 at 24 hours. **Figure 9G** shows the reduction of LPS induced MCP-1 levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:4, 1:8, 1:16, 1:32, and 1:64 at 24 hours. **Figure 9H** shows the reduction of LPS induced IL-9 levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:8 and 1:16, at two time periods (6 hours and 24 hours). **Figure 9I** shows the increase of LPS induced IL-2R levels in the macrophage activation syndrome model in the presence of cancer and CAR-19, following administration of Apocells at a macrophage/monocyte:Apocell ratio of 1:4, 1:8, 1:16, 1:32, and 1:64 at 24 hours. **Figure 9J** shows that apoptotic cells do not down regulate IL-2 release from cells. Apoptotic cells were incubated with macrophages/monocytes in the presence of cancer and CAR-19, over a 24 hour time period with increasing doses of apoptotic cells (n=3). Empty bar (outline only) – 2.5×10^6 apoptotic cells per well; Black – 5×10^6 apoptotic cells per well; Grey – 10×10^6 apoptotic cells per well.

[0046] **Figure 10.** Effect of Apoptotic Cells or Apoptotic Cell Supernatant or a co-culture of Apoptotic cells and Monocytes following LPS exposure during CAR T-cell treatment mimicking CAR T-cell clinical therapy. Extremely high secretion of IL-6 was documented when lipopolysaccharides (LPS) were added to the cytotoxic assay. Results show that exposure to Apoptotic cells (Apocell), or supernatant of apoptotic cells (ApoSup) or supernatant of co-culture of apoptotic cells and monocytes/macrophages (ApoMon Sup), down regulated IL-6, wherein IL-6 was reduced to acceptable levels.

The results show Raji cell number (x-axis) vs. at absorbance at 492 nm (y-axis). All cell numbers exhibited significant readings relative to the unlysed counterpart.

[0051] **Figure 15.** Addition of early apoptotic cells does not affect CAR T-cell anti-tumor activity. E/T ratio shows the CD19+CAR T-cell to HeLa cell ratio. Survival is of CD19+ Tumor cells. Filled circle CD19+ HeLa; Empty triangle CD19+ HeLa + Naïve T cells; Filled triangle CD19+ HeLa + CAR T-CD19; Empty circle CD19+ HeLa + CAR T-CD19 + ApoCells.

[0052] **Figure 16.** Cytokine Analysis (GM-CSF) in Raji Burkett Lymphoma Cells in the Presence and Absence of Apoptotic cells. The bar graph presents the concentration measurements of cytokine GM-CSF (pg/ml) found in culture supernatants of Raji cells incubated in the presence of monocytes and LPS, followed by addition of Naïve T-cells (Raji + Naïve T), CD19+ CAR T-cells (Raji + CAR T), CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:8 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:8), CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:32 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:32), and CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:64 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:64).

[0053] **Figure 17.** Cytokine Analysis (TNF-alpha) in Raji Burkett Lymphoma Cells in the Presence and Absence of Apoptotic cells. The bar graph presents the concentration measurements of cytokine TNF-alpha (TNF-a) (pg/ml) found in culture supernatants of Raji cells incubated in the presence of monocytes and LPS, followed by addition of Naïve T-cells (Raji + Naïve T), CD19+ CAR T-cells (Raji + CAR T), CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:8 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:8), CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:32 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:32), and CD19+ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:64 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:64).

[0054] **Figures 18A and 18B.** **Figure 18A** presents the experimental scheme to analyze the influence of apoptotic cells on CAR T-cell therapy. SCID mice were injected on day 1 with Raji cancer cells, followed on day 6 by administration of CAR T-CD19 cells (CAR T-cell therapy) and Apoptotic cells. **Figure 18B** shows that CAR T-cell therapy was not negatively influenced by co-administration of ApoCells. Survival Curve: SCID mice were injected with CD19+ Raji cells with or without addition of early apoptotic cells.

[0055] **Figures 19A, 19B, and 19C** show increased release of pro-inflammatory cytokines from a

tumor, in a solid tumor *in vivo* model. **Figure 19A** shows slight increase of IL-6 released from a solid tumor present in the peritoneum of BALB/c and SCID mice, wherein the IL-6 release is significantly increased in the presence of HeLa CAR-CD-19 CAR T-cells. Similarly, **Figure 19B** shows a slight increase of IP-10 released from a solid tumor present in the peritoneum of BALB/c and SCID mice, wherein the IP-10 release is significantly increased in the presence of HeLa CAR-CD-19 CAR T-cells, and **Figure 19C** shows that surprisingly even TNF- α release is increased by in the presence of HeLa CAR-CD-19 CAR T-cells.

DETAILED DESCRIPTION

[0056] In the following detailed description, numerous specific details are set forth in order to provide a thorough understanding of the methods disclosed herein. However, it will be understood by those skilled in the art that these methods may be practiced without these specific details. In other instances, well-known methods, procedures, and components have not been described in detail so as not to obscure the methods disclosed herein.

[0057] In one embodiment, disclosed herein is a method of maintaining or increasing the proliferation rate of chimeric antigen receptor-expressing T-cells (CAR T-cell) during CAR T-cell cancer therapy, the method comprising the step of administering a composition comprising apoptotic cells or an apoptotic cell supernatant to said subject, and wherein said proliferation rate is maintained or increased in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.

[0058] In a related embodiment, the method does not reduce or inhibit the efficacy of said CAR T-cell cancer therapy. In another related embodiment the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject not administered said apoptotic cells or said apoptotic cell supernatant.

[0059] In one embodiment, CRS occurs spontaneously. In another embodiment, CRS occurs in response to LPS. In another embodiment, CRS occurs in response to IFN- γ .

[0060] In one embodiment, disclosed herein is a method of increasing the efficacy of chimeric antigen receptor T-cell (CAR T-cell) cancer therapy, the method comprising the step of administering CAR T-cells and an additional agent selected from the group comprising apoptotic cells, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said efficacy said CAR T-cells is increased in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said additional agent. In a related embodiment, the level of production of at least one pro-inflammatory cytokine is reduced

compared with the level of said pro-inflammatory cytokine in a subject received CAR T-cell cancer therapy and not administered a composition comprising said agent. In another related embodiment, the pro-inflammatory cytokine comprises IL-6.

5 [0061] In a related embodiment, when apoptotic cells or an apoptotic cell supernatant is administered, said method increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant. In another embodiment, when apoptotic cells or an apoptotic cell supernatant is administered, said method maintains the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant. In another embodiment, when apoptotic cells or an apoptotic cell supernatant is administered, said method maintains or increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant. In another related embodiment, the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject
10 not administered said additional agent.
15

[0062] In a related embodiment, CAR T-cells and said additional agent or any combination thereof are comprised in a single composition. In another related embodiment, said CAR T-cell and said additional agent or any combination thereof are comprised in at least two compositions.

[0063] In one embodiment, disclosed herein is a method of treating, preventing, inhibiting, reducing
20 the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cell) and an additional agent, said additional agent comprising apoptotic cells, apoptotic supernatants or a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said method treats, prevents,
25 inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.

[0064] In a related embodiment, said method has increased efficacy treating, preventing, inhibiting, reducing the incidence of, ameliorating or alleviating said cancer or said tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.

30 In another related embodiment, the level of production of at least one pro-inflammatory cytokine is reduced compared with the level of said pro-inflammatory cytokine in a subject administered said CAR T-cells and not administered a composition comprising said agent. In another related embodiment, said pro-inflammatory cytokine comprises IL-6. In another related embodiment, said additional agent comprises apoptotic cells or an apoptotic cell supernatant, said method increases

the levels of IL-2 in the subject compared with a subject administered said CAR T-cells and not administered said apoptotic cells or said apoptotic cell supernatant. In another related embodiment, said CAR T-cells and said additional agent or any combination thereof are comprised in a single composition. In yet another related embodiment, said CAR T-cells and said additional agent or any combination thereof are comprised in at least two compositions.

[0065] In a related embodiment, the administration of said additional agent occurs prior to, concurrent with, or following the administration of said CAR T-cells. In another related embodiment, said apoptotic cells comprise apoptotic cells in an early-apoptotic state. In another related embodiment, said apoptotic cells are autologous to said subject or are pooled third-party donor cells.

[0066] In a related embodiment, said apoptotic cell supernatant is obtained by a method comprising the steps of (a) providing apoptotic cells, (b) culturing the cells of step (a), and (c) separating the supernatant from the cells. In another related embodiment, said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant and said method further comprises the steps of: (d) providing white blood cells, (e) optionally, washing the apoptotic cells and the white blood cells, (f) co-culturing the apoptotic cells and the white blood cells, wherein steps (d)-(f) are in place of step (b). In another related embodiment, the provided white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells. Thus, in some embodiments, apoptotic supernatants comprise a supernatant produced by culturing apoptotic cells with macrophages, wherein the macrophage ingests the apoptotic cells and the supernatant produced from this co-culturing is used. In some embodiments, apoptotic supernatants comprise a supernatant produced by culturing apoptotic cells, wherein the supernatant is produced from materials secreted by the apoptotic cells.

[0067] *Genetically modified immune cells*

[0068] Genetic modification of immune cells is well known as a strategy for immune-cell therapies against cancer. These immune-cell therapies are based on the manipulation and administration of autologous or allogeneic immune cells to a subject in need. Immune-cell based therapies include natural killer cells therapies, dendrite cell therapies, and T-cell immunotherapies including those utilizing naïve T-cells, effector T-cells also known as T-helper cells, cytotoxic T-cells, and regulatory T-cells (Tregs).

[0069] In one embodiment, disclosed herein are compositions comprising genetically modified immune cells. In another embodiment, the genetically modified immune cell is a T-cell. In another embodiment, a T-cell is a naïve T-cell. In another embodiment, a T-cell is a naïve CD4⁺ T-cell. In another embodiment, a T-cell is a naïve T-cell. In another embodiment, a T-cell is a naïve CD8⁺ T-

cell. In another embodiment, the genetically modified immune cell is a natural killer (NK) cell. In another embodiment, the genetically modified immune cell is a dendritic cell. In still another embodiment, the genetically modified T-cell is a cytotoxic T lymphocyte (CTL cell). In another embodiment, the genetically modified T-cell is a regulatory T-cell (Treg). In another embodiment, the genetically modified T-cell is a chimeric antigen receptor (CAR) T-cell. In another embodiment, the genetically modified T-cell is a genetically modified T-cell receptor (TCR) cell.

[0070] In one embodiment, disclosed herein are compositions comprising genetically modified immune cells and an additional agent selected from the group comprising apoptotic cells, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof. In another embodiment, disclosed herein are compositions comprising genetically modified immune cells, apoptotic cells, and an additional agent selected from the group comprising a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

In another embodiment, disclosed herein are compositions comprising genetically modified immune cells, an apoptotic cell supernatant, and an additional agent selected from the group comprising a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

[0071] In one embodiment, the immune cells are cytotoxic. In another embodiment, cytotoxic cells for genetic modification can be obtained from bone marrow of the subject (autologous) or a donor (allogeneic). In other cases, the cells are obtained from a stem cell. For example, cytotoxic cells can be derived from human pluripotent stem cells such as human embryonic stem cells or human induced pluripotent T-cells. In the case of induced pluripotent stem cells (IPSCs), such pluripotent T-cells can be obtained using a somatic cell from the subject to which genetically modified cytotoxic cells will be provided. In one embodiment, immune cells may be obtained from a subject or donor by harvesting cells by venipuncture, by apheresis methods, by white cell mobilization followed by apheresis or venipuncture, or by bone marrow aspiration.

[0072] In one embodiment, immune cells, for example T-cell, are generated and expanded by the presence of specific factors *in vivo*. In another embodiment, T-cell generation and maintenance is affected by cytokines *in vivo*. In another embodiment, cytokines that affect generation and maintenance to T-helper cells *in vivo* comprise IL-1, IL-2, IL-4, IL-6, IL-12, IL-21, IL-23, IL-25, IL-33, and TGF β . In another embodiment, Treg cells are generated from naïve T-cells by cytokine induction *in vivo*. In still another embodiment, TGF- β and/or IL-2 play a role in differentiating naïve T-cell to become Treg cells.

[0073] In another embodiment, the presence of a cytokine selected from the group comprising IL-1, IL-2, IL-4, IL-6, IL-12, IL-21, IL-23, IL-25, IL-33, and TGF β , maintains or increases the proliferation rate or both, of T-cells *in vivo*. In another embodiment, the presence of a cytokine IL-2 and/or TGF β , maintains or increases the proliferation rate or both, of T-cells *in vivo*. In another embodiment, the presence of a cytokine selected from the group comprising IL-1, IL-2, IL-4, IL-6, IL-12, IL-21, IL-23, IL-25, IL-33, and TGF β , maintains or increases the proliferation rate or both, of CAR T-cells *in vivo*. In another embodiment, the presence of a cytokine IL-2 and/or TGF β , maintains or increases the proliferation rate or both, of CAR T-cells *in vivo*. In another embodiment, the presence of a cytokine selected from the group comprising IL-1, IL-2, IL-4, IL-6, IL-12, IL-21, IL-23, IL-25, IL-33, and TGF β , maintains or increases the proliferation rate or both, of TCR T-cells *in vivo*. In another embodiment, the presence of a cytokine IL-2 and/or TGF β , maintains or increases the proliferation rate or both, of TCR T-cells *in vivo*. In another embodiment, the presence of a cytokine selected from the group comprising IL-1, IL-2, IL-4, IL-6, IL-12, IL-21, IL-23, IL-25, IL-33, and TGF β , maintains or increases the proliferation rate or both, of T-reg cells *in vivo*. In another embodiment, the presence of a cytokine IL-2 and/or TGF β , maintains or increases the proliferation rate or both, of T-reg cells *in vivo*.

[0074] In one embodiment T-cells having an altered expression or form of STAT5B encoded protein or BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate or both. In another embodiment, said altered expression increases expression of STAT5B polypeptide. In another embodiment, said altered expression increases expression of BACH2 polypeptide.

[0075] In another embodiment, T-cells having an altered expression of a STAT5B encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, T-cells having an altered form of a STAT5B encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, T-cells having an altered form of a BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*.

[0076] In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 1 year. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 2 years. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for

greater than 3 years. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 4 years. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 5 years. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 10 years. In another embodiment, T-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 20 years.

[0077] In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 1 year. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 2 years. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 3 years. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 4 years. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 5 years. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 10 years. In another embodiment, T-cells having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 20 years.

[0078] In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 1 year. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 2 years. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 3 years. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 4 years. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 5 years. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 10 years. In another embodiment, T-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo* for greater than 20 years.

[0079] In another embodiment, T-cells having an altered form of a BACH2 encoded protein

maintain or increase their proliferation rate *in vivo* for greater than 1 year. In another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 2 years. In another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 3 years.

5 In another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 4 years. In another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 5 years. In another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 10 years. In
10 another embodiment, T-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo* for greater than 20 years.

[0080] In another embodiment, CAR T-cells having an altered expression of a STAT5B encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, CAR T-cells having an altered expression of a BACH2 encoded protein are
15 maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, CAR T-cells having an altered form of a STAT5B encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, CAR T-cells having an altered form of a BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*.

20 [0081] In another embodiment, TCR T-cells having an altered expression of a STAT5B encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, TCR T-cells having an altered expression of a BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, TCR T-cells having an altered form of a STAT5B encoded protein are maintained for
25 an extended time period or have an increased proliferation rate *in vivo*. In another embodiment, TCR T-cells having an altered form of a BACH2 encoded protein are maintained for an extended time period or have an increased proliferation rate *in vivo*.

[0082] In another embodiment, Treg-cells having an altered expression of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo*. In another embodiment, Treg-cells
30 having an altered expression of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo*. In another embodiment, Treg-cells having an altered form of a STAT5B encoded protein maintain or increase their proliferation rate *in vivo*. In another embodiment, Treg-cells having an altered form of a BACH2 encoded protein maintain or increase their proliferation rate *in vivo*.

[0083] In one embodiment, methods for maintaining or increasing the proliferation rate of a genetically modified immune cell are disclosed herein, wherein the method comprises the step of administering apoptotic cells or an apoptotic supernatant. In another embodiment, methods for increasing the efficacy of a genetically modified immune cell are disclosed herein, wherein the method comprises the step of administering an additional agent comprising apoptotic cells, an apoptotic supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof. In another embodiment, methods for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor disclosed herein administer a genetically modified immune cell and an additional agent, wherein said additional agent comprises apoptotic cells, an apoptotic supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

[0084] *Chimeric Antigen Receptor-Expressing T-Cells (CAR T-Cells)*

[0085] In one embodiment, chimeric antigen receptors (CARs) are a type of antigen-targeted receptor composed of intracellular T-cell signaling domains fused to extracellular tumor-binding moieties, most commonly single-chain variable fragments (scFvs) from monoclonal antibodies. CARs directly recognize cell surface antigens, independent of MHC-mediated presentation, permitting the use of a single receptor construct specific for any given antigen in all patients. Initial CARs fused antigen-recognition domains to the CD3 ζ activation chain of the T-cell receptor (TCR) complex. While these first generation CARs induced T-cell effector function in vitro, they were largely limited by poor antitumor efficacy in vivo. Subsequent CAR iterations have included secondary costimulatory signals in tandem with CD3 ζ , including intracellular domains from CD28 or a variety of TNF receptor family molecules such as 4-1BB (CD137) and OX40 (CD134). Further, third generation receptors include two costimulatory signals in addition to CD3 ζ , most commonly from CD28 and 4-1BB. Second and third generation CARs dramatically improved antitumor efficacy, in some cases inducing complete remissions in patients with advanced cancer.

[0086] In one embodiment, a CAR T-cell is an immunoresponsive cell comprising an antigen receptor, which is activated when its receptor binds to its antigen.

[0087] In one embodiment, the CAR T-cells used in the compositions and methods as disclosed herein are first generation CAR T-cells. In another embodiment, the CAR T-cells used in the compositions and methods as disclosed herein are second generation CAR T-cells. In another embodiment, the CAR T-cells used in the compositions and methods as disclosed herein are third generation CAR T-cells. In another embodiment, the CAR T-cells used in the compositions and

methods as disclosed herein are fourth generation CAR T-cells. In one embodiment, each generation of CAR T-cells is more potent than the CAR T-cells of earlier generations.

[0088] In one embodiment, first-generation CARs have one signaling domain, typically the cytoplasmic signaling domain of the CD3 TCR ζ chain.

5 [0089] In another embodiment, the CAR T-cells as disclosed herein are second generation CAR T-cells. In another embodiment, CAR T-cells as disclosed herein comprise a tripartite chimeric receptor (TPCR). In one embodiment, CAR T-cells as disclosed herein, comprise one or more signaling moieties that activate naïve T-cells in a co-stimulation independent manner. In another embodiment, the CAR T-cells further encode one or more members of the tumor necrosis factor
10 receptor family, which in one embodiment, is CD27, 4-1BB (CD137), or OX40 (CD134), or a combination thereof.

[0090] Third-generation CAR T-cells attempt to harness the signaling potential of 2 costimulatory domains: in one embodiment, the CD28 domain followed by either the 4-1BB or OX-40 signaling domains. In another embodiment, the CAR T-cells used in the compositions and methods as
15 disclosed herein further encode a co-stimulatory signaling domain, which in one embodiment is CD28. In another embodiment, the signaling domain is the CD3 ζ -chain, CD97, GDI Ia-CD18, CD2, ICOS, CD27, CD154, CDS, OX40, 4-1BB, CD28 signaling domain, or combinations thereof.

[0091] In one embodiment, telomere length and replicative capacity correlate with the engraftment efficiency and antitumor efficacy of adoptively transferred T-cell lines. In one embodiment, CD28
20 stimulation maintains telomere length in T-cells.

[0092] In one embodiment, CAR-modified T-cell potency may be further enhanced through the introduction of additional genes, including those encoding proliferative cytokines (ie, IL-12) or costimulatory ligands (ie, 4-1BBL), thus producing “armored” fourth-generation CAR-modified T-cells. In one embodiment, “armored CAR T-cells,” are CAR T-cells which are protected from the
25 inhibitory tumor microenvironment. In another embodiment, the “armored” CAR technology incorporates the local secretion of soluble signaling proteins to amplify the immune response within the tumor microenvironment with the goal of minimizing systemic side effects. In one embodiment, the signaling protein signal is IL-12, which can stimulate T-cell activation and recruitment. In one embodiment, “armored” CAR technology is especially useful in solid tumor indications, in which
30 microenvironment and potent immunosuppressive mechanisms have the potential to make the establishment of a robust anti-tumor response more challenging.

[0093] In one embodiment, CAR T-cells are genetically modified to encode molecules involved in the prevention of apoptosis, the remodeling of the tumor microenvironment, induction of homeostatic proliferation, and chemokine receptors that promote directed T-cell homing.

[0094] In another embodiment, CAR T-cell therapy used in the compositions and methods as disclosed herein is enhanced using the expression of cytokine transgenes, combination therapy with small molecule inhibitors, or monoclonal antibodies. In another embodiment, other strategies aimed at improving CAR T-cell therapy including using dual CARs and chemokine receptors to more specifically target tumor cells are to be considered part of the CAR T-cells and CAR T-cell therapy as disclosed herein.

[0095] In one embodiment, the CAR T-cells of the compositions and methods as disclosed herein comprise a second binding domain that can lead to either an inhibitory or amplifying signal, in order to increase specificity of CAR T-cells for cancer cells versus normal cells. For example, a CAR T-cell can be engineered such that it would be triggered in the presence of one target protein, but if a second protein is present it would be inhibited. Alternatively, it could also be engineered such that two target proteins would be required for maximal activation. These approaches may increase the specificity of the CAR for tumor relative to normal tissue.

[0096] In one embodiment, the CAR T-cells used in the compositions and methods as disclosed herein encode antibody-based external receptor structures and cytosolic domains that encode signal transduction modules composed of the immunoreceptor tyrosine-based activation motif.

[0097] In one embodiment, the CAR T-cell further encodes a single-chain variable fragment (scFv) that binds a polypeptide that has immunosuppressive activity. In another embodiment, the polypeptide that has immunosuppressive activity is CD47, PD-1, CTLA-4, or a combination thereof.

[0098] In one embodiment, the CAR T-cell further encodes a single-chain variable fragment (scFv) that binds a polypeptide that has immunostimulatory activity. In another embodiment, the polypeptide that has immunostimulatory activity is CD28, OX-40, 4-1 BB or a combination thereof. In another embodiment, the CAR T-cell further encodes a CD40 ligand (CD40L), which, in one embodiment, enhances the immunostimulatory activity of the antigen.

[0099] In one embodiment, a method as disclosed herein comprises obtaining immune cells from a subject, and genetically modifying the immune cells to express a chimeric antigen receptor. In another embodiment, a method as disclosed herein comprises obtaining immune cells from a subject, genetically modifying the immune cells to express a chimeric antigen receptor and combining with apoptotic cell population resulting in reduced cytokine production in a subject but substantially unaffected cytotoxicity relative to immune cells expressing a CAR not administered with an apoptotic cell population (**Figures 2A-2B and 3**). In another embodiment, a method as disclosed herein comprises obtaining immune cells from a subject, genetically modifying the immune cells to express a chimeric antigen receptor and combining with an apoptotic cell

supernatant or a composition comprising the supernatant, resulting in reduced cytokine production in a subject but substantially unaffected cytotoxicity relative to immune cells expressing a CAR not administered with an apoptotic cell supernatant. In another embodiment, administration of an apoptotic cell population or a supernatant from apoptotic cells does not reduce the efficacy of the immune cells expressing the chimeric antigen receptor.

[0100] Accordingly, one embodiment as disclosed herein relates to cytotoxic immune cells (e.g., NK cells or T-cells) comprising chimeric antigen receptors (CARs) whereby the cells retain their cytotoxic function. In another embodiment, the chimeric antigen receptor is exogenous to the T-cell. In another embodiment, the CAR is recombinantly expressed. In another embodiment, the CAR is expressed from a vector.

[0101] In one embodiment, the T-cell utilized to generate CAR T-cells is a naïve CD4⁺ T-cell. In another embodiment, the T-cell utilized to generate CAR T-cells is a naïve CD8⁺ T-cell. In another embodiment, the T-cell utilized to generate CAR T-cells is an effector T-cell. In another embodiment, the T-cell utilized to generate CAR T-cells is a regulatory T-cell (Treg). In another embodiment, the T-cell utilized to generate CAR T-cells is a cytotoxic T-cell.

[0102] CAR T-cells have been described extensively in the literature, see for example Themelli et al. (2015) New Cell Sources for T Cell Engineering and Adoptive Immunotherapy. Cell Stem Cell 16: 357-366; Sharpe and Mount (2015) Genetically modified T cells in cancer therapy: opportunities and challenges. Diseases Models & Mechanisms 8:337-350; Han et al. (2013) Journal of Hematology & Oncology 6:47-53; Wilkie et al. (2010) J Bio Chem 285(33):25538-25544; and van der Stegen et al. (2013) J. Immunol 191: 4589-4598. CAR T-cells are available to order from a commercial source such as Creative Biolabs (NY USA), which provides custom construction and production services for Chimeric Antigen Receptors (CAR) and also provides premade CAR constructs stock, which can induce protective immunity encoded by recombinant adenovirus vaccine.

[0103] *T-cell receptors (TCRs) cells*

[0104] In one embodiment, compositions and methods as disclosed herein utilize a designer T-cell receptor (TCR) cells in addition to or in place of CAR T-cells. The TCR is a multi-subunit transmembrane complex that mediates the antigen-specific activation of T-cells. The TCR is composed of two different polypeptide chains. The TCR confers antigenic specificity on the T cell, by recognizing an antigen epitope on the target cell, for example a tumor or cancer cell. Following contact with the antigen present on the tumor or cancer cell, T-cells proliferate and acquire the phenotype and function to allow them eliminate the cancer or tumor cells.

[0105] In one embodiment, TCR T-cell therapy comprises introducing a T-cell receptor (TCR) that

is specific to an epitope of a protein of interest into a T-cell. In another embodiment, the protein of interest is a tumor-associated antigen. In another embodiment, the genetically engineered TCR recognizes a tumor antigen epitope presented by the major histocompatibility complex (MHC) on the tumor cell along with T-cell activating domains. In another embodiment, the T-cell receptors
 5 recognize antigens irrespectively of their intracellular or membrane localization. In another embodiment, TCRs recognize tumor cells that intracellularly express a tumor associated antigen. In one embodiment TCRs recognize internal antigens. In another embodiment, TCRs recognize angiogenic factors. In another embodiment, an angiogenic factor is a molecule involved in the formation of new blood vessels. Various genetically modified T-cell receptors and methods of their
 10 production are known in the art.

[0106] In one embodiment, TCR T-cell therapy is used to treat, prevent, inhibit, ameliorate, reduce the incidence of, or alleviate a cancer or a tumor. In one embodiment, TCR T-cell therapy is used to treat, prevent, inhibit, ameliorate, reduce the incidence of, or alleviate advanced metastatic disease, including those with hematological (lymphoma and leukemia) and solid tumors (refractory
 15 melanoma, sarcoma). In one embodiment, the TCR T-cell therapy used in the compositions and methods as disclosed herein treat a malignancy listed in Table 1 of Sadelain et al., (Cancer Discov. 2013 Apr; 3(4): 388–398).

[0107] In another embodiment, the T-cell receptor is genetically modified to bind NY-ESO-1 epitopes, and the TCR-engineered T-cell is anti-NY-ESO-1. In another embodiment, the T-cell
 20 receptor is genetically modified to bind HPV-16 E6 epitopes, and the TCR-engineered T-cell is anti-HPV-16 E6. In another embodiment, the T-cell receptor is genetically modified to bind HPV-16 E7 epitopes, and the TCR-engineered T-cell is anti-HPV-16 E7. In another embodiment, the T-cell receptor is genetically modified to bind MAGE A3/A6 epitopes, and the TCR-engineered T-cell is anti-MAGE A3/A6. In another embodiment, the T-cell receptor is genetically modified to bind
 25 MAGE A3 epitopes, and the TCR-engineered T-cell is anti-MAGE A3. In another embodiment, the T-cell receptor is genetically modified to bind SSX2 epitopes, and the TCR-engineered T-cell is anti-SSX2. In another embodiment, the T-cell receptor is genetically modified to bind a target antigen disclosed herein. Using the tools well known in the art, a skilled would appreciate that the T-cell receptor may be genetically modified to bind a target antigen present on a cancer or tumor
 30 cell, wherein the TCR-engineer T-cell comprises an anti-tumor or anti-cancer cell.

[0108] In one embodiment, a method as disclosed herein comprises obtaining immune cells from a subject, and genetically modifying the immune cells to express a recombinant T-cell receptor (TCR). In another embodiment, a method as disclosed herein comprises obtaining immune cells from a subject, genetically modifying the immune cells to express a recombinant TCR and

combining with an additional agent, wherein said additional agent comprises an apoptotic cell population, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

5 [0109] In one embodiment, the T-cell utilized to generate TCR T-cells is a naïve CD4⁺ T-cell. In another embodiment, the T-cell utilized to generate TCR T-cells is a naïve CD8⁺ T-cell. In another embodiment, the T-cell utilized to generate TCR T-cells is an effector T-cell. In another embodiment, the T-cell utilized to generate TCR T-cells is a regulatory T-cell (Treg). In another embodiment, the T-cell utilized to generate TCR T-cells is a cytotoxic T-cell.

10 [0110] TCR T-cells have been described extensively in the literature, see for example Sharpe and Mount (2015) *ibid.*; Essand M, Loskog ASI (2013) Genetically engineered T cells for the treatment of cancer (Review). J Intern Med 273: 166–181; and Kershaw et al. (2014) Clinical application of genetically modified T cells in cancer therapy. Clinical & Translational Immunology 3:1-7.

[0111] *Targeting antigens*

15 [0112] In one embodiment, the CAR binds to an epitope of an antigen via an antibody or an antibody fragment that is directed to the antigen. In another embodiment, the antibody is a monoclonal antibody. In another embodiment, the antibody is a polyclonal antibody. In another embodiment, the antibody fragment is a single-chain variable fragment (scFv).

[0113] In one embodiment, the TCR binds to an epitope of an antigen via a genetically modified T-
20 cell receptor.

[0114] In another embodiment, the CAR T-cells of the compositions as disclosed herein bind to a tumor associated antigen (TAA). In another embodiment, said tumor associated antigen is: Mucin 1, cell surface associated (MUC1) or polymorphic epithelial mucin (PEM), Arginine-rich, mutated in early stage tumors (Armet), Heat Shock Protein 60 (HSP60), calnexin (CANX),
25 methylenetetrahydrofolate dehydrogenase (NADP⁺ dependent) 2, methenyltetrahydrofolate cyclohydrolase (MTHFD2), fibroblast activation protein (FAP), matrix metalloproteinase (MMP6), B Melanoma Antigen-1 (BAGE-1), aberrant transcript of N-acetyl glucosaminyl transferase V (GnTV), Q5H943, Carcinoembryonic antigen (CEA), Pmel, Kallikrein-4, Mammaglobin-1, MART-1, GPR143-OA1, prostate specific antigen (PSA), TRP1, Tyrosinase, FGP-5, NEU proto-oncogene, Aft, MMP-2, prostate specific membrane antigen (PSMA), Telomerase-associated
30 protein-2, Prostatic acid phosphatase (PAP), Uroplakin II or Proteinase 3.

[0115] In another embodiment, the CAR binds to CD19 or CD20 to target B cells in the case where one would like to destroy B cells as in leukemia. CD19 is a B cell lineage specific surface receptor whose broad expression, from pro-B cells to early plasma cells, makes it an attractive target for the

immunotherapy of B cell malignancies. In another embodiment, the CAR binds to ROR1, CD22, or GD2. In another embodiment, the CAR binds to NY-ESO-1. In another embodiment, the CAR binds to MAGE family proteins. In another embodiment, the CAR binds to mesothelin. In another embodiment, the CAR binds to c-erbB2. In another embodiment, the CAR binds to mutational antigens that are tumor specific, such as BRAFV600E mutations and BCR-ABL translocations. In another embodiment, the CAR binds to viral antigens which are tumor-specific, such as EBV in HD, HPV in cervical cancer, and polyomavirus in Merkel cancer. In another embodiment, the CAR T-cell binds to Her2/neu. In another embodiment, the CAR T-cell binds to EGFRvIII.

[0116] In one embodiment, the chimeric antigen receptor (CAR) T-cell binds the CD19 antigen. In another embodiment, the CAR binds the CD22 antigen. In another embodiment, the CAR binds to alpha folate receptor. In another embodiment, the CAR binds to CAIX. In another embodiment, the CAR binds to CD20. In another embodiment, the CAR binds to CD23. In another embodiment, the CAR binds to CD24. In another embodiment, the CAR binds to CD30. In another embodiment, the CAR binds to CD33. In another embodiment, the CAR binds to CD38. In another embodiment, the CAR binds to CD44v6. In another embodiment, the CAR binds to CD44v7/8. In another embodiment, the CAR binds to CD123. In another embodiment, the CAR binds to CD171. In another embodiment, the CAR binds to carcinoembryonic antigen (CEA). In another embodiment, the CAR binds to EGFRvIII. In another embodiment, the CAR binds to EGP-2. In another embodiment, the CAR binds to EGP-40. In another embodiment, the CAR binds to EphA2. In another embodiment, the CAR binds to Erb-B2. In another embodiment, the CAR binds to Erb-B 2,3,4. In another embodiment, the CAR binds to Erb-B3/4. In another embodiment, the CAR binds to FBP. In another embodiment, the CAR binds to fetal acetylcholine receptor. In another embodiment, the CAR binds to G_{D2} . In another embodiment, the CAR binds to G_{D3} . In another embodiment, the CAR binds to HER2. In another embodiment, the CAR binds to HMW-MAA. In another embodiment, the CAR binds to IL-11Ralpha. In another embodiment, the CAR binds to IL-13Ralpha1. In another embodiment, the CAR binds to KDR. In another embodiment, the CAR binds to kappa-light chain. In another embodiment, the CAR binds to Lewis Y. In another embodiment, the CAR binds to L1-cell adhesion molecule. In another embodiment, the CAR binds to MAGE-A1. In another embodiment, the CAR binds to mesothelin. In another embodiment, the CAR binds to CMV infected cells. In another embodiment, the CAR binds to MUC1. In another embodiment, the CAR binds to MUC16. In another embodiment, the CAR binds to NKG2D ligands. In another embodiment, the CAR binds to NY-ESO-1 (amino acids 157-165). In another embodiment, the CAR binds to oncofetal antigen (h5T4). In another embodiment, the CAR binds to PSCA. In another embodiment, the CAR binds to PSMA. In another embodiment, the CAR binds to

ROR1. In another embodiment, the CAR binds to TAG-72. In another embodiment, the CAR binds to VEGF-R2 or other VEGF receptors. In another embodiment, the CAR binds to B7-H6. In another embodiment, the CAR binds to CA9. In another embodiment, the CAR binds to $\alpha_v\beta_6$ integrin. In another embodiment, the CAR binds to 8H9. In another embodiment, the CAR binds to NCAM. In another embodiment, the CAR binds to fetal acetylcholine receptor.

[0117] In another embodiment, the chimeric antigen receptor (CAR) T-cell targets the CD19 antigen, and has a therapeutic effect on subjects with B-cell malignancies, ALL, Follicular lymphoma, CLL, and Lymphoma. In another embodiment, the CAR T-cell targets the CD22 antigen, and has a therapeutic effect on subjects with B-cell malignancies. In another embodiment, the CAR T-cell targets alpha folate receptor or folate receptor alpha, and has a therapeutic effect on subjects with ovarian cancer or epithelial cancer. In another embodiment, the CAR T-cell targets CAIX or G250/CAIX, and has a therapeutic effect on subjects with renal cell carcinoma. In another embodiment, the CAR T-cell targets CD20, and has a therapeutic effect on subjects with Lymphomas, B-cell malignancies, B-cell lymphomas, Mantle cell lymphoma and, indolent B-cell lymphomas. In another embodiment, the CAR T-cell targets CD23, and has a therapeutic effect on subjects with CLL. In another embodiment, the CAR T-cell targets CD24, and has a therapeutic effect on subjects with pancreatic adenocarcinoma. In another embodiment, the CAR T-cell targets CD30, and has a therapeutic effect on subjects with Lymphomas or Hodgkin lymphoma. In another embodiment, the CAR T-cell targets CD33, and has a therapeutic effect on subjects with AML. In another embodiment, the CAR T-cell targets CD38, and has a therapeutic effect on subjects with Non-Hodgkin lymphoma. In another embodiment, the CAR T-cell targets CD44v6, and has a therapeutic effect on subjects with several malignancies. In another embodiment, the CAR T-cell targets CD44v7/8, and has a therapeutic effect on subjects with cervical carcinoma. In another embodiment, the CAR T-cell targets CD123, and has a therapeutic effect on subjects with myeloid malignancies. In another embodiment, the CAR T-cell targets CEA, and has a therapeutic effect on subjects with colorectal cancer. In another embodiment, the CAR T-cell targets EGFRvIII, and has a therapeutic effect on subjects with Glioblastoma. In another embodiment, the CAR T-cell targets EGP-2, and has a therapeutic effect on subjects with multiple malignancies. In another embodiment, the CAR T-cell targets EGP-40, and has a therapeutic effect on subjects with colorectal cancer. In another embodiment, the CAR T-cell targets EphA2, and has a therapeutic effect on subjects with Glioblastoma. In another embodiment, the CAR T-cell targets Erb-B2 or ErbB3/4, and has a therapeutic effect on subjects with Breast cancer and others, prostate cancer, colon cancer, various tumors. In another embodiment, the CAR T-cell targets Erb-B 2,3,4, and has a therapeutic effect on subjects with Breast cancer and others. In another embodiment, the CAR T-cell targets FBP, and

has a therapeutic effect on subjects with Ovarian cancer. In another embodiment, the CAR T-cell targets fetal acetylcholine receptor, and has a therapeutic effect on subjects with Rhabdomyosarcoma. In another embodiment, the CAR T-cell targets G_{D2}, and has a therapeutic effect on subjects with Neuroblastoma, melanoma, or Ewing's sarcoma. In another embodiment, the CAR T-cell targets G_{D3}, and has a therapeutic effect on subjects with Melanoma. In another embodiment, the CAR T-cell targets HER2, and has a therapeutic effect on subjects with medulloblastoma, pancreatic adenocarcinoma, Glioblastoma, Osteosarcoma, or Ovarian cancer. In another embodiment, the CAR T-cell targets HMW-MAA, and has a therapeutic effect on subjects with Melanoma. In another embodiment, the CAR T-cell targets IL-11Ralpha, and has a therapeutic effect on subjects with Osteosarcoma. In another embodiment, the CAR T-cell targets IL-13Ralpha1, and has a therapeutic effect on subjects with Glioma, Glioblastoma, or medulloblastoma. In another embodiment, the CAR T-cell targets IL-13 receptor alpha2, and has a therapeutic effect on subjects with several malignancies. In another embodiment, the CAR T-cell targets KDR, and has a therapeutic effect on subjects with tumors by targeting tumor neovasculature. In another embodiment, the CAR T-cell targets kappa-light chain, and has a therapeutic effect on subjects with B-cell malignancies (B-NHL, CLL). In another embodiment, the CAR T-cell targets Lewis Y, and has a therapeutic effect on subjects with various carcinomas or epithelial-derived tumors. In another embodiment, the CAR T-cell targets L1-cell adhesion molecule, and has a therapeutic effect on subjects with Neuroblastoma. In another embodiment, the CAR T-cell targets MAGE-A1 or HLA-A1 MAGE A1, and has a therapeutic effect on subjects with Melanoma. In another embodiment, the CAR T-cell targets mesothelin, and has a therapeutic effect on subjects with Mesothelioma. In another embodiment, the CAR T-cell targets CMV infected cells, and has a therapeutic effect on subjects with CMV. In another embodiment, the CAR T-cell targets MUC1, and has a therapeutic effect on subjects with breast or ovarian cancer. In another embodiment, the CAR T-cell targets MUC16, and has a therapeutic effect on subjects with ovarian cancer. In another embodiment, the CAR T-cell targets NKG2D ligands, and has a therapeutic effect on subjects with myeloma, ovarian, and other tumors. In another embodiment, the CAR T-cell targets NY-ESO-1 (157-165) or HLA-A2 NY-ESO-1, and has a therapeutic effect on subjects with multiple myeloma. In another embodiment, the CAR T-cell targets oncofetal antigen (h5T4), and has a therapeutic effect on subjects with various tumors. In another embodiment, the CAR T-cell targets PSCA, and has a therapeutic effect on subjects with prostate carcinoma. In another embodiment, the CAR T-cell targets PSMA, and has a therapeutic effect on subjects with prostate cancer/tumor vasculature. In another embodiment, the CAR T-cell targets ROR1, and has a therapeutic effect on subjects with B-CLL and mantle cell lymphoma. In another embodiment, the

CAR T-cell targets TAG-72, and has a therapeutic effect on subjects with adenocarcinomas or gastrointestinal cancers. In another embodiment, the CAR T-cell targets VEGF-R2 or other VEGF receptors, and has a therapeutic effect on subjects with tumors by targeting tumor neovasculature. In another embodiment, the CAR T-cell targets CA9, and has a therapeutic effect on subjects with renal cell carcinoma. In another embodiment, the CAR T-cell targets CD171, and has a therapeutic effect on subjects with renal neuroblastoma. In another embodiment, the CAR T-cell targets NCAM, and has a therapeutic effect on subjects with neuroblastoma. In another embodiment, the CAR T-cell targets fetal acetylcholine receptor, and has a therapeutic effect on subjects with rhabdomyosarcoma. In another embodiment, the CAR binds to one of the target antigens listed in Table 1 of Sadelain et al. (Cancer Discov. 2013 Apr; 3(4): 388–398), which is incorporated by reference herein in its entirety. In another embodiment, CAR T-cells bind to carbohydrate or glycolipid structures.

[0118] In one embodiment the CAR binds to an angiogenic factor, thereby targeting tumor vasculature. In one embodiment, the angiogenic factor is VEGFR2. in another embodiment, the angiogenic factor is endoglin. In another embodiment, an angiogenic factor of the present invention is Angiogenin; Angiopoietin-1; Del-1; Fibroblast growth factors: acidic (aFGF) and basic (bFGF); Follistatin; Granulocyte colony-stimulating factor (G-CSF); Hepatocyte growth factor (HGF) /scatter factor (SF); Interleukin-8 (IL-8); Leptin; Midkine; Placental growth factor; Platelet-derived endothelial cell growth factor (PD-ECGF); Platelet-derived growth factor-BB (PDGF-BB); Pleiotrophin (PTN); Progranulin; Proliferin; Transforming growth factor-alpha (TGF-alpha); Transforming growth factor-beta (TGF-beta); Tumor necrosis factor-alpha (TNF-alpha); Vascular endothelial growth factor (VEGF)/vascular permeability factor (VPF). In another embodiment, an angiogenic factor is an angiogenic protein. In one embodiment, a growth factor is an angiogenic protein. In one embodiment, an angiogenic protein for use in the compositions and methods of the present invention is Fibroblast growth factors (FGF); VEGF; VEGFR and Neuropilin 1 (NRP-1); Angiopoietin 1 (Ang1) and Tie2; Platelet-derived growth factor (PDGF; BB-homodimer) and PDGFR; Transforming growth factor-beta (TGF- β), endoglin and TGF- β receptors; monocyte chemotactic protein-1 (MCP-1); Integrins α V β 3, α V β 5 and α 5 β 1; VE-cadherin and CD31; ephrin; plasminogen activators; plasminogen activator inhibitor-1; Nitric oxide synthase (NOS) and COX-2; AC133; or Id1/Id3. In one embodiment, an angiogenic protein for use in the compositions and methods of the present invention is an angiopoietin, which in one embodiment, is Angiopoietin 1, Angiopoietin 3, Angiopoietin 4 or Angiopoietin 6. In one embodiment, endoglin is also known as CD105; EDG; HHT1; ORW; or ORW1. In one embodiment, endoglin is a TGFbeta co-receptor.

[0119] In another embodiment, the CAR T-cells bind to an antigen associated with an infectious

agent. In one embodiment, the infectious agent is *Mycobacterium tuberculosis*. In one embodiment, said *Mycobacterium tuberculosis* associated antigen is: Antigen 85B, Lipoprotein IpqH, ATP dependent helicase putative, uncharacterized protein Rv0476/MTO4941 precursor or uncharacterized protein Rv1334/MT1376 precursor.

5 [0120] In another embodiment, the CAR binds to an antibody. In one embodiment, the CAR T-cell is an “antibody-coupled T-cell receptor” (ACTR). According to this embodiment, the CAR T-cell is a universal CAR T-cell. In another embodiment, the CAR T-cell having an antibody receptor is administered before, after, or at the same time as the antibody is administered and then binds to the antibody, bringing the T-cell in close proximity to the tumor or cancer. In another embodiment, the
10 antibody is directed against a tumor cell antigen. In another embodiment, the antibody is directed against CD20. In another embodiment, the antibody is rituximab.

[0121] In another embodiment, the antibody is Trastuzumab (Herceptin; Genentech): humanized IgG1, which is directed against ERBB2. In another embodiment, the antibody is Bevacizumab (Avastin; Genentech/Roche): humanized IgG1, which is directed against VEGF. In another
15 embodiment, the antibody is Cetuximab (Erbix; Bristol-Myers Squibb): chimeric human–murine IgG1, which is directed against EGFR. In another embodiment, the antibody is Panitumumab (Vectibix; Amgen): human IgG2, which is directed against EGFR. In another embodiment, the antibody is Ipilimumab (Yervoy; Bristol-Myers Squibb): IgG1, which is directed against CTLA4.

[0122] In another embodiment, the antibody is Alemtuzumab (Campath; Genzyme): humanized
20 IgG1, which is directed against CD52. In another embodiment, the antibody is Ofatumumab (Arzerra; Genmab): human IgG1, which is directed against CD20. In another embodiment, the antibody is Gemtuzumab ozogamicin (Mylotarg; Wyeth): humanized IgG4, which is directed against CD33. In another embodiment, the antibody is Brentuximab vedotin (Adcetris; Seattle Genetics): chimeric IgG1, which is directed against CD30. In another embodiment, the antibody is
25 90Y-labelled ibritumomab tiuxetan (Zevalin; IDEC Pharmaceuticals): murine IgG1, which is directed against CD20. In another embodiment, the antibody is 131I-labelled tositumomab (Bexxar; GlaxoSmithKline): murine IgG2, which is directed against CD20.

[0123] In another embodiment, the antibody is Ramucirumab, which is directed against vascular endothelial growth factor receptor-2 (VEGFR-2). In another embodiment, the antibody is
30 ramucirumab (Cyramza Injection, Eli Lilly and Company), blinatumomab (BLINCYTO, Amgen Inc.), pembrolizumab (KEYTRUDA, Merck Sharp & Dohme Corp.), obinutuzumab (GAZYVA, Genentech, Inc.; previously known as GA101), pertuzumab injection (PERJETA, Genentech, Inc.), or denosumab (Xgeva, Amgen Inc.). In another embodiment, the antibody is Basiliximab (Simulect; Novartis). In another embodiment, the antibody is Daclizumab (Zenapax; Roche).

[0124] In another embodiment, the antibody to which the CAR T-cell is coupled is directed to a tumor or cancer antigen or a portion thereof, that is described herein and/or that is known in the art. In another embodiment, the antibody to which the CAR T-cell is coupled is directed to a tumor-associated antigen. In another embodiment, the antibody to which the CAR T-cell is coupled is directed to a tumor-associated antigen or a portion thereof that is an angiogenic factor.

[0125] A skilled artisan would appreciate that a genetically modified TCR may be engineered to recognize any of the antigens described above to which a CAR binds. In one embodiment, a TCR T-cell binds to an antigen described above as a CAR T-cell binding target. In another embodiment, a TCR recognizes any antigen disclosed herein. In another embodiment, the antigen to which the TCR recognizes is a tumor or cancer antigen or a portion thereof, that is described herein and/or that is known in the art. In another embodiment, the TCR recognizes a tumor-associated antigen. In another embodiment, the TCR recognizes a tumor-associated antigen or a portion thereof that is an angiogenic factor.

[0126] *Dendritic Cells*

[0127] In one embodiment, dendritic cells (DCs) are antigen-producing and presenting cells of the mammalian immune system that process antigen material and present it on the cell surface to the T-cells of the immune system and are thereby capable of sensitizing T-cells to both new and recall antigens. In another embodiment, DCs are the most potent antigen-producing cells, acting as messengers between the innate and the adaptive immune systems. DC cells may be used, in one embodiment, to prime specific antitumor immunity through the generation of effector cells that attack and lyse tumors.

[0128] Dendritic cells are present in those tissues that are in contact with the external environment, such as the skin (where there is a specialized dendritic cell type called the Langerhans cell) and the inner lining of the nose, lungs, stomach and intestines. They can also be found in an immature state in the blood. Once activated, they migrate to the lymph nodes where they interact with T-cells and B cells to initiate and shape the adaptive immune response. At certain development stages, they grow branched projections, the dendrites that give the cell its name. Dendritic cells may be engineered to express particular tumor antigens.

[0129] The three signals that are required for T-cell activation are: (i) presentation of cognate antigen in self MHC molecules; (ii) costimulation by membrane-bound receptor-ligand pairs; and (iii) soluble factors to direct polarization of the ensuing immune response. Dendritic cells (DCs) are able to provide all of the three signals required for T-cell activation making them an excellent cancer vaccine platform.

[0130] Therefore, in one embodiment, disclosed herein are a composition comprising dendritic cells

and an additional agent, wherein said additional agent comprises apoptotic cells, apoptotic supernatants, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof.

[0131] In another embodiment, disclosed herein is a method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject comprising the step of administering dendritic cells and a composition comprising an additional agent, wherein said agent comprises apoptotic cells, apoptotic supernatants, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, to said subject.

10 [0132] *Cytokine Storm and Cytokine Release Syndrome*

[0133] In one embodiment, a method as disclosed herein includes providing immune cells, such as NK cells, dendritic cells, TCR T-cells, or T-cells comprising engineered chimeric antigen receptors (CAR T-cells), with at least an additional agent to decrease toxic cytokine release or "cytokine release syndrome" (CRS) or "severe cytokine release syndrome" (sCRS) or "cytokine storm" that may occur in the subject. In another embodiment the CRS, sCRS or cytokine storm occurs as a result of administration of the immune cells. In another embodiment, the CRS, sCRS or cytokine storm is the result of a stimulus, condition, or syndrome separate from the immune cells (see below). In another embodiment, a cytokine storm, cytokine cascade, or hypercytokinemia is a more severe form of cytokine release syndrome.

20 [0134] In one embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or a composition comprising said apoptotic cells. In another embodiment, the additional agent for decreasing harmful cytokine release comprises an apoptotic cell supernatant or a composition comprising said supernatant. In another embodiment, the additional agent for decreasing harmful cytokine release comprises a CTLA-4 blocking agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and a CTLA-4 blocking agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises an alpha-1 anti-trypsin or fragment thereof or analogue thereof. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and an alpha-1 anti-trypsin or fragment thereof or analogue thereof. In another embodiment, the additional agent for decreasing harmful cytokine release comprises a tellurium-based compound. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and a tellurium-based compound. In another embodiment, the additional agent for decreasing harmful cytokine release

comprises an immune modulating agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and an immune modulating agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises Treg cells. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and Treg cells.

[0135] A skilled artisan would appreciate that decreasing toxic cytokine release or toxic cytokine levels comprises decreasing or inhibiting production of toxic cytokine levels in a subject, or inhibiting or reducing the incidence of cytokine release syndrome or a cytokine storm in a subject.

In another embodiment toxic cytokine levels are reduced during CRS or a cytokine storm. In another embodiment, decreasing or inhibiting the production of toxic cytokine levels comprises treating CRS or a cytokine storm. In another embodiment, decreasing or inhibiting the production of toxic cytokine levels comprises preventing CRS or a cytokine storm. In another embodiment, decreasing or inhibiting the production of toxic cytokine levels comprises alleviating CRS or a cytokine storm. In another embodiment, decreasing or inhibiting the production of toxic cytokine levels comprises ameliorating CRS or a cytokine storm. In another embodiment, the toxic cytokines comprise pro-inflammatory cytokines. In another embodiment, pro-inflammatory cytokines comprise IL-6. In another embodiment, pro-inflammatory cytokines comprise IL-1 β . In another embodiment, pro-inflammatory cytokines comprise TNF- α . In another embodiment, pro-inflammatory cytokines comprise IL-6, IL-1 β , or TNF- α , or any combination thereof.

[0136] In one embodiment, cytokine release syndrome is characterized by elevated levels of several inflammatory cytokines and adverse physical reactions in a subject such as low blood pressure, high fever and shivering. In another embodiment, inflammatory cytokines comprise IL-6, IL-1 β , and TNF- α . In another embodiment, CRS is characterized by elevated levels of IL-6, IL-1 β , or TNF- α , or any combination thereof. In another embodiment, CRS is characterized by elevated levels of IL-8, or IL-13, or any combination thereof. In another embodiment, a cytokine storm is characterized by increases in TNF-alpha, IFN-gamma, IL-1beta, IL-2, IL-6, IL-8, IL-10, IL-13, GM-CSF, IL-5, fractalkine, or a combination thereof or a subset thereof. In yet another embodiment, IL-6 comprises a marker of CRS or cytokine storm. In another embodiment, patients with larger tumor burdens have higher incidence and severity of cytokine release syndrome.

[0137] In another embodiment, cytokines increased in CRS or a cytokine storm in humans and mice may comprise any combination of cytokines listed in Tables 1 and 2 below.

Table 1: Panel of Cytokines Increased in CRS or Cytokine Storm in Humans and/or Mice

Cytokine (Analyte)	Human model (clinical trials)	Mouse model (pre-clinical)			Cells secreting this cytokine	Notes / other
		CAR-T (H) origin	Mouse origin	Not specified		
Flt-3L	*				DC (?)	
Fractalkine	*				APC, Endothelial cells (?)	= CX3CL1, Neurotactin (Mouse)
M-CSF						= CSF1
GM-CSF	*			* (<i>in vitro</i>)	T cell, MØ	
IFN-α	*				T cell, MØ, Monocyte	
IFN-β	?			?	T cell, MØ, Monocyte	
IFN-γ	*	*		* (<i>in vitro</i>)	cytotoxic T cells, helper T cells, NK cells, MØ, Monocyte, DC	
IL- 1 α	*				Monocyte, MØ, Epithel	
IL- 1 β	*			*	Macrophages, DCs, fibroblasts, endothelial cells, hepatocytes	
IL- 1 Rα	*					
IL- 2	*	*		* (<i>in vitro</i>)	T cells	
IL- 2Rα	*				lymphocytes	
IL- 4	*	*		* (<i>in vitro</i>)	Th2 cells	
IL- 5	*	*		*	T cells	
IL- 6	*		*	*	monocytes/ macrophages, dendritic cells, T cells, fibroblasts, keratinocytes, endothelial cells, adipocytes, myocytes, mesangial cells, and osteoblasts	
IL- 7	*			*	<i>In vitro</i> by BM stromal cells	
IL- 8	*				Macrophages, monocytes	
IL - 9	*	*			T cells, T helper	
IL- 10	*	*	*	* (<i>in vitro</i>)	monocytes/macrophages, mast cells, B cells, regulatory T cells, and	

					helper T cells	
IL- 12	*			*	MØ, Monocyte, DC, activated lymphocytes, neutrophils	= p70 (p40+p35)
IL- 13	*	*			T cells	

[0138] In one embodiment, cytokines Flt-3L, Fractalkine, GM-CSF, IFN- γ , IL-1 β , IL-2, IL-2R α , IL-4, IL-5, IL-6, IL-7, IL-8, IL-9, IL-10, IL-12, and IL-13 of Table 1 are considered to be significant in CRS or cytokine storm. In another embodiment, IFN- α , IFN- β , IL-1, and IL-1R α of Table 1 appear to be important in CRS or cytokine storm. In another embodiment, M-CSF has unknown importance. In another embodiment, any cytokine listed in Table 1, or combination thereof, may be used as a marker of CRS or cytokine storm.

Table 2: Panel of Cytokines Increased in CRS or Cytokine Storm in Humans and/or Mice

Cytokine (Analyte)	Human model (clinical trials)	Mouse model (pre-clinical)			Cells secreting this cytokine	Notes / other
		CAR-T (H) origin	Mouse origin	Not specified		
IL- 15	*			*	Fibroblasts, monocytes (?)	22
IL- 17	*			*	T cells	
IL- 18					Macrophages	
IL- 21	*				T helper cells, NK cells	
IL- 22	*				activated DC and T cells	
IL- 23						
IL- 25						Protective?
IL- 27	*				APC	
IP-10	*				Monocytes (?)	
MCP-1	*				Endothel, fibroblast, epithel, monocytes	= CXCL10
MCP-3	*				PBMCs, MØ (?)	= CCL2

MIP-1α	*			* (<i>in vitro</i>)	T cells	= CXCL9
MIP-1β	*				T cells	= CCL3
PAF	?				platelets, endothelial cells, neutrophils, monocytes, and macrophages, mesangial cells	= CCL4
PGE2	*			*	Gastrointestinal mucosa and other	
RANTES	*				Monocytes	
TGF-β	*			*	M $\emptyset$, lymphocytes, endothel, platelets ...	= CCL5
TNF-α	*	*	*	* (<i>in vitro</i>)	Macrophages, NK cells, T cells	
TNF-αR1	*					
HGF						
MIG	*				T cell chemoattractant, induced by IFN- γ	

[0139] In one embodiment, IL-15, IL-17, IL-18, IL-21, IL-22, IP-10, MCP-1, MIP-1 α , MIP-1 β , and TNF- α of Table 2 are considered to be significant in CRS or cytokine storm. In another embodiment, IL-27, MCP-3, PGE2, RANTES, TGF- β , TNF- α R1, and MIG of Table 2 appear to be important in CRS or cytokine storm. In another embodiment, IL-23 and IL-25 have unknown importance. In another embodiment, any cytokine listed in Table 2, or combination thereof, may be used as a marker of CRS or cytokine storm. In another embodiment, mouse cytokines IL-10, IL-1 β , IL-2, IP-10, IL-4, IL-5, IL-6, IFN α , IL-9, IL-13, IFN- γ , IL-12p70, GM-CSF, TNF- α , MIP-1 α , MIP-1 β , IL-17A, IL-15/IL-15R and IL-7 appear to be important in CRS or cytokine storm.

[0140] A skilled artisan would appreciate that the term "cytokine" may encompass cytokines (e.g., interferon gamma (IFN- γ), granulocyte macrophage colony stimulating factor, tumor necrosis factor alpha), chemokines (e.g., MIP 1 alpha, MIP 1 beta, RANTES), and other soluble mediators of inflammation, such as reactive oxygen species and nitric oxide.

[0141] In one embodiment, increased release of a particular cytokine, whether significant, important or having unknown importance, does not *a priori* mean that the particular cytokine is part of a cytokine storm. In one embodiment, an increase of at least one cytokine is not the result of a cytokine storm or CRS. In another embodiment, CAR T-cells may be the source of increased levels

of a particular cytokine or group of cytokines.

[0142] In another embodiment, cytokine release syndrome is characterized by any or all of the following symptoms: Fever with or without rigors, malaise, fatigue, anorexia, myalgias, arthalgias, nausea, vomiting, headache Skin Rash, Nausea, vomiting, diarrhea, Tachypnea, hypoxemia
 5 Cardiovascular Tachycardia, widened pulse pressure, hypotension, increased cardiac output (early), potentially diminished cardiac output (late), Elevated D-dimer, hypofibrinogenemia with or without bleeding, Azotemia Hepatic Transaminitis, hyperbilirubinemia, Headache, mental status changes, confusion, delirium, word finding difficulty or frank aphasia, hallucinations, tremor, dymetria, altered gait, seizures. In another embodiment, a cytokine storm is characterized by IL-2 release and
 10 lymphoproliferation. In another embodiment, a cytokine storm is characterized by increases in cytokines released by CAR T-cells. In another embodiment, a cytokine storm is characterized by increases in cytokines released by cells other than CAR T-cells.

[0143] In another embodiment, cytokine storm leads to potentially life-threatening complications including cardiac dysfunction, adult respiratory distress syndrome, neurologic toxicity, renal and/or
 15 hepatic failure, and disseminated intravascular coagulation.

[0144] A skilled artisan would appreciate that the characteristics of a cytokine release syndrome (CRS) or cytokine storm are estimated to occur a few days to several weeks following the trigger for the CRS or cytokine storm. In one embodiment, CAR T-cells are a trigger for CRS or a cytokine storm. In another embodiment, a trigger for CRS or a cytokine storm is not CAR T-cells.

[0145] In one embodiment, measurement of cytokine levels or concentration, as an indicator of cytokine storm, may be expressed as –fold increase, per cent (%) increase, net increase or rate of change in cytokine levels or concentration. In another embodiment, absolute cytokine levels or concentrations above a certain level or concentration may be an indication of a subject undergoing or about to experience a cytokine storm. In another embodiment, absolute cytokine levels or
 25 concentration at a certain level or concentration, for example a level or concentration normally found in a control subject not undergoing CAR-T cell therapy, may be an indication of a method for inhibiting or reducing the incidence of a cytokine storm in a subject undergoing CAR T-cell.

[0146] A skilled artisan would appreciate that the term “cytokine level” may encompass a measure of concentration, a measure of fold change, a measure of percent (%) change, or a measure of rate
 30 change. Further, the methods for measuring cytokines in blood, saliva, serum, urine, and plasma are well known in the art.

[0147] In one embodiment, despite the recognition that cytokine storm is associated with elevation of several inflammatory cytokines, IL-6 levels may be used as a common measure of cytokine storm and/or as a common measure of the effectiveness of a treatment for cytokine storms. A skilled

artisan would appreciate that other cytokines may be used as markers of a cytokine storm, for example TNF- α , IB-1 α , IL-8, IL-13, or INF- γ . Further, that assay methods for measuring cytokines are well known in the art. A skilled artisan would appreciate that methods affecting a cytokine storm may similarly affect cytokine release syndrome.

5 [0148] In one embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or a cytokine storm. In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject vulnerable to experiencing cytokine release syndrome or a cytokine storm. In another embodiment, methods disclosed herein decrease or inhibit cytokine production in a subject
10 experiencing cytokine release syndrome or a cytokine storm, wherein production of any cytokine or group of cytokines listed in Tables 1 and/or 2 is decreased or inhibited. In another embodiment, cytokine IL-6 production is decreased or inhibited. In another embodiment, cytokine IL-beta1 production is decreased or inhibited. In another embodiment, cytokine IL-8 production is decreased or inhibited. In another embodiment, cytokine IL-13 production is decreased or inhibited. In
15 another embodiment, cytokine TNF-alpha production is decreased or inhibited. In another embodiment, cytokines IL-6 production, IL-1beta production, or TNF-alpha production, or any combination thereof is decreased or inhibited.

[0149] In one embodiment, cytokine release syndrome is graded. In another embodiment, Grade 1 describes cytokine release syndrome in which symptoms are not life threatening and require
20 symptomatic treatment only, e.g., fever, nausea, fatigue, headache, myalgias, malaise. In another embodiment, Grade 2 symptoms require and respond to moderate intervention, such as oxygen, fluids or vasopressor for hypotension. In another embodiment, Grade 3 symptoms require and respond to aggressive intervention. In another embodiment, Grade 4 symptoms are life-threatening symptoms and require ventilator and patients display organ toxicity.

25 [0150] In another embodiment, a cytokine storm is characterized by IL-6 and interferon gamma release. In another embodiment, a cytokine storm is characterized by release of any cytokine or combination thereof, listed in Tables 1 and 2. In another embodiment, a cytokine storm is characterized by release of any cytokine or combination thereof, known in the art.

[0151] In one embodiment, symptoms onset begins minutes to hours after the infusion begins. In
30 another embodiment, symptoms coincide with peak cytokine levels.

[0152] In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing CAR T-cell cancer therapy comprises administering an apoptotic cell population or an apoptotic cell supernatant or compositions thereof. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or

compositions thereof may aid the CAR T-cell therapy. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or compositions thereof may aid in the inhibition or reducing the incidence of the CRS or cytokine storm. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or compositions thereof may aid in treating the CRS or cytokine storm. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or compositions thereof may aid in preventing the CRS or cytokine storm. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or compositions thereof may aid in ameliorating the CRS or cytokine storm. In another embodiment, the apoptotic cell population or an apoptotic cell supernatant or compositions thereof may aid in alleviating the CRS or cytokine storm.

[0153] In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing CAR T-cell cancer therapy, and being administered an apoptotic cell population or an apoptotic cell supernatant or compositions thereof, comprises administering an additional agent. In another embodiment, the additional agent may aid the CAR T-cell therapy. In another embodiment, the additional agent may aid in the inhibition or reducing the incidence of the CRS or cytokine storm. In another embodiment, the additional agent may aid in treating the CRS or cytokine storm. In another embodiment, the additional agent may aid in preventing the CRS or cytokine storm. In another embodiment, the additional agent may aid in ameliorating the CRS or cytokine storm. In another embodiment, the additional agent may aid in alleviating the CRS or cytokine storm.

[0154] In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing CAR T-cell cancer therapy comprises administering an additional agent. In another embodiment, the additional agent may aid the CAR T-cell therapy. In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing TCR T-cell cancer therapy comprises administering an additional agent. In another embodiment, the additional agent may aid the TCR T-cell therapy. In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing comprises administering an additional agent. In another embodiment, the additional agent may aid the . In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing NK cell therapy comprises administering an additional agent. In another embodiment, the additional agent may aid the NK cell therapy.

[0155] In another embodiment, the additional agent may aid in the inhibition or reducing the incidence of the CRS or cytokine storm. In another embodiment, the additional agent may aid in

treating the CRS or cytokine storm. In another embodiment, the additional agent may aid in preventing the CRS or cytokine storm. In another embodiment, the additional agent may aid in ameliorating the CRS or cytokine storm. In another embodiment, the additional agent may aid in alleviating the CRS or cytokine storm.

5 [0156] In one embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or a composition comprising said apoptotic cells. In another embodiment, the additional agent for decreasing harmful cytokine release comprises an apoptotic cell supernatant or a composition comprising said supernatant. In another embodiment, the additional agent for decreasing harmful cytokine release comprises a CTLA-4 blocking agent. In another embodiment,
10 the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and a CTLA-4 blocking agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises an alpha-1 anti-trypsin or fragment thereof or analogue thereof. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions
15 thereof, and an alpha-1 anti-trypsin or fragment thereof or analogue thereof. In another embodiment, the additional agent for decreasing harmful cytokine release comprises a tellurium-based compound. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and a tellurium-based compound. In another embodiment, the additional agent for decreasing harmful cytokine release
20 comprises an immune modulating agent. In another embodiment, the additional agent for decreasing harmful cytokine release comprises apoptotic cells or apoptotic cell supernatants or compositions thereof, and an immune modulating agent.

[0157] In another embodiment, compositions and methods as disclosed herein utilize combination therapy of CAR T-cells with one or more CTLA-4-blocking agents such as Ipilimumab. In another
25 embodiment, compositions and methods as disclosed herein utilize combined therapy comprising apoptotic cells, CAR T-cells, and one or more CTLA-4-blocking agents. In another embodiment, compositions and methods as disclosed herein utilize combination therapy of TCR T-cells with one or more CTLA-4-blocking agents such as Ipilimumab. In another embodiment, compositions and methods as disclosed herein utilize combined therapy comprising apoptotic cells, TCR T-cells, and
30 one or more CTLA-4-blocking agents. In another embodiment, compositions and methods as disclosed herein utilize combination therapy of dendritic cells with one or more CTLA-4-blocking agents such as Ipilimumab. In another embodiment, compositions and methods as disclosed herein utilize combined therapy comprising apoptotic cells, dendritic cells, and one or more CTLA-4-blocking agents. In another embodiment, compositions and methods as disclosed herein utilize

combination therapy of NK cells with one or more CTLA-4-blocking agents such as Ipilimumab. In another embodiment, compositions and methods as disclosed herein utilize combined therapy comprising apoptotic cells, NK cells, and one or more CTLA-4-blocking agents.

[0158] In another embodiment, CTLA-4 is a potent inhibitor of T-cell activation that helps to maintain self-tolerance. In another embodiment, administration of an anti-CTLA-4 blocking agent, which in another embodiment, is an antibody, produces a net effect of T-cell activation.

[0159] In another embodiment, other toxicities resulting from CAR T-cell, TCR T-cell, dendritic cell, or NK cell administration that may be treated, prevented, inhibited, ameliorated, reduced in incidence or alleviated by the compositions and methods as disclosed herein comprise B cell aplasia or tumor lysis syndrome (TLS).

[0160] In one embodiment, a method of inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing CAR T-cell cancer therapy does not affect the efficacy of the CAR T-cell therapy. In another embodiment, a method of inhibiting or reducing the incidence of CRS or a cytokine storm in a subject undergoing CAR T-cell cancer therapy, does reduce the efficacy of the CAR T-cells therapy by more than about 5%. In another embodiment, a method of inhibiting or reducing the incidence of CRS or a cytokine storm in a subject undergoing CAR T-cell cancer therapy, does reduce the efficacy of the CAR T-cells therapy by more than about 10%. In another embodiment, a method of inhibiting or reducing the incidence of CRS or a cytokine storm in a subject undergoing CAR T-cell cancer therapy, does reduce the efficacy of the CAR T-cells therapy by more than about 15%. In another embodiment, a method of inhibiting or reducing the incidence of CRS or a cytokine storm in a subject undergoing CAR T-cell cancer therapy, does reduce the efficacy of the CAR T-cells therapy by more than about 20%.

[0161] Any appropriate method of quantifying cytotoxicity can be used to determine whether activity in an immune cell modified to express a CAR remains substantially unchanged. For example, cytotoxicity can be quantified using a cell culture-based assay such as the cytotoxic assays described in the Examples. Cytotoxicity assays can employ dyes that preferentially stain the DNA of dead cells. In other cases, fluorescent and luminescent assays that measure the relative number of live and dead cells in a cell population can be used. For such assays, protease activities serve as markers for cell viability and cell toxicity, and a labeled cell permeable peptide generates fluorescent signals that are proportional to the number of viable cells in the sample. For example a cytotoxicity assay may use 7-AAD in a flow cytometry analysis. Kits for various cytotoxicity assays are commercially available from manufacturers such as Promega, Abcam, and Life Technologies.

[0162] In another embodiment, a measure of cytotoxicity may be qualitative. In another embodiment, a measure of cytotoxicity may be quantitative. In a further embodiment a measure of

cytotoxicity may be related to the change in expression of a cytotoxic cytokine. In another embodiment, a measure of cytotoxicity may be determined by survival curve and tumor load in bone marrow and liver.

[0163] In one embodiment, the methods as disclosed herein comprise an additional step that is useful in overcoming rejection of allogeneic donor cells. In one embodiment, the methods comprise the step of full or partial lymphodepletion prior to administration of the CAR T-cells, which in one embodiment, are allogeneic CAR T-cells. In another embodiment, the lymphodepletion is adjusted so that it delays the host versus graft reaction for a period sufficient to allow said allogeneic T-cells to attack the tumor to which they are directed, but to an extent insufficient to require rescue of the host immune system by bone marrow transplantation. In another embodiment, agents that delay egression of the allogeneic T-cells from lymph nodes, such as 2-amino-2-[2-(4-octylphenyl)ethyl]propane-1,3-diol (FTY720), 5-[4-phenyl-5-(trifluoromethyl)thiophen-2-yl]-3-[3-(trifluoromethyl)phenyl]-1,2,4-oxadiazole (SEW2871), 3-(2-(hexylphenylamino)-2-oxoethylamino)propanoic acid (W123), 2-ammonio-4-(2-chloro-4-(3-phenoxyphenylthio)phenyl)-2-(hydroxymethyl)but-yl hydrogen phosphate (KRP-203 phosphate) or other agents known in the art, may be used as part of the compositions and methods as disclosed herein to allow the use of allogeneic CAR T-cells having efficacy and lacking initiation of graft vs host disease. In one embodiment, MHC expression by the allogeneic T-cells is silenced to reduce the rejection of the allogeneic cells. In another embodiment, the apoptotic cells prevent rejection of the allogeneic cells.

[0164] *Cytokine Release Associated with CAR T-cell Therapy*

[0165] In one embodiment, cytokine release occurs between a few days to 2 weeks after administration of immune therapy such as CAR T-cell therapy. In one embodiment, hypotension and other symptoms follow the cytokine release, i.e. from few days to few weeks. Therefore, in one embodiment, apoptotic cells or the apoptotic cell supernatant are administered to subjects at the same time as immune therapy as prophylaxis. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-3 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 days after administration of immune therapy.

[0166] In another embodiment, apoptotic cells or apoptotic cell supernatant are administered to subjects 2-3 hours after administration of immune therapy. In another embodiment, apoptotic cells

or supernatant are administered to subjects 7 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 hours after administration of immune therapy.

[0167] In an alternative embodiment, apoptotic cells or the apoptotic cell supernatant are administered to subjects prior to immune therapy as prophylaxis. In another embodiment, apoptotic cells or supernatant are administered to subjects 1 day before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-3 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 days before administration of immune therapy.

[0168] In another embodiment, apoptotic cells or apoptotic cell supernatant are administered to subjects 2-3 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 hours before administration of immune therapy.

[0169] In another embodiment, apoptotic cells or apoptotic cell supernatant may be administered therapeutically, once cytokine release syndrome has occurred. In one embodiment, apoptotic cells or supernatant may be administered once cytokine release leading up to or attesting to the beginning of cytokine release syndrome is detected. In one embodiment, apoptotic cells or supernatant can terminate the increased cytokine levels, or the cytokine release syndrome, and avoid its sequelae.

[0170] In another embodiment, apoptotic cells or apoptotic cell supernatant may be administered therapeutically, at multiple time points. In another embodiment, administration of apoptotic cells or apoptotic cell supernatant is at least at two time points described herein. In another embodiment, administration of apoptotic cells or apoptotic cell supernatant is at least at three time points described herein. In another embodiment, administration of apoptotic cells or apoptotic cell

supernatant is prior to CRS or a cytokine storm, and once cytokine release syndrome has occurred, and any combination thereof.

[0171] In one embodiment, the chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy and the apoptotic cell therapy or supernatant are administered together. In another embodiment, the CAR T-cell therapy is administered after the apoptotic cell therapy or supernatant. In another embodiment, the CAR T-cell therapy is administered prior to the apoptotic cell therapy or supernatant. According to this aspect and in one embodiment, apoptotic cell therapy or supernatant is administered approximately 2–3 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy or supernatant is administered approximately 6-7 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy or supernatant is administered approximately 9 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy is administered up to several months after CAR T-cell therapy.

[0172] Therefore, in one embodiment, apoptotic cells or the apoptotic cell supernatant are administered to subjects at the same time as immune therapy as prophylaxis. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-3 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 days after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 days after administration of immune therapy.

[0173] In another embodiment, apoptotic cells or apoptotic cell supernatant are administered to subjects 2-3 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 hours after administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 hours after administration of immune therapy.

[0174] In an alternative embodiment, apoptotic cells or the apoptotic cell supernatant are administered to subjects prior to immune therapy as prophylaxis. In another embodiment, apoptotic cells or supernatant are administered to subjects 1 day before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-3 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are

administered to subjects 7 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 days before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 days before administration of immune therapy.

[0175] In another embodiment, apoptotic cells or apoptotic cell supernatant are administered to subjects 2-3 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 7 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 10 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 14 hours before administration of immune therapy. In another embodiment, apoptotic cells or supernatant are administered to subjects 2-14 hours before administration of immune therapy.

[0176] In another embodiment, apoptotic cells or apoptotic cell supernatant may be administered therapeutically, once cytokine release syndrome has occurred. In one embodiment, apoptotic cells or supernatant may be administered once cytokine release leading up to or attesting to the beginning of cytokine release syndrome is detected. In one embodiment, apoptotic cells or supernatant can terminate the increased cytokine levels, or the cytokine release syndrome, and avoid its sequelae.

[0177] In another embodiment, apoptotic cells or apoptotic cell supernatant may be administered therapeutically, at multiple time points. In another embodiment, administration of apoptotic cells or apoptotic cell supernatant is at least at two time points described herein. In another embodiment, administration of apoptotic cells or apoptotic cell supernatant is at least at three time points described herein. In another embodiment, administration of apoptotic cells or apoptotic cell supernatant is prior to CRS or a cytokine storm, and once cytokine release syndrome has occurred, and any combination thereof.

[0178] In one embodiment, the chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy and the apoptotic cell therapy or supernatant are administered together. In another embodiment, the CAR T-cell therapy is administered after the apoptotic cell therapy or supernatant. In another embodiment, the CAR T-cell therapy is administered prior to the apoptotic cell therapy or supernatant. According to this aspect and in one embodiment, apoptotic cell therapy or supernatant is administered approximately 2-3 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy or supernatant is administered approximately 6-7 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy or supernatant is administered approximately 9 weeks after the CAR T-cell therapy. In another embodiment, apoptotic cell therapy

is administered up to several months after CAR T-cell therapy.

[0179] In other embodiments, an additional agent is administered to subjects at the same time as immune therapy as prophylaxis. In one embodiment the additional agent comprises apoptotic cells, an apoptotic supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, of a tellurium-based compound, or an immune-modulating compounds, or any combination thereof. In another embodiment, the additional agent is administered to subjects 2-3 days after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 7 days after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 10 days after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 14 days after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 2-14 days after administration of immune therapy.

[0180] In another embodiment, the additional agent is administered to subjects 2-3 hours after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 7 hours after administration of immune therapy. In another embodiment the additional agent is administered to subjects 10 hours after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 14 hours after administration of immune therapy. In another embodiment, the additional agent is administered to subjects 2-14 hours after administration of immune therapy.

[0181] In an alternative embodiment, the additional agent is administered to subjects prior to immune therapy as prophylaxis. In another embodiment, the additional agent is administered to subjects 1 day before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 2-3 days before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 7 days before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 10 days before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 14 days before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 2-14 days before administration of immune therapy.

[0182] In another embodiment, the additional agent is administered to subjects 2-3 hours before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 7 hours before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 10 hours before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 14 hours before administration of immune therapy. In another embodiment, the additional agent is administered to subjects 2-14 hours

before administration of immune therapy.

[0183] In another embodiment, the additional agent is administered therapeutically, once cytokine release syndrome has occurred. In one embodiment, the additional agent is administered once cytokine release leading up to or attesting to the beginning of cytokine release syndrome is detected.

5 In one embodiment, the additional agent can terminate the increased cytokine levels, or the cytokine release syndrome, and avoid its sequelae.

[0184] In another embodiment, the additional agent is administered therapeutically, at multiple time points. In another embodiment, administration of the additional agent is at least at two time points described herein. In another embodiment, administration of the additional agent is at least at three
10 time points described herein. In another embodiment, administration of the additional agent is prior to CRS or a cytokine storm, and once cytokine release syndrome has occurred, and any combination thereof.

[0185] In one embodiment, the chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy and the additional agent is administered together. In another embodiment, the CAR T-cell therapy is
15 administered the additional agent. In another embodiment, the CAR T-cell therapy is administered prior to the additional agent. According to this aspect and in one embodiment, the additional agent is administered approximately 2–3 weeks after the CAR T-cell therapy. In another embodiment, the additional agent is administered approximately 6-7 weeks after the CAR T-cell therapy. In another
20 embodiment, the additional agent is administered approximately 9 weeks after the CAR T-cell therapy. In another embodiment, the additional agent is administered up to several months after CAR T-cell therapy.

[0186] In one embodiment, CAR T-cells are heterologous to the subject. In one embodiment, CAR T-cells are derived from one or more donors. In one embodiment, CAR T-cells are derived from one or more bone marrow donors. In another embodiment, CAR T-cells are derived from one or
25 more blood bank donations. In one embodiment, the donors are matched donors. In one embodiment, CAR T-cells are universal allogeneic CAR T-cells. In another embodiment, CAR T-cells are syngeneic CAR T-cells. In another embodiment, CAR T-cells are from unmatched third party donors. In another embodiment, CAR T-cells are from pooled third party donor T-cells. In one embodiment, the donor is a bone marrow donor. In another embodiment, the donor is a blood bank
30 donor. In one embodiment, CAR T-cells of the compositions and methods as disclosed herein comprise one or more MHC unrestricted tumor-directed chimeric receptors. In one embodiment, non-autologous T-cells may be engineered or administered according to protocols known in the art to prevent or minimize autoimmune reactions, such as described in U.S. Patent Application No. 20130156794, which is incorporated herein by references in its entirety.

[0187] In another embodiment, CAR T-cells are autologous to the subject. In one embodiment, the patient's own cells are used. In this embodiment, if the patient's own cells are used, then the CAR T-cell therapy is administered after the apoptotic cell therapy.

[0188] In one embodiment, apoptotic cells are heterologous to the subject. In one embodiment, apoptotic cells are derived from one or more donors. In one embodiment, apoptotic cells are derived from one or more bone marrow donors. In another embodiment, apoptotic cells are derived from one or more blood bank donations. In one embodiment, the donors are matched donors. In another embodiment, apoptotic cells are from unmatched third party donors. In one embodiment, apoptotic cells are universal allogeneic apoptotic cells. In another embodiment, apoptotic cells are from a syngeneic donor. In another embodiment, apoptotic cells are from pooled third party donor cells. In one embodiment, the donor is a bone marrow donor. In another embodiment, the donor is a blood bank donor. In another embodiment, apoptotic cells are autologous to the subject. In this embodiment, the patient's own cells are used.

[0189] According to some embodiments, the therapeutic mononuclear-enriched cell preparation disclosed herein or the apoptotic cell supernatant is administered to the subject systemically. In another embodiment, administration is via the intravenous route. Alternately, the therapeutic mononuclear enriched cell or supernatant may be administered to the subject according to various other routes, including, but not limited to, the parenteral, intraperitoneal, intra-articular, intramuscular and subcutaneous routes. Each possibility represents a separate embodiment as disclosed herein.

[0190] According to some embodiments, the therapeutic mononuclear-enriched cell preparation disclosed herein or the additional agent is administered to the subject systemically. In another embodiment, administration is via the intravenous route. Alternately, the therapeutic mononuclear enriched cell or the additional agent may be administered to the subject according to various other routes, including, but not limited to, the parenteral, intraperitoneal, intra-articular, intramuscular and subcutaneous routes. Each possibility represents a separate embodiment as disclosed herein.

[0191] In one embodiment, the preparation is administered in a local rather than systemic manner, for example, via injection of the preparation directly into a specific region of a patient's body. In another embodiment, a specific region comprises a tumor or cancer.

[0192] In another embodiment, the therapeutic mononuclear enriched cells or supernatant are administered to the subject suspended in a suitable physiological buffer, such as, but not limited to, saline solution, PBS, HBSS, and the like. In addition the suspension medium may further comprise supplements conducive to maintaining the viability of the cells. In another embodiment, the additional agent is administered to the subject suspended in a suitable physiological buffer, such as,

but not limited to, saline solution, PBS, HBSS, and the like.

[0193] According to some embodiments the pharmaceutical composition is administered intravenously. According to another embodiment, the pharmaceutical composition is administered in a single dose. According to alternative embodiments the pharmaceutical composition is administered in multiple doses. According to another embodiment, the pharmaceutical composition is administered in two doses. According to another embodiment, the pharmaceutical composition is administered in three doses. According to another embodiment, the pharmaceutical composition is administered in four doses. According to another embodiment, the pharmaceutical composition is administered in five or more doses. According to some embodiments, the pharmaceutical composition is formulated for intravenous injection.

[0194] In one embodiment, any appropriate method of providing modified CAR-expressing immune cells to a subject can be used for methods described herein. In one embodiment, methods for providing cells to a subject comprise hematopoietic cell transplantation (HCT), infusion of donor-derived NK cells into cancer patients or a combination thereof.

[0195] In another embodiment, disclosed herein is a method of inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprising the step of administering a composition comprising apoptotic cells to said subject.

[0196] In another embodiment, disclosed herein is a method of inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprising the step of administering an apoptotic cell supernatant, such as an apoptotic cell-phagocyte supernatant, to said subject.

[0197] In another embodiment, disclosed herein is a method of inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprising the step of administering an at least one additional agent to said subject.

[0198] In certain embodiments, a CAR T-cell therapy comprises administering a composition disclosed herein comprising CAR T-cells and either apoptotic cells or an apoptotic cell supernatant, or another or combination of additional agents as disclosed herein. In alternative embodiments, a CAR T-cell therapy comprises administering a composition disclosed herein comprising CAR T-cells and a composition comprising either apoptotic cells or an apoptotic cell supernatant, or an additional agent or combination thereof as disclosed herein..

[0199] *Cytokine Release Associated with Non CAR T-cell Applications*

[0200] In one embodiment, disclosed herein is a method of decreasing or inhibiting cytokine

production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm, comprising the step of administering a composition comprising apoptotic cells or an apoptotic supernatant to said subject, wherein said administering decreases or inhibits cytokine production in said subject. In another embodiment, decrease or inhibition of cytokine production is compared with a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm and not administered apoptotic cells or an apoptotic supernatant. In another embodiment, methods for decreasing or inhibiting cytokine production decrease or inhibit pro-inflammatory cytokine production. In another embodiment, methods for decreasing or inhibiting cytokine production decrease or inhibit production of at least one pro-inflammatory cytokine. In another embodiment, methods for decreasing or inhibiting cytokine production decrease or inhibit production of at least cytokine IL-6. In another embodiment, methods for decreasing or inhibiting cytokine production decrease or inhibit production of at least cytokine IL-1 β . In another embodiment, methods for decreasing or inhibiting cytokine production decrease or inhibit production of at least cytokine TNF- α . In another embodiment, methods disclosed herein for decreasing or inhibiting cytokine production, result in reduction or inhibition of production of cytokines IL-6, IL-1 β , or TNF- α , or any combination in said subject compared with a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm and not administered apoptotic cells or an apoptotic supernatant.

[0201] Cancers or tumors may also affect the absolute level of cytokines including pro-inflammatory cytokines. The level of tumor burden in a subject may affect cytokine levels, particularly pro-inflammatory cytokines. A skilled artisan would appreciate that the phrase “decrease or inhibit” or grammatical variants thereof may encompass fold decrease or inhibition of cytokine production, or a net decrease or inhibition of cytokine production, or percent (%) decrease or inhibition, or may encompass a rate of change of decrease or inhibition of a cytokine production.

[0202] In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm comprising the step of administering apoptotic cells or a composition comprising apoptotic cells to said subject.

[0203] In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm comprising the step of administering an apoptotic cell supernatant, such as an apoptotic cell-phagocyte supernatant, or a composition comprising said supernatant to said subject.

[0204] In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm comprising the step of administering an apoptotic cell supernatant, such as an additional agent selected from the group comprising apoptotic cells, an
 5 apoptotic supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or a composition comprising said supernatant to said subject.

[0205] In one embodiment, an infection causes the cytokine release syndrome or cytokine storm in the subject. In one embodiment, the infection is an influenza infection. In one embodiment, the
 10 influenza infection is H1N1. In another embodiment, the influenza infection is an H5N1 bird flu. In another embodiment, the infection is severe acute respiratory syndrome (SARS). In another embodiment, the subject has Epstein-Barr virus-associated hemophagocytic lymphohistiocytosis (HLH). In another embodiment, the infection is sepsis. In one embodiment, the sepsis is gram-negative. In another embodiment, the infection is malaria. In another embodiment, the infection is
 15 an Ebola virus infection. In another embodiment, the infection is variola virus. In another embodiment, the infection is a systemic Gram-negative bacterial infection. In another embodiment, the infection is Jarisch-Herxheimer syndrome.

[0206] In one embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is hemophagocytic lymphohistiocytosis (HLH). In another embodiment, HLH is sporadic
 20 HLH. In another embodiment, HLH is macrophage activation syndrome (MAS). In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is MAS.

[0207] In one embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is chronic arthritis. In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is systemic Juvenile Idiopathic Arthritis (sJIA), also known as Still's
 25 Disease.

[0208] In one embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is Cryopyrin-associated Periodic Syndrome (CAPS). In another embodiment, CAPS comprises Familial Cold Auto-inflammatory Syndrome (FCAS), also known as Familial Cold Urticaria (FCU). In another embodiment, CAPS comprises Muckle-Well Syndrome (MWS). In
 30 another embodiment, CAPS comprises Chronic Infantile Neurological Cutaneous and Articular (CINCA) Syndrome. In yet another embodiment, CAPS comprises FCAS, FCU, MWS, or CINCA Syndrome, or any combination thereof. In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is FCAS. In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is FCU. In another embodiment, the cause of the

cytokine release syndrome or cytokine storm in a subject is MWS. In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is CINCA Syndrome. In still another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is FCAS, FCU, MWS, or CINCA Syndrome, or any combination thereof.

5 [0209] In another embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is a cryopyrinopathy comprising inherited or de novo gain of function mutations in the NLRP3 gene, also known as the CIASI gene.

[0210] In one embodiment, the cause of the cytokine release syndrome or cytokine storm in a subject is a hereditary auto-inflammatory disorder.

10 [0211] In one embodiment, the trigger for the release of inflammatory cytokines is a lipopolysaccharide (LPS), Gram-positive toxins, fungal toxins, glycosylphosphatidylinositol (GPI) or modulation of RIG-1 gene expression.

[0212] In another embodiment, the subject experiencing cytokine release syndrome or cytokine storm does not have an infectious disease. In one embodiment, the subject has acute pancreatitis. In
15 another embodiment, the subject has tissue injury, which in one embodiment, is severe burns or trauma. In another embodiment, the subject has acute respiratory distress syndrome. In another embodiment, the subject has cytokine release syndrome or cytokine storm secondary to drug use. In another embodiment, the subject has cytokine release syndrome or cytokine storm secondary to toxin inhalation.

20 [0213] In another embodiment, the subject has cytokine release syndrome or cytokine storm secondary to receipt of immunotherapy, which in one embodiment is immunotherapy with superagonistic CD28-specific monoclonal antibodies (CD28SA). In one embodiment, the CD28SA is TGN1412. In another embodiment, the immunotherapy is CAR T-cell therapy. In another embodiment, the immunotherapy is .

25 [0214] In another embodiment, apoptotic cells or supernatant or a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, may be used to control cytokine release syndrome or cytokine storm that results from administration of a pharmaceutical composition. In one embodiment, the pharmaceutical composition is oxaliplatin, cytarabine, lenalidomide, or a
30 combination thereof.

[0215] In another embodiment, apoptotic cells or the supernatant or a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, may be used to control cytokine release syndrome or cytokine storm that results from administration of an antibody. In one embodiment, the

antibody is monoclonal. In another embodiment, the antibody is polyclonal. In one embodiment, the antibody is rituximab. In another embodiment, the antibody is Orthoclone OKT3 (muromonab-CD3). In another embodiment, the antibody is alemtuzumab, tosituzumab, CP-870,893, LO-CD2a/BTI-322 or TGN1412.

5 [0216] In another embodiment, examples of diseases for which control of inflammatory cytokine production can be beneficial include cancers, allergies, any type of infection, toxic shock syndrome, sepsis, any type of autoimmune disease, arthritis, Crohn's disease, lupus, psoriasis, or any other disease for which the hallmark feature is toxic cytokine release that causes deleterious effects in a subject.

10 [0217] *Alpha-1-antitrypsin (AAT)*

[0218] Alpha-1-antitrypsin (AAT) is a circulating 52-kDa glycoprotein that is produced mainly by the liver. AAT is primarily known as a serine protease inhibitor and is encoded by the gene SERPINA1. AAT inhibits neutrophil elastase, and inherited deficiency in circulating AAT results in lung-tissue deterioration and liver disease. Serum AAT concentrations in healthy individuals
15 increase twofold during inflammation.

[0219] There is a negative association between AAT levels and the severity of several inflammatory diseases. For example, reduced levels or activity of AAT have been described in patients with HIV infection, diabetes mellitus, hepatitis C infection-induced chronic liver disease, and several types of vasculitis.

20 [0220] Increasing evidence demonstrates that human serum derived alpha-1-anti-trypsin (AAT) reduces production of pro-inflammatory cytokines, induces anti-inflammatory cytokines, and interferes with maturation of dendritic cells.

[0221] Indeed, the addition of AAT to human peripheral blood mononuclear cells (PBMC) inhibits LPS induced release of TNF- α and IL-1 β but increases IL-1 receptor antagonist (IL-1Ra) and IL-10
25 production.

[0222] AAT reduces *in vitro* IL-1 β -mediated pancreatic islet toxicity, and AAT monotherapy prolongs islet allograft survival, promotes antigen-specific immune tolerance in mice, and delays the development of diabetes in non-obese diabetic (NOD) mice. AAT was shown to inhibit LPS-induced acute lung injury in experimental models. Recently, AAT was shown to reduce the size of
30 infarct and the severity of heart failure in a mouse model of acute myocardial ischemia-reperfusion injury.

[0223] Monotherapy with clinical-grade human AAT (hAAT) reduced circulating pro-inflammatory cytokines, diminished Graft vs Host Disease (GvHD) severity, and prolonged animal survival after experimental allogeneic bone marrow transfer (Tawara et al., Proc Natl Acad Sci U S

A. 2012 Jan 10;109(2):564-9), incorporated herein by reference. AAT treatment reduced the expansion of alloreactive T effector cells but enhanced the recovery of T regulatory T-cells, (Tregs) thus altering the ratio of donor T effector to T regulatory cells in favor of reducing the pathological process. *In vitro*, AAT suppressed LPS-induced *in vitro* secretion of proinflammatory cytokines such as TNF- α and IL-1 β , enhanced the production of the anti-inflammatory cytokine IL-10, and impaired NF- κ B translocation in the host dendritic cells. Marcondes, Blood. 2014 (Oct 30;124(18):2881-91) incorporated herein by reference show that treatment with AAT not only ameliorated GvHD but also preserved and perhaps even enhanced the graft vs leukemia (GVL) effect.

[0224] In one embodiment, disclosed herein are compositions comprising chimeric antigen receptor-expressing T-cells (CAR T-cells) and Alpha-1-antitrypsin (AAT). In another embodiment, CAR T-cells and Alpha-1-antitrypsin (AAT) are in separate compositions. In another embodiment, AAT comprises a full length AAT or a functional fragment thereof. In another embodiment, AA comprises an analogue of a full length AAT or a functional fragment thereof. In another embodiment, a composition comprising AAT further comprises apoptotic cells or an apoptotic cell supernatant.

[0225] In another embodiment, disclosed herein is a method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cells) and a composition comprising Alpha-1-antitrypsin (AAT) to said subject. In another embodiment, the method further comprises apoptotic cells or an apoptotic cell supernatant.

[0226] In another embodiment, disclosed herein is a method of inhibiting or reducing the incidence of cytokine release syndrome or cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprising the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject. In another embodiment, a method of treating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject. In another embodiment, a method of preventing cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject. In another embodiment, a method of ameliorating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject. In another embodiment, a method of

method of alleviating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject.

[0227] In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm, comprising the step of administering a composition comprising Alpha-1-antitrypsin (AAT) to said subject.

[0228] In one embodiment, AAT is administered alone to control cytokine release. In another embodiment, both AAT and apoptotic cells or a composition thereof, or apoptotic cell supernatants or a composition thereof, are administered to control cytokine release.

[0229] *Immuno-Modulatory Agents*

[0230] A skilled artisan would appreciate that immune-modulating agents may encompass extracellular mediators, receptors, mediators of intracellular signaling pathways, regulators of translation and transcription, as well as immune cells. In one embodiment, an additional agent disclosed herein is an immune-modulatory agent known in the art. In another embodiment, use in the methods disclosed here of an immune-modulatory agent reduces the level of at least one cytokine. In another embodiment, use in the methods disclosed here of an immune-modulatory agent reduces or inhibits CRS or a cytokine storm.

[0231] In one embodiment, an immune-modulatory agent comprises compounds that block, inhibit or reduce the release of cytokines or chemokines. In another embodiment, an immune-modulatory agent comprises compounds that block, inhibit or reduce the release of IL-21 or IL-23, or a combination thereof. In another embodiment, an immune-modulatory agent comprises an antiretroviral drug in the chemokine receptor-5 (CCR5) receptor antagonist class, for example maraviroc. In another embodiment, an immune-modulatory agent comprises an anti-DNAM-1 antibody. In another embodiment, an immune-modulatory agent comprises damage/pathogen-associated molecules (DAMPs/PAMPs) selected from the group comprising heparin sulfate, ATP, and uric acid, or any combination thereof. In another embodiment, an immune-modulatory agent comprises a sialic acid binding Ig-like lectin (Siglecs). In another embodiment, an immune-modulatory agent comprises a cellular mediator of tolerance, for example regulatory CD4⁺ CD25⁺ T cells (Tregs) or invariant natural killer T cells (iNK T-cells). In another embodiment, an immune-modulatory agent comprises dendritic cells. In another embodiment, an immune-modulatory agent comprises monocytes. In another embodiment, an immune-modulatory agent comprises macrophages. In another embodiment, an immune-modulatory agent comprises JAK2 or JAK3 inhibitors selected from the group comprising ruxolitinib and tofacitinib. In another embodiment, an

immune-modulatory agent comprises an inhibitor of spleen tyrosine kinase (Syk), for example fostamatinib. In another embodiment, an immune-modulatory agent comprises histone deacetylase inhibitor vorinostat acetylated STAT3. In another embodiment, an immune-modulatory agent comprises neddylation inhibitors, for example MLN4924. In another embodiment, an immune-modulatory agent comprises an miR-142 antagonist. In another embodiment, an immune-modulatory agent comprises a chemical analogue of cytidine, for example Azacitidine. In another embodiment, an immune-modulatory agent comprises an inhibitor of histone deacetylase, for example Vorinostat. In another embodiment, an immune-modulatory agent comprises an inhibitor of histone methylation.

10 [0232] *Tellurium-based compounds*

[0233] Tellurium is a trace element found in the human body. Various tellurium compounds, have immune-modulating properties, and have been shown to have beneficial effects in diverse preclinical and clinical studies. A particularly effective family of tellurium-containing compounds is disclosed for example, in U.S. Patent Nos. 4,752,614; 4,761,490; 4,764,461 and 4,929,739. The immune-modulating properties of this family of tellurium-containing compounds is described, for example, in U.S. Patent Nos. 4,962,207, 5,093,135, 5,102,908 and 5,213,899, which are all incorporated by reference as if fully set forth herein.

[0234] One promising compound is ammonium trichloro(dioxyethylene-O,O')tellurate, which is also referred to herein and in the art as AS101. AS101, as a representative example of the family of tellurium-containing compound discussed hereinabove, exhibits antiviral (Nat. Immun. Cell Growth Regul. 7(3):163-8, 1988; AIDS Res Hum Retroviruses. 8(5):613-23, 1992), and tumoricidal activity (Nature 330(6144):173-6, 1987; J. Clin. Oncol. 13(9):2342-53, 1995; J. Immunol. 161(7):3536-42, 1998). Further, AS101 is characterized by low toxicity.

[0235] In one embodiment, a composition comprising tellurium-containing immune-modulator compounds may be used in methods disclosed herein, where the tellurium-based compound stimulates the innate and acquired arm of the immune response. For example, it has been shown that AS101 is a potent activator of interferon (IFN) in mice (J. Natl. Cancer Inst. 88(18):1276-84, 1996) and humans (Nat. Immun. Cell Growth Regul. 9(3):182-90, 1990; Immunology 70(4):473-7, 1990; J. Natl. Cancer Inst. 88(18):1276-84, 1996.)

[0236] In another embodiment, tellurium-based compounds induce the secretion of a spectrum of cytokines, such as IL-1 α , IL-6 and TNF- α .

[0237] In another embodiment, a tellurium-based compound comprises a tellurium-based compound known in the art to have immune-modulating properties. In another embodiment, a tellurium-based compound comprises ammonium trichloro(dioxyethylene-O,O')tellurate.

[0238] In one embodiment, a tellurium-based compound inhibits the secretion of at least one cytokine. In another embodiment, a tellurium-based compound reduces the secretion of at least one cytokine. In another embodiment, a tellurium-based compound inhibits or reduces a cytokine release syndrome (CRS) of a cytokine storm.

5 [0239] In one embodiment, disclosed herein are compositions comprising chimeric antigen receptor-expressing T-cells (CAR T-cells) and a tellurium-based compound. In another embodiment, CAR T-cells and Tellurium-based compound are in separate compositions. In another embodiment, AAT comprises a full length AAT or a functional fragment thereof. In another embodiment, AA comprises an analogue of a full length AAT or a functional fragment thereof

10 [0240] In another embodiment, disclosed herein is a method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cells) and a composition comprising a Tellurium-based compound to said subject.

[0241] In another embodiment, disclosed herein is a method of inhibiting or reducing the incidence
15 of cytokine release syndrome or cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprising the step of administering a composition comprising a Tellurium-based compound to said subject. In another embodiment, a method of treating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition
20 comprising a Tellurium-based compound to said subject. In another embodiment, a method of preventing cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising a Tellurium-based compound to said subject. In another embodiment, a method of ameliorating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric
25 antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising a Tellurium-based compound to said subject. In another embodiment, a method of alleviating cytokine release syndrome or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) therapy, comprises the step of administering a composition comprising a Tellurium-based compound to said subject.

30 [0242] In another embodiment, disclosed herein is a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to cytokine release syndrome or cytokine storm, comprising the step of administering a composition comprising a Tellurium-based compound to said subject.

[0243] In one embodiment, a tellurium-based compound is administered alone to control cytokine

release. In another embodiment, both a tellurium-based compound and apoptotic cells or a composition thereof, or apoptotic cell supernatants or a composition thereof, are administered to control cytokine release.

[0244] *Genetic modification*

5 [0245] In one embodiment, genetic modification of T-cells, dendritic cells, and/or apoptotic cells may be accomplished using RNA, DNA, recombinant viruses, or a combination thereof. In one embodiment, vectors derived from gamma retroviruses or lentiviruses are used in the compositions and methods as disclosed herein. In another embodiment, these vectors can integrate into the host genome, with potentially permanent expression of the transgene and have low intrinsic
10 immunogenicity. In another embodiment, another vector that integrates into the host genome and/or has low intrinsic immunogenicity may be used in the compositions and methods as disclosed herein. In another embodiment, the non-viral-vector-mediated sleeping beauty transposon system is used to insert the CAR and other genes into the T-cell. In another embodiment, “suicide genes” are integrated into the T-cells, in which expression of a pro-apoptotic gene is under the control of an
15 inducible promoter responsive to a systemically delivered drug.

[0246] In one embodiment, genetic modification may be transient. In another embodiment, genetic modification may utilize messenger RNA (mRNA). In another embodiment, large numbers of cells may be infused on multiple occasions in transiently engineered T-cells, such as mRNA-transfected T-cells. In another embodiment, RNA-based electroporation of lymphocytes using in vitro–
20 transcribed mRNA mediates transient expression of proteins for approximately one week and obviates the risk of integrating viral vectors. In another embodiment, mRNA-transduced dendritic cells or mRNA-electroporated T and NK lymphocytes.

[0247] It has been demonstrated that genetically modified T-cells can persist after adoptive transfer for more than a decade without adverse effects, indicating that genetically modifying human T-cells
25 is fundamentally safe.

[0248] In another embodiment, the genetic modification of the compositions and in the methods as disclosed herein may be any method that is known in the art.

[0249] *Apoptotic Cells*

[0250] In one embodiment, apoptotic cells (Apocells) for use in compositions and methods as
30 disclosed herein are as described in WO 2014/087408, which is incorporated by reference herein in its entirety. In another embodiment, apoptotic cells for use in compositions and methods as disclosed herein are produced in any way that is known in the art. In another embodiment, apoptotic cells for use in compositions and methods disclosed herein are autologous with a subject undergoing therapy. In another embodiment, apoptotic cells for use in compositions and methods disclosed

herein are allogeneic with a subject undergoing therapy. In another embodiment, a composition comprising apoptotic cells comprises apoptotic cells as disclosed herein or as is known in art.

[0251] In one embodiment, apoptotic cells comprise a cell preparation comprising mononuclear-enriched cells, wherein the preparation comprises at least 85% mononuclear cells, wherein at least
5 40% of the cells in the preparation are in an early-apoptotic state, wherein at least 85% of the cells in the preparation are viable cells and wherein the preparation comprises no more than 15% CD15^{high} expressing cells.

[0252] A skilled artisan would appreciate that the term “early-apoptotic state” may encompass cells that show early signs of apoptosis without late signs of apoptosis. Examples of early signs of
10 apoptosis in cells include exposure of phosphatidylserine (PS) and the loss of mitochondrial membrane potential. Examples of late events include propidium iodide (PI) admission into the cell and the final DNA cutting. In order to document that cells are in an “early apoptotic” state, in one embodiment, PS exposure detection by Annexin-V and PI staining are used, and cells that are stained with Annexin V but not with PI are considered to be “early apoptotic cells”. In another
15 embodiment, cells that are stained by both Annexin-V FITC and PI are considered to be “late apoptotic cells”. In another embodiment, cells that do not stain for either Annexin-V or PI are considered non-apoptotic viable cells.

[0253] In one embodiment, apoptotic cells comprise cells in an early apoptotic state. In another embodiment, apoptotic cells comprise cells wherein at least 90% of said cells are in an early
20 apoptotic state. In another embodiment, apoptotic cells comprise cells wherein at least 80% of said cells are in an early apoptotic state. In another embodiment, apoptotic cells comprise cells wherein at least 70% of said cells are in an early apoptotic state. In another embodiment, apoptotic cells comprise cells wherein at least 60% of said cells are in an early apoptotic state. In another embodiment, apoptotic cells comprise cells wherein at least 50% of said cells are in an early
25 apoptotic state.

[0254] In another embodiment, early apoptotic cells are stable. In another embodiment, early apoptotic cells are stable for at least 24 hours. In another embodiment, early apoptotic cells are stable for 24 hours. In another embodiment, early apoptotic cells are stable for more than 24 hours. In another embodiment, early apoptotic cells are stable for at least 36 hours. In another embodiment,
30 early apoptotic cells are stable for 48 hours. In another embodiment, early apoptotic cells are stable for at least 36 hours. In another embodiment, early apoptotic cells are stable for more than 36 hours. In another embodiment, early apoptotic cells are stable for at least 48 hours. In another embodiment, early apoptotic cells are stable for 48 hours. In another embodiment, early apoptotic cells are stable for at least 48 hours. In another embodiment, early apoptotic cells are stable for more than 48 hours.

In another embodiment, early apoptotic cells are stable for at least 72 hours. In another embodiment, early apoptotic cells are stable for 72 hours. In another embodiment, early apoptotic cells are stable for at least 72 hours. In another embodiment, early apoptotic cells are stable for more than 72 hours.

[0255] A skilled artisan would appreciate that the term “stable” encompasses apoptotic cells that remain PS-positive (Phosphatidylserine-positive) with only a very small percent of PI-positive (Propidium iodide-positive). PI-positive cells provide an indication of membrane stability wherein a PI-positive cells permits admission into the cells, showing that the membrane is less stable. In one embodiment, stable early apoptotic cells remain in early apoptosis for at least 24 hours, for at least 36 hours, for at least 48 hours, or for at least 72 hours. In another embodiment, stable early apoptotic cells remain in early apoptosis for 24 hours, for 36 hours, for 48 hours, or for 72 hours. In another embodiment, stable early apoptotic cells remain in early apoptosis for more than 24 hours, for more than 36 hours, for more than 48 hours, or for more than 72 hours. In another embodiment, stable early apoptotic cells maintain their state for an extended time period. In one embodiment, the composition comprising apoptotic cells further comprises an anti-coagulant.

[0256] In one embodiment, the anti-coagulant is selected from the group consisting of: heparin, acid citrate dextrose (ACD) Formula A and a combination thereof.

[0257] In one embodiment, the composition further comprises methylprednisolone. At one embodiment, the concentration of methylprednisolone does not exceed 30 μ g/ml. In one embodiment, about 140×10^6 - 210×10^6 apoptotic cells are administered.

[0258] In one embodiment, the apoptotic cells are used at a high dose. In one embodiment, the apoptotic cells are used at a high concentration. In one embodiment, human apoptotic polymorphonuclear neutrophils (PMNs) are used. In one embodiment, a group of cells, of which 50% are apoptotic cells, are used. In one embodiment, apoptotic cells are verified by May-Giemsa-stained cytopreps. In one embodiment, viability of cells are assessed by trypan blue exclusion. In one embodiment, the apoptotic and necrotic status of the cells are confirmed by annexin V/propidium iodide staining with detection by FACS.

[0259] In some embodiments, apoptotic cells disclosed herein comprise no necrotic cells. In some embodiments, apoptotic cells disclosed herein comprise less than 1% necrotic cells. In some embodiments, apoptotic cells disclosed herein comprise less than 2% necrotic cells. In some embodiments, apoptotic cells disclosed herein comprise less than 3% necrotic cells. In some embodiments, apoptotic cells disclosed herein comprise less than 4% necrotic cells. In some embodiments, apoptotic cells disclosed herein comprise less than 5% necrotic cells.

[0260] In one embodiment, a dose of 10×10^6 apoptotic cells is administered. In another embodiment, a dose of 10×10^7 apoptotic cells is administered. In another embodiment, a dose of

10x10⁸ apoptotic cells is administered. In another embodiment, a dose of 10x10⁹ apoptotic cells is administered. In another embodiment, a dose of 10x10¹⁰ apoptotic cells is administered. In another embodiment, a dose of 10x10¹¹ apoptotic cells is administered. In another embodiment, a dose of 10x10¹² apoptotic cells is administered. In another embodiment, a dose of 10x10⁵ apoptotic cells is administered. In another embodiment, a dose of 10x10⁴ apoptotic cells is administered. In another embodiment, a dose of 10x10³ apoptotic cells is administered. In another embodiment, a dose of 10x10² apoptotic cells is administered.

[0261] In one embodiment, a high dose of apoptotic cells is administered. In one embodiment, a dose of 35x10⁶ apoptotic cells is administered. In another embodiment, a dose of 210x10⁶ apoptotic cells is administered. In another embodiment, a dose of 70x10⁶ apoptotic cells is administered. In another embodiment, a dose of 140x10⁶ apoptotic cells is administered. In another embodiment, a dose of 35-210x10⁶ apoptotic cells is administered.

[0262] According to some embodiments, obtaining a mononuclear-enriched cell composition according to the production method disclosed herein is effected by leukapheresis. A skilled artisan would appreciate that the term “leukapheresis” may encompass an apheresis procedure in which leukocytes are separated from the blood of a donor. According to some embodiments, the blood of a donor undergoes leukapheresis and thus a mononuclear-enriched cell composition is obtained according to the production method disclosed herein. It is to be noted, that the use of at least one anticoagulant during leukapheresis is required, as is known in the art, in order to prevent clotting of the collected cells.

[0263] According to some embodiments, the leukapheresis procedure is configured to allow collection of mononuclear-enriched cell composition according to the production method disclosed herein. According to some embodiments, cell collections obtained by leukapheresis comprise at least 65%. In other embodiments, at least 70%, or at least 80% mononuclear cells. Each possibility represents a separate embodiment as disclosed herein. According to some embodiments, blood plasma from the cell-donor is collected in parallel to obtaining of the mononuclear-enriched cell composition according to the production method disclosed herein. According to some embodiments, about 300-600ml of blood plasma from the cell-donor are collected in parallel to obtaining the mononuclear-enriched cell composition according to the production method disclosed herein. According to some embodiments, blood plasma collected in parallel to obtaining the mononuclear-enriched cell composition according to the production method disclosed herein is used as part of the freezing and/or incubation medium. Each possibility represents a separate embodiment as disclosed herein. Additional detailed methods of obtaining an enriched population of apoptotic cells for use in the compositions and methods as disclosed herein may be found in WO

2014/087408, which is incorporated herein by reference in its entirety.

[0264] It is to be noted that, according to some embodiments, that while the initial mononuclear-enriched cell preparation comprises at least 65% mononuclear cells, at least 70%, or at least 80% mononuclear cells, the final pharmaceutical composition disclosed herein, following the production method disclosed herein, comprises at least 85%. In another embodiment, at least 90%, or at least 95% mononuclear cells. Each possibility represents a separate embodiment as disclosed herein.

[0265] In one embodiment, the apoptotic cells may be administered by any method known in the art including, but not limited to, intravenous, subcutaneous, intranodal, intratumoral, intrathecal, intrapleural, intraperitoneal and directly to the thymus.

[0266] In one embodiment, the apoptotic cells are allogeneic. In one embodiment the apoptotic cells are from pooled third party donors. In one embodiment, the methods as disclosed herein comprise an additional step that is useful in overcoming rejection of allogeneic donor cells, including one or more steps described in U.S. Patent Application 20130156794, which is incorporated herein by reference in its entirety. In one embodiment, the methods comprise the step of full or partial lymphodepletion prior to administration of the apoptotic cells, which in one embodiment, are allogeneic apoptotic cells. In one embodiment, the lymphodepletion is adjusted so that it delays the host versus graft reaction for a period sufficient to allow the allogeneic apoptotic cells to control cytokine release. In another embodiment, the methods comprise the step of administering agents that delay egression of the allogeneic apoptotic T-cells from lymph nodes, such as 2-amino-2-[2-(4-octylphenyl)ethyl]propane-1,3-diol (FTY720), 5-[4-phenyl-5-(trifluoromethyl)thiophen-2-yl]-3-[3-(trifluoromethyl)phenyl]-1,2,4-oxadiazole (SEW2871), 3-(2-(hexylphenylamino)-2-oxoethylamino)propanoic acid (W123), 2-ammonio-4-(2-chloro-4-(3-phenoxyphenylthio)phenyl)-2-(hydroxymethyl)but-yl hydrogen phosphate (KRP-203 phosphate) or other agents known in the art, may be used as part of the compositions and methods as disclosed herein to allow the use of allogeneic apoptotic cells having efficacy and lacking initiation of graft vs host disease. In another embodiment, MHC expression by the allogeneic apoptotic T-cells is silenced to reduce the rejection of the allogeneic cells.

[0267] In another embodiment, the methods comprise the step of irradiating apoptotic cells derived from WBCs from a donor prior to administration to a recipient. In one embodiment, cells are irradiated in a way that will avoid proliferation and/or activation of residual viable cells within the apoptotic cell population. In another embodiment, the irradiated apoptotic cells preserve all their early apoptotic-, immune modulation-, stability-properties. In another embodiment, the irradiation step uses UV radiation. In another embodiment, the radiation step uses gamma radiation. In another embodiment, the apoptotic cells comprise a decreased percent of living non-apoptotic cells,

comprise a preparation having a suppressed cellular activation of any living non-apoptotic cells present within the apoptotic cell preparation, or comprise a preparation having reduced proliferation of any living non-apoptotic cells present within the apoptotic cell preparation, or any combination thereof.

5 [0268] In one embodiment, a pooled mononuclear apoptotic cell preparation comprising mononuclear cells in an early apoptotic state, wherein said pooled mononuclear apoptotic cells comprise a decreased percent of living non-apoptotic cells, a preparation having a suppressed cellular activation of any living non-apoptotic cells, or a preparation having reduced proliferation of any living non-apoptotic cells, or any combination thereof. In another embodiment, the pooled
10 mononuclear apoptotic cells have been irradiated. In another embodiment, disclosed herein is a pooled mononuclear apoptotic cell preparation that in some embodiments, originates from the white blood cell fraction (WBC) obtained from donated blood.

[0269] In one embodiment, the apoptotic cell preparation is irradiated. In another embodiment, said irradiation comprises gamma irradiation or UV irradiation. In yet another embodiment, the
15 irradiated preparation has a reduced number of non-apoptotic cells compared with a non-irradiated apoptotic cell preparation. In another embodiment, the irradiated preparation has a reduced number of proliferating cells compared with a non-irradiated apoptotic cell preparation. In another embodiment, the irradiated preparation has a reduced number of potentially immunologically active cells compared with a non-irradiated apoptotic cell population.

20 [0270] In one embodiment, pooled blood comprises 3rd party blood not matched between donor and recipient.

[0271] A skilled artisan would appreciate that the term “pooled” may encompass blood collected from multiple donors, prepared and possibly stored for later use. This combined pool of blood may then be processed to produce a pooled mononuclear apoptotic cell preparation. In another
25 embodiment, a pooled mononuclear apoptotic cell preparation ensures that a readily available supply of mononuclear apoptotic cells is available. In another embodiment, cells are pooled just prior to the incubation step wherein apoptosis is induced. In another embodiment, cells are pooled following the incubation step at the step of resuspension. In another embodiment, cells are pooled just prior to an irradiation step. In another embodiment, cells are pooled following an irradiation
30 step. In another embodiment, cells are pooled at any step in the methods of preparation.

[0272] In one embodiment, a pooled apoptotic cell preparation is derived from cells present in between about 2 and 25 units of blood. In another embodiment, said pooled apoptotic cell preparation is comprised of cells present in between about 2-5, 2-10, 2-15, 2-20, 5-10, 5-15, 5-20, 5-25, 10-15, 10-20, 10-25, 6-13, or 6-25 units of blood. In another embodiment, said pooled apoptotic

cell preparation is comprised of cells present in about 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24 or 25 units of blood. The number of units of blood needed is also dependent upon the efficiency of WBC recovery from blood. For example, low efficiency WBC recovery would lead to the need for additional units, while high efficiency WBC recovery would lead to fewer units needed. In some embodiments, each unit is a bag of blood. In another embodiment, a pooled apoptotic cell preparation is comprised of cells present in at least 25 units of blood, at least 50 units of blood, or at least 100 units of blood. Each possibility represents a separate embodiment as disclosed herein.

[0273] In one embodiment, the units of blood comprise white blood cell (WBC) fractions from blood donations. In another embodiment, the donations may be from a blood center or blood bank. In another embodiment, the donations may be from donors in a hospital gathered at the time of preparation of the pooled apoptotic cell preparation. In another embodiment, units of blood comprising WBCs from multiple donors are saved and maintained in an independent blood bank created for the purpose of compositions and methods thereof as disclosed herein. In another embodiment, a blood bank developed for the purpose of compositions and methods thereof as disclosed herein, is able to supply units of blood comprising WBC from multiple donors and comprises a leukapheresis unit.

[0274] In one embodiment, the units of pooled WBCs are not restricted by HLA matching. Therefore, the resultant pooled apoptotic cell preparation comprises cell populations not restricted by HLA matching. Accordingly, in certain embodiments a pooled mononuclear apoptotic cell preparation comprises allogeneic cells.

[0275] An advantage of a pooled mononuclear apoptotic cell preparation that is derived from pooled WBCs not restricted by HLA matching, is a readily available source of WBCs and reduced costs of obtaining WBCs.

[0276] In one embodiment, pooled blood comprises blood from multiple donors independent of HLA matching. In another embodiment, pooled blood comprises blood from multiple donors wherein HLA matching with the recipient has been taken into consideration. For example, wherein 1 HLA allele, 2 HLA alleles, 3 HLA alleles, 4 HLA alleles, 5 HLA alleles, 6 HLA alleles, or 7 HLA alleles have been matched between donors and recipient. In another embodiment, multiple donors are partially matched, for example some of the donors have been HLA matched wherein 1 HLA allele, 2 HLA alleles, 3 HLA alleles, 4 HLA alleles, 5 HLA alleles, 6 HLA alleles, or 7 HLA alleles have been matched between some of the donors and recipient. Each possibility comprises an embodiment as disclosed herein.

[0277] In certain embodiments, some viable non-apoptotic cells (apoptosis resistant) may remain

following the induction of apoptosis step described below. The presence of these viable non-apoptotic cells is, in one embodiment, observed prior to an irradiation step. These viable non-apoptotic cells may be able to proliferate or be activated. In one embodiment, the pooled mononuclear apoptotic cell preparation derived from multiple donors may be activated against the host, activated against one another, or both.

[0278] In one embodiment, an irradiated cell preparation as disclosed herein has suppressed cellular activation and reduced proliferation compared with a non-irradiated cell preparation. In another embodiment, the irradiation comprises gamma irradiation or UV irradiation. In another embodiment, an irradiated cell preparation has a reduced number of non-apoptotic cells compared with a non-irradiated cell preparation. In another embodiment, the irradiation comprises about 15 Grey units (Gy). In another embodiment, the irradiation comprises about 20 Grey units (Gy). In another embodiment, the irradiation comprises about 25 Grey units (Gy). In another embodiment, the irradiation comprises about 30 Grey units (Gy). In another embodiment, the irradiation comprises about 35 Grey units (Gy). In another embodiment, the irradiation comprises about 40 Grey units (Gy). In another embodiment, the irradiation comprises about 45 Grey units (Gy). In another embodiment, the irradiation comprises about 50 Grey units (Gy). In another embodiment, the irradiation comprises about 55 Grey units (Gy). In another embodiment, the irradiation comprises about 60 Grey units (Gy). In another embodiment, the irradiation comprises about 65 Grey units (Gy). In another embodiment, the irradiation comprises up to 2500 Gy. In another embodiment, an irradiated pooled apoptotic cell preparation maintains the same or a similar apoptotic profile, stability and efficacy as a non-irradiated pooled apoptotic cell preparation.

[0279] In one embodiment, a pooled mononuclear apoptotic cell preparation as disclosed herein is stable for up to 24 hours. In another embodiment, a pooled mononuclear apoptotic cell preparation is stable for at least 24 hours. In another embodiment, a pooled mononuclear apoptotic cell preparation is stable for more than 24 hours. In yet another embodiment, a pooled mononuclear apoptotic cell preparation as disclosed herein is stable for up to 36 hours. In still another embodiment, a pooled mononuclear apoptotic cell preparation is stable for at least 36 hours. In a further embodiment, a pooled mononuclear apoptotic cell preparation is stable for more than 36 hours. In another embodiment, a pooled mononuclear apoptotic cell preparation as disclosed herein is stable for up to 48 hours. In another embodiment, a pooled mononuclear apoptotic cell preparation is stable for at least 48 hours. In another embodiment, a pooled mononuclear apoptotic cell preparation is stable for more than 48 hours.

[0280] In one embodiment, methods of producing the pooled cell preparation comprising an irradiation step preserves the early apoptotic, immune modulation, and stability properties observed

in an apoptotic preparation derived from a single match donor wherein the cell preparation may not include an irradiation step. In another embodiment, a pooled mononuclear apoptotic cell preparation as disclosed herein does not elicit a graft versus host disease (GVHD) response.

[0281] Irradiation of the cell preparation is considered safe in the art. Irradiation procedures are currently performed on a routine basis to donated blood to prevent reactions to WBC.

[0282] In another embodiment, the percent of apoptotic cells in a pooled mononuclear apoptotic cell preparation as disclosed herein is close to 100%, thereby reducing the fraction of living non-apoptotic cells in the cell preparation. In one embodiment, the percent of apoptotic cells is at least 40%. In another embodiment, the percent of apoptotic cells is at least 50%. In yet another embodiment, the percent of apoptotic cells is at least 60%. In still another embodiment, the percent of apoptotic cells is at least 70%. In a further embodiment, the percent of apoptotic cells is at least 80%. In another embodiment, the percent of apoptotic cells is at least 90%. In yet another embodiment, the percent of apoptotic cells is at least 99%. Accordingly, a cell preparation comprising a reduced or non-existent fraction of living non-apoptotic cells may in one embodiment provide a pooled mononuclear apoptotic cell preparation that does not elicit GVHD in a recipient. Each possibility represents an embodiment as disclosed herein.

[0283] Alternatively, in another embodiment, the percentage of living non-apoptotic WBC is reduced by specifically removing the living cell population, for example by targeted precipitation. In another embodiment, the percent of living non-apoptotic cells may be reduced using magnetic beads that bind to phosphatidylserine. In another embodiment, the percent of living non-apoptotic cells may be reduced using magnetic beads that bind a marker on the cell surface of non-apoptotic cells but not apoptotic cells. In another embodiment, the apoptotic cells may be selected for further preparation using magnetic beads that bind to a marker on the cell surface of apoptotic cells but not non-apoptotic cells. In yet another embodiment, the percentage of living non-apoptotic WBC is reduced by the use of ultrasound.

[0284] In one embodiment the apoptotic cells are from pooled third party donors.

[0285] In one embodiment, a pooled cell preparation comprises at least one cell type selected from the group consisting of: lymphocytes, monocytes and natural killer cells. In another embodiment, a pooled cell preparation comprises an enriched population of mononuclear cells. In one embodiment, a pooled mononuclear is a mononuclear enriched cell preparation comprises cell types selected from the group consisting of: lymphocytes, monocytes and natural killer cells. In another embodiment, the mononuclear enriched cell preparation comprises no more than 15%, alternatively no more than 10%, typically no more than 5% polymorphonuclear leukocytes, also known as granulocytes (i.e., neutrophils, basophils and eosinophils). In another embodiment, a pooled mononuclear cell

preparation is devoid of granulocytes. Each possibility represents a separate embodiment as disclosed herein.

[0286] In another embodiment, the pooled mononuclear enriched cell preparation comprises no more than 15%, alternatively no more than 10%, typically no more than 5% CD15^{high} expressing cells. In one embodiment, a pooled apoptotic cell preparation comprises less than 15% CD15 high expressing cells. Each possibility represents a separate embodiment as disclosed herein.

[0287] In one embodiment, the pooled mononuclear enriched cell preparation disclosed herein comprises at least 80% mononuclear cells, at least 85% mononuclear cells, alternatively at least 90% mononuclear cells, or at least 95% mononuclear cells, wherein each possibility is a separate embodiment disclosed herein. According to some embodiments, the pooled mononuclear enriched cell preparation disclosed herein comprises at least 85% mononuclear cells.

[0288] In another embodiment, any pooled cell preparation that has a final pooled percent of mononuclear cells of at least 80% is considered a pooled mononuclear enriched cell preparation as disclosed herein. Thus, pooling cell preparations having increased polymorphonuclear cells (PMN) with cell preparations having high mononuclear cells with a resultant “pool” of at least 80% mononuclear cells comprises a preparation as disclosed herein. According to some embodiments, mononuclear cells comprise lymphocytes and monocytes.

[0289] A skilled artisan would appreciate that the term “mononuclear cells” may encompass leukocytes having a one lobed nucleus. In another embodiment, a pooled apoptotic cell preparation as disclosed herein comprises less than 5% polymorphonuclear leukocytes.

[0290] In one embodiment, the apoptotic cells are T-cells. In another embodiment, the apoptotic cells are derived from the same pooled third party donor T-cells as the CAR T-cells. In another embodiment, the apoptotic cells are derived from the CAR T-cell population.

[0291] Surprisingly, the apoptotic cells reduce production of cytokines associated with the cytokine storm including but not limited to IL-6, and interferon-gamma (IFN- γ), alone or in combination, while the effectiveness of CAR T-cell therapy was maintained (Example 2). In one embodiment, the apoptotic cells affect cytokine expression levels in macrophages. In another embodiment, the apoptotic cells reduce cytokine expression levels in macrophages. In one embodiment, the apoptotic cells suppress cytokine expression levels in macrophages. In one embodiment, the apoptotic cells inhibit cytokine expression levels in macrophages. In one embodiment, the apoptotic cells maintain IFN- γ levels to match or nearly match levels present prior to CAR –T cell administration. In another embodiment, apoptotic cells affect cytokine expression levels in macrophages but do not affect cytokine expression levels in the CAR T-cells. In another embodiment, the apoptotic cells affect cytokine expression levels in DCs, but do not affect cytokine expression levels in the CAR T-cells.

It was therefore unexpected that apoptotic cells would be useful in maintaining the effectiveness CAR T-cell therapy.

[0292] In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in reduction of CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in reduction of severe CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in suppression of CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in suppression of severe CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in inhibition of CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in inhibition of severe CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in prevention of CRS. In another embodiment, the effect of apoptotic cells on cytokine expression levels in macrophages, DCs, or a combination thereof, results in prevention of severe CRS.

[0293] In another embodiment, the apoptotic cells trigger death of T-cells, but not via changes in cytokine expression levels.

[0294] In another embodiment, apoptotic cells antagonize the priming of macrophages and dendritic cells to secrete cytokines that would otherwise amplify the cytokine storm. In another embodiment, apoptotic cells increase Tregs which suppress the inflammatory response and/or prevent excess release of cytokines.

295. In one embodiment, administration of apoptotic cells inhibits one or more pro-inflammatory cytokines. In one embodiment, the pro-inflammatory cytokine comprises IL-1beta, IL-6, TNF-alpha, or IFN-gamma, or any combination thereof. In another embodiment, administration of apoptotic cells promotes the secretion of one or more anti-inflammatory cytokines. In one embodiment, the anti-inflammatory cytokine comprises TGF-beta, IL10, or PGE2, or any combination thereof.

296. In another embodiment, administration of apoptotic cells inhibits dendritic cell maturation following exposure to TLR ligands. In another embodiment, administration of apoptotic cells creates potentially tolerogenic dendritic cells, which in one embodiment, are capable of migration, and in one embodiment, the migration is due to CCR7. In another embodiment, administration of apoptotic cells elicits various signaling events which in one embodiment is TAM receptor signaling (Tyro3, Axl and Mer) which in one embodiment, inhibits inflammation in antigen-presenting cells.

In one embodiment, Tyro-3, Axl, and Mer constitute the TAM family of receptor tyrosine kinases (RTKs) characterized by a conserved sequence within the kinase domain and adhesion molecule-like extracellular domains. In another embodiment, administration of apoptotic cells activates signaling through MerTK. In another embodiment, administration of apoptotic cells activates the phosphatidylinositol 3-kinase (PI3K)/AKT pathway, which in one embodiment, negatively regulates NF- κ B. In another embodiment, administration of apoptotic cells negatively regulates the inflammasome which in one embodiment leads to inhibition of pro-inflammatory cytokine secretion, DC maturation, or a combination thereof. In another embodiment, administration of apoptotic cells upregulates expression of anti-inflammatory genes such as *Nr4a*, *Thbs1*, or a combination thereof. In another embodiment, administration of apoptotic cells induces a high level of AMP which in one embodiment, is accumulated in a Pannexin1-dependent manner. In another embodiment, administration of apoptotic cells suppresses inflammation.

[0297] *Apoptotic Cell Supernatants (ApoSup and ApoSup Mon)*

[0298] In one embodiment, compositions for use in the methods and treatments as disclosed herein include an apoptotic cell supernatant as disclosed herein.

[0299] In some embodiments, the apoptotic cell supernatant is obtained by a method comprising the steps of a) providing apoptotic cells, b) culturing the apoptotic cells of step a), and c) separating the supernatant from the cells.

[0300] In one embodiment, apoptotic cells for use making an apoptotic cell supernatant as disclosed herein are autologous with a subject undergoing therapy. In another embodiment, apoptotic cells for use in making an apoptotic cell supernatant disclosed herein are allogeneic with a subject undergoing therapy.

[0301] The apoptotic cells from which the apoptotic cell supernatant is obtained may be cells chosen from any cell type of a subject, or any commercially available cell line, subjected to a method of inducing apoptosis known to the person skilled in the art. The method of inducing apoptosis may be hypoxia, ozone, heat, radiation, chemicals, osmotic pressure, pH shift, X-ray irradiation, gamma-ray irradiation, UV irradiation, serum deprivation, corticoids or combinations thereof, or any other method described herein or known in the art. In another embodiment, the method of inducing apoptosis produces apoptotic cells in an early apoptotic state.

[0302] In one embodiment, the apoptotic cells are leukocytes.

[0303] In an embodiment, said apoptotic leukocytes are derived from peripheral blood mononuclear cells (PBMC). In another embodiment, said leukocytes are from pooled third party donors. In another embodiment, said leukocytes are allogeneic.

[0304] According to one embodiment, the apoptotic cells are provided by selecting non-adherent

leukocytes and submitting them to apoptosis induction, followed by a cell culture step in culture medium. "Leukocytes" used to make the apoptotic cell-phagocyte supernatant may be derived from any lineage, or sub-lineage, of nucleated cells of the immune system and/or hematopoietic system, including but not limited to dendritic cells, macrophages, masT-cells, basophils, hematopoietic stem
5 cells, bone marrow cells, natural killer cells, and the like. The leukocytes may be derived or obtained in any of various suitable ways, from any of various suitable anatomical compartments, according to any of various commonly practiced methods, depending on the application and purpose, desired leukocyte lineage, etc. In one embodiment, the source leukocytes are primary leukocytes. In another embodiment, the source leukocytes are primary peripheral blood leukocytes.

10 [0305] Primary lymphocytes and monocytes may be conveniently derived from peripheral blood. Peripheral blood leukocytes include 70-95 percent lymphocytes, and 5-25 percent monocytes.

[0306] Methods for obtaining specific types of source leukocytes from blood are routinely practiced. Obtaining source lymphocytes and/or monocytes can be achieved, for example, by harvesting blood in the presence of an anticoagulant, such as heparin or citrate. The harvested blood
15 is then centrifuged over a Ficoll cushion to isolate lymphocytes and monocytes at the gradient interface, and neutrophils and erythrocytes in the pellet.

[0307] Leukocytes may be separated from each other via standard immunomagnetic selection or immunofluorescent flow cytometry techniques according to their specific surface markers, or via centrifugal elutriation. For example, monocytes can be selected as the CD14+ fraction, T-
20 lymphocytes can be selected as CD3+ fraction, B-lymphocytes can be selected as the CD19+ fraction, macrophages as the CD206+ fraction.

[0308] Lymphocytes and monocytes may be isolated from each other by subjecting these cells to substrate-adherent conditions, such as by static culture in a tissue culture-treated culturing recipient, which results in selective adherence of the monocytes, but not of the lymphocytes, to the cell-
25 adherent substrate.

[0309] Leukocytes may also be obtained from peripheral blood mononuclear cells (PBMCs), which may be isolated as described herein.

[0310] One of ordinary skill in the art will possess the necessary expertise to suitably culture primary leukocytes so as to generate desired quantities of cultured source leukocytes as disclosed
30 herein, and ample guidance for practicing such culturing methods is available in the literature of the art.

[0311] One of ordinary skill in the art will further possess the necessary expertise to establish, purchase, or otherwise obtain suitable established leukocyte cell lines from which to derive the apoptotic leukocytes. Suitable leukocyte cell lines may be obtained from commercial suppliers, such

as the American Tissue Type Collection (ATCC). It will be evident to the person skilled in the art that source leukocytes should not be obtained via a technique which will significantly interfere with their capacity to produce the apoptotic leukocytes.

5 [0312] In an embodiment, the apoptotic cells comprise a cell preparation comprising mononuclear-enriched cells, wherein the preparation comprises at least 85% mononuclear cells, wherein at least 40% of the cells in the preparation are in an early-apoptotic state, wherein at least 85% of the cells in the preparation are viable cells and wherein the preparation comprises no more than 15% CD15^{high} expressing cells.

10 [0313] In another embodiment, the apoptotic cells may be apoptotic lymphocytes. Apoptosis of lymphocytes, such as primary lymphocytes, may be induced by treating the primary lymphocytes with serum deprivation, a corticosteroid, or irradiation. In another embodiment, inducing apoptosis of primary lymphocytes via treatment with a corticosteroid is effected by treating the primary lymphocytes with dexamethasone. In another embodiment, with dexamethasone at a concentration of about 1 micromolar. In another embodiment, inducing apoptosis of primary lymphocytes via
15 irradiation is effected by treating the primary lymphocytes with gamma- irradiation. In another embodiment, with a dosage of about 66 rad. Such treatment results in the generation of apoptotic lymphocytes suitable for the co-culture step with phagocytes.

[0314] In a further embodiment, apoptotic cells may be apoptotic monocytes, such as primary monocytes. To generate apoptotic monocytes the monocytes are subjected to in vitro conditions of
20 substrate/surface-adherence under conditions of serum deprivation. Such treatment results in the generation of non-pro-inflammatory apoptotic monocytes suitable for the co-culture step with phagocytes.

[0315] In other embodiments, the apoptotic cells may be any apoptotic cells described herein, including allogeneic apoptotic cells, third party apoptotic cells, and pools of apoptotic cells.

25 [0316] In other embodiments, the apoptotic cell supernatant may be obtained through the co-culture of apoptotic cells with other cells.

[0317] Thus, in one embodiment, the apoptotic cell supernatant is an apoptotic cell supernatant obtained by a method comprising the steps of a) providing apoptotic cells, b) providing other cells, c) optionally washing the cells from step a) and b), d) co-culturing the cells of step a) and b), and
30 optionally e) separating the supernatant from the cells.

[0318] In one embodiment, the other cells co-cultured with the apoptotic cells are white blood cells.

[0319] Thus, in one embodiment, the apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant obtained by a method comprising the steps of a) providing apoptotic cells, b) providing white blood cells, c) optionally washing the cells from step a) and b), d) co-culturing the

cells of step a) and b), and optionally e) separating the supernatant from the cells.

[0320] In one embodiment, the white blood cells may be phagocytes, such as macrophages, monocytes or dendritic cells.

5 [0321] In one embodiment, the white blood cells may be B cells, T-cells, or natural killer (NK cells).

[0322] Thus, in one embodiment, compositions for use in the methods and treatments as disclosed herein include apoptotic cell-phagocyte supernatants as described in WO 2014/106666, which is incorporated by reference herein in its entirety. In another embodiment, apoptotic cell-phagocyte supernatants for use in compositions and methods as disclosed herein are produced in any way that
10 is known in the art.

[0323] In some embodiments, the apoptotic supernatant comprises an apoptotic cell-phagocyte supernatant that is obtained from a co-culture of phagocytes with apoptotic cells,

[0324] In some embodiments, the apoptotic cell-phagocyte supernatant is obtained by a method comprising the steps of a) providing phagocytes, b) providing apoptotic cells, c) optionally washing
15 the cells from step a) and b), d) co-culturing the cells of step a) and b), and optionally e) separating the supernatant from the cells. In some embodiments, an apoptotic supernatant comprises a supernatant produced by phagocytic cells that ingest the apoptotic cells.

[0325] The term "phagocytes" denotes cells that protect the body by ingesting (phagocytosing) harmful foreign particles, bacteria, and dead or dying cells. Phagocytes include for example cells
20 called neutrophils, monocytes, macrophages, dendritic cells, and mast T-cells, preferentially dendritic cells and monocytes/macrophages. The phagocytes may be dendritic cells (CD4+ HLA-DR+ Lineage- BDCA1 /BDCA3+), macrophages (CD14+ CD206+ HLA-DR+), or derived from monocytes (CD14+). Techniques to distinguish these different phagocytes are known to the person skilled in the art.

25 [0326] In an embodiment, monocytes are obtained by a plastic adherence step. Said monocytes can be distinguished from B and T-cells with the marker CD14+, whereas unwanted B cells express CD19+ and T-cells CD3+. After Macrophage Colony Stimulating Factor (M-CSF) induced maturation the obtained macrophages are in one embodiment, positive for the markers CD14+, CD206+, HLA-DR+.

30 [0327] In an embodiment, said phagocytes are derived from peripheral blood mononuclear cells (PBMC).

[0328] Phagocytes may be provided by any method known in the art for obtaining phagocytes. In one embodiment, phagocytes such as macrophages or dendritic cells can be directly isolated from a subject or be derived from precursor cells by a maturation step.

[0329] In one embodiment, macrophages may be directly isolated from the peritoneum cavity of a subject and cultured in complete RRPMI medium. Macrophages can also be isolated from the spleen.

5 [0330] Phagocytes are also obtainable from peripheral blood monocytes. In said example, monocytes when cultured differentiate into monocyte-derived macrophages upon addition of, without limitation to, macrophage colony stimulating factor (M-CSF) to the cell culture media.

[0331] For example, phagocytes may be derived from peripheral blood mononuclear cells (PBMC). For example, PBMC may be isolated from cytopheresis bag from an individual through Ficoll gradient centrifugation, plated in a cell-adherence step for 90 min in complete RPMI culture
10 medium (10% FBS, 1 % Penicillin/Streptomycin). Non-adherent T-cells are removed by a plastic adherence step, and adherent T-cells cultured in complete RPMI milieu supplemented with recombinant human M-CSF. After the culture period, monocyte-derived macrophages are obtained.

[0332] Phagocytes can be selected by a cell-adherence step. Said "cell adherence step" means that
15 the adhesion of the cultured cells to a surface, a cell adherent surface (e.g. a tissue culture dish, a matrix, a sac or bag with the appropriate type of nylon or plastic). A skilled artisan would appreciate that the term "Cell adherent surfaces" may encompass hydrophilic and negatively charged, and may be obtained in any of various ways known in the art, In another embodiment by modifying a polystyrene surface using, for example, corona discharge, or gas-plasma. These
20 processes generate highly energetic oxygen ions which graft onto the surface polystyrene chains so that the surface becomes hydrophilic and negatively charged. Culture recipients designed for facilitating cell-adherence thereto are available from various commercial suppliers (e.g. Corning, Perkin-Elmer, Fisher Scientific, Evergreen Scientific, Nunc, etc.).

[0333] B cells, T-cells and NK cells may be provided by any method known in the art for obtaining
25 such cells. In one embodiment, B cells, T-cells or NK cells can be directly isolated from a subject or be derived from precursor cells by a maturation step. In another embodiment, the B, T or NK cells can be from a B, T or NK cell line. One of ordinary skill in the art will possess the necessary expertise to establish, purchase, or otherwise obtain suitable established B cells, T-cells and NK cell lines. Suitable cell lines may be obtained from commercial suppliers, such as the American Tissue
30 Type Collection (ATCC).

[0334] In an embodiment, said apoptotic cells and said white blood cells, such as the phagocytes, B, T or NK cells, are cultured individually prior to the co-culture step d).

[0335] The cell maturation of phagocytes takes place during cell culture, for example due to addition of maturation factors to the media. In one embodiment said maturation factor is M-CSF,

which may be used for example to obtain monocyte-derived macrophages.

[0336] The culture step used for maturation or selection of phagocytes might take several hours to several days. In another embodiment said pre-mature phagocytes are cultured for 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44, 46, 48, 50, 52, 54, 56, 58 hours in an appropriate culture medium.

[0337] The culture medium for phagocytes is known to the person skilled in the art and can be for example, without limitation, RPMI, DMEM, X-vivo and Ultraculture milieus.

[0338] In an embodiment, co-culture of apoptotic cells and phagocytes takes place in a physiological solution.

10 [0339] Prior to this "co-culture", the cells may be submitted to a washing step. In one embodiment, the white blood cells (e.g. the phagocytes) and the apoptotic cells are washed before the co-culture step. In another embodiment, the cells are washed with PBS.

[0340] During said co-culture the white blood cells (e.g. the phagocytes such as macrophages, monocytes, or phagocytes, or the B, T or NK cells) and the apoptotic cells may be mixed in a ratio of 10:1, 9:1, 8:1, 7:1, 6:1, 5:1, 4:1, 3:1, 2:1, or 1 :1, or in a ratio of (white blood cells : apoptotic cells) 1:2, 1:3, 1:4, 1:5, 1:6, 1:7, 1:8, 1:9, or 1:10. In one example, the ratio of white blood cells to apoptotic cells is 1:5.

[0341] The co-culture of the cells might be for several hours to several days. In some embodiments, said apoptotic cells are cultured for 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44, 46, 48, 50, 52 hours. A person skilled in the art can evaluate the optimal time for co-culture by measuring the presence of anti-inflammatory compounds, the viable amount of white blood cells and the amount of apoptotic cells which have not been eliminated so far.

[0342] The elimination of apoptotic cells by phagocytes is observable with light microscopy due to the disappearance of apoptotic cells.

25 [0343] In one embodiment, the culture of apoptotic cells, such as the co-culture with culture with white blood cells (e.g. phagocytes such as macrophages, monocytes, or phagocytes, or the B, T or NK cells), takes place in culture medium and/or in a physiological solution compatible with administration e.g. injection to a subject.

[0344] A skilled artisan would appreciate that a "physiological solution" may encompass a solution which does not lead to the death of white blood cells within the culture time. In some embodiments, the physiological solution does not lead to death over 2, 4, 6, 8, 10, 12, 14, 16, 18, 20, 22, 24, 26, 28, 30, 32, 34, 36, 38, 40, 42, 44, 46, 48, 50, 52 hours. In other embodiment, 48 hours, or 30 hours.

[0345] In one embodiment, the white blood cells (e.g. phagocytes such as macrophages, monocytes, or phagocytes, or the B, T or NK cells) and the apoptotic cells are incubated in the

physiological solution for at least 30 min. This time of culture allows phagocytosis initiation and secretion of cytokines and other beneficial substances.

[0346] In an embodiment, such a physiological solution does not inhibit apoptotic leukocyte elimination by leukocyte-derived macrophages.

5 [0347] At the end of the culture or the co-culture step, the supernatant is optionally separated from the cultured apoptotic cells or the co-cultured cells. Techniques to separate the supernatant from the cells are known in the art. For example, the supernatant may be collected and/or filtered and/or centrifuged to eliminate cells and debris. For example, the supernatant may be centrifuged at 3000 rpm for 15 minutes at room temperature to separate it from the cells.

10 [0348] The supernatant may be "inactivated" prior to use, for example by irradiation. Therefore, the method for preparing the apoptotic cell supernatant may comprise an optional additional irradiation step f). Said "irradiation" step can be considered as a disinfection method that uses X-ray irradiation (25-45 Gy) at sufficiently rate to kill microorganisms, as routinely performed to inactivate blood products.

15 [0349] Irradiation of the supernatant is considered safe in the art. Irradiation procedures are currently performed on a routine basis to donated blood to prevent reactions to WBC.

[0350] In one embodiment, the apoptotic cell supernatant is formulated into a pharmaceutical composition suitable for administration to a subject, as described in detail herein.

20 [0351] In one embodiment, the final product is stored at +4°C. In another embodiment, the final product is for use in the next 48 hours.

[0352] In one embodiment, the apoptotic cell supernatant, such as an apoptotic cell-phagocyte supernatant, or pharmaceutical composition comprising the supernatant, may be lyophilized, for example for storage at -80 °C.

25 [0353] In one specific embodiment, as described in Example 1 of WO 2014/106666, an apoptotic cell-phagocyte supernatant may be made using thymic cells as apoptotic cells. After isolation, thymic cells are irradiated (e.g. with a 35 X-Gray irradiation) and cultured in complete DMEM culture medium for, for example, 6 hours to allow apoptosis to occur. In parallel, macrophages are isolated from the peritoneum cavity, washed and cultured in complete RPMI (10% FBS, Peni-Strepto, EAA, Hepes, NaP and 2-MercaptoEthanol). Macrophages and apoptotic cells are then
30 washed and co-cultured for another 48 hour period in phenol-free X-vivo medium at a 1/5 macrophage/apoptotic cell ratio. Then, supernatant is collected, centrifuged to eliminate debris and may be frozen or lyophilized for conservation. Macrophage enrichment may be confirmed using positive staining for F4/80 by FACS. Apoptosis may be confirmed by FACS using positive staining for Annexin-V and 7AAD exclusion.

[0354] In an embodiment, the apoptotic cell supernatant is enriched in TGF- β levels both in active and latent forms of TGF- β , compared to supernatants obtained from either macrophages or apoptotic cells cultured separately. In an embodiment, IL-10 levels are also increased compared to macrophages cultured alone and dramatically increased compared to apoptotic cells cultured alone.

5 In another embodiment, inflammatory cytokines such as IL-6 are not detectable and IL-1 β and TNF are undetectable or at very low levels.

[0355] In an embodiment, the apoptotic cell supernatant, when compared to supernatants from macrophages cultured alone or from apoptotic cells cultured alone, has increased levels of IL-1 α , TIMP-1, CXCL1/KC and CCL2/JE/MCP1, which might be implicated in a tolerogenic role of the
10 supernatant to control inflammation, in addition to TGF- β and IL-10.

[0356] In another specific embodiment, as described in Example 3 of WO 2014/106666, human apoptotic cell-phagocyte supernatant may be made from the co-culture of macrophages derived from peripheral blood mononuclear cells (PBMC) cultured with apoptotic PBMC. Thus, PBMC are isolated from cytopheresis bag from a healthy volunteer through, for example, Ficoll gradient
15 centrifugation. Then PBMC are plated for 90 min in complete RPMI culture medium (10% FBS, 1 % Penicillin/Streptomycin). Then, non-adherent-cells are removed and rendered apoptotic using, for example, a 35 Gy dose of X-ray irradiation and cultured in complete RPMI milieu for 4 days (including cell wash after the first 48 hrs of culture), in order to allow apoptosis to occur. In parallel, non-adherent T-cells are cultured in complete RPMI milieu supplemented with 50 μ g/mL of
20 recombinant human M-CSF for 4 days including cell wash after the first 48 hrs. At the end of the 4-day culture period, monocyte-derived macrophages and apoptotic cells are washed and cultured together in X-vivo medium for again 48 hours at a one macrophage to 5 apoptotic cell ratio. Then supernatant from the latter culture is collected, centrifuged to eliminate cells and debris, and may be frozen or lyophilized for conservation and subsequent use.

25 [0357] In an embodiment, as described in WO 2014/106666, human apoptotic cell-phagocyte supernatant may be obtained in 6 days from peripheral blood mononuclear cells (PBMC). Four days to obtain PBMC- derived macrophages using M-CSF addition in the culture, and 2 more days for the co-culture of PBMC-derived macrophages with apoptotic cells, corresponding to the non-adherent PBMC isolated at day 0.

30 [0358] In an embodiment, as described in WO 2014/106666, a standardized human apoptotic cell-phagocyte supernatant may be obtained independently of the donor or the source of PBMC (cytopheresis or buffy coat). The plastic-adherence step is sufficient to obtain a significant starting population of enriched monocytes (20 to 93% of CD14+ cells after adherence on plastic culture dish). In addition, such adherent cells demonstrate a very low presence of B and T-cells (1.0% of

CD19+ B cells and 12.8% of CD3+ T-cells). After 4 days of culture of T-cells in the presence of M-CSF, the proportion of monocytes derived- macrophages is significantly increased from 0.1 % to 77.7% of CD14+CD206+HLA-DR+ macrophages. At that time, monocyte-derived macrophages may be co-cultured with apoptotic non-adherent PBMC (47.6% apoptotic as shown by annexin V staining and 7AAD exclusion) to produce the apoptotic cell-phagocyte supernatant during 48 hours. [0359] In an embodiment, the collected apoptotic cell-phagocyte supernatant, contains significantly more latent TGF than in the culture supernatant of monocyte-derived macrophages alone or monocyte-derived macrophages treated in inflammatory conditions (+ LPS), and only contains trace or low level of inflammatory cytokines such as IL-1 β or TNF.

[0360] In one embodiment, the composition comprising the apoptotic cell supernatant further comprises an anti-coagulant. In one embodiment, the anti-coagulant is selected from the group consisting of: heparin, acid citrate dextrose (ACD) Formula A and a combination thereof.

[0361] In another embodiment, an anti-coagulant is added during the process of manufacturing apoptotic cells. In another embodiment, the anti-coagulant added is selected from the group comprising ACD and heparin, or any combination thereof. In another embodiment, ACD is at a concentration of 1%. In another embodiment, ACD is at a concentration of 2%. In another embodiment, ACD is at a concentration of 3%. In another embodiment, ACD is at a concentration of 4%. In another embodiment, ACD is at a concentration of 5%. In another embodiment, ACD is at a concentration of 6%. In another embodiment, ACD is at a concentration of 7%. In another embodiment, ACD is at a concentration of 8%. In another embodiment, ACD is at a concentration of 9%. In another embodiment, ACD is at a concentration of 10%. In another embodiment, ACD is at a concentration of between about 1-10%. In another embodiment, ACD is at a concentration of between about 2-8 %. In another embodiment, ACD is at a concentration of between about 3-7%. In another embodiment, ACD is at a concentration of between about 1-5%. In another embodiment,

ACD is at a concentration of between about 5-10%. In another embodiment, heparin is at a final concentration of 0.5 U/ml. In another embodiment, heparin is at a final concentration of about 0.1 U/ml-1.0 U/ml. In another embodiment, heparin is at a final concentration of about 0.2 U/ml-0.9 U/ml. In another embodiment, heparin is at a final concentration of about 0.3 U/ml-0.7 U/ml. In another embodiment, heparin is at a final concentration of about 0.1 U/ml-0.5 U/ml. In another embodiment, heparin is at a final concentration of about 0.5 U/ml-1.0 U/ml. In another embodiment, heparin is at a final concentration of about 0.01 U/ml-1.0 U/ml. In another embodiment, heparin is at a final concentration of 0.1 U/ml. In another embodiment, heparin is at a final concentration of 0.2 U/ml. In another embodiment, heparin is at a final concentration of 0.3 U/ml. In another embodiment, heparin is at a final concentration of 0.4 U/ml. In another

embodiment, heparin is at a final concentration of 0.5 U/ml. In another embodiment, heparin is at a final concentration of 0.6 U/ml. In another embodiment, heparin is at a final concentration of 0.7 U/ml. In another embodiment, heparin is at a final concentration of 0.8 U/ml. In another embodiment, heparin is at a final concentration of 0.9 U/ml. In another embodiment, heparin is at a final concentration of 1.0 U/ml. In another embodiment, ACD is at a concentration of 5% and heparin is at a final concentration of 0.5 U/ml.

[0362] In one embodiment, the composition comprising the apoptotic cell supernatant further comprises methylprednisolone. At one embodiment, the concentration of methylprednisolone does not exceed 30 µg/ml.

[0363] In one embodiment, the composition may be used at a total dose or aliquot of apoptotic cell supernatant derived from the co-culture of about 14×10^9 of CD45+ cells obtained by cytopheresis equivalent to about 200 million of cells per kilogram of body weight (for a 70 kg subject). In an embodiment, such a total dose is administered as unit doses of supernatant derived from about 100 million cells per kilogram body weight, and/or is administered as unit doses at weekly intervals, In another embodiment both of which. Suitable total doses according to this embodiment include total doses of supernatant derived from about 10 million to about 4 billion cells per kilogram body weight. In another embodiment, the supernatant is derived from about 40 million to about 1 billion cells per kilogram body weight. In yet another embodiment the supernatant is derived from about 80 million to about 500 million cells per kilogram body weight. In still another embodiment, the supernatant is derived from about 160 million to about 250 million cells per kilogram body weight. Suitable unit doses according to this embodiment include unit doses of supernatant derived from about 4 million to about 400 million cells per kilogram body weight. In another embodiment, the supernatant is derived from about 8 million to about 200 million cells per kilogram body weight. In another embodiment, the supernatant is derived from about 16 million to about 100 million cells per kilogram body weight. In yet another embodiment, the supernatant is derived from about 32 million to about 50 million cells per kilogram body weight.

[0364] In another embodiment, a dose of apoptotic cell supernatant derived from the co-culture of about 10×10^6 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^7 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^8 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^9 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^{10} apoptotic cells is administered. In another embodiment, a dose derived from 10×10^{11} apoptotic cells is administered. In another embodiment, a dose derived from 10×10^{12} apoptotic cells is administered. In another embodiment, a dose derived from 10×10^5 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^4

apoptotic cells is administered. In another embodiment, a dose derived from 10×10^3 apoptotic cells is administered. In another embodiment, a dose derived from 10×10^2 apoptotic cells is administered. [0365] In one embodiment, a dose of apoptotic cell supernatant derived from 35×10^6 apoptotic cells is administered. In another embodiment, a dose derived from 210×10^6 apoptotic cells is administered. In another embodiment, a dose derived from 70×10^6 apoptotic cells is administered. In another embodiment, a dose derived from 140×10^6 apoptotic cells is administered. In another embodiment, a dose derived from $35-210 \times 10^6$ apoptotic cells is administered.

[0366] In one embodiment, the apoptotic cell supernatant, or composition comprising said apoptotic cell supernatant, may be administered by any method known in the art including, but not limited to, intravenous, subcutaneous, intranodal, intratumoral, intrathecal, intrapleural, intraperitoneal and directly to the thymus, as discussed in detail herein.

[0367] Surprisingly, the apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants, reduces production of cytokines associated with the cytokine storm such as IL-6. Another cytokine, IL-2, is not involved in cytokine release syndrome although is secreted by DCs and macrophages in small quantities. It is, however, required for the survival and proliferation of CAR-T-cells and is mostly produced by these T-cells. Unexpectedly, the apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants, do not reduce IL-2 levels sufficiently to negatively affect the survival of CAR T-cells.

[0368] In one embodiment, the apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants, affect cytokine expression levels in macrophages and DCs, but do not affect cytokine expression levels in the T-cells themselves. It was therefore unexpected that apoptotic cell supernatants would be useful in enhancing CAR T-cell therapy or .

[0369] In another embodiment, the apoptotic cell supernatants trigger death of T-cells, but not via changes in cytokine expression levels.

[0370] In another embodiment, apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants antagonize the priming of macrophages and dendritic cells to secrete cytokines that would otherwise amplify the cytokine storm. In another embodiment, apoptotic cell supernatants increase Tregs which suppress the inflammatory response and/or prevent excess release of cytokines.

[0371] In one embodiment, administration of apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants, inhibits one or more pro-inflammatory cytokines. In one embodiment, the pro-inflammatory cytokine comprises IL-1beta, IL-6, TNF-alpha, or IFN-gamma, or any combination thereof. In another embodiment, administration of apoptotic cell supernatants promotes the secretion of one or more anti-inflammatory cytokines. In one embodiment, the anti-

inflammatory cytokine comprises TGF-beta, IL10, or PGE2, or any combination thereof.

[0372] In another embodiment, administration of apoptotic cell supernatants, such as apoptotic cell-phagocyte supernatants, inhibits dendritic cell maturation following exposure to TLR ligands. In another embodiment, administration of apoptotic cell supernatants creates potentially tolerogenic dendritic cells, which in one embodiment, are capable of migration, and in one embodiment, the migration is due to CCR7. In another embodiment, administration of apoptotic cell supernatants elicits various signaling events which in one embodiment is TAM receptor signaling (Tyro3, Axl and Mer) which in one embodiment, inhibits inflammation in antigen-presenting cells. In one embodiment, Tyro-3, Axl, and Mer constitute the TAM family of receptor tyrosine kinases (RTKs) characterized by a conserved sequence within the kinase domain and adhesion molecule-like extracellular domains. In another embodiment, administration of apoptotic cell supernatants activates signaling through MerTK. In another embodiment, administration of apoptotic cell supernatants activates the phosphatidylinositol 3-kinase (PI3K)/AKT pathway, which in one embodiment, negatively regulates NF- κ B. In another embodiment, administration of apoptotic cell supernatants negatively regulates the inflammasome which in one embodiment leads to inhibition of pro-inflammatory cytokine secretion, DC maturation, or a combination thereof. In another embodiment, administration of apoptotic cell supernatants upregulates expression of anti-inflammatory genes such as *Nr4a*, *Thbs1*, or a combination thereof. In another embodiment, administration of apoptotic cell supernatants induces a high level of AMP which in one embodiment, is accumulated in a Pannexin1-dependent manner. In another embodiment, administration of apoptotic cell supernatants suppresses inflammation.

[0373] *Compositions*

[0374] In one embodiment, disclosed herein is a pharmaceutical composition for the treatment of a condition or disease as described herein. In another embodiment, pharmaceutical compositions disclosed here are for maintaining or increasing the proliferation rate of a genetically modified immune cells. In a further embodiment, methods for maintaining or increasing the proliferation rate of genetically modified immune cells further comprise reducing or inhibiting the incidence of cytokine release syndrome (CRS) or cytokine storm. In another embodiment, disclosed herein are pharmaceutical compositions for increasing the efficacy of a genetically modified immune cell therapy. In another embodiment, compositions used in the methods for increasing the efficacy of an immune cell therapy further comprise reducing or inhibiting the incidence of CRS or a cytokine storm. In another embodiment, disclosed herein are compositions for methods treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer of a tumor in a subject. In another embodiment, compositions used in the methods for treating, preventing, reducing the

incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, further comprise reducing or inhibiting the incidence of CRS or a cytokine storm.

[0375] In another embodiment, a pharmaceutical composition comprises a genetically modified immune cell or a genetically modified receptor thereof. In another embodiment, a genetically modified immune cell comprises a T-cell. In another embodiment, a genetically modified immune cell comprises a chimeric antigen receptor CAR T-cell. In another embodiment, a genetically modified immune cell comprises a chimeric antigen receptor TCR T-cell. In another embodiment, a genetically modified immune cell comprises a cytotoxic T lymphocyte. In another embodiment, a genetically modified immune cell comprises a dendritic cell. In another embodiment, a genetically modified immune cell comprises a natural killer cell. In another embodiment, a genetically modified receptor comprises a genetically modified T-cell receptor.

[0376] In still another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a genetically modified immune cell or a genetically modified receptor thereof, as described herein in a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a CAR T-cell as described herein in, and a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a TCR T-cell as described herein in, and a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a cytotoxic T-cell, as described herein, and a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a genetically modified dendritic cell, as described herein, and a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a genetically modified natural killer cell, as described herein, and a pharmaceutically acceptable excipient. In another embodiment, a pharmaceutical composition for the treatment of a condition or a disease as described herein comprises an effective amount of a genetically modified T-cell receptor, as described herein, and a pharmaceutically acceptable excipient.

[0377] In another embodiment, the condition or disease as described herein is a tumor or cancer. In another embodiment, disclosed herein is a composition comprising the genetically modified immune cell or receptor thereof, for example a CAR T-cell, that binds to a protein or peptide of interest as described herein. In another embodiment, disclosed herein is a composition comprising

the genetically modified immune cell or receptor thereof, for example a TCR T-cell, that recognizes and binds a protein or peptide of interest as described herein. In another embodiment, the protein or peptide of interest comprises a tumor antigen or a fragment thereof.

[0378] In another embodiment, a composition disclosed herein and used in methods disclosed
5 herein comprises apoptotic cells or an apoptotic cell supernatant, and a pharmaceutically acceptable excipient. In yet another embodiment, a composition comprising an effective amount of a genetically modified immune cell or a genetically modified receptor thereof may be the same composition as comprises an apoptotic cell population or an apoptotic cell supernatant. In another
10 embodiment, a composition comprising an effective amount of a CAR T-cell, or a TCR T-cell, or a cytotoxic T-cell, or a genetically modified dendritic cell, or a genetically modified natural killer cell may be the same composition as comprises an apoptotic cell population or an apoptotic cell supernatant. In yet another embodiment, a composition comprising an effective amount of
15 genetically modified T-cell receptor may be the same composition as comprises an apoptotic cell population or an apoptotic cell supernatant. In still another embodiment, a composition comprising an effective amount of a genetically modified immune cell selected from the group comprising a CAR T-cell, a TCR T-cell, a cytotoxic T-cell, a natural killer cell, or a dendritic cell, is not the same
20 composition as comprises an apoptotic cell population or an apoptotic cell supernatant. In another embodiment, a composition comprises a chimeric antigen receptor-expressing T-cell (CAR T-cell) and either apoptotic cells or an apoptotic cell supernatant, and a pharmaceutically acceptable excipient. In another embodiment, a composition comprises a genetically modified T-cell receptor
expressing T-cell (TCR T-cell) and either apoptotic cells or an apoptotic cell supernatant, and a pharmaceutically acceptable excipient. In another embodiment, a composition comprising an effective amount of a genetically modified T-cell receptor is not the same composition as comprises
an apoptotic cell population or an apoptotic cell supernatant.

[0379] In another embodiment, apoptotic cells comprised in a composition comprise apoptotic cells
25 in an early apoptotic state. In another embodiment, apoptotic cells comprised in a composition are pooled third party donor cells. In another embodiment, an apoptotic cell supernatant comprised in a composition disclosed herein is collected from early apoptotic cells. In another embodiment, an apoptotic cell supernatant comprised in a composition disclosed herein, is collected pooled third
30 party donor cells.

[0380] In one embodiment, a composition comprising a genetically modified immune cells, for example a CAR T-cell, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically

modified immune cells, for example a CAR T-cell, and apoptotic cells further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a CAR T-cell, and an apoptotic cell supernatant, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm.

[0381] In one embodiment, a composition comprising a genetically modified immune cells, for example a TCR T-cell, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a TCR T-cell, and apoptotic cells further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a TCR T-cell, and an apoptotic cell supernatant, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm.

[0382] In one embodiment, a composition comprising a genetically modified immune cells, for example a dendritic cell, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a dendritic, and apoptotic cells further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a dendritic, and an apoptotic cell supernatant, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm.

[0383] In one embodiment, a composition comprising a genetically modified immune cells, for example a NK cell, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a NK cell, and apoptotic cells further comprises an additional

pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm. In another embodiment, a composition comprising a genetically modified immune cells, for example a NK cell, and an apoptotic cell supernatant, further comprises an additional pharmaceutical composition for preventing, suppressing, or modulating cytokine release in a patient with cytokine release syndrome or experiencing a cytokine storm.

[0384] In one embodiment, the additional pharmaceutical composition comprises a CTLA-4 blocking agent, which in one embodiment is Ipilimumab. In another embodiment, the additional pharmaceutical composition comprises a alpha-1 anti-trypsin, as disclosed herein, or a fragment thereof, or an analogue thereof. In another embodiment, the additional pharmaceutical composition comprises a tellurium-based compound, as disclosed herein. In another embodiment, the additional pharmaceutical composition comprises an immune modulating agent, as disclosed herein. In another embodiment, the additional pharmaceutical composition comprises a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating compound, or any combination thereof.

[0385] In one embodiment, the composition comprising the genetically modified immune cell, for example a CAR T-cell and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent comprises a single composition. In another embodiment, the composition comprising the genetically modified immune cell, for example CAR T-cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein each of the genetically modified immune cell, which in one embodiment is CAR T-cells, the CTLA-4 blocking agent, the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the apoptotic cells, the apoptotic cell supernatant, the tellurium-based compound, or the immune modulating agent, or any combination thereof, are comprised in a separate composition. In yet another embodiment, the composition comprising the genetically modified immune cell, which in one embodiment is CAR T-cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein the genetically modified immune cells, which in one embodiment are CAR T-cells, the CTLA-4 blocking agent, or the alpha-1 anti-trypsin or

fragment thereof or analogue thereof, the tellurium-based compound, or the immune modulating agent, or any combination thereof, or any combination thereof are present in the genetically modified immune cell, for example a CAR T-cell, composition, and the apoptotic cells, or the apoptotic cell supernatant, are comprised in a separate composition.

5 [0386] In one embodiment, the composition comprising the genetically modified immune cell, for example a TCR T-cell and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent comprises a single composition. In another embodiment, the composition comprising the genetically modified immune cell, for example TCR T-cells and the pharmaceutical composition comprising
10 any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein each of the genetically modified immune cell, which in one embodiment is TCR T-cells, the CTLA-4
15 blocking agent, the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the apoptotic cells, the apoptotic cell supernatant, the tellurium-based compound, or the immune modulating agent, or any combination thereof, are comprised in a separate composition. In yet another embodiment, the composition comprising the genetically modified immune cell, which in one embodiment is TCR T-cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an
20 alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein the genetically modified immune cells, which in one embodiment are TCR T-cells, the CTLA-4 blocking agent, or the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the tellurium-based compound, or the immune modulating
25 agent, or any combination thereof, or any combination thereof are present in the genetically modified immune cell, for example a TCR T-cell, composition, and the apoptotic cells, or the apoptotic cell supernatant, are comprised in a separate composition.

[0387] In one embodiment, the composition comprising the genetically modified immune cell, for example a dendritic cell and the pharmaceutical composition comprising any one of a CTLA-4
30 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent comprises a single composition. In another embodiment, the composition comprising the genetically modified immune cell, for example dendritic cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue

thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein each of the genetically modified immune cell, which in one embodiment is dendritic cells, the CTLA-4 blocking agent, the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the apoptotic cells, the apoptotic cell supernatant, the tellurium-based compound, or the immune modulating agent, or any combination thereof, are comprised in a separate composition. In yet another embodiment, the composition comprising the genetically modified immune cell, which in one embodiment is dendritic cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein the genetically modified immune cells, which in one embodiment are dendritic cells, the CTLA-4 blocking agent, or the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the tellurium-based compound, or the immune modulating agent, or any combination thereof, or any combination thereof are present in the genetically modified immune cell, for example a dendritic cell, composition, and the apoptotic cells, or the apoptotic cell supernatant, are comprised in a separate composition.

[0388] In one embodiment, the composition comprising the genetically modified immune cell, for example a NK cell and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent comprises a single composition. In another embodiment, the composition comprising the genetically modified immune cell, for example NK cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, or an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein each of the genetically modified immune cell, which in one embodiment is NK cells, the CTLA-4 blocking agent, the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the apoptotic cells, the apoptotic cell supernatant, the tellurium-based compound, or the immune modulating agent, or any combination thereof, are comprised in a separate composition. In yet another embodiment, the composition comprising the genetically modified immune cell, which in one embodiment is NK cells and the pharmaceutical composition comprising any one of a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, apoptotic cells, an apoptotic cell supernatant, a tellurium-based compound, or an immune modulating agent, or any combination thereof, comprises multiple compositions, wherein the genetically modified immune cells, which in

one embodiment are NK cells, the CTLA-4 blocking agent, or the alpha-1 anti-trypsin or fragment thereof or analogue thereof, the tellurium-based compound, or the immune modulating agent, or any combination thereof, or any combination thereof are present in the genetically modified immune cell, for example a NK cell, composition, and the apoptotic cells, or the apoptotic cell supernatant, are comprised in a separate composition.

[0389] A skilled artisan would appreciate that a "pharmaceutical composition" may encompass a preparation of one or more of the active ingredients described herein with other chemical components such as physiologically suitable carriers and excipients. The purpose of a pharmaceutical composition is to facilitate administration of a compound to an organism.

[0390] A skilled artisan would appreciate that the phrases "physiologically acceptable carrier", "pharmaceutically acceptable carrier", "physiologically acceptable excipient", and "pharmaceutically acceptable excipient", may be used interchangeably may encompass a carrier, excipient, or a diluent that does not cause significant irritation to an organism and does not abrogate the biological activity and properties of the administered active ingredient.

[0391] A skilled artisan would appreciate that an "excipient" may encompass an inert substance added to a pharmaceutical composition to further facilitate administration of an active ingredient. In one embodiment, excipients include calcium carbonate, calcium phosphate, various sugars and types of starch, cellulose derivatives, gelatin, vegetable oils and polyethylene glycols.

[0392] Techniques for formulation and administration of drugs are found in "Remington's Pharmaceutical Sciences," Mack Publishing Co., Easton, PA, latest edition, which is incorporated herein by reference.

[0393] In one embodiment, compositions are administered at the same time. In an alternative embodiment, compositions are administered at different times. In another embodiment, compositions comprising apoptotic cells are administered prior to infusion or genetically modified immune cells or receptors thereof. In another embodiment, compositions comprising apoptotic cells are administered prior to CAR- T-cell infusion. In another embodiment, compositions comprising apoptotic cells are administered prior to cytotoxic T-cell infusion. In another embodiment, compositions comprising apoptotic cells are administered prior to natural killer cell infusion. In another embodiment, compositions comprising apoptotic cells are administered prior to dendritic infusion. In another embodiment, compositions comprising apoptotic cells are administered prior to infusion of a genetically modified T-cell receptor.

[0394] In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to infusion or genetically modified immune cells or receptors thereof. In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to CAR-

T-cell infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to cytotoxic T-cell infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to natural killer cell infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to dendritic infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to infusion of a genetically modified T-cell receptor.

[0395] In another embodiment, compositions comprising apoptotic cell supernatants are administered prior to infusion of genetically modified immune cells or receptors thereof. In another embodiment, compositions comprising apoptotic cells are administered about 24 hours prior to genetically modified immune cell or receptor thereof infusion. In another embodiment, compositions comprising apoptotic cells are administered about 24 hours prior to CAR T-cell, or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered about 24 hours prior to CAR T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cells are administered about 2 hours, 4 hours, 6 hours, 8 hours, 10 hours, 12 hours, 14 hours, 16 hours, 18 hours 20 hours, 22 hours, 24 hours, 36 hours, 48 hours, 60 hours, or 72 hours prior to CAR- T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered about 2 hours, 4 hours, 6 hours, 8 hours, 10 hours, 12 hours, 14 hours, 16 hours, 18 hours 20 hours, 22 hours, 24 hours, 36 hours, 48 hours, 60 hours, or 72 hours prior to CAR T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. Each possibility represents a separate embodiment as disclosed herein.

[0396] In another embodiment, compositions comprising apoptotic cells are administered after infusion of genetically modified immune cells or genetically modified receptors thereof. In another embodiment, composition comprising apoptotic cells are administered after CAR- T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered after infusion of genetically modified immune cells or genetically modified receptors thereof. In another embodiment, compositions comprising apoptotic cell supernatants are administered after CAR T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cells are administered about 24 hours after CAR-T-cell or cytotoxic T-cells, or

TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cells are administered after infusion of genetically modified immune cells or genetically modified receptors thereof.. In another embodiment, compositions comprising apoptotic cell supernatants are administered about 24 hours
5 after CAR T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cells are administered about 2 hours, 4 hours, 6 hours, 8 hours, 10 hours, 12 hours, 14 hours, 16 hours, 18 hours 20 hours, 22 hours, 24 hours, 36 hours, 48 hours, 60 hours, or 72 hours after CAR- T-cell or cytotoxic T-cells, or TCR T-cells, or natural killer cells, or dendritic cell or
10 genetically modified T-cell receptor infusion. In another embodiment, compositions comprising apoptotic cell supernatants are administered about 2 hours, 4 hours, 6 hours, 8 hours, 10 hours, 12 hours, 14 hours, 16 hours, 18 hours 20 hours, 22 hours, 24 hours, 36 hours, 48 hours, 60 hours, or 72 hours after CAR T-cell or cytotoxic T-cells, or natural killer cells, or dendritic cell or genetically modified T-cell receptor infusion. Each possibility represents a separate embodiment as disclosed
15 herein.

[0397] *Formulations*

[0398] Compositions disclosed herein comprising genetically modified immunoresponsive cells or comprising the apoptotic cells or comprising the apoptotic cell supernatants, or any combination thereof, can be conveniently provided as sterile liquid preparations, e.g., isotonic aqueous solutions,
20 suspensions, emulsions, dispersions, or viscous compositions, which may be buffered to a selected pH. Liquid preparations are normally easier to prepare than gels, other viscous compositions, and solid compositions. Additionally, liquid compositions are somewhat more convenient to administer, especially by injection. Viscous compositions, on the other hand, can be formulated within the appropriate viscosity range to provide longer contact periods with specific tissues. Liquid or viscous
25 compositions can comprise carriers, which can be a solvent or dispersing medium containing, for example, water, saline, phosphate buffered saline, polyol (for example, glycerol, propylene glycol, liquid polyethylene glycol, and the like) and suitable mixtures thereof.

[0399] Sterile injectable solutions can be prepared by incorporating the genetically modified immunoresponsive cells or apoptotic cell supernatants utilized in practicing the methods disclosed
30 herein, in the required amount of the appropriate solvent with various amounts of the other ingredients, as desired. Such compositions may be in admixture with a suitable carrier, diluent, or excipient such as sterile water, physiological saline, glucose, dextrose, or the like. The compositions can also be lyophilized. The compositions can contain auxiliary substances such as wetting, dispersing, or emulsifying agents (e.g., methylcellulose), pH buffering agents, gelling or viscosity

enhancing additives, preservatives, flavoring agents, colors, and the like, depending upon the route of administration and the preparation desired. Standard texts, such as "REMINGTON'S PHARMACEUTICAL SCIENCE", 17th edition, 1985, incorporated herein by reference, may be consulted to prepare suitable preparations, without undue experimentation.

5 [0400] Various additives which enhance the stability and sterility of the compositions, including antimicrobial preservatives, antioxidants, chelating agents, and buffers, can be added. Prevention of the action of microorganisms can be ensured by various antibacterial and antifungal agents, for example, parabens, chlorobutanol, phenol, sorbic acid, and the like. Prolonged absorption of the injectable pharmaceutical form can be brought about by the use of agents delaying absorption, for
10 example, aluminum monostearate and gelatin. According to the disclosure herein, however, any vehicle, diluent, or additive used would have to be compatible with the genetically modified immunoresponsive cells or their progenitors.

[0401] The compositions can be isotonic, i.e., they can have the same osmotic pressure as blood and lacrimal fluid. The desired isotonicity of the compositions as disclosed herein may be
15 accomplished using sodium chloride, or other pharmaceutically acceptable agents such as dextrose, boric acid, sodium tartrate, propylene glycol or other inorganic or organic solutes. Sodium chloride may be preferred particularly for buffers containing sodium ions.

[0402] Viscosity of the compositions, if desired, can be maintained at the selected level using a pharmaceutically acceptable thickening agent. Methylcellulose may be preferred because it is
20 readily and economically available and is easy to work with.

[0403] Other suitable thickening agents include, for example, xanthan gum, carboxymethyl cellulose, hydroxypropyl cellulose, carbomer, and the like. The preferred concentration of the thickener will depend upon the agent selected. The important point is to use an amount that will achieve the selected viscosity. Obviously, the choice of suitable carriers and other additives will
25 depend on the exact route of administration and the nature of the particular dosage form, e.g., liquid dosage form (e.g., whether the composition is to be formulated into a solution, a suspension, gel or another liquid form, such as a time release form or liquid-filled form).

[0404] Those skilled in the art will recognize that the components of the compositions should be selected to be chemically inert and will not affect the viability or efficacy of the genetically
30 modified immunoresponsive cells as described in the methods disclosed herein. This will present no problem to those skilled in chemical and pharmaceutical principles, or problems can be readily avoided by reference to standard texts or by simple experiments (not involving undue experimentation), from this disclosure and the documents cited herein.

[0405] One consideration concerning the therapeutic use of genetically modified

immunoresponsive cells disclosed herein is the quantity of cells necessary to achieve an optimal effect. The quantity of cells to be administered will vary for the subject being treated. In a one embodiment, between 10^4 to 10^{10} , between 10^5 to 10^9 , or between 10^6 and 10^8 genetically modified immunoresponsive cells disclosed herein are administered to a human subject. More effective cells may be administered in even smaller numbers. In some embodiments, at least about 1×10^8 , 2×10^8 , 3×10^8 , 4×10^8 , and 5×10^8 genetically modified immunoresponsive cells disclosed herein are administered to a human subject. The precise determination of what would be considered an effective dose may be based on factors individual to each subject, including their size, age, sex, weight, and condition of the particular subject. Dosages can be readily ascertained by those skilled in the art from this disclosure and the knowledge in the art.

[0406] The skilled artisan can readily determine the amount of cells and optional additives, vehicles, and/or carrier in compositions and to be administered in methods disclosed herein. Typically, any additives (in addition to the active cell(s) and/or agent(s)) are present in an amount of 0.001 to 50% (weight) solution in phosphate buffered saline, and the active ingredient is present in the order of micrograms to milligrams, such as about 0.0001 to about 5 wt %. In another embodiment about 0.0001 to about 1 wt %. In still another embodiment, about 0.0001 to about 0.05 wt% or about 0.001 to about 20 wt %. In a further embodiment, about 0.01 to about 10 wt %. In another embodiment, about 0.05 to about 5 wt %. Of course, for any composition to be administered to an animal or human, and for any particular method of administration, it is preferred to determine therefore: toxicity, such as by determining the lethal dose (LD) and LD50 in a suitable animal model e.g., rodent such as mouse; and, the dosage of the composition(s), concentration of components therein and timing of administering the composition(s), which elicit a suitable response. Such determinations do not require undue experimentation from the knowledge of the skilled artisan, this disclosure and the documents cited herein. And, the time for sequential administrations can be ascertained without undue experimentation.

[0407] *Nucleic acid sequences, vectors, cells*

[0408] In one embodiment, disclosed herein are an isolated nucleic acid sequence encoding a chimeric antigen receptor (CAR) as described herein for uses in the compositions and methods as disclosed herein. In another embodiment, disclosed herein are a vector comprising the nucleic acid sequence encoding a chimeric antigen receptor (CAR) as described herein.

[0409] In one embodiment, disclosed herein are an isolated nucleic acid sequence encoding a genetically modified T-cell receptor (TCR) as described herein for uses in the compositions and methods as disclosed herein. In another embodiment, disclosed herein are a vector comprising the nucleic acid sequence encoding a genetically modified T-cell receptor (TCR) as described herein.

[0410] Genetic modification of immunoresponsive cells (e.g., T-cells, CTL cells, NK cells, dendritic cells) can be accomplished by transducing a substantially homogeneous cell composition with a recombinant DNA construct. In one embodiment, a retroviral vector (either gamma-retroviral or lentiviral) is employed for the introduction of the DNA construct into the cell. For example, a polynucleotide encoding a receptor that binds an antigen (e.g., a tumor antigen, or a valiant, or a fragment thereof), can be cloned into a retroviral vector and expression can be driven from its endogenous promoter, from the retroviral long terminal repeat, or from a promoter specific for a target cell type of interest. Non-viral vectors may be used as well.

[0411] Non-viral approaches can also be employed for the expression of a protein in cell. For example, a nucleic acid molecule can be introduced into a cell by administering the nucleic acid in the presence of lipofection (Feigner et al., Proc. Natl. Acad. Sci. U.S.A. 84:7413, 1987; Ono et al., Neuroscience Letters 17:259, 1990; Brigham et al, Am. J. Med. Sci. 298:278, 1989; Staubinger et al, Methods in Enzymology 101 :512, 1983), asialoorosomucoid-polylysine conjugation (Wu et al., Journal of Biological Chemistry 263: 14621, 1988; Wu et al., Journal of Biological Chemistry 264:16985, 1989), or by micro-injection under surgical conditions (Wolff et al., Science 247: 1465, 1990). Other non-viral means for gene transfer include transfection in vitro using calcium phosphate, DEAE dextran, electroporation, and protoplast fusion. Liposomes can also be potentially beneficial for delivery of DNA into a cell. Transplantation of normal genes into the affected tissues of a subject can also be accomplished by transferring a normal nucleic acid into a cultivatable cell type ex vivo (e.g., an autologous or heterologous primary cell or progeny thereof), after which the cell (or its descendants) are injected into a targeted tissue or are injected systemically. Recombinant receptors can also be derived or obtained using transposases or targeted nucleases (e.g. Zinc finger nucleases, meganucleases, or TALE nucleases). Transient expression may be obtained by RNA electroporation. cDNA expression for use in polynucleotide therapy methods can be directed from any suitable promoter (e.g., the human cytomegalovirus (CMV), simian virus 40 (SV40), or metallothionein promoters), and regulated by any appropriate mammalian regulatory element or intron (e.g. the elongation factor 1a enhancer/promoter/intron structure). For example, if desired, enhancers known to preferentially direct gene expression in specific cell types can be used to direct the expression of a nucleic acid. The enhancers used can include, without limitation, those that are characterized as tissue- or cell-specific enhancers. Alternatively, if a genomic clone is used as a therapeutic construct, regulation can be mediated by the cognate regulatory sequences or, if desired, by regulatory sequences derived from a heterologous source, including any of the promoters or regulatory elements described above.

[0412] In another embodiment, disclosed herein are a cell comprising the vector comprising the

nucleic acid sequence encoding a chimeric antigen receptor (CAR) as disclosed herein. In another embodiment, disclosed herein are a cell comprising the vector comprising the nucleic acid sequence encoding a genetically modified T-cell receptor (TCR) as disclosed herein.

[0413] *Kits*

5 [0414] In one embodiment, disclosed herein are a kit for treatment of a neoplasia, pathogen infection, an autoimmune disorder, or an allogeneic transplant, the kit comprising a CAR T-cells and apoptotic cells as disclosed herein, either separately or pre-mixed.

[0415] In another embodiment, disclosed herein are a kit for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, the kit
10 comprising a CAR T-cells and apoptotic cells as disclosed herein, either separately or pre-mixed. In another embodiment, disclosed herein are a kit for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, the kit comprising a CAR T-cells and an apoptotic cell supernatant as disclosed herein, either separately or pre-mixed.

[0416] In one embodiment, disclosed herein are a kit for treatment of a neoplasia, pathogen
15 infection, an autoimmune disorder, or an allogeneic transplant, the kit comprising a TCR T-cells and apoptotic cells as disclosed herein, either separately or pre-mixed.

[0417] In another embodiment, disclosed herein are a kit for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, the kit comprising a TCR T-cells and apoptotic cells as disclosed herein, either separately or pre-mixed. In
20 another embodiment, disclosed herein are a kit for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, the kit comprising a TCR T-cells and an apoptotic cell supernatant as disclosed herein, either separately or pre-mixed.

[0418] Disclosed herein are kits for the treatment or prevention of a neoplasia, pathogen infection, immune disorder or allogeneic transplant, or for treating, preventing, inhibiting, reducing the
25 incidence of, ameliorating, or alleviating a cancer or a tumor. In one embodiment, the kit includes a therapeutic or prophylactic composition containing an effective amount of an immunoresponsive cells and apoptotic cells as disclosed herein in unit dosage form. In another embodiment, the kit includes a therapeutic or prophylactic composition containing an effective amount of an immunoresponsive cells and an apoptotic cell supernatant as disclosed herein in unit dosage form.

30 In particular embodiments, the cells further comprise a co-stimulatory ligand. In another embodiment, kits further comprise an additional agent selected from the group comprising a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof. In some embodiments, the kit comprises a sterile container which contains a therapeutic or prophylactic vaccine; such

containers can be boxes, ampules, bottles, vials, tubes, bags, pouches, blister-packs, or other suitable container forms known in the art. Such containers can be made of plastic, glass, laminated paper, metal foil, or other materials suitable for holding medicaments.

[0419] If desired, the immunoresponsive cells and apoptotic cells or apoptotic cell supernatant are provided together with instructions for administering the cells to a subject having or at risk of developing a neoplasia, pathogen infection, immune disorder or allogeneic transplant or tumors or cancer. The instructions will generally include information about the use of the composition for the treatment or prevention of neoplasia, pathogen infection, immune disorder, allogeneic transplant, tumor or cancer. In other embodiments, the instructions include at least one of the following:

description of the therapeutic agent; dosage schedule and administration for treatment or prevention of a neoplasia, pathogen infection, immune disorder or allogeneic transplant, cancers, tumors, or symptoms thereof; precautions; warnings; indications; counter-indications; over dosage information; adverse reactions; animal pharmacology; clinical studies; and/or references. The instructions may be printed directly on the container (when present), or as a label applied to the container, or as a separate sheet, pamphlet, card, or folder supplied in or with the container.

[0420] A skilled artisan would appreciate that the term "antigen recognizing receptor" may encompass a receptor that is capable of activating an immune cell (e.g., a T-cell) in response to antigen binding. Exemplary antigen recognizing receptors may be native or endogenous T-cell receptors or chimeric antigen receptors in which a tumor antigen-binding domain is fused to an intracellular signaling domain capable of activating an immune cell (e.g., a T-cell).

[0421] A skilled artisan would appreciate that the term "antibody" means not only intact antibody molecules, but also fragments of antibody molecules that retain immunogen-binding ability. Such fragments are also well known in the art and are regularly employed both in vitro and in vivo. Accordingly, the skilled artisan would appreciate that the term "antibody" means not only intact immunoglobulin molecules but also the well-known active fragments $F(ab^1)_2$, and Fab. $F(ab')_2$ and Fab fragments that lack the Fc fragment of intact antibody, clear more rapidly from the circulation, and may have less non-specific tissue binding of an intact antibody (Wahl et al., J. Nucl. Med. 24:316-325 (1983)). The antibodies disclosed herein comprise whole native antibodies, bispecific antibodies; chimeric antibodies; Fab, Fab', single chain V region fragments (scFv), fusion polypeptides, and unconventional antibodies.

[0422] A skilled artisan would appreciate that the term "single-chain variable fragment" or "scFv" encompasses a fusion protein of the variable regions of the heavy (VH) and light chains (VL) of an immunoglobulin covalently linked to form a VH::VL heterodimer. The heavy (VH) and light chains (VL) are either joined directly or joined by a peptide-encoding linker (e.g., 30, 15, 20, 25 amino

acids), which connects the N-terminus of the VH with the C-terminus of the VL, or the C-terminus of the VH with the N-terminus of the VL. The linker is usually rich in glycine for flexibility, as well as serine or threonine for solubility. Despite removal of the constant regions and the introduction of a linker, scFv proteins retain the specificity of the original immunoglobulin. Single chain Fv polypeptide antibodies can be expressed from a nucleic acid including VH- and VL-encoding sequences as described by Huston, et al. (Proc. Nat. Acad. Sci. USA, 85:5879-5883, 1988). See, also, U.S. Patent Nos. 5,091,513, 5,132,405 and 4,956,778; and U.S. Patent Publication Nos. 20050196754 and 20050196754. Antagonistic scFvs having inhibitory activity have been described (see, e.g., Zhao et al., Hybridoma (Larchmt) 2008 27(6):455-51 ; Peter et al., J Cachexia Sarcopenia Muscle 2012 August 12; Shieh et al., J Immunol 2009 183(4):2277-85; Giomarelli et al., Thromb Haemost 2007 97(6):955-63; Fife et al., J Clin Invest 2006 116(8):2252-61 ; Brocks et al., Immunotechnology 1997 3(3):173-84; Moosmayer et al., Ther Immunol 1995 2(10):31-40). Agonistic scFvs having stimulatory activity have been described (see, e.g., Peter et al., J Biol Chem 2003 278(38):36740-7; Xie et al., Nat Biotech 1997 15(8):768-71 ; Ledbetter et al., Crit Rev Immunol 1997 17(5-6):427-55; Ho et al., Biochim Biophys Acta 2003 1638(3):257-66).

[0423] By "affinity" is meant a measure of binding strength. Without being bound to theory, affinity depends on the closeness of stereochemical fit between antibody combining sites and antigen determinants, on the size of the area of contact between them, and on the distribution of charged and hydrophobic groups. Affinity also includes the term "avidity," which refers to the strength of the antigen-antibody bond after formation of reversible complexes. Methods for calculating the affinity of an antibody for an antigen are known in the art, including use of binding experiments to calculate affinity. Antibody activity in functional assays (e.g., flow cytometry assay) is also reflective of antibody affinity. Antibodies and affinities can be phenotypically characterized and compared using functional assays (e.g., flow cytometry assay).

[0424] A skilled artisan would appreciate that the term "chimeric antigen receptor" or "CAR" may encompass an antigen-binding domain that is fused to an intracellular signaling domain capable of activating or stimulating an immune cell. In one embodiment, the CAR's extracellular binding domain is composed of a single chain variable fragment (scFv) derived from fusing the variable heavy and light regions of a murine or humanized monoclonal antibody. Alternatively, scFvs may be used that are derived from Fab's (instead of from an antibody, e.g., obtained from Fab libraries), in various embodiments, this scFv is fused to a transmembrane domain and then to an intracellular signaling domain. In various embodiments, the CAR is selected to have high affinity or avidity for the antigen.

[0425] *Polypeptides and Analogs*

[0426] Also included in the methods disclosed herein are anti-MUC1, CD28, CD3 ζ , and various scFv polypeptides or fragments thereof that are modified in ways that enhance their anti-neoplastic activity (e.g., a humanized monoclonal antibody) when expressed in an immunoresponsive cell. In certain embodiments, the methods disclosed herein comprise optimizing an amino acid sequence or nucleic acid sequence by producing an alteration in the sequence. Such alterations may include certain mutations, deletions, insertions, or post-translational modifications. The disclosure provided herein further includes analogs of any naturally-occurring polypeptide disclosed herein. Analogs can differ from a naturally-occurring polypeptide disclosed herein by amino acid sequence differences, by post-translational modifications, or by both. Analogs disclosed herein will generally exhibit at least 85%, 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%>, 99% or more identity with all or part of a naturally-occurring amino acid sequence disclosed herein. The length of sequence comparison is at least 5, 10, 15 or 20 amino acid residues. In another embodiment, at least 25, 50, or 75 amino acid residues. In still another embodiment, more than 100 amino acid residues. Again, in an exemplary approach to determining the degree of identity, a BLAST program may be used, with a probability score between e^{-3} and e^{-100} indicating a closely related sequence. Modifications include in vivo and in vitro chemical derivatization of polypeptides, e.g., acetylation, carboxylation, phosphorylation, or glycosylation; such modifications may occur during polypeptide synthesis or processing or following treatment with isolated modifying enzymes. Analogs can also differ from the naturally-occurring polypeptides disclosed herein by alterations in primary sequence. These include genetic variants, both natural and induced (for example, resulting from random mutagenesis by irradiation or exposure to ethanemethyl sulfate or by site-specific mutagenesis as described in Sambrook, Fritsch and Maniatis, *Molecular Cloning: A Laboratory Manual* (2d ed.), CSH Press, 1989, or Ausubel et al, *supra*). Also included are cyclized peptides, molecules, and analogs which contain residues other than L-amino acids, e.g., D-amino acids or non-naturally occurring or synthetic amino acids, e.g., beta (β) or gamma (γ) amino acids.

[0427] Non-protein analogs have a chemical structure designed to mimic the functional activity of a protein disclosed herein. Such analogs are administered according to methods disclosed herein. Such analogs may exceed the physiological activity of the original polypeptide. Methods of analog design are well known in the art, and synthesis of analogs can be carried out according to such methods by modifying the chemical structures such that the resultant analogs increase the antineoplastic activity of the original polypeptide when expressed in an immunoresponsive cell. These chemical modifications include, but are not limited to, substituting alternative R groups and varying the degree of saturation at specific carbon atoms of a reference polypeptide. In another embodiment, the protein analogs are relatively resistant to in vivo degradation, resulting in a more

prolonged therapeutic effect upon administration. Assays for measuring functional activity include, but are not limited to, those described in the Examples below.

[0428] The term "immunosuppressive activity" describes induction of signal transduction or changes in protein expression in a cell (e.g., an activated immunoresponsive cell) resulting in a decrease in an immune response. Polypeptides known to suppress or decrease an immune response via their binding include CD47, PD-1, CTLA-4, and their corresponding ligands, including SIRPa, PD-L1, PD-L2, B7-1, and B7-2. Such polypeptides are present in the tumor microenvironment and inhibit immune responses to neoplastic cells. In various embodiments, inhibiting, blocking, or antagonizing the interaction of immunosuppressive polypeptides and/or their ligands enhances the immune response of the immunoresponsive cell.

[0429] The term "immunostimulatory activity" describes induction of signal transduction or changes in protein expression in a cell (e.g., an activated immunoresponsive cell) resulting in an increased immune response. Immunostimulatory activity may include pro-inflammatory activity. Polypeptides known to stimulate or increase an immune response via their binding include CD28, OX-40, 4-1BB, and their corresponding ligands, including B7-1, B7-2, OX-40L, and 4-1BBL. Such polypeptides are present in the tumor microenvironment and activate immune responses to neoplastic cells. In various embodiments, promoting, stimulating, or agonizing pro-inflammatory polypeptides and/or their ligands enhances the immune response of the immunoresponsive cell.

[0430] Nucleic acid molecules useful in the methods disclosed herein include any nucleic acid molecule that encodes a polypeptide disclosed herein or a fragment thereof. Such nucleic acid molecules need not be 100% identical with an endogenous nucleic acid sequence, but will typically exhibit substantial identity. Polynucleotides having "substantial identity" to an endogenous sequence are typically capable of hybridizing with at least one strand of a double-stranded nucleic acid molecule. By "hybridize" is meant pair to form a double-stranded molecule between complementary polynucleotide sequences (e.g., a gene described herein), or portions thereof, under various conditions of stringency. (See, e.g., Wahl, G. M. and S. L. Berger (1987) *Methods Enzymol.* 152:399; immel, A. R. (1987) *Methods Enzymol.* 152:507).

[0431] A skilled artisan would appreciate that the term "substantially identical" may encompass a polypeptide or nucleic acid molecule exhibiting at least 50% identity to a reference amino acid sequence (for example, any one of the amino acid sequences described herein) or nucleic acid sequence (for example, any one of the nucleic acid sequences described herein). In one embodiment, such a sequence is at least 60%, 80% or 85%, 90%, 95% or even 99% identical at the amino acid level or nucleic acid to the sequence used for comparison.

[0432] Sequence identity is typically measured using sequence analysis software (for example,

Sequence Analysis Software Package of the Genetics Computer Group, University of Wisconsin Biotechnology Center, 1710 University Avenue, Madison, Wis. 53705, BLAST, BESTFIT, GAP, or PILEUP/PRETTYBOX programs). Such software matches identical or similar sequences by assigning degrees of homology to various substitutions, deletions, and/or other modifications.

5 Conservative substitutions typically include substitutions within the following groups: glycine, alanine; valine, isoleucine, leucine; aspartic acid, glutamic acid, asparagine, glutamine; serine, threonine; lysine, arginine; and phenylalanine, tyrosine. In an exemplary approach to determining the degree of identity, a BLAST program may be used, with a probability score between e^{-3} and e^{-100} indicating a closely related sequence.

10 [0433] A skilled artisan would appreciate that the term "analog" may encompass a structurally related polypeptide or nucleic acid molecule having the function of a reference polypeptide or nucleic acid molecule.

[0434] A skilled artisan would appreciate that the term "ligand" may encompass a molecule that binds to a receptor. In particular, the ligand binds a receptor on another cell, allowing for cell-to-cell
15 recognition and/or interaction.

[0435] A skilled artisan would appreciate that the term "constitutive expression" may encompass expression under all physiological conditions.

[0436] A skilled artisan would appreciate that the term "disease" may encompass any condition or disorder that damages or interferes with the normal function of a cell, tissue, or organ. Examples of
20 diseases include neoplasia or pathogen infection of cell.

[0437] A skilled artisan would appreciate that the term "effective amount" may encompass an amount sufficient to have a therapeutic effect. In one embodiment, an "effective amount" is an amount sufficient to arrest, ameliorate, or inhibit the continued proliferation, growth, or metastasis (e.g., invasion, or migration) of a neoplasia.

25 [0438] A skilled artisan would appreciate that the term "neoplasia" may encompass a disease characterized by the pathological proliferation of a cell or tissue and its subsequent migration to or invasion of other tissues or organs. Neoplasia growth is typically uncontrolled and progressive, and occurs under conditions that would not elicit, or would cause cessation of, multiplication of normal cells. Neoplasias can affect a variety of cell types, tissues, or organs, including but not limited to an
30 organ selected from the group consisting of bladder, bone, brain, breast, cartilage, glia, esophagus, fallopian tube, gallbladder, heart, intestines, kidney, liver, lung, lymph node, nervous tissue, ovaries, pancreas, prostate, skeletal muscle, skin, spinal cord, spleen, stomach, testes, thymus, thyroid, trachea, urogenital tract, ureter, urethra, uterus, and vagina, or a tissue or cell type thereof. Neoplasias include cancers, such as sarcomas, carcinomas, or plasmacytomas (malignant tumor of

the plasma cells).

[0439] A skilled artisan would appreciate that the term "pathogen" may encompass a virus, bacteria, fungi, parasite or protozoa capable of causing disease.

[0440] A skilled artisan would appreciate that the term "tumor antigen" or "tumor associated antigen" may encompass an antigen (e.g., a polypeptide) that is uniquely or differentially expressed on a tumor cell compared to a normal or non- IS neoplastic cell. With reference to the compositions and methods disclosed herein, a tumor antigen includes any polypeptide expressed by a tumor that is capable of activating or inducing an immune response via an antigen recognizing receptor (e.g., CD 19, MUC1) or capable of suppressing an immune response via receptor-ligand binding (e.g., CD47, PD-L1/L2, B7.1/2).

[0441] A skilled artisan would appreciate that the term "virus antigen" may encompass a polypeptide expressed by a virus that is capable of inducing an immune response.

[0442] The terms "comprises", "comprising", and are intended to have the broad meaning ascribed to them in U.S. Patent Law and can mean "includes", "including" and the like. Similarly, the term "consists of" and "consists essentially of" have the meanings ascribed to them in U.S. Patent Law. The compositions and methods as disclosed herein are envisioned to either comprise the active ingredient or specified step, consist of the active ingredient or specified step, or consist essentially of the active ingredient or specified step.

[0443] A skilled artisan would appreciate that the term "treatment" may encompass clinical intervention in an attempt to alter the disease course of the individual or cell being treated, and can be performed either for prophylaxis or during the course of clinical pathology. Therapeutic effects of treatment include, without limitation, preventing occurrence or recurrence of disease, alleviation of symptoms, diminishment of any direct or indirect pathological consequences of the disease, preventing metastases, decreasing the rate of disease progression, amelioration or palliation of the disease state, and remission or improved prognosis. By preventing progression of a disease or disorder, a treatment can prevent deterioration due to a disorder in an affected or diagnosed subject or a subject suspected of having the disorder, but also a treatment may prevent the onset of the disorder or a symptom of the disorder in a subject at risk for the disorder or suspected of having the disorder.

[0444] A skilled artisan would appreciate that the term "subject" may encompass a vertebrate, in one embodiment, to a mammal, and in one embodiment, to a human. Subject may also refer, in one embodiment, to domesticated such as cows, sheep, horses, cats, dogs and laboratory animals such as mice, rats, gerbils, hamsters, etc.

[0445] In one embodiment, disclosed herein are TCR T-cells in which the TCR is directed to a

peptide of interest. In one embodiment, the TCR binds to a peptide of interest. In another embodiment, the TCR recognizes a peptide of interest. In another embodiment, the TCR is a ligand of the peptide of interest. In another embodiment, the peptide of interest is a ligand of the TCR. Each of these embodiments is to be considered part disclosed herein.

5 [0446] In one embodiment, the immune cell as disclosed herein is not a T-cell. In another embodiment, the immune cell as disclosed herein is not an NK cell. In another embodiment, the immune cell as disclosed herein is not a CTL. In another embodiment, the immune cell as disclosed herein is not a regulatory T-cell. In another embodiment, the immune cell is not a human embryonic stem cell. In another embodiment, the immune cell is not a pluripotent stem cell from which
10 lymphoid cells may be differentiated.

[0447] *Methods of Use*

[0448] One approach to immunotherapy involves engineering a patient's own immune cells to create genetically modified immune cells that will recognize and attack their tumor. Immune cells are collected and genetically modified, as described herein, for example to produce chimeric antigen
15 receptors (CAR) on their cell surface that will allow the immune cell, for example a T-cell, to recognize a specific protein antigen on a tumor or cancer cell. An expanded population of genetically modified immune cells, for example CAR T-cells, is then administered to the patient. In one embodiment, the administered cells multiply in the patient's body and recognize and kill cancer and tumor cells that harbor the antigen on their surface. In another embodiment, the administered
20 cells multiply in a patient's body and recognize and kill tumor-associated antigens, which leads to the death of cancer and tumor cells.

[0449] In one embodiment, disclosed herein are methods for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor comprising the step of administering a composition as disclosed herein.

25 [0450] In another embodiment, disclosed herein are methods for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor comprising the step of administering genetically modified immune cells and a composition comprising an additional agent, wherein said additional agent comprises apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based
30 compound, or an immune modulating agent, or any combination thereof, wherein said method treats, prevents, inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered said genetically modified immune cells and not administered the additional agent. In another embodiment, said genetically modified immune cells comprise genetically modified T-cell, cytotoxic T-cells, Treg cells, effector T-cells, helper T-cells,

NK cells, or dendritic cells.

[0451] In another embodiment, disclosed herein are methods for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cells) and a composition comprising an additional agent, wherein said additional agent comprises apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said method treats, prevents, inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered said genetically modified immune cells and not administered the additional agent.

[0452] In another embodiment, disclosed herein are methods for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor comprising the step of administering genetically modified T-cell receptor cells (TCR T-cells) and a composition comprising an additional agent, wherein said additional agent comprises apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said method treats, prevents, inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered said genetically modified immune cells and not administered the additional agent.

[0453] In another embodiment, administration of apoptotic cells or an apoptotic supernatant or compositions thereof does not reduce the efficacy for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor, of said administering chimeric antigen receptor-expressing T-cells. In another embodiment, administration of an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof does not reduce the efficacy for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor, of said administering chimeric antigen receptor-expressing T-cells.

[0454] In another embodiment, administration of apoptotic cells or an apoptotic supernatant or compositions thereof increases the efficacy for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor, of said administering chimeric antigen receptor-expressing T-cells. In another embodiment, administration of an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating

agent, or any combination thereof, or compositions thereof increases the efficacy for treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor, of said administering chimeric antigen receptor-expressing T-cells.

[0455] In one embodiment, methods increasing the efficacy of a genetically modified immune cell cancer therapy comprise administering said genetically modified immune cells and an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof, wherein the efficacy is increased compared with a subject not administered said additional agent. In another embodiment said genetically modified immune cells are T-cells. In another embodiment, a T-cell is a naïve T-cell. In another embodiment, a T-cell is a naïve CD4⁺ T-cell. In another embodiment, a T-cell is a naïve T-cell. In another embodiment, a T-cell is a naïve CD8⁺ T-cell. In another embodiment, the genetically modified immune cell is a natural killer (NK) cell. In another embodiment, the genetically modified immune cell is a dendritic cell. In still another embodiment, the genetically modified T-cell is a cytotoxic T lymphocyte (CTL cell). In another embodiment, the genetically modified T-cell is a regulatory T-cell (Treg). In another embodiment, the genetically modified T-cell is a chimeric antigen receptor (CAR) T-cell. In another embodiment, the genetically modified T-cell is a genetically modified T-cell receptor cell (TCR T-cell). In another embodiment, methods increasing the efficacy of a CAR T-cell cancer therapy comprise administering said genetically modified immune cells and an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof, wherein the efficacy is increased compared with a subject not administered said additional agent.

[0456] In another embodiment, methods herein reduce the level of production of at least one pro-inflammatory cytokine compared with the level of said pro-inflammatory cytokine in a subject receiving an immune cancer therapy and not administered an additional agent. In another embodiment, methods herein inhibit or reduce the incidence of cytokine release syndrome or cytokine storm in a subject undergoing a genetically modified immune cell cancer therapy and not administered an additional agent.

[0457] In another embodiment, methods disclosed herein reduce IL-6.

[0458] In another embodiment, methods herein increase the production of at least one cytokine compared with the level of said cytokine in a subject receiving an immune cancer therapy and not administered an additional agent. In some embodiments, the additional agent is apoptotic cells, In

other embodiment, the additional agent is an apoptotic cell supernatant. In another embodiment, methods disclosed herein increase IL-2.

[0459] A skilled artisan would appreciate that the term “production” as used herein in reference to a cytokine, may encompass expression of the cytokine as well as secretion of the cytokine from a cell.

5 In one embodiment, increased production of a cytokine results in increased secretion of the cytokine from the cell. In an alternate embodiment, decreased production of a cytokine results in decreased secretion of the cytokine from the cell. In another embodiment, methods disclosed herein decrease secretion of at least one cytokine. In another embodiment, methods disclosed herein decrease secretion of IL-6. In another embodiment, methods disclosed herein increase secretion of at least
10 one cytokine. In another embodiment, methods disclosed herein increase secretion of IL-2.

[0460] In another embodiment, a cell secreting at least one cytokine is a tumor cell. In another embodiment, a cell secreting at least one cytokine is a T-cell. In another embodiment, a cell secreting at least one cytokine is an immune cell. In another embodiment, a cell secreting at least one cytokine is a macrophage. In another embodiment, a cell secreting at least one cytokine is a B
15 cell lymphocyte. In another embodiment, a cell secreting at least one cytokine is a mast cell. In another embodiment, a cell secreting at least one cytokine is an endothelial cell. In another embodiment, a cell secreting at least one cytokine is a fibroblast. In another embodiment, a cell secreting at least one cytokine is a stromal cell. A skilled artisan would recognize that the level of cytokines may be increased or decreased in cytokine secreting cells depending on the environment
20 surrounding the cell.

[0461] In yet another embodiment, an additional agent used in the methods disclosed herein increases secretion of at least one cytokine. In yet another embodiment, an additional agent used in the methods disclosed herein maintains secretion of at least one cytokine. In still another embodiment, an additional agent used in the methods disclosed herein does not decrease secretion
25 of at least one cytokine. In another embodiment, an additional agent used in the methods disclosed herein increases secretion of IL-2. In another embodiment, an additional agent used in the methods disclosed herein increases secretion of IL-2R. In another embodiment, an additional agent used in the methods disclosed herein maintains secretion levels of IL-2. In another embodiment, an additional agent used in the methods disclosed herein maintains secretion levels of IL-2R. In
30 another embodiment, an additional agent used in the methods disclosed herein does not decrease secretion levels of IL-2R. In another embodiment, an additional agent used in the methods disclosed herein maintains or increases secretion levels of IL-2. In another embodiment, an additional agent used in the methods disclosed herein maintains or increases secretion levels of IL-2R. In another embodiment, an additional agent used in the methods disclosed herein does not

decrease secretion levels of IL-2R.

[0462] In still a further embodiment, an additional agent used in the methods disclosed herein decreases secretion of IL-6. In another embodiment, an additional agent used in the methods disclosed herein maintains, increases, or does not decrease secretion levels of IL-2 while decreasing secretion of IL-6. In another embodiment, an additional agent used in the methods disclosed herein maintains, increases, or does not decrease secretion levels of IL-2R while decreasing secretion of IL-6.

[0463] In one embodiment, methods of increasing the efficacy of a CAR T-cell cancer therapy disclosed herein comprises decreasing the level of IL-6 in said subject, said method comprising administering CAR T-cells and an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof, wherein the efficacy is increased compared with a subject not administered said additional agent. In another embodiment, methods of increasing the efficacy of a CAR T-cell cancer therapy disclosed herein comprises increasing the level of IL-2 in said subject, said method comprising administering CAR T-cells and an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof, wherein the efficacy is increased compared with a subject not administered said additional agent. In another embodiment, methods of increasing the efficacy of a CAR T-cell cancer therapy disclosed herein comprises increasing proliferation of said CAR T-cells, said method comprising administering CAR T-cells and an additional agent comprising apoptotic cells, a supernatant from apoptotic cells, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof, wherein the efficacy and proliferation of said CAR T-cells is increased compared with a subject not administered said additional agent.

[0464] In one embodiment, methods of increasing the efficacy of CAR T-cell cancer therapy, decrease or inhibit cytokine production in the subject, said methods comprising the step of administering a composition comprising CAR T-cells and a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof. In another embodiment, methods of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or tumor also decrease or inhibit cytokine production in the subject, said methods comprising the step of administering a composition comprising CAR T-cells and a CTLA-4 blocking agent, an alpha-1

anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions thereof.

[0465] In another embodiment, disclosed herein are methods of treating cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell cancer therapy.

5 [0466] In another embodiment, methods of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or tumor, decrease or inhibit cytokine production in a subject, said methods comprising the step of administering a composition comprising CAR T-cells and a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment or analog thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, or compositions
10 thereof.

[0467] In another embodiment, disclosed herein are methods of preventing cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell cancer therapy. In another embodiment, disclosed herein are methods of alleviating cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell cancer therapy. In another embodiment, disclosed herein
15 are methods of ameliorating cytokine release syndrome or cytokine storm in a subject undergoing CAR T-cell cancer therapy. In another embodiment, administration of apoptotic cells or an apoptotic supernatant or compositions thereof does not reduce the efficacy of the CAR T-cell therapy.

[0468] In one embodiment, disclosed herein are methods of inhibiting or reducing the incidence of
20 a cytokine release syndrome (CRS) or a cytokine storm in a subject undergoing chimeric antigen receptor-expressing T-cell (CAR T-cell) cancer therapy, wherein the method comprises the step of administering a composition comprising apoptotic cells or an apoptotic cell supernatant or compositions thereof to said subject. In another embodiment, inhibiting or reducing the incidence of a cytokine release syndrome (CRS) or a cytokine storm is determined by measuring cytokine levels
25 in a subject undergoing chimeric antigen receptor-expressing T-cell cancer therapy and being administered apoptotic cells or an apoptotic supernatant. In another embodiment, measured levels of cytokines are compared with cytokine levels in a subject not undergoing CAR T-cell cancer therapy. In another embodiment, measured cytokine levels are compared with cytokine levels in a subject not administer apoptotic cells or an apoptotic supernatant. In yet another embodiment,
30 measured cytokine levels are compared with a control subject.

[0469] In another embodiment, the level of pro-inflammatory cytokines are reduced in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant or compositions thereof. In another embodiment, methods disclosed herein reduce or inhibit the level of production of at least one pro-inflammatory cytokines

compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant or compositions thereof.

[0470] In another embodiment, a method disclosed herein may further comprise administration of additional agents. Alternatively, a method disclosed herein may comprise administration of additional agents and not apoptotic cells or an apoptotic cell supernatant. In still a further embodiment, additional agents may be those compounds or compositions that maintain, enhance, or improve, or any combination thereof, CAR T-cell cancer therapy. In yet a further embodiment, additional agents that maintain, enhance, or improve CAR T-cell cancer therapy include CTLA-4 blocking agents, an alpha-1 anti-trypsin or functional fragment thereof, or an analogue thereof, a tellurium-based compound, or an immune-modulating drug, or any combination thereof. In another embodiment, an additional agent includes apoptotic cells or an apoptotic supernatant. In another embodiment, administration of an additional agent, as described herein, is prior to, concurrent with, or following said CAR T-cell cancer therapy.

[0471] In one embodiment, an IL-6 receptor antagonist, which in one embodiment is tocilizumab is used with the compositions and methods as disclosed herein.

[0472] In one embodiment, adoptively transferred T-cells engraft and expand more efficiently in a lymphopenic host. Thus, in one embodiment, the subject is subjected to lymphodepletion prior to transfer of CAR T-cells or other modified immune cells. In another embodiment, the subject receiving the CAR T-cells is given T-cell-supportive cytokines.

[0473] In one embodiment, the T-cells are effector T-cells. In another embodiment, the T-cells are naïve T-cells. In another embodiment, the T-cells are central memory (T_{CM}) T-cells. In another embodiment, the T-cells are Th17 cells. In another embodiment, the T-cells are T stem memory cells. In another embodiment, the T-cells are regulatory T-cells. In another embodiment, the T-cells are cytotoxic T-cells. In another embodiment, the T-cells have high replicative capacity. In another embodiment, T-cell expansion occurs in the patient. In another embodiment, small numbers of cells may be transferred to a patient. In another embodiment, T-cell expansion occurs *in vitro*. In another embodiment, large numbers of cells may be transferred to a patient, cells and/or supernatants may be transferred to a patient on multiple occasions, or a combination thereof.

[0474] In one embodiment, an advantage of CAR T-cells is that because they are specific for cell-surface molecules, they overcome the constraints of MHC-restricted TCR recognition and avoid tumor escape through impairments in antigen presentation or human leukocyte antigen expression.

[0475] In one embodiment, disclosed herein is a method of reducing a tumor burden in a subject, said method comprising the step of administering to said subject any of the compositions as described herein.

[0476] In one embodiment, reducing the tumor burden comprises reducing the number of tumor cells in the subject. In another embodiment, reducing the tumor burden comprises reducing tumor size in the subject. In another embodiment, reducing the tumor burden comprises eradicating the tumor in the subject.

5 [0477] In another embodiment, disclosed herein is a method of inducing tumor cell death in a subject, said method comprising the step of administering to said subject any of the compositions as described herein. In another embodiment, a method as disclosed herein for inducing tumor cell death in a subject comprises administering immune cells, such as NK cells or T-cells comprising engineered chimeric antigen receptors with at least an additional agent to decrease toxic cytokine
10 release or "cytokine release syndrome" (CRS) or "severe cytokine release syndrome" (sCRS) or "cytokine storm" in the subject.

[0478] In another embodiment, disclosed herein is a method of increasing or lengthening the survival of a subject having neoplasia, comprising the step of administering to said subject any of the compositions as described herein. In another embodiment, a method of increasing or
15 lengthening the survival of a subject comprises administering immune cells, such as NK cells or T-cells comprising engineered chimeric antigen receptors with at least an additional agent to decrease toxic cytokine release or "cytokine release syndrome" (CRS) or "severe cytokine release syndrome" (sCRS) or "cytokine storm" in the subject.

[0479] In another embodiment, disclosed herein is a method of increasing or lengthening the
20 survival of a subject having neoplasia, comprising the step of administering to said subject any of the compositions as described herein.

[0480] In another embodiment, disclosed herein is a method of preventing neoplasia in a subject, said method comprising the step of administering to said subject any of the compositions as described herein.

25 [0481] In one embodiment, the neoplasia is selected from the group consisting of blood cancer, B cell leukemia, multiple myeloma, lymphoblastic leukemia (ALL), chronic lymphocytic leukemia, non-Hodgkin's lymphoma, ovarian cancer, or a combination thereof.

[0482] In another embodiment, disclosed herein is a method of treating blood cancer in a subject in need thereof, comprising the step of administering to said subject any of the compositions as
30 described herein. In one embodiment, the blood cancer is selected from the group consisting of B cell leukemia, multiple myeloma, acute lymphoblastic leukemia (ALL), chronic lymphocytic leukemia, and non-Hodgkin's lymphoma.

[0483] In another embodiment, disclosed herein is a method of treating a cancer or a tumor in a subject, said method comprising the step of administering to said subject any of the compositions as

described herein. In another embodiment, disclosed herein is a method of preventing a cancer or a tumor in a subject, said method comprising the step of administering to said subject any of the compositions as described herein. In another embodiment, disclosed herein is a method of inhibiting a cancer or a tumor in a subject, said method comprising the step of administering to said subject
 5 any of the compositions as described herein. In another embodiment, disclosed herein is a method of reducing a cancer or a tumor in a subject, said method comprising the step of administering to said subject any of the compositions as described herein. In another embodiment, disclosed herein is a method of ameliorating a cancer or a tumor in a subject, said method comprising the step of administering to said subject any of the compositions as described herein. In another embodiment,
 10 disclosed herein is a method of alleviating a cancer or a tumor in a subject, said method comprising the step of administering to said subject any of the compositions as described herein.

[0484] In one embodiment, disclosed herein are methods of maintaining or increasing the proliferation rate of a genetically modified immune cell during an immunotherapy, the method comprising the step of administering a composition comprising apoptotic cells or an apoptotic
 15 supernatant during the immunotherapy. In another embodiment, said genetically modified immune cells comprise a T-cell, a naïve T-cell, a naïve CD4+ T-cell, a naïve CD8+ T-cell, a natural killer (NK) cell, a dendritic cell, a cytotoxic T lymphocyte (CTL cell), a regulatory T-cell (Treg), a chimeric antigen receptor (CAR) T-cell, or a genetically modified T-cell receptor (TCR) cell. In another embodiment, disclosed herein are methods of maintaining or increasing the proliferation
 20 rate of a CAR T-cell during an immunotherapy, the method comprising the step of administering a composition comprising apoptotic cells or an apoptotic supernatant during the immunotherapy.

[0485] In another embodiment, methods of maintaining or increasing the proliferation rate of the genetically modified immune cells does not reduce or inhibit the efficacy of the immunotherapy. For example, in another embodiment, methods of maintaining or increasing the proliferation rate of
 25 CAR T-cells does not reduce or inhibit the efficacy of the CAR T-cell cancer therapy. In another embodiment, methods of maintaining or increasing the proliferation rate of the genetically modified immune cells, for example CAR T-cells, decrease or inhibit cytokine production in the subject.

[0486] In one embodiment, a method of decreasing or inhibiting cytokine production in a subject experiencing cytokine release syndrome or cytokine storm or vulnerable to a cytokine release
 30 syndrome or cytokine storm, as disclosed herein, decreases or inhibits cytokine production. In another embodiment, the method decreases or inhibits pro-inflammatory cytokine production. In a further embodiment, the method decreases or inhibits at least one pro-inflammatory cytokine. In another embodiment, wherein the subject is undergoing CAR T-cell cancer therapy, the method does not reduce the efficacy of the CAR T-cell therapy.

[0487] The methods provided herein comprise administering a T-cell, NK cell, or CTL cell disclosed herein, in an amount effective to achieve the desired effect, be it palliation of an existing condition or prevention of recurrence. For treatment, the amount administered is an amount effective in producing the desired effect. An effective amount can be provided in one or a series of administrations. An effective amount can be provided in a bolus or by continuous perfusion.

[0488] A skilled artisan would recognize that an "effective amount" (or, "therapeutically effective amount") may encompass an amount sufficient to effect a beneficial or desired clinical result upon treatment. An effective amount can be administered to a subject in one or more doses. In terms of treatment, an effective amount is an amount that is sufficient to palliate, ameliorate, stabilize, reverse or slow the progression of the disease, or otherwise reduce the pathological consequences of the disease. The effective amount is generally determined by the physician on a case-by-case basis and is within the skill of one in the art. Several factors are typically taken into account when determining an appropriate dosage to achieve an effective amount. These factors include age, sex and weight of the subject, the condition being treated, the severity of the condition and the form and effective concentration of the antigen-binding fragment administered.

[0489] In one embodiment, methods disclosed herein comprise administering a composition comprising a genetically modified cell, and the additional agent or combination thereof, comprised in a single composition. In another embodiment, methods comprise administering a composition comprising a CAR T-cell, and the additional agent or combination thereof, comprised in a single composition. In another embodiment, methods comprise administering a composition comprising a TCR T-cell, and the additional agent or combination thereof, comprised in a single composition.

[0490] In one embodiment, methods disclosed herein comprise administering a composition comprising a genetically modified cell, and the additional agent or combination thereof, comprised in at least two compositions. In another embodiment, methods comprise administering a composition comprising a CAR T-cell, and the additional agent or combination thereof, comprised in at least two compositions. In another embodiment, methods comprise administering a composition comprising a TCR T-cell, and the additional agent or combination thereof, comprised in at least two compositions.

[0491] For adoptive immunotherapy using antigen-specific T-cells, for example CAR T-cells, cell doses in the range of 10^6 - 10^{10} (e.g., 10^9) are typically infused. Upon administration of the genetically modified cells into the host and subsequent differentiation, T-cells are induced that are specifically directed against the specific antigen. "Induction" of T-cells may include inactivation of antigen-specific T-cells such as by deletion or anergy. Inactivation is particularly useful to establish or reestablish tolerance such as in autoimmune disorders. The modified cells can be administered by

any method known in the art including, but not limited to, intravenous, subcutaneous, intranodal, intratumoral, intrathecal, intrapleural, intraperitoneal and directly to the thymus. In one embodiment, the T-cells are not administered intraperitoneally. In one embodiment, the T-cells are administered intratumorally.

5 [0492] Compositions comprising genetically modified immunoresponsive cells as disclosed herein (e.g., T-cells, N cells, CTL cells, or their progenitors) can be provided systemically or directly to a subject for the treatment of a neoplasia, pathogen infection, or infectious disease. In one embodiment, cells disclosed herein are directly injected into an organ of interest (e.g., an organ affected by a neoplasia). Alternatively, compositions comprising genetically modified
10 immunoresponsive cells are provided indirectly to the organ of interest, for example, by administration into the circulatory system (e.g., the tumor vasculature). Expansion and differentiation agents can be provided prior to, during or after administration of the cells to increase production of T-cells, NK cells, or CTL cells *in vitro* or *in vivo*.

[0493] As described above in methods disclosed herein, compositions comprising additional agents
15 may be provided prior to, concurrent with, or following administrations of the genetically modified immune cells. In one embodiment, in methods disclosed herein genetically modified immune cells for example CAR T-cells are administered prior to an additional agent as disclosed herein. In another embodiment, in methods disclosed herein genetically modified immune cells for example CAR T-cells are administered concurrent with an additional agent, as disclosed herein. In another
20 embodiment, in methods disclosed herein genetically modified immune cells for example CAR T-cells are administered following administration of an additional agent.

[0494] In one embodiment, methods disclosed herein administer compositions comprising apoptotic cells as disclosed herein. In another embodiment, methods disclosed herein administer compositions comprising apoptotic cell supernatants as disclosed herein.

25 [0495] The modified cells can be administered in any physiologically acceptable vehicle, normally intravascularly, although they may also be introduced into bone or other convenient site where the cells may find an appropriate site for regeneration and differentiation (e.g., thymus). Usually, at least 1×10^5 cells will be administered, eventually reaching 1×10^{10} or more. Genetically modified immunoresponsive cells disclosed herein may comprise a purified population of cells. Those skilled
30 in the art can readily determine the percentage of genetically modified immunoresponsive cells in a population using various well-known methods, such as fluorescence activated cell sorting (FACS). In some embodiments, ranges of purity in populations comprising genetically modified immunoresponsive cells are about 50 to about 55%, about 55 to about 60%, and about 65 to about 70%. In other embodiments, the purity is about 70 to about 75%, about 75 to about 80%, about 80

to about 85%. In further embodiments, the purity is about 85 to about 90%, about 90 to about 95%, and about 95 to about 100%. Dosages can be readily adjusted by those skilled in the art (e.g., a decrease in purity may require an increase in dosage). The cells can be introduced by injection, catheter, or the like. If desired, factors can also be included, including, but not limited to, interleukins, e.g. IL-2, IL-3, IL-6, IL-11, IL7, IL12, IL15, IL21, as well as the other interleukins, the colony stimulating factors, such as G-, M- and GM-CSF, interferons, e.g. gamma-interferon and erythropoietin.

[0496] Compositions include pharmaceutical compositions comprising genetically modified immunoresponsive cells or their progenitors and a pharmaceutically acceptable carrier.

Administration can be autologous or heterologous. For example, immunoresponsive cells, or progenitors can be obtained from one subject, and administered to the same subject or a different, compatible subject. Peripheral blood derived immunoresponsive cells disclosed herein or their progeny (e.g., in vivo, ex vivo or in vitro derived) can be administered via localized injection, including catheter administration, systemic injection, localized injection, intravenous injection, or parenteral administration. When administering a therapeutic composition as disclosed herein (e.g., a pharmaceutical composition containing a genetically modified immunoresponsive cell), it will generally be formulated in a unit dosage injectable form (solution, suspension, emulsion).

[0497] In another embodiment, disclosed herein is a method of producing a composition comprising CAR T-cells or other immune cells as disclosed herein and apoptotic cells or an apoptotic cell supernatant, the method comprising introducing into the T-cell or immune cell the nucleic acid sequence encoding the CAR that binds to an antigen of interest. In an alternative embodiment, the compositions comprising CAR T-cells or other immune cells as disclosed herein are separate from the composition comprising apoptotic cells or an apoptotic supernatant.

[0498] In one embodiment, disclosed herein is a method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a malignancy comprising the step of administering a composition comprising chimeric antigen receptor-expressing T-cells (CAR T-cells) and apoptotic cells or an apoptotic cell supernatant.

[0499] A skilled artisan would appreciate that an anti-tumor immunity response elicited by the genetically modified immune cells, for example CAR-modified T cells, may be an active or a passive immune response. In addition, the CAR mediated immune response may be part of an adoptive immunotherapy approach in which CAR-modified T-cells induce an immune response specific to the antigen binding moiety in the CAR.

[0500] A skilled artisan would appreciate that immunotherapeutics may encompass the use of immune effector cells and molecules to target and destroy cancer cells. The immune effector may

be, for example, an antibody specific for some marker on the surface of a tumor cell. The antibody alone may serve as an effector of therapy or it may recruit other cells to actually effect cell killing. The antibody also may be conjugated to a drug or toxin (chemotherapeutic, radionuclide, ricin A chain, cholera toxin, pertussis toxin, etc.) and serve merely as a targeting agent. Alternatively, the effector may be a lymphocyte carrying a surface molecule that interacts, either directly or indirectly, with a tumor cell target. Various effector cells include cytotoxic T cells and NK cells.

[0501] *Malignancies*

[0502] In one embodiment, disclosed herein are method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor comprising the step of administering chimeric antigen receptor-expressing T-cells (CAR T-cells) and a composition comprising apoptotic cells or an apoptotic cell supernatant or compositions thereof. As disclosed herein, these methods may further comprise administering an additional agent in an effort to inhibit or decrease the incidence of CRS or cytokine storm.

[0503] In one embodiment, the cancer is a B-cell malignancy. In one embodiment, the B-cell malignancy is leukemia. In another embodiment, the B-cell malignancy is acute lymphoblastic leukemia (ALL). In another embodiment, the B-cell malignancy is chronic lymphocytic leukemia.

[0504] In one embodiment, the cancer is leukemia. In one embodiment, the cancer is lymphoma. In one embodiment, the lymphoma is large B-cell lymphoma.

[0505] In one embodiment, the tumor is a solid tumor. In another embodiment, a solid tumor is an abnormal mass of tissue lacking cysts or liquid areas. In another embodiment, solid tumors are neoplasms (new growth of cells) or lesions (damage of anatomic structures or disturbance of physiological functions) formed by an abnormal growth of body tissue cells other than blood, bone marrow or lymphatic cells. In another embodiment, a solid tumor consists of an abnormal mass of cells which may stem from different tissue types such as liver, colon, breast, or lung, and which initially grows in the organ of its cellular origin. However, such cancers may spread to other organs through metastatic tumor growth in advanced stages of the disease.

[0506] In one embodiment, the tumor is a solid tumor. In another embodiment, examples of solid tumors are sarcomas, carcinomas, and lymphomas. In one embodiment, the solid tumor is an intra-peritoneal tumor.

[0507] In another embodiment, the solid tumor comprises an Adrenocortical Tumor (Adenoma and Carcinoma), a Carcinoma, a Colorectal Carcinoma, a Desmoid Tumor, a Desmoplastic Small Round Cell Tumor, an Endocrine Tumor, an Ewing Sarcoma, a Germ Cell Tumor, a Hepatoblastoma a Hepatocellular Carcinoma, a Melanoma, a Neuroblastoma, an Osteosarcoma, a Retinoblastoma, a Rhabdomyosarcoma, a Soft Tissue Sarcoma Other Than Rhabdomyosarcoma,

and a Wilms Tumor. In one embodiment, the solid tumor is a breast tumor. In another embodiment, the solid tumor is a prostate cancer. In another embodiment, the solid tumor is a colon cancer. In one embodiment, the tumor is a brain tumor. In another embodiment, the tumor is a pancreatic tumor. In another embodiment, the tumor is a colorectal tumor.

5 [0508] In another embodiment, compositions and methods as disclosed herein have therapeutic and/or prophylactic efficacy against sarcomas and carcinomas (e.g., fibrosarcoma, myxosarcoma, liposarcoma, chondrosarcoma, osteogenic sarcoma, chordoma, angiosarcoma, endotheliosarcoma, lymphangiosarcoma, lymphangioendotheliosarcoma, synovioma, mesothelioma, Ewing's tumor, leiomyosarcoma, rhabdomyosarcoma, colon carcinoma, pancreatic cancer, breast cancer, ovarian
10 cancer, prostate cancer, squamous cell carcinoma, basal cell carcinoma, adenocarcinoma, sweat gland carcinoma, sebaceous gland carcinoma, papillary carcinoma, papillary adenocarcinomas, cystadenocarcinoma, medullary carcinoma, bronchogenic carcinoma, renal cell carcinoma, hepatoma, bile duct carcinoma, choriocarcinoma, seminoma, embryonal carcinoma, Wilm's tumor, cervical cancer, uterine cancer, testicular cancer, lung carcinoma, small cell lung carcinoma, bladder
15 carcinoma, epithelial carcinoma, glioma, astrocytoma, medulloblastoma, craniopharyngioma, ependymoma, pinealoma, hemangioblastoma, acoustic neuroma, oligodendroglioma, schwannoma, meningioma, melanoma, neuroblastoma, and retinoblastoma). The compositions and methods as disclosed herein may be used to treat, prevent, inhibit, ameliorate, reduce the incidence of, or alleviate any solid tumor known in the art.

20 [0509] In another embodiment, the tumor is a hematological tumor. In one embodiment, hematological tumors are cancer types affecting blood, bone marrow, and lymph nodes. Hematological tumors may derive from either of the two major blood cell lineages: myeloid and lymphoid cell lines. The myeloid cell line normally produces granulocytes, erythrocytes, thrombocytes, macrophages, and mast cells, whereas the lymphoid cell line produces B, T, NK and
25 plasma cells. Lymphomas (e.g. Hodgkin's Lymphoma), lymphocytic leukemias, and myeloma are derived from the lymphoid line, while acute and chronic myelogenous leukemia (AML, CML), myelodysplastic syndromes and myeloproliferative diseases are myeloid in origin.

[0510] In another embodiment, compositions and methods as disclosed herein have therapeutic and/or prophylactic efficacy against leukemias (e.g., acute leukemia, acute lymphocytic leukemia, acute myelocytic leukemia, acute myeloblastic leukemia, acute promyelocyte leukemia, acute
30 myelomonocytic leukemia, acute monocytic leukemia, acute erythroleukemia, chronic leukemia, chronic myelocytic leukemia, chronic lymphocytic leukemia), polycythemia vera, lymphoma (Hodgkin's disease, non-Hodgkin's disease), Waldenstrom's macroglobulinemia, heavy chain disease. The compositions and methods as disclosed herein may be used to treat, prevent, inhibit,

ameliorate, reduce the incidence of, or alleviate any hematological tumor known in the art.

[0511] In one embodiment, disclosed herein are active fragments of any one of the polypeptides or peptide domains disclosed herein. A skilled artisan would appreciate that the term "a fragment" may encompass at least 5, 10, 13, or 15 amino acids. In other embodiments a fragment is at least 20 contiguous amino acids. Fragments disclosed herein can be generated by methods known to those skilled in the art or may result from normal protein processing (e.g., removal of amino acids from the nascent polypeptide that are not required for biological activity or removal of amino acids by alternative mRNA splicing or alternative protein processing events).

[0512] The terms "antibody" and "immunoglobulin" are used interchangeably in the broadest sense and specifically refer to a polyclonal antibody, a monoclonal antibody, or any fragment thereof, which retains the binding activity of the antibody. In certain embodiments, methods disclosed herein comprise use of a chimeric antibody, a humanized antibody, or a human antibody.

[0513] A skilled artisan would appreciate that the term "polyclonal antibody (or antibodies)" may encompass a population of different antibodies directed against different determinants (epitopes) of the same antigen.

[0514] A skilled artisan would appreciate that the term "monoclonal antibody (or antibodies)" may encompass a population of substantially homogenous antibodies, i.e., the individual antibodies comprising the population are identical except for possibly naturally occurring mutations that may be present in minor amounts. Monoclonal antibodies are directed against a single antigenic site.

[0515] The monoclonal antibodies disclosed herein can be made using the hybridoma method first described by Kohler et al, Nature, 256: 495 (1975), or may be made by recombinant DNA methods (e.g. U.S. Pat. No. 4,816,567).

[0516] In the hybridoma method, a mouse or other appropriate host animal, such as a hamster, is immunized to elicit lymphocytes that produce or are capable of producing antibodies that will specifically bind to the protein used for immunization. Antibodies to the protein of interest generally are raised in animals by subcutaneous (sc) or intraperitoneal (ip) injections of the desired protein of interest and an adjuvant. In one embodiment, the animals are immunized with the protein of interest coupled to Keyhole limpet hemocyanin (KLH, Sigma Aldrich) as a carrier protein.

[0517] The protein of interest used for animal immunization are prepared using methods well-known in the art. For example, the protein of interest may be produced by recombinant methods or by peptide synthesis methods.

[0518] Alternatively, lymphocytes may be immunized in vitro and then fused with myeloma cells using a suitable fusing agent, such as polyethylene glycol, to form a hybridoma cell (Goding, Monoclonal Antibodies: Principles and Practice, pp. 59-103 (Academic Press, 1986)).

[0519] The binding affinity of the monoclonal antibody can, for example, be determined by the Scatchard analysis of Munson et al., Anal Biochem., 107: 220 (1980).

[0520] The antibodies disclosed herein can be produced by using combinatorial libraries to screen for synthetic antibody clones with the desired activity. In principle, synthetic antibody clones are selected by screening phage libraries containing phage that display various fragments of antibody variable region (Fv) fused to phage coat protein using methods well known in the art.

[0521] A skilled artisan would appreciate that the term "any fragment thereof which retains the binding activity of the antibody" may encompass a portion of an antibody, which may comprise the antigen-binding or variable region thereof, which is capable of binding to the target antigen of the intact antibody. Examples of antibody fragments include Fab, Fab', F(ab')₂, and Fv fragments.

[0522] These antibody fragments may be generated by recombinant techniques or by traditional means, such as enzymatic digestion. Papain digestion of 6 antibodies produces two identical antigen-binding fragments, called "Fab" fragments, each with a single binding site, and a residual "Fc" fragment. Pepsin treatment yields an F(ab')₂ fragment that has two antigen-combining sites and is still capable of cross-linking antigen. "Fv" is the minimum antibody fragment which contains a complete antigen-recognition and binding site.

[0523] The polyclonal antibodies and the monoclonal antibodies disclosed herein are prepared using methods well known in the art.

[0524] In one embodiment, disclosed herein are a CAR T-cell or related composition in which the CAR is endogenous to the T-cell. In one embodiment, "endogenous" comprises a nucleic acid molecule (e.g., a cDNA, DNA or RNA molecule) or polypeptide that is normally expressed in a cell or tissue.

[0525] In another embodiment, disclosed herein are a CAR T-cell or related composition in which the CAR is exogenous to the T-cell. In one embodiment, "exogenous" comprises a nucleic acid molecule or polypeptide that is not endogenously present in the cell, or not present at a level sufficient to achieve the functional effects obtained when artificially over-expressed. A skilled artisan would appreciate that the term "exogenous" would therefore encompass any recombinant nucleic acid molecule or polypeptide expressed in a cell, such as foreign, heterologous, and over-expressed nucleic acid molecules and polypeptides.

[0526] In one embodiment, disclosed herein are immune cells, in one embodiment, CAR T-cells in which the T-cell is autologous to the subject. In another embodiment, the CAR T-cells are heterologous to the subject. In one embodiment, the CAR T-cells are allogeneic. In one

embodiment, the CAR T-cells are universal allogeneic CAR T-cells. In another embodiment, the T-cells may be autologous, allogeneic, or derived in vitro from engineered progenitor or stem cells.

[0527] In another embodiment, the CAR T-cells and apoptotic cells described herein, are both derived from the same source. In a further embodiment, the CAR T-cells and apoptotic cells

5 described herein, are both derived from the subject (**Figure 2B**). In an alternative embodiment, the

CAR T-cells and apoptotic cells described herein, are derived from different sources. In yet another

embodiment, the CAR T-cells are autologous and the apoptotic cells described herein, are allogeneic (**Figure 3**). A skilled artisan would appreciate that similarly, an apoptotic cell

supernatant may be made from cells derived from the same source as the CAR T-cell, which may in

10 one embodiment be autologous cells, or an apoptotic cell supernatant may be made from cells

derived from a source different from the source of CAR T-cells. In addition, apoptotic cell

supernatants may be obtained from different sources. In some embodiments, an apoptotic

supernatant is obtained from cells undergoing apoptosis. In some embodiments, an apoptotic

supernatant is obtained from a combination cell cultures wherein apoptotic cells are co-cultured

15 with macrophages and the supernatant is collected.

[0528] In some embodiments, a donor comprises a HLA matched donor. In some embodiments, a donor is an unmatched HLA donor.

[0529] A skilled artisan would appreciate that the term "heterologous" may encompass a tissue, cell, nucleic acid molecule or polypeptide that is derived from a different organism. In one

20 embodiment, a heterologous protein is a protein that was initially cloned from or derived from a

different T-cell type or a different species from the recipient and that is not normally present in a

cell or sample obtained from a cell.

[0530] A skilled artisan would appreciate that the term "autologous" may encompass a tissue, cell, nucleic acid molecule or polypeptide in which the donor and recipient is the same person.

25 [0531] A skilled artisan would appreciate that the term "allogeneic" may encompass a tissue, cell,

nucleic acid molecule or polypeptide that is derived from separate individuals of the same species.

In one embodiment, allogeneic donor cells are genetically distinct from the recipient.

[0532] In another embodiment, compositions and methods as disclosed herein utilize combination therapy with apoptotic cells or apoptotic supernatants as disclosed herein, and one or more CTLA-

30 4-blocking agents such as Ipilimumab. In one embodiment, CTLA-4 is a potent inhibitor of T-cell

activation that helps to maintain self-tolerance. In one embodiment, administration of an anti-

CTLA-4 blocking agent, which in another embodiment, is an antibody, produces a net effect of T-

cell activation. In another embodiment, compositions and methods as disclosed herein utilize

combined therapy comprising apoptotic cells, CAR T-cells, and one or more CTLA-4-blocking

agents.

[0533] In some cases, a polypeptide of and for use in the methods as disclosed herein comprises at least one conservative amino acid substitution relative to an unmodified amino acid sequence. In other cases, the polypeptide comprises a non-conservative amino acid substitution. In such cases, polypeptides having such modifications exhibit increased stability or a longer half-life relative to a polypeptide lacking such an amino acid substitution.

[0534] In one embodiment, methods as disclosed herein may be represented as uses of the compositions as described herein for various therapeutic and prophylactic purposes as described herein, or alternatively, uses of the compositions as described herein in the preparation of a medicament or a therapeutic composition or a composition for various therapeutic and prophylactic purposes as described herein.

[0535] In one embodiment, the compositions and methods as disclosed herein comprise the various components or steps. However, in another embodiment, the compositions and methods as disclosed herein consist essentially of the various components or steps, where other components or steps may be included. In another embodiment, the compositions and methods as disclosed herein consist of the various components or steps.

[0536] In some embodiments, the term “comprise” may encompass the inclusion of other components of the composition which affect the efficacy of the composition that may be known in the art. In some embodiments, the term “consisting essentially of” comprises a composition, which has chimeric antigen receptor-expressing T-cells (CAR T-cells), and apoptotic cells or any apoptotic cell supernatant. However, other components may be included that are not involved directly in the utility of the composition. In some embodiments, the term “consisting” encompasses a composition having chimeric antigen receptor-expressing T-cells (CAR T-cells), and apoptotic cells or an apoptotic cell supernatant as disclosed herein, in any form or embodiment as described herein.

[0537] In one embodiment, “treating” comprises therapeutic treatment and “preventing” comprises prophylactic or preventative measures, wherein the object is to prevent or lessen the targeted pathologic condition or disorder as described hereinabove. Thus, in one embodiment, treating may include directly affecting or curing, suppressing, inhibiting, preventing, reducing the severity of, delaying the onset of, reducing symptoms associated with the disease, disorder or condition, or a combination thereof. Thus, in one embodiment, “treating,” “ameliorating,” and “alleviating” refer *inter alia* to delaying progression, expediting remission, inducing remission, augmenting remission, speeding recovery, increasing efficacy of or decreasing resistance to alternative therapeutics, or a combination thereof. In one embodiment, “preventing” refers, *inter alia*, to delaying the onset of symptoms, preventing relapse to a disease, decreasing the number or frequency of relapse episodes,

increasing latency between symptomatic episodes, or a combination thereof. In one embodiment, “suppressing” or “inhibiting”, refers *inter alia* to reducing the severity of symptoms, reducing the severity of an acute episode, reducing the number of symptoms, reducing the incidence of disease-related symptoms, reducing the latency of symptoms, ameliorating symptoms, reducing secondary
5 symptoms, reducing secondary infections, prolonging patient survival, or a combination thereof.

[0538] In one embodiment, a composition as disclosed herein is administered once. In another embodiment, the composition is administered twice. In another embodiment, the composition is administered three times. In another embodiment, the composition is administered four times. In another embodiment, the composition is administered at least four times. In another embodiment,
10 the composition is administered more than four times.

[0539] In one embodiment, CAR T-cells as disclosed herein are administered once. In another embodiment, CAR T-cells are administered twice. In another embodiment, CAR T-cells are administered three times. In another embodiment, CAR T-cells are administered four times. In another embodiment, CAR T-cells are administered at least four times. In another embodiment, the
15 composition is administered more than four times.

[0540] A skilled artisan would appreciate that the term “about”, may encompass a deviance of between 0.0001-5% from the indicated number or range of numbers. Further, it may encompass a deviance of between 1 -10% from the indicated number or range of numbers. In addition, it may encompass a deviance of up to 25% from the indicated number or range of numbers.

[0541] A skilled artisan would appreciate that the singular form "a", "an" and "the" include plural references unless the context clearly dictates otherwise. For example, the term "an agent" or "at least an agent" may include a plurality of agents, including mixtures thereof.

[0542] Throughout this application, various embodiments disclosed herein may be presented in a range format. It should be understood that the description in range format is merely for convenience and brevity and should not be construed as an inflexible limitation on the scope of the disclosure.
25 Accordingly, the description of a range should be considered to have specifically disclosed all the possible sub ranges as well as individual numerical values within that range. For example, description of a range such as from 1 to 6 should be considered to have specifically disclosed sub ranges such as from 1 to 3, from 1 to 4, from 1 to 5, from 2 to 4, from 2 to 6, from 3 to 6 etc., as
30 well as individual numbers within that range, for example, 1, 2, 3, 4, 5, and 6. This applies regardless of the breadth of the range.

[0543] Whenever a numerical range is indicated herein, it is meant to include any cited numeral (fractional or integral) within the indicated range. The phrases “ranging/ranges between” a first indicated number and a second indicated number and “ranging/ranges from” a first indicated

number “to” a second indicated number are used herein interchangeably and are meant to include the first and second indicated numbers and all the fractional and integral numerals there between.

[0544] In one embodiment, the composition as disclosed herein is a therapeutic composition. In another embodiment, the composition as disclosed herein has therapeutic efficacy.

5 [0545] In one embodiment, disclosed herein are a composition which provides reduced inflammatory cytokine or chemokine release compared to a composition comprising CAR T-cells alone, but with comparable cytotoxicity compared to a composition comprising CAR T-cells alone.

EXAMPLES

EXAMPLE 1: Apoptotic Cell Production Processes

10

[0546] **Objective:** To produce early-apoptotic cells for use in methods described herein.

[0547] **Methods:**

[0548] Methods of making populations of early-apoptotic cells have been well documented in International Publication No. WO 2014/087408 and United States Application Publication No.

15 US2015/0275175-A1, see for example, the Methods section preceding the Examples at “ApoCell Preparation” and “Generation of apoptotic cells” (paragraphs [0223] through [0288]), and Examples 11, 12, 13, and 14, which are incorporated herein in their entirety.

[0549] The flow chart presented in **Figure 1** provides an overview of one embodiment of the steps used during the manufacturing process of a population of early apoptotic cells, wherein
20 anticoagulants are included in the preparation steps. Indicated in the flow chart are the time points at which the anti-coagulants were added during the manufacturing process. As is described in detailed in Example 14 of International Publication No. WO 2014/087408 and United States Application Publication No. US US-2015-0275175-A1, cell populations were prepared wherein anti-coagulants were added at the time of freezing, at the time of incubation, or at the time of freezing and at the
25 time of incubation. Anti-coagulant ACD formula A was supplemented with 10 U/ml heparin at a final concentration of 5% ACD of the total volume and 0.5 U/ml heparin. Methods including anti-coagulant consistently produced yields of at least 40% early apoptotic cells, even in the presence of plasma comprising high triglyceride concentrations.

[0550] The methods sections cited above and Example 11 provide details of preparing another
30 embodiment of apoptotic cell populations that is in the absence of anti-coagulant.

[0551] **Results:**

[0552] Inclusion of anticoagulants both at the time of freezing and during incubation after thawing resulted in the most consistently high yield of stable early-apoptotic cells. This consistent high yield

of stable early apoptotic cells was produced even in the cases when the donor plasma is high in triglycerides (*See*, Examples 12 and 13 of International Publication No. WO 2014/087408 and United States Application Publication No. US US-2015-0275175-A1). Note that anti-coagulants were not added to the PBS media used for formulation of the final early apoptotic cell dose for infusion.

[0553] Table 3 below shows the comparison of cell populations (batches of cells) prepared with and without anti-coagulant added.

[0554] **Table 3: Cell population analysis comparison between batches prepared with and without anticoagulant**

[0556] Methods of preparation of early apoptotic cell wherein anti-coagulants were not added yielded early apoptotic cell population of at least 40% early apoptotic cells, and often at least 50% early apoptotic cells.

5 **EXAMPLE 2: Effect Of Apoptotic Cells On Cytokine Release In An**
 In Vitro Cytokine Storm Model

[0557] **Objective:** Test the effect of apoptotic cells on the level of cytokine storm markers (cytokines IL-6, IL-10, MIP-1 α , IL-8, TNF- α , MIP-1 β , MCP-1, and IL-9) in a cytokine storm induced in an LPS-Sterile model of macrophage activation syndrome.

10 [0558] **Methods:**

[0559] *Cell lines and culturing reagents*

[0560] The human lymphoma cell line Raji (eCACC, UK, access no. 85011429), the human cervical adenocarcinoma cell line HeLa (ATCC, USA, number: CCL-2) and HeLa-CD19 (ProMab, USA, cat. no. PM-Hela-CD19) were cultured in RPMI 1640 (Gibco, ThermoFisher Scientific, USA, cat. no. 31870-025) supplemented with 10% FBS (Gibco, ThermoFisher Scientific, South America, cat. no. 12657-029), 2 mM GlutaMAX (Gibco, ThermoFisher Scientific, USA, cat. no. 35050-038), and 100 U/ml Penicillin + 100 U/ml Streptomycin (Gibco, ThermoFisher Scientific, USA, cat. no. 15140-122), henceforth referred to as “Complete Medium”. HeLa-CD19 medium was further supplemented with 1 μ g/ml puromycin (Sigma-Aldrich, USA, cat. no. P9620), as the selective
 15 antibiotics, during standard culturing.
 20 [0561] All cells were kept in sub-confluent conditions. Raji cells were maintained in a concentration range of 0.3×10^6 - 2×10^6 cell/ml. HeLa and HeLa-CD19 cells were passaged when receptacle was filled to 90% confluence.

[0562] Primary monocytes were isolated from blood donations buffy coats (Sheba Medical Center,
 25 Israel). First, peripheral blood mononuclear cells (PBMCs) were isolated on a Ficoll density gradient (Ficoll-Paque PLUS, GE Healthcare, UK, cat. no. 17-1440-03). Upon centrifugation (800x g, 2-8°C, 20 min. with break 0), the interphase containing the PBMCs were transferred to a fresh test tube and washed with RPMI-1640 (Lonza, Switzerland, cat. no. BE12-918F) supplemented with 2 mM L-glutamine (Lonza, Switzerland, cat. no. BE17-605E) and 10 mM Hepes (Lonza, Switzerland, cat. no. BE17-737B), henceforth “Wash Medium”, and centrifuged (650x g, 2-8°C, 10
 30 min.). Pelleted cells were re-suspended in “Wash Medium” to a concentration of 15×10^6 cell/ml. Cells were seeded as a 0.9 ml drop at the center of a 35-mm plate (Corning, USA, cat. no. 430165). Plates were incubated for 1.5h in a humidified incubator (37°C, 5% CO₂), allowing monocytes to adhere, and then washed three times with pre-warmed PBS (Lonza, Switzerland, cat. no. BE17-

516F), removing other cell types. After washing, cells were cultured in 2 ml RPMI 1640 (Gibco, ThermoFisher Scientific, USA, cat. no. 31870-025) supplemented with 10% FBS (Gibco, ThermoFisher Scientific, South America, cat. no. 12657-029), 2 mM GlutaMAX (Gibco, ThermoFisher Scientific, USA, cat. no. 35050-038), and 100 U/ml Penicillin + 100 U/ml Streptomycin (Gibco, ThermoFisher Scientific, USA, cat. no. 15140-122), aka “Complete Medium”.

[0563] All cell lines were cultured in a humidified incubator at 37°C and containing 5% CO₂.

[0564] In brief, and following manufacturer’s guidelines, target cells (HeLa or HeLa-CD19) were cultured alone or in conjunction with monocytes. After target cells adhered to the plate (6h-overnight), cultures were exposed to 1×10^6 ApoCells for 1h, after which these cells were washed off by 4-5 washes of RPMI. Removal of ApoCells cells was confirmed visually under a light microscope. 10 ng/ml LPS (Sigma-Aldrich, USA, cat. no. L4391) was introduced to the co-culture and incubated for 1h. After incubation, LPS was removed by 3-5 washing cycles with RPMI. Viable CD19-CAR T cells or naïve T cells were added at the designated E/T ratio(s) and incubated for 4h. To collect media, plates were centrifuged at 250x g, 2-25°C, 4 min. (Centrifuge 5810 R, Eppendorf, Germany) to sediment cells. 50 µl of supernatant medium from each well was transferred to a fresh flat-bottom 96-well microplate well (Corning, USA, cat. no. 3596) and 50 µl CytoTox 96 Reagent was added to each well. Plates were incubated in the dark at room temperature for 30 min., after which the reaction was terminated by addition of 50 µl Stop Solution per well. Absorbance was read at 492 nm using Infinite F50 (Tecan, Switzerland) and captured using Magellan F50 software. Data analysis and graph generation was performed using Microsoft Excel 2010.

[0565] Analysis of cytokine release was performed using Liminex technology following incubation with apoptotic cells or incubation with supernatant from apoptotic cells.

[0566] **Results: Figures 9A through 9H** show that there was a significant reduction in the levels of cytokine storm markers IL-10, IL-6, MIP-1 α , IL-8, TNF- α , MIP-1 β , MCP-1, and IL-9 which were induced by LPS in an *in vitro* model of macrophage activation syndrome. While administration of ApoCells to achieve a macrophage:ApoCell ratio of 1:8 resulted in significantly decreased levels of both IL-10, IL-6, MIP-1 α , IL-8, TNF- α , MIP-1 β , MCP-1, and IL-9 released into the medium (**Figures 9A, 9B, 9C, 9D, 9E, 9F, 9G, 9H**), administration of ApoCells to achieve a macrophage:ApoCell ratio of 1:16 actually inhibited or nearly inhibited the release of cytokines IL-10, IL-6, MIP-1 α , IL-8, TNF- α , MIP-1 β , MCP-1, and IL-9 in this model.

[0567] Addition of apoptotic cells resulted in the inhibition of at least 20 pro-inflammatory cytokine and chemokines induced in macrophage activating, a sample of the results are shown in

Figures 9A-9H. The common mechanism for pro-inflammatory cytokine and chemokine release is NF- κ B inhibition.

[0568] The inhibition of release of pro-inflammatory cytokines and chemokines appears to be specific, as examination of cytokine IL-2R (IL-2 receptor) levels under similar conditions showed that IL-2R levels released was not influenced in the same manner at the pro-inflammatory cytokines. (**Figure 9I**). Addition of apoptotic cells increased the release of IL-2R at 1:4 and 1:8 ratios. Further, **Figure 9J** shows that apoptotic cells had no influence on release of IL-2 over a 24 hour time period. Activation of the IL-2 receptor is considered to have an essential role in key functions of the immune system including tolerance.

[0569] **Conclusion:** Addition of early apoptotic cells in a cytokine storm model of macrophage activation syndrome in the presence of cancer and CAR-19, resulted in significant reduction and, surprisingly even prevention of pro-inflammatory cytokines, for example IL-10, IL-6, MIP-1 α , IL-8, TNF- α , MIP-1 β , MCP-1, and IL-9, while increasing or not affecting cytokine IL-2R levels. Thus, the results here show that while pro-inflammatory cytokines were reduced by incubation with apoptotic cells, IL-2 and IL-2R were not influenced in the same manner with incubation of early apoptotic cells. Thus, the T-cell associated cytokines are not influenced by the CAR T-cell therapy + apoptotic cells, whereas the innate immunity cytokines, for example those released from monocytes, macrophages, and dendritic cells are.

EXAMPLE 3: Effect of Apoptotic Cells on Cytokine Storm Without a Negative Effect on The CAR-T Cell Efficacy

[0570] **Objective:** Test the effect of apoptotic cells or supernatants derived from apoptotic cells on cytokine storm marker cytokines and CAR T-cell efficacy on tumor cells.

[0571] **Methods:**

[0572] *T4+ CAR T-cells*

[0573] A solid tumor model (van der Stegen et al., 2013 *ibid*) reported to induce cytokine storms in mice was utilized. In this model, T cells were engineered with a chimeric antigen receptor (CAR) targeting certain ErbB dimers (T4⁺ CAR-T cells), which are often highly up-regulated in specific solid tumors such as head and neck tumors and ovarian cancers. T-cells were isolated from PBMC separated from peripheral blood using CD3 micro-beads. Vectors containing the chimeric T4+ receptor were constructed and transducer into the isolated T-cells, resulting in T4+ CAR T-cells. For the experiments performed herein, T4+ CAR T-cells were purchased from Creative Biolabs (NY USA) or Promab Biotechnologies (CA USA). **Figure 4** presents flow cytometry curves verifying the surface expression of 4 $\alpha\beta$ chimeric receptor on the T4+ CAR T-cells using an anti-

CD124 monoclonal antibody (Wilkie et al., *ibid*). In addition, a PCR procedure was performed and verified the presence of the vector in transduced T cells.

[0574] *SKOV3-luc cells*

[0575] SKOV3-luc ovarian adenocarcinoma tissue culture cells were purchased from Cell BioLabs (cat. #AKR-232). SKOV3-luc highly express ErbB receptors and are a target for the T4⁺ CAR-T cells (van der Stegen et al., 2013, *ibid*). These cells had been further manipulated to constitutively express the firefly luciferase gene, allowing tracking of cell proliferation *in vitro* and tumor growth and recession *in vivo*.

[0576] *Apoptotic cells*

10 [0577] Apoptotic cells were prepared as per Example 1.

[0578] *Apoptotic cell supernatants*

[0579] Eight (8) million apoptotic cells per seeded per well in a 12-well plate. After 24 hours the cells were centrifuge (290g, 4 degrees Celsius, 10 minutes). Supernatant was collected and frozen in aliquots at -80 degrees until use. Different numbers of cells are used to make supernatants. Some
15 aliquots contain concentrated supernatants.

[0580] *Monocyte isolation*

[0581] PBMCs were isolated using Ficoll (GE healthcare, United Kingdom) from peripheral blood\ buffy coat obtained from healthy, eligible donors. Cells were brought to a concentration of 15x10⁶ cells\ml in RPMI1640 (Gibco, Thermo Fisher Scientific, MA, USA) and seeded in a 0.9ml
20 drop in the middle of 35mm plates (Corning, NY, USA). Plates were then incubated at 37⁰C in 5% CO₂ for 1 hour. At the end of incubation, cells were washed three times with PBS (Biological industries, Beit Haemek, Israel) and adhesion was determined using a light microscope. Cells were then incubated with complete media (RPMI1640+ 10% heat inactivated FBS+ 1% Glutamax+ 1% PenStrep, all from Gibco).

25 [0582] An alternative method of monocyte isolation was also used wherein human mononuclear cells were isolated from heparinized peripheral blood by density gradient centrifugation. The isolated mononuclear cells then were separated into monocyte, B-cell and T-cell populations by positively selecting monocytes as the CD14+ fraction by magnetic bead separation (Miltenyi Biotec., Auburn, CA, USA), positively selecting B-cells as the CD22+ fraction, and negatively
30 selecting T-cells as the CD14-CD22- fraction. Purity was greater than 95 percent for monocytes.

[0583] For macrophage differentiation, at the end of adhesion, cells were washed three times with PBS then incubated with RPMI1640+ 1% Glutamax+ 1% PenStrep and 10% heat inactivated human AB serum (Sigma, MO, USA). Cells were incubated at 37⁰C and 5% for 7-9 days, with media exchange at day 3 and day 6. Differentiation was determined by morphology via light

microscope.

[0584] *Supernatant from apo+ monocytes*

[0585] CD14+ monocytes were cultured with apoptotic cells as prepared above at a ratio of 1:16, for 24h. The number of monocytes was: 0.5 million cells per well in a 12-well plate and the number of apoptotic cells was: 8 million cells per well in a 12-well plate. After incubation for 24 hours the cells were centrifuge (290g, 4 degrees Celsius, 10 minutes). Supernatant was collected and frozen in aliquots at -80 degrees until use. Similar procedures could be performed at different ratios of monocytes:apoptotic cells and/or using other sources of cells, such as macrophages and dendritic cells.

10 [0586] *In vitro culturing conditions*

[0587] Initial experiments were performed by incubating SKOV3-luc cancer cells with apoptotic cells, or apoptotic supernatants, for 1 hour followed by co-culturing with T4+ CAR T-cells (+/- monocytes-macrophages) for 48 hours.

[0588] In order to simulate *in vivo* conditions, 1×10^5 THP-1 cells/ml (HTCC USA), or monocytes or macrophages or dendritic cells, will be differentiated with 200 nM (123.4 ng/ml) phorbol myristate acetate (PMA) for 72 hrs and will then be cultured in complete medium without PMA for an additional 24h. Next, cancer or tumor cells – for example SKOV3-luc cells will be plated in a 24-well plate at 5×10^5 SKOV3-luc cells/well on the differentiated THP-1 cells. Following initial culturing of the cancer or tumor cells, 4×10^5 - 8×10^5 apoptotic cells (ApoCell) will be added to the culture for 1-3h to induce an immunotolerant environment. The ratio of cancer cell to ApoCell will be optimized for each cell type. After washing, the co-culture will be treated with 10 ng/ml LPS after which 1×10^6 T4+ CAR T cells (or a quantity to be determined by an effector/target (E/T) ratio graph) will be added. The ratios of tumor cells and T4+ CAR T-cells will be varied in order to generate effector/target (E/T) ratio graphs for each tumor or cancer cell type.

25 [0589] To assay for SKOV3 cancer cell cytotoxicity, lysates were prepared and luciferase activity was determined after the 48 hour incubation period. Additional experiments will be performed assaying for cancer or tumor cell cytotoxicity for the other cancer cell types and at intervals within the 48h incubation time period. Alternatively, Promega's CytoTox 96 Non-Radioactive Cytotoxicity Assay (Promega, cat #G1780) will be used.

30 [0590] *Lysate Preparation*

[0591] SKOV3-luc cell lysates were prepared by washing the SKOV3-luc monolayer with PBS to remove any residual serum and adding 70 μ l CCLR lysis buffer x1/well (for 24-well plates). Detachment was further enhanced by physical scraping of well bottoms. Following vortexing for 15 seconds, lysates were centrifuged at 12,000g for 2 minutes at 4°C. Supernatants were collected and

stored at -80°C.

[0592] *In vitro Luciferase Activity*

[0593] To detect luciferase activity in SKOV3-luc cells in culture, Luciferase Assay System (Promega, cat. #E1501) was used. Calibration of this kit with the luminometer reader (Core Facility, Faculty of Medicine, Ein Kerem, Hebrew University of Jerusalem) was done by using QuantiLum recombinant luciferase (Promega, cat. #E170A). 612 ag - 61.2 µg (10^{-20} - 10^{-9} moles) was used to determine detection range and following manufacturer's guidelines. In brief, each rLuciferase quantity in 20 µl volume was placed in a well of black 96-well plates (Nunc). Each quantity was done in triplicate. 100 µl LAR (luciferin substrate from Luciferase Assay System kit) was added to each well and read immediately with a 10 second exposure.

[0594] For luciferase activity reading, lysates were thawed on ice and 20 µl samples were placed in a black 96-well plate (Nunc). Each sample was read in duplicate. 100 µl LAR was added and luminescence was read for 10 second exposure period every 2.5 minutes for 25 minutes and every 40 seconds for the ensuing 10 minutes.

[0595] *Cytokine Analysis*

[0596] Initial assays for IL-2, IL-2 receptor (IL-2R), IL-6, IL-1α, IL-4, IL-2, TNF-α were performed. To assay for cytokine release reduction of IL-2, IL-2 receptor (IL-2R), IL-6, IL-1α, IL-4, IL-2, TNF-α as well as other cytokines, supernatants were be collected and examined for selected cytokine using Luminex MagPix reader and ELISA assays.

[0597] **Results:**

[0598] **SKOV3-luc growth**

[0599] SKOV3-luc growth was followed using luciferase activity as an indicator, to determine target SKOV3-luc cell number in future experiments. 3.8×10^4 - 3.8×10^5 SKOV3-luc cells/well were plated in 24-well plates (Corning) and luciferase activity was monitored daily for 3 days. 1.9×10^5 cells/well or higher cell number plated reach confluence and present growth saturation indicated by luciferase activity 2 days after plating (**Figure 5**). Note that 3.8×10^4 - 1.1×10^5 SKOV3-luc cells/well were still in the linear or exponential growth phase three days after plating (**Figure 5**, plots orange, turquoise and purple). Negative control (3.8×10^5 SKOV3-luc cells without LAR substrate) displayed only background-level reading and demonstrates that bioluminescent readings from SKOV3-luc cells result from luciferase activity.

[0600] *Verification of T4⁺ CAR-T cell activity against SKOV3-luc tumor cells*

[0601] To corroborate the T4⁺ CAR-T cell activity, monolayers of SKOV3-luc were exposed to either 1,000,000 (one million) T4⁺ CAR-T cells or to 1,000,000 (one million) non-transduced T cells. After 24h incubation, T4⁺ CAR-T cells reduced SKOV3-luc proliferation by 30% compared to

the non-transduced T cell control (**Figure 6**), showing anti-tumor activity of the T4⁺ CAR-T cells.

[0602] *Activity of stand-alone T4⁺ CAR-T cells against SKOV3-luc tumor cells was compared to activity post exposure to Apoptotic Cells*

[0603] Apoptotic cells (ApoCell) and apoptotic cell supernatants (ApoSup and ApoMon Sup) were tested to determine if they interfere with T4⁺ CAR-T cell anti-tumor activity. The SKOV3-luc tumor cells were incubate with Apoptotic Cells for one hour, followed by the addition of T4⁺ CAR-T cells (500,000, five hundred thousands) or T4⁺ non-transduced T cells (500,000, five hundred thousands) (ratio of 1:2 T4⁺ CAR-T cells to Apoptotic Cells). The tumor cell/Apoptotic cell/T4⁺ CAR T-cells were then co-cultured for 48h. The control SKOV3-luc tumor cells were co-cultured with T4⁺ CAR-T cells and Hartman solution (the vehicle of Apoptotic Cells), but without Apoptotic Cells, for 48h.

[0604] The results showed that after 48h incubation, T4⁺ CAR-T cells anti-tumor activity was superior to incubation with non-transduced T cells. Similar incubations were performed with apoptotic cells or apoptotic cell supernatants. Surprisingly, T4⁺ CAR T-cell anti-tumor activity was comparable with or without exposure to apoptotic cells or apoptotic cell supernatants. (**Figure 7**).

[0605] *Effect of Apoptotic Cells on amelioration, reduction or inhibition of cytokine storms resulting from CAR-T treatment*

[0606] The effect of apoptotic cells to reduce cytokine storms was examined next. IL-6 is a prototype pro-inflammatory cytokine that is released in cytokine storms (Lee DW et al. (2014) Blood 124(2): 188-195) and is often used as a marker of a cytokine storm response.

[0607] Cultures were established to mimic an *in vivo* CAR T-cell therapy environment. SKOV3-luc tumor cells were cultured in the presence of human monocyte-macrophages and T4⁺ CAR T-cells. The concentration of IL-6 measured in the culture media was approximately 500-600 pg/ml. This concentration of IL-6 is representative of a cytokine storm.

[0608] Unexpectedly, IL-6 levels measured in the cultured media of SKOV3-luc tumor cells, human monocyte-macrophages, T4⁺ CAR-T cells, wherein the tumor cells had been previously incubated with apoptotic cells for one hour (ratio of 1:2 T4⁺ CAR-T cells to Apoptotic Cells) were dramatically reduced. Similarly, IL-6 levels measured in the cultured media of SKOV3-luc tumor cells, human monocyte-macrophages, T4⁺ CAR-T cells, wherein the tumor cells had been previously incubated with apoptotic cell supernatants for one hour, were also dramatically reduced. This reduction in concentration of IL-6 is representative of a decrease in the cytokine storm (**Figure 8**).

[0609] It was concluded that unexpectedly, apoptotic cells and apoptotic supernatants do not abrogate the effect of CAR-T cells on tumor cell proliferation while at the same time they down

regulating pro-inflammatory cytokines such as IL-6, which was been described as a major cytokine leading to morbidity.

[0610] *Analysis using a wider range of cytokines*

[0611] To further evaluate the effect on a possible wider range and levels of cytokines that are not generated during experimental procedures but do appear in clinical settings during a human cytokine storm, LPS (10 ng/ml) was added to the SKOV3-luc culture conditions outlined above. The addition of LPS is expected to exponentially increase the cytokine storm level. As expected, the addition of LPS increased the cytokine storm effect and as a result IL-6 levels increased to approximately 30,000 pg/ml. Other cytokines known to be expressed in high levels during a cytokine storm showed elevated levels, for example: TNF- α (250–300 pg/ml), IL-10 (200-300 pg/ml), IL1-alpha (40-50 pg/ml) and IL-18 (4-5 pg/ml). As shown in **Figure 10**, exposure to apoptotic cells dramatically reduced the levels of IL-6 even during the exponential state of the cytokine storm to almost normal levels that may be seen in clinical settings, and is not always seen in experimental procedures with CAR T-cells. This effect was similar across the other pro-inflammatory cytokines TNF-alpha, IL-10, IL1-alpha, IL-1 β , and IL-18, which showed a reduction of between 20-90%. Similar results were found when using apoptotic cell supernatants in place of the apoptotic cells.

[0612] *Effect of Apoptotic Cells on IL-2 and IL-2R*

[0613] The concentration of IL-2 measured in culture supernatants following incubation of SKOV3-luc cells with T4+ CAR T-cells was 1084 pg/ml. Surprisingly, when SKOC3-luc cells were first incubated with apoptotic cells and then T4+ CAR T-cells the concentration of IL-2 increased to 1190 pg/ml. Similarly, the concentration of IL-2R measured in culture supernatants following incubation of SKOV3-luc cells with T4+ CAR T-cells was 3817 pg/ml. Surprisingly, when SKOC3-luc cells were first incubated with apoptotic cells and then T4+ CAR T-cells the concentration of IL-2R increased to 4580 pg/ml. In SKOV3-luc alone the concentration of IL-2 was 3.2 pg/ml and with the addition of apoptotic cells the concentration was 10.6 pg/ml. In SKOV3-luc alone the concentration of IL-2R was 26.3 pg/ml and with the addition of apoptotic cells the concentration was 24.7 pg/ml.

[0614] **Conclusion**

[0615] CAR-T cell therapy has been documented to cause cytokine storms in a significant number of patients. These results demonstrate that apoptotic cells and apoptotic cell supernatants surprisingly decreased cytokine storms cytokine markers without affecting CAR-T cell efficacy against tumor cells. Moreover, it appears that apoptotic cells increase cytokine IL-2, which may increase duration of CAR T-cell therapy by maintaining or increasing CAR T-cell proliferation.

EXAMPLE 4: Apoptotic Cell Therapy Prevents Cytokine Storms in Mice Administered CAR T-Cell Therapy

5 [0616] **Objective:** Test the *in vivo* effect of apoptotic cells or apoptotic cell supernatants in a solid tumor model (SKOV3 ovarian adenocarcinoma), in order to determine T4+ CAR T-cell efficacy and the level of cytokine storm marker cytokines.

[0617] **Materials and Methods**

[0618] ***In vitro studies***

10 [0619] *In vitro* methods including methods of making, culturing, and analyzing the results described above and relevant for use of T4+ CAR T-cells that recognize the ErbB target antigen (referred to herein as “T4+ CAR T-cells”, SKOV3-luc cells, apoptotic cells, apoptotic supernatants, monocytes, macrophages, and the various assays, have all been described above in Example 1. The same methods were used herein.

15 [0620] ***In vivo studies***

[0621] *Mice*

[0622] 7-8 week old SCID-beige mice and NSGS mice were purchased from Harlan (Israel) and kept in the SPF animal facility in Sharett Institute.

[0623] SKOV3-luc tumor cells (1×10^6 or 2×10^6) are inoculated into SCID beige mice or NSGS
20 mice, by either i.p. in PBS or s.c. in 200 μ l Matrigel (BD Biosciences). Tumor engraftment is confirmed by bioluminescence imaging (BLI) at about 14-18 days post injection, and mice are sorted into groups with similar signal intensity prior to T-cell administration.

[0624] Mice will receive 30×10^6 apoptotic cells either 24 hours prior to administration of T4+ CAR T-cells or concurrent with administration of T4+ CAR T-cells (10 - 30×10^6 T4+ CAR T-cells).

25 Tumor growth will be followed by bioluminescence imaging (BLI) and circulating cytokine levels will be determined by Luminex.

[0625] ***In vivo Luciferase assay***

[0626] Tumor growth was monitored weekly through firefly luciferase activity. In brief, 3 mg D-luciferin (E1605, Promega, USA)/mouse (100 μ l of 30 mg/ml D-luciferin) was injected i.p. into
30 isoflurane-anesthetized mice and ventral images were acquired 10 minutes after injection using IVIS Imaging System and Live Image image capture software (both from Perkin Elmer, USA).

[0627] Image acquisition parameters were chosen for each image session by imaging mice that received 0.5×10^6 SKOV3-luc cells/mouse, 5 minutes post D-luciferin injection the “auto” option.

Capture parameters were set for binning 4, F/stop 1.2 and exposure of 2-4 minutes using the 24x lens. Data analysis and quantification was performed with the Live Image software and graphs were generated using Microsoft's Excel program.

[0628] *In vivo Cytotoxicity*

- 5 [0629] To assess *in vivo* toxicity of T-cells, organs are collected from mice, formalin fixed, and subjected to histopathologic analysis.

[0630] *Cytokine analysis*

- [0631] Supernatants and sera are analyzed using Luminex MagPix reader and/or ELISA kits, cytometric bead arrays (Th1/Th2/Th17; BD Biosciences) as described by the manufacturers. For
10 example, analysis may be for pro-inflammatory cytokine, which in one case would be IL-6, though, in one embodiment, any of the cytokines listed in Tables 1 and 2 or known in the art may be analyzed herein.

[0632] **Results**

[0633] *Calibrating SKOV3-luc tumors in vivo*

- 15 [0634] 0.5×10^6 , 1×10^6 or 4.5×10^6 SKOV3-luc cells were injected i.p. to SCID beige mice and bioluminescence imaging (BLI) was conducted weekly in order to follow tumor growth, as described in the Methods (data not shown).

[0635] *Clinical score of mice*

- [0636] Mice displayed no clinical symptoms for the initial 4 weeks. However, 28 days post
20 SKOV3-luc injection, the mice that received the high dose (4.5×10^6 ; purple line) began to lose weighed steadily (**Figure 11A**) and the overall appearance of the mice deteriorated, manifested in lethargy, abnormal pacing and general loss of activity. This group was culled at the day 39, and an abdominal autopsy was performed to expose tumor appearance and size (**Figure 11B**). SKOV3-luc tumors were large, solid, vascularized and displayed a whitish shining complexion. One large tumor
25 predominated on the side of the injection (left) either caudal or rostral in the abdominal cavity. This tumor encompassed approximately 25-75% of the cavity and clearly pressed and disturbed the intestines. Smaller foci were also observed at various locations within the abdominal cavity. Tumors were contained within the abdominal cavity and no other tumors were observed in any other part of the body in any mice. Mice receiving low (0.5×10^6) or medium (1×10^6) dose of SKOV3-luc cease
30 gaining weight 40 days after SKOV3-luc injection and began to steadily lose weighed. Experiment was terminated 50 days after SKOV3-luc injection.

[0637] *SKOV3-luc Tumor Kinetics*

[0638] PBS was injected to control for SKOV3-luc cells and these mice did not exhibit any luciferase activity throughout the experiment (**Figure 12**, Left panel). Tumor detection and growth

was dose-dependent. Lower dose (0.5×10^6 SKOV3-luc cells) began to display tumors 25 days post-injection (4/5 animals), medium dose (1×10^6) injections showed tumors at 18 days post-injection (4/5 animals), whereas at higher dose (4.5×10^6) tumors were detected as early as 11 days post-injection in 3/5 animals and by day 18 all animals displayed well-established tumors (**Figure 12 and Figures 13A-13D**).

[0639] *CAR T-cell therapy induces cytokine release syndrome*

[0640] Three groups of tumor-free mice as well as mice with tumors are administered (i.p. or directly into the tumor) increasing doses of T4+ CAR T-cells (3×10^6 , 10×10^6 or 30×10^6). At the highest dose, tumor-free mice and mice with tumors demonstrate subdued behavior, piloerection, and reduced mobility within 24 h, accompanied by rapid weight loss followed by death within 48 hrs. At least Human interferon-gamma and mouse IL-6 are detectable in blood samples from the mice given the highest dose of CAR T-cells. Animals that receive a high dose of CAR T-cells directed to a different tumor antigen do not exhibit weight loss or behavioral alterations.

[0641] *Administration of apoptotic cells inhibits or reduces the incidence of cytokine release syndrome induced by CAR T-cell therapy*

[0642] One group of mice given the highest dose of CAR T-cells is concomitantly administered 2.10×10^8 /kg apoptotic cells, which was previously demonstrated to be a safe and effective dose. Mice receiving human CAR T + apoptotic cells have significantly lowered levels of mouse IL-6, lower weight loss, and reduced mortality.

EXAMPLE 5: Effect of Combination Immune Therapy on in vitro Diffuse Tumor Models

[0643] **Objective:** Test the effect of apoptotic cells or supernatants derived from apoptotic cells in a diffuse tumor model where the cancer is widely spread and not localized or confined, in order to determine CAR T-cell efficacy on the cancer cells and the level of cytokine storm marker cytokines.

[0644] **Methods:**

[0645] *CD19+ T4+ CAR T-cells ("CD19+ CAR T-cells")*

CD19-specific CAR-T cells were purchased from ProMab (Lot # 012916). The T cells were 30% positive for CAR (according to manufacturer's FACS data – Fab staining). Briefly, cells were thawed into AimV + 5% heat-inactivated FBS, centrifuged (300g, 5 minutes, room-temperature), and resuspended in AimV. On day 6 of the experiment 20×10^6 cells were injected IV per mouse (70% AnnexinPI negative, of which 30% CAR positive).

[0646] Recombinant HeLa cells expressing CD19 will be used as a control cell-type that also

expresses CD19 on their cell surface.

[0647] *CD123+ CAR T-cells*

[0648] T4+ CAR T-cells will also be engineered with a CAR targeting CD123 epitopes (referred to herein as “CD123+ CAR T-cells”).

5 [0649] *Raji cells, CD19 expressing HeLa cells, and CD123 expressing leukemic cells*

[0650] Raji cells Raji cells were purchased from ECACC (Cat. #: 85011429), and routinely cultured in complete medium (RPMI-1640 supplemented with 10% H.I. FBS, 1% Glutamax, 1% Penicillin / Streptomycin), and maintained at a concentration of $3 \times 10^5 - 3 \times 10^6$ cells/ml. On day 1 of the experiment 0.1×10^6 cells were injected IV per mouse.

10 [0651] Similarly, CD19 expressing HeLa cells will be generated in the laboratory and used as a target for CD19+ CAR T-cells. CD123 expressing leukemic cells will be used as targets for CD123+ CAR T-cells. In addition, primary cancer cells will be utilized as a target for CAR T-cells.

[0652] HeLa cells expressing CD19 were prepared using methods known in the art. Cells will be cultured as is well known in the art.

15 [0653] CD123 is a membrane biomarker and a therapeutic target in hematologic malignancies. CD123 expressing leukemic cells, for example leukemic blasts and leukemic stem cells will be cultured as is known in the art.

[0654] *Apoptotic cells, Apoptotic cell supernatants and monocyte isolation*, will be prepared as described in Example 1. Early apoptotic cells produced were at least 50% annexin V-positive and
20 less than 5% PI-positive cells.

[0655] *Macrophages*. Were generated from CD14positive cells by adherence.

[0656] *Dendritic cells*. Were CD14 derived grown in the presence of IL4 and GMCSF.

[0657] *Flow-cytometry*. The following antibodies were used :hCD19-PE (eBiosciences, Cat. # 12-0198-42); mIgG1-PE (eBiosciences, Cat. # 12-0198-42); hCD3-FITC (eBiosciences, Cat. # 11-0037-42); mIgG2a-FITC (eBiosciences, Cat. # 11-4724-82). Acquisition was performed using
25 FACS Calibur, BD.

[0658] *Naïve T cells*. Naïve T cells were isolated from Buffy coat using magnetic beads (BD), and cryopreserved in 90% human AB serum and 10% DMSO. Thawing and injection was identical to the CAR-T cells.

30 [0659] *In vitro culturing conditions*

[0660] *Cell lines and culturing reagents*

[0661] The human lymphoma cell line Raji (eCACC, UK, access no. 85011429), the human cervical adenocarcinoma cell line HeLa (ATCC, USA, number: CCL-2) and HeLa-CD19 (ProMab,

USA, cat. no. PM-Hela-CD19) were cultured in RPMI 1640 (Gibco, ThermoFisher Scientific, USA, cat. no. 31870-025) supplemented with 10% FBS (Gibco, ThermoFisher Scientific, South America, cat. no. 12657-029), 2 mM GlutaMAX (Gibco, ThermoFisher Scientific, USA, cat. no. 35050-038), and 100 U/ml Penicillin + 100 U/ml Streptomycin (Gibco, ThermoFisher Scientific, USA, cat. no. 15140-122), henceforth referred to as “Complete Medium”. HeLa-CD19 medium was further supplemented with 1 µg/ml puromycin (Sigma-Aldrich, USA, cat. no. P9620), as the selective antibiotics, during standard culturing.

[0662] All cells were kept in sub-confluent conditions. Raji cells were maintained in a concentration range of 0.3×10^6 - 2×10^6 cell/ml. HeLa and HeLa-CD19 cells were passaged when receptacle was filled to 90% confluence.

[0663] Primary monocytes were isolated from blood donations buffy coats (Sheba Medical Center, Israel). First, peripheral blood mononuclear cells (PBMCs) were isolated on a Ficoll density gradient (Ficoll-Paque PLUS, GE Healthcare, UK, cat. no. 17-1440-03). Upon centrifugation (800x g, 2-8°C, 20 min. with break 0), the interphase containing the PBMCs were transferred to a fresh test tube and washed with RPMI-1640 (Lonza, Switzerland, cat. no. BE12-918F) supplemented with 2 mM L-glutamine (Lonza, Switzerland, cat. no. BE17-605E) and 10 mM Hepes (Lonza, Switzerland, cat. no. BE17-737B), henceforth “Wash Medium”, and centrifuged (650x g, 2-8°C, 10 min.). Pelleted cells were re-suspended in “Wash Medium” to a concentration of 15×10^6 cell/ml. Cells were seeded as a 0.9 ml drop at the center of a 35-mm plate (Corning, USA, cat. no. 430165). Plates were incubated for 1.5h in a humidified incubator (37°C, 5% CO₂), allowing monocytes to adhere, and then washed three times with pre-warmed PBS (Lonza, Switzerland, cat. no. BE17-516F), removing other cell types. After washing, cells were cultured in 2 ml RPMI 1640 (Gibco, ThermoFisher Scientific, USA, cat. no. 31870-025) supplemented with 10% FBS (Gibco, ThermoFisher Scientific, South America, cat. no. 12657-029), 2 mM GlutaMAX (Gibco, ThermoFisher Scientific, USA, cat. no. 35050-038), and 100 U/ml Penicillin + 100 U/ml Streptomycin (Gibco, ThermoFisher Scientific, USA, cat. no. 15140-122), aka “Complete Medium”.

[0664] All cell lines were cultured in a humidified incubator at 37°C and containing 5% CO₂.

[0665] CD19-CAR T cells (ProMab, USA, cat. no. FMC63) were delivered either in AIM-V medium or frozen. Cryopreserved CAR T cells for *in vitro* experiments were thawed on the day of the experiment in a 35-38°C bath and immediately immersed in pre-warmed AIM V medium (Gibco, ThermoFisher Scientific, USA, cat. no. 12055-091) supplemented with 5% FBS (Gibco, South America, cat. no. 12657-029). DMSO was removed by centrifuging the cells (300x g, room temperature, 5 min.) and re-suspending in pre-warmed AIM V medium. Concentration and viability

of CD19-CAR+ cell population was determined by anti-FLAG (BioLegend, USA, cat. no. 637310) staining and by Annexin V and PI staining (MEBCYTO Apoptosis kit, MBL, USA, cat. no. 4700) read with FACSCalibur flow cytometer (BD, USA).

[0666] For Naïve T cell isolation, PBMCs were extracted either from leukapheresis fractions collected from informed consenting eligible donors at Hadassah Medical Center (Ein Kerem Campus, Jerusalem, Israel) using a Cobe Spectra™ apheresis apparatus (Gambro BCT, USA) according to Leukapheresis Unit's SOP or from buffy coats (Sheba Medical Center, Israel) loaded on a Ficoll density gradient and centrifuged 800x g, 2-8°C, 20 min. T cells were isolated from the positive fraction using MagniSort Human CD3 Positive Selection Kit (eBioscience, USA, cat. no. 8802-6830-74) following manufacturer's guidelines. T cells were cryopreserved in "Complete Medium" (defined above) containing an additional 20% FBS (Gibco, ThermoFisher Scientific, South America, cat. no. 12657-029) and 5% DMSO (CryoSure-DMSO, WAK-Chemie Medical GmbH, Germany, cat. no. WAK-DMSO-70) and thawed on the day of experiment parallel to the CD19-CAR T cells.

[0667] a *LDH cytotoxicity assay*

[0668] Lactate dehydrogenase (LDH), a stable cytosolic enzyme, is released by cells undergoing lysis in a correlative manner. Hence, LDH levels in the medium can be used to quantify cytotoxic activity. CytoTox 96 Non-Radioactive Cytotoxicity Assay (Promega, USA, cat. no. G1780) is a colorimetric assay to quantify LDH levels in the medium. A tetrazolium salt substrate (iodonitro-tetrazolium violet, INT) is introduced to the medium in excess and LDH converts the substrate into a red formazan product. The amount of red color formed is directly proportional to the number of cells lysed.

[0669] In brief, and following manufacturer's guidelines, target cells (HeLa or HeLa-CD19) were cultured alone or in conjunction with monocytes. After target cells adhered to the plate (6h-overnight), cultures were exposed to $y \times 10^6$ ApoCells cells for 1h, after which these cells were washed off by 4-5 washes of RPMI. Removal of ApoCells cells was confirmed visually under a light microscope. 10 ng/ml LPS (Sigma-Aldrich, USA, cat. no. L4391) was introduced to the co-culture and incubated for 1h. After incubation, LPS was removed by 3-5 washing cycles with RPMI. Viable CD19-CAR T cells or naïve T cells were added at the designated E/T ratio(s) and incubated for 4h. To collect media, plates were centrifuged at 250x g, 2-25°C, 4 min. (Centrifuge 5810 R, Eppendorf, Germany) to sediment cells. 50 µl of supernatant medium from each well was transferred to a fresh flat-bottom 96-well microplate well (Corning, USA, cat. no. 3596) and 50 µl CytoTox 96 Reagent was added to each well. Plates were incubated in the dark at room temperature for 30 min., after which the reaction was terminated by addition of 50 µl Stop Solution per well.

Absorbance was read at 492 nm using Infinite F50 (Tecan, Switzerland) and captured using Magellan F50 software. Data analysis and graph generation was performed using Microsoft Excel 2010.

[0670] *Flow cytometry cytotoxicity assay*

- 5 [0671] HeLa-CD19 (target) and HeLa (control) cells were pre-stained with 5 μ M carboxyfluorescein succinimidyl ester (CFSE, Life Technologies, USA, cat. no. C1157), mixed together, and plated on either fresh plates or on plates populated with isolated primary monocyte. After target cells adhere to the plate (6h-overnight), cultures were exposed to $y \times 10^6$ ApoCells cells for 1h. Plates were washed with RPMI 3-5 times and visually verified that suspended ApoCells cells were washed off. 10 ng/ml LPS was introduced to the co-culture and incubated for 1h, after which LPS was removed by 3-5 washing cycles with RPMI. Viable CD19-CAR T cells were then added to the co-cultures as indicated by specific E/T ratio(s) and incubated for 4h. After incubation, cells were harvested by adding trypsin-EDTA (Biological Industries, Israel, cat. no. 03-052-1B) and incubating for 4 min. at 37°C. To terminate the enzymatic activity, two- to four-fold volume of “complete medium” was added. Cells were collected, centrifuged at 200x g for 5 min. at room temperature and re-suspended in 100 μ l RPMI (Gibco, ThermoFisher Scientific, USA, cat. no. 15140-122). Staining ensued first against anti-CD19 (eBioscience, USA, cat. no. 12-0198-42), incubated in dark for 30 min. at room temperature. After centrifugation (290x g, 1 min., 2-8°C) and re-suspended in 300 μ l RPMI, cells were stained against anti-7AAD (eBioscience, USA, cat. no. 00-6993-50). Analysis was gated on 7ADD-negative cells (live cells), where live target cell (HeLa-CD19) and live control cells (HeLa) was calculated. Percent survival was calculated by dividing percent live target cells by percent live control cells. To correct for variation in starting cell numbers and spontaneous target cell death, percent survival was divided by the ratio of percent target cells to percent control cells cultured without effector cells (CD19-CAR T cells). Finally, percent cytotoxicity was determined by subtracting the corrected survival percentage from 100%².

[0672] Initial experiments are performed by incubating Raji cancer cells with CD19+ CAR T-cells (+/- monocytes-macrophages) for 48 hours in order to determine optimal ratios of CD19+ CAR T-cells to target Raji cancer cells, beginning with 5×10^4 Raji cells/well in a 96-well plate. An effector/target (E/T) ratio plate is constructed based on the results.

- 30 [0673] Combination immunotherapy experiments are performed by incubating the Raji cancer cells with apoptotic cells, or apoptotic supernatants, for 1 hour followed by co-culturing with CD19+ CAR T-cells (+/- monocytes-macrophages) for 48 hours.

[0674] In order to simulate *in vivo* conditions, 1×10^5 THP-1 cells/ml will be differentiated with 200 nM (123.4 ng/ml) phorbol myristate acetate (PMA) for 72 hrs and will then be cultured in complete

medium without PMA for an additional 24h. Next, Raji cancer cells will be plated in a 24-well plate at 5×10^5 Raji cells/well on the differentiated THP-1 cells.

[0675] Following initial culturing of the Raji cancer cells, 4×10^5 - 8×10^5 apoptotic cells (ApoCell) will be added to the culture for 1-3h to induce an immunotolerant environment. The ratio of cancer cell to ApoCell will be optimized for each cell type. After washing, the co-culture will be treated with a pre-determined number of CD19⁺ CAR-T cells based on the E/T ratio graph. In certain experiments, 10 ng/ml LPS will be added to the culture media prior to addition of the CD19⁺ CAR T-cells. In other experiments, interferon γ (IFN- γ) will be added to the culture media prior to addition of the CD19⁺ CAR T-cells. The addition of LPS or IFN- γ is expected to exponentially increase the cytokine storm level.

[0676] To assay for Raji cancer cell cytotoxicity, lysates are prepared and viability is determined after the 48 hour incubation period. Additional experiments will be performed assaying for Raji cell cytotoxicity at intervals within the 48h incubation time period. Alternatively, Promega's CytoTox 96 Non-Radioactive Cytotoxicity Assay (Promega, cat #G1780) will be used.

[0677] Similar experiments are run with CD19 expressing HeLa cells and CD19⁺ CAR T-cells.

[0678] Similar experiments are run with CD123 expressing leukemic cells and CD123⁺ CAR T-cells.

[0679] *Cytokine Analysis*

[0680] Initial cytokine assays examine the levels of MIP1a, IL-4, IL-2, IL-2R, IL-6, IL8, IL-9, IL-10, IL-13, IL-15, INF- γ , GMCSF, TNF- α , in the culture supernatant.

[0681] Additional cytokine assays examine the level of cytokines IL-10, IL-1 β , IL-2, IP-10, IL-4, IL-5, IL-6, IFN α , IL-9, IL-13, IFN- γ , IL-12p70, GM-CSF, TNF- α , MIP-1 α , MIP-1 β , IL-17A, IL-15/IL-15R, or IL-7, or any combination thereof.

[0682] Cultures were established to mimic an *in vivo* CAR T-cell therapy environment. Raji Burkett Lymphoma cells were cultured in the presence of human monocyte-macrophages, LPS and CD19⁺ CAR T-cells without and with the addition of apoptotic cells.

[0683] Raji cells were incubated in the presence of monocytes and LPS, followed by addition of Naïve T-cells (Raji + Naïve T), CD19⁺ CAR T-cells (Raji + CAR T), CD19⁺ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:8 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:8), CD19⁺ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:32 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:32), and CD19⁺ CAR T-cells and apoptotic cells (ApoCell) at a ratio of 1:64 CAR T-cells:ApoCells (Raji + CAR T+ApoCell 1:64). Concentration measurements were made following GM-CSF and TNF- α (TNF-a).

[0684] To assay for cytokine release reduction of IL-6, IL-8, and IL-13, as well as other cytokines,

supernatants will be collected and examined for selected cytokine using Luminex MagPix reader and ELISA assays. Cytokines (mouse or human) may be evaluated by Luminex technology using MAPIX system analyzer (Mereck Millipore)) and MILIPLEX analysis software (Merek Millipore). Mouse IL-6R α , MIG (CXCL9) and TGF- β 1 were evaluated by Quantikine ELISA (R&D systems).

5 [0685] *Tissue Analysis*

[0686] Bone marrow and liver were evaluated using flow cytometry and immunohistochemistry. Upon sacrifice liver and bone marrow were collected for histopathological analysis. Tissues were fixed in 4% formalin for 48h at room temperature, and then submitted to the animal facility at the Hebrew University for processing. Bones were decalcified prior to processing. Paraffin sections
10 were stained for Hematoxylin and Eosin, and CD19.

[0687] *IFN- γ Effect*

[0688] IFN- γ effect is evaluated both by STAT1 phosphorylation and biological products.

[0689] **Results:**

[0690] *Calibrating cell number for Cytotoxicity assay*

15 [0691] To determine the number of Raji cells to be used in the *in vitro* model, sensitivity limits of the cytotoxicity assay was assessed. 5×10^4 - 20×10^4 Raji cells/well were plated in a 96-well plate, in quadruplicate. Lysis was performed on one set of quadruplicate to be compared with cells that are still completely viable. Lysis was momentary, adding the lysis solution immediately prior to centrifugation to simulate partial cell cytotoxicity. Indeed, all cell quantities exhibited readings well
20 above viable cells, with the 5×10^4 cell number producing the greatest relative reading (**Figure 14**; extrapolation of data). Therefore, subsequent experiments will be using this cell number as default, unless otherwise required by experimental deign.

[0692] *Verification of CD19⁺ CAR-T cell activity against Raji Burkett Lymphoma cells*

[0693] To corroborate the CD19⁺ CAR T-cell activity, monolayers of Raji cancer cells are exposed
25 to either 1,000,000 (one million) CD19⁺ CAR-T cells or to 1,000,000 (one million) non-transduced T cells. After 24h incubation, CD19⁺ CAR-T cells reduce Raji cancer cell proliferation, showing anti-tumor activity of the CD19⁺ CAR-T cells.

[0694] *Activity of stand-alone CD19⁺ CAR-T cells against Raji Burkett Lymphoma cells was compared to activity post exposure to Apoptotic Cells*

30 [0695] Apoptotic cells (ApoCell) and apoptotic cell supernatants (ApoSup and ApoMon Sup) are tested to determine if they interfere with CD19⁺ CAR-T cell anti-tumor activity. The Raji Burkett Lymphoma cells are incubate with Apoptotic Cells for one hour, followed by the addition of CD19⁺ CAR-T cells (500,000, five hundred thousands) or CD19⁺ non-transduced T cells (500,000, five hundred thousands) (ratio of 1:2 CD19⁺ CAR-T cells to Apoptotic Cells). The tumor

cell/Apoptotic cell/CD19⁺ CAR T-cells are then co-cultured for 48h. The control Raji Burkett Lymphoma cells are co-cultured with CD19⁺ CAR-T cells and Hartman solution (the vehicle of Apoptotic Cells), but without Apoptotic Cells, for 48h.

[0696] The results are showing that after 48h incubation, CD19⁺ CAR-T cells anti-tumor activity was superior to incubation with non-transduced T cells. Similar incubations will be performed with apoptotic cell supernatants. Surprisingly, CD19⁺ CAR T-cell anti-tumor activity is comparable with or without exposure to apoptotic cells or apoptotic cell supernatants.

[0697] No negative effect of apoptotic cells on CAR-modified T cells against CD19 both in vitro was seen with comparable E/T ratio results of CAR T in the presence or absence of apoptotic cells.

[0698] *Verification of CD19⁺ CAR-T cell activity against HeLa Leukemia cells*

[0699] HeLa cells are specific CD19 expressing cells, which renders them susceptible to CAR CD19⁺ T-cell activity. In addition, in contrast to Raji cells, which are a non-adherent cell line, HeLa cells are adherent.

[0700] To corroborate the CD19⁺ CAR T-cell activity, monolayers of HeLa cancer cells were exposed to either 1,000,000 (one million) CD19⁺ CAR-T cells or to 1,000,000 (one million) non-transduced T cells. After 24h incubation, CD19⁺ CAR-T cells reduce HeLa cancer cell proliferation, showing anti-tumor activity of the CD19⁺ CAR-T cells (**Figure 15** CD19⁺ + RPMI and CD19⁺ + CAR T-19 cells).

[0701] *Activity of stand-alone CD19⁺ CAR-T cells against CD19⁺ HeLa cells was compared to activity post exposure to Apoptotic Cells*

[0702] Apoptotic cells (ApoCell) were tested to determine if they interfere with CD19⁺ CAR-T cell anti-tumor activity. The HeLa cells were incubated with Apoptotic Cells for one hour, followed by the addition of CD19⁺ CAR-T cells (500,000, five hundred thousand) or CD19⁺ non-transduced T cells (Naïve T cells; 500,000, five hundred thousand) (ratio of 1:2 CD19⁺ CAR-T cells to Apoptotic Cells). The tumor cell/Apoptotic cell/CD19⁺ CAR T-cells were then co-cultured for 48h. The control HeLa cells were co-cultured with CD19⁺ CAR-T cells and RPMI (the vehicle of Apoptotic Cells), but without Apoptotic Cells, for 48h. The CD19⁺ CAR-T cell:HeLa cell ratio (E/T ratio) ranged from 5-20 (**Figure 15**).

[0703] **Figure 15** shows that after 48h incubation, CD19⁺ CAR-T cells anti-tumor activity was superior to incubation with non-transduced T cells (Naïve cells) or buffer alone. Similar incubations were performed with apoptotic cells. Surprisingly, CD19⁺ CAR T-cell anti-tumor activity was comparable with or without exposure to apoptotic cells. Similar experiments are performed using apoptotic cell supernatants. **Figure 15** shows the same *in vitro* cytotoxicity effect of CAR T-CD19 therapy with or without the addition of ApoCells.

[0704] No negative effect of the apoptotic cells on CAR-modified T cells against CD19+HeLa cells was observed at comparable E/T ratios in the presence or absence of apoptotic cells.

[0705] Thus, the same *in vitro* cytotoxic effect of the CD19⁺CAR T-cells was observed with or without the addition of early apoptotic cells.

5 [0706] *Effect of Apoptotic Cells on amelioration, reduction or inhibition of cytokine storms resulting from CAR-T treatment*

[0707] Cytokines IL-8 and IL-13 are measured in the culture media prior to and following addition of CD19+ CAR T-cells and are showing a concentration consistent with a cytokine storm. Addition of apoptotic cells or apoptotic cell supernatant is showing a reduction of IL-8 and IL-13
10 concentrations in the media.

[0708] *Analysis using a wider range of cytokines*

[0709] To further evaluate the effect on a possible wider range and levels of cytokines that are not generated during experimental procedures but do appear in clinical settings during a human cytokine storm, LPS (10 ng/ml) was added to the Raji cell culture conditions outlined above in the
15 presence of cancer and CAR-19. The addition of LPS was expected to exponentially increase the cytokine storm level. Exposure to apoptotic cells is dramatically reduced the levels of cytokines. The results presented in **Figure 16** and **Figure 17** show that while addition of CD19+ CAR T-cell greatly increases cytokine concentration (pg/ml) of GM-CSF and TNF- α in the culture medium, there is a significant decrease of both GM-CSF and TNF- α in the presence of apoptotic cells. The
20 decrease in the cytokine concentration is dose dependent with respect to apoptotic cell ratio of CAR T-cells to apoptotic cells.

[0710] *Conclusion:*

[0711] Apoptotic cells were able to down regulate cytokine markers of cytokine storm associated with CAR T-cell clinical procedures. Significantly, the apoptotic cells did not show an effect on the
25 tumor activity of the CAR T-cells. Apoptotic cells decreased pro-inflammatory cytokines that originated from innate immunity and inhibit IFN- γ effect without harming IFN- γ levels and CAR-T cytotoxicity.

***EXAMPLE 6: Apoptotic Cell Therapy Prevents Cytokine Storms in A Diffuse Cancer in vivo
Model Administered Car T-Cell Therapy***

30 [0712] **Objective:** Test the *in vivo* effect of apoptotic cells or supernatants derived from apoptotic cells in a diffuse tumor model, in order to determine CAR T-cell efficacy on the cancer cells and the level of cytokine storm marker cytokines.

[0713] **Materials and Methods**

[0714] *In vitro studies*

[0715] See methods described in Example 5 for *in vitro* studies.

[0716] *Cells and cell culture*

[0717] Raji Burkitt lymphoma cells (Sigma-Aldrich cat. # 85011429) were cultured as per the manufacture's guidelines. CD19+ CAR T-cells, cell cultures, apoptotic cells, apoptotic cell supernatants, monocyte isolation, and *in vitro* measurements are as above for Examples. Early apoptotic cells produced were least 50% annexin V-positive and less than 5% PI-positive cells.

[0718] *In vivo studies*

[0719] *Mice*

[0720] 7-8 week old SCID beige mice were purchased from Envigo (formerly known as Harlan). Mice were kept in an SPF free animal facility in compliance with institutional IACUC guidelines. During the course of the experiments the mice were monitored daily, and weighted 3 times a week. Mice showing hind limb paralysis were sacrificed. Upon sacrifice bone marrow and liver were collected for FACS analysis and histological processing, and sera were frozen at -80°C for cytokine profiling. *In vivo experiments*

[0721] SCID beige mice (C.B-17/IcrHsd-Prkdc-SCID-Lyst-bg, Harlan, Israel) were housed in SPF conditions at The Authority for Animal Facilities (AAF), The Hebrew University of Jerusalem (Ein Kerem Campus, Israel) and following the Association for Assessment and Accreditation of Laboratory Animal Care (AAALAC). The studies were approved by The Hebrew University Ethics Committee for Animal Experiments, and animal suffering was minimized as possible.

[0722] (**Figure 18A**) For the disseminating tumor model, 7-8 week female SCID beige mice were injected i.v. with 1×10^5 Raji cells suspended in 200 μ l RPMI (Gibco, , ThermoFisher Scientific, USA, cat. no. 15140-122) per mouse (day 1). On day 6, mice of pertinent groups were inoculated i.v. with 30×10^6 cells ApoCells in 200 μ l Hartmann's solution Lactated Ringer's Injection, Teva Medical, Israel, cat. no. AWN2324) per mouse. On day 6, mice of relevant groups were inoculated i.v. with 10×10^6 viable CD19-CAR T cells or naïve T cells in 200 μ l AIM V per mouse. Control mice received equal volume of RPMI for each treatment.

[0723] Mice were examined for clinical indications and weighed twice a week and were sacrificed upon development of hind limb paralysis. Pathological samples of bone and liver were prepared by the Animal Facility Unit of The Hebrew University of Jerusalem and stained against human CD20 (Cell Marque, USA, clone L26, cat. no. 120M-84), to detect Raji cells, and against human CD3 (Cell Signaling Technology, USA, cat. no. 85061), to detect human T cells.

[0724] In certain experiments, LPS will be administered to the animal subject prior to addition of the CD19+ CAR T-cells. In other experiments, interferon- γ (IFN- γ) will be administered prior to

addition of the CD19+ CAR T-cells. The addition of LPS or IFN- γ is expected to exponentially increase the cytokine storm level.

[0725] Cytokine assays examine the level of cytokines including but not limited to IL-10, IL-1 β , IL-2, IP-10, IL-4, IL-5, IL-6, IFN α , IL-9, IL-13, IFN- γ , IL-12p70, GM-CSF, TNF- α , MIP-1 α , MIP-1 β , IL-17A, IL-15/IL-15R, or IL-7, or any combination thereof. Cytokines (mouse or human) are evaluated by Luminex technology using MAPIX system analyzer (Mereck Millipore)) and MILIPLEX analysis software (Merek Millipore). Mouse IL-6R α , MIG (CXCL9) and TGF- β 1 are evaluated by Quantikine ELISA (R&D systems).

[0726] *Tissue Analysis*

[0727] Bone marrow and liver are evaluated using flow cytometry and immunohistochemistry. Upon sacrifice liver and bone marrow were collected for histopathological analysis. Tissues were fixed in 4% formalin for 48h at room temperature, and then submitted to the animal facility at the Hebrew University for processing. Bones were decalcified prior to processing. Paraffin sections were stained for Hematoxylin and Eosin, and CD19.

[0728] *IFN- γ Effect*

[0729] IFN- γ effect is evaluated both by STAT1 phosphorylation and biological products.

[0730] **Results**

[0731] *CAR T-cell therapy induces cytokine release syndrome*

[0732] Three groups of tumor-free mice as well as mice with tumors are administered (i.p. or directly into the tumor) increasing doses of CD19+ CAR T-cells (3×10^6 , 10×10^6 or 30×10^6). At the highest dose, tumor-free mice and mice with tumors demonstrate subdued behavior, piloerection, and reduced mobility within 24 h, accompanied by rapid weight loss followed by death within 48 hrs. Human interferon-gamma, and mouse IL-6, IL-8, and IL-13 are detectable in blood samples from the mice given the highest dose of CD19+ CAR T-cells. Animals that receive a high dose of CD19+ CAR T-cells directed to a different tumor antigen do not exhibit weight loss or behavioral alterations.

[0733] *Administration of apoptotic cells inhibits or reduces the incidence of cytokine release syndrome induced by CAR T-cell therapy*

[0734] One group of mice given the highest dose of CD19+ CAR T-cells is concomitantly administered 2.10×10^8 /kg apoptotic cells, which was previously demonstrated to be a safe and effective dose. Mice receiving human CD19+ CAR T + apoptotic cells have significantly lowered levels of at least one mouse pro-inflammatory cytokines, lower weight loss, and reduced mortality.

[0735] *Administration of apoptotic cells in combination with CAR T-cell administration did not affect CAR T-cell anti-tumor activity*

[0736] **Figure 18B** shows that the expected death of SCID mice injected with CD19⁺ Raji cells without administration of CD19⁺CAR T-cells was 18-21 days. Forty percent (40%) of the mice who received CD19⁺CAR T-cells survived to at least day 30 (**Figure 18** blue and yellow lines). The percentage of survivors was independent of the addition of apoptotic cells (**Figure 18**). The surviving mice were sacrifice on day 30.

[0737] Conclusion: There was comparable survival and no negative effect of apoptotic cells on CAR-modified T cells against CD19 *in vivo*.

[0738] Significant down regulation ($p < 0.01$) of pro-inflammatory cytokines including, IL-6, IP-10, TNF- α , MIP-1 α , MIP-1 β was documented. IFN- γ was not downregulated but its effect on macrophages and dendritic cells was inhibited both at the level of phosphorylated STAT1 and IFN- γ -induced expression of CXCL10 and CXCL9.

[0739] *Conclusion:*

[0740] Apoptotic cells decrease pro-inflammatory cytokines that originate from innate immunity and inhibit IFN- γ effect without harming IFN- γ levels and CAR-T cytotoxicity.

EXAMPLE 7: APOPTOTIC CELL THERAPY PREVENTS CYTOKINE STORMS IN A SOLID TUMOR CANCER IN VIVO MODEL ADMINISTERED CAR T-CELL THERAPY

[0741] **Objective:** Test the *in vivo* effect of apoptotic cells or supernatants derived from apoptotic cells in a solid tumor model, in order to determine CAR T-cell efficacy on the cancer cells and the level of cytokine storm marker cytokines.

[0742] Materials and Methods

[0743] *In vitro* studies

[0744] *Cells and cell culture*

[0745] CD19⁺ CAR T-cells, Second generation CAR-T-CD19 cells containing TMCD28 were used, cell cultures, apoptotic cells, apoptotic cell supernatants, monocyte isolation, and *in vitro* measurements were as above for Examples 1 & 3 & 5. Early apoptotic cells produced were least 50% annexin V-positive and less than 5% PI-positive cells.

[0746] *In vivo* studies

[0747] *Mice*

[0748] 7-8 week old SCID-beige mice and NSGS mice were purchased from Harlan (Israel) and kept in the SPF animal facility in Sharett Institute.

[0749] SCID beige mice or NSGS mice were inoculated with CD19 expressing Hela cells, that can adhere to the peritoneum, in order to form solid intra-peritoneal tumors. Mice were sorted into groups prior to T-cell administration.

[0750] Six days post i.v. inoculation, mice were administered 10×10^6 CD19+ CAR T-cells with and without apoptotic cell (ApoCell) preconditioning on day 5. Mice receiving pre-conditioning were administered 5×10^6 or 30×10^6 ApoCells. Tumors were surveyed weekly and circulating cytokine levels were monitored weekly and determined by the Luminex system. 25 mouse cytokines and 32 human cytokines were evaluated using the Luminex technology. Upon termination of the experiment, mice were culled and organs (bone marrow, liver and spleen) were examined (by FACS and immunohistochemistry) for the presence/size of tumors.

[0751] Cytokine assays examined the level of cytokines including but not limited to GM-CSF, IFN γ , IL-1 β , IL-10, IL-12p70, IL-13, IL-15, IL-17A, IL-2, IL-4, IL-5, IL-6, IL-7, IL-9, MIP-1 α , TNF α , MIP-1 β , IFN α , and IP-10. Cytokines (mouse or human) were evaluated by Luminex technology using MAPIX system analyzer (Mereck Millipore)) and MILIPLEX analysis software (Merek Millipore). Mouse IL-6R α , MIG (CXCL9) and TGF- β 1 were evaluated by Quantikine ELISA (R&D systems).

[0752] *Tissue Analysis*

[0753] Bone marrow and liver are evaluated using flow cytometry and immunohistochemistry.

[0754] *IFN- γ Effect*

[0755] IFN- γ effect was evaluated both by STAT1 phosphorylation and biological products.

[0756] **Results**

[0757] *CAR T-cell therapy induces cytokine release syndrome*

[0758] Three groups of tumor-free mice as well as mice with tumors were administered (i.p. or directly into the tumor) increasing doses of CD19+ CAR T-cells (3×10^6 , 10×10^6 or 30×10^6). At the highest dose, tumor-free mice and mice with tumors demonstrate subdued behavior, piloerection, and reduced mobility within 24 h, accompanied by rapid weight loss followed by death within 48 hrs.

[0759] **Figures 19A-19C** graphically show the increased levels of IL-6, IP-10 and surprisingly even TNF- α cytokine release from tumors even before the presence of CAR T-cells. **Figures 19A-19C** show that unexpectedly IL-6, IP-10, and TNF- α were increased by the presence of cancer cells even without CAR T-cell therapy. In the presence of CAR T-Cell therapy (Hela-CAR T-cell CD-19) the release of cytokines was significantly augmented. These results show that the tumor itself releases pro-inflammatory cytokines.

[0760] In order to evaluate the benefit of the addition of early apoptotic cells, cytokines GM-CSF, IFN γ , IL-1 β , IL-10, IL-12p70, IL-13, IL-15, IL-17A, IL-2, IL-4, IL-5, IL-6, IL-7, IL-9, MIP-1 α , TNF α , MIP-1 β , IFN α , and IP-10 were measured in three experiments, wherein the results showed that macrophage associated cytokines were down-regulated in the presence of ApoCell

administration, while T-cell associated cytokine levels were not significantly changed (Table 4).

[0761] **Table 4:** Cytokine levels from an intra-peritoneum *in vivo* model that contained CD19 expressing Hela cells solid tumor, +/- CAR T-cell CD19 therapy, and +/- ApoCell

Pg/ml	Before Tumor Car or Apo	After tumor + CAR	After tumor, CAR, +with ApoCell
GM-CSF	4±2	88±10	12±4
IFN γ	4±1	5±8	5±21
IL-1 β	8±3	14±6	16±8
IL-10	76±13	222±44	36±22
IL-12p70	5±1	188±22	12±11
IL-13	6±2	8±1	8±4
IL-15	4±2	6±2	8±2
IL-2	4±2	26±2	29±2
IL-4	1±2	16±4	18±6
IL-6	24±6	820±56	74±12
MIP-1 α	8±5	99±13	18±8
TNF α	6±2	760±33	17±15
MIP-1 β	7±1	144±21	21±10
IFN α	74±12	68±36	71±14
IP-10	8±4	188±33	21±16

5 [0762] Table 4 shows cytokine measurement twenty-four (24) hours after CAR T-Cell administration +/- ApoCells. Resultant cytotoxicity from CAR T-cell therapy elevated cytokines including GM-CSF, IL-10, IL-12p70, IL-6, MIP-1 α , TNF α , MIP-1 β , and IP-10, the levels of which were significantly down regulated ($p < 0.05-0.0001$) in the presence of ApoCells. These cytokines are mainly associated with macrophages. In contrast, the levels of cytokines associated
10 with T-cells such as IL-2, IL-4, IL-13, and IL 15 were not changed significantly.

[0763] The results presented in **Figures 19A-C** and Table 4, illustrate that the CRS in the context of cancer and CAR has several ingredients: a tumor that can secrete cytokines; an innate immunity that respond to tumor and to CAR and to other factors; and that CAR T-cells that secrete cytokines causes death that influence innate immunity. ApoCells are interacting with innate immunity, mainly
15 macrophages, monocytes and dendritic cells, to down regulate the response of these macrophages, monocytes and dendritic cells without interacting with T cells or CAR T cells.

[0764] Animals that received a high dose of CD19+ CAR T-cells directed to a different tumor antigen do not exhibit weight loss or behavioral alterations.

[0765] *Administration of apoptotic cells inhibits or reduces the incidence of cytokine release syndrome induced by CAR T-cell therapy*
20

[0766] One group of mice given the highest dose of CD19+ CAR T-cells was concomitantly administered 2.10×10^8 /kg apoptotic cells, which was previously demonstrated to be a safe and effective dose. Apoptotic cells had no negative effect *in vitro* or *in vivo* on CAR-modified T cells

with specificity against CD19. There were comparable E/T ratios for CAR T-cells in the presence/absence of apoptotic cells *in vitro*, and comparable survival curves *in vivo* (Data not shown).

[0767] Mice receiving human CD19+ CAR T + apoptotic cells had significantly lowered levels of at least one mouse pro-inflammatory cytokines, lower weight loss, and reduced mortality.

[0768] No negative effect of apoptotic cells on CAR-modified T cells against CD19 *in vivo* was seen with comparable E/T ratio results of CAR T in the presence or absence of apoptotic cells, and a comparable survival curve *in vivo*.

[0769] Significant down regulation ($p < 0.01$) of pro-inflammatory cytokines including, IL-6, IP-10, TNF- α , MIP-1 α , MIP-1 β was documented (Data not shown). IFN- γ was not downregulated but its effect on macrophages and dendritic cells was inhibited both at the level of phosphorylated STAT1 and IFN- γ -induced expression of CXCL10 and CXCL9 (Data not shown).

[0770] *Conclusion:*

[0771] . CRS evolves from several factors, including tumor biology, interaction with monocytes/macrophages/dendritic cells, and as a response to the CAR T cell effect and expansion. Apoptotic cells decrease pro-inflammatory cytokines that originate from innate immunity and inhibit the IFN- γ effect on monocyte/macrophages/ dendritic cells without harming IFN- γ levels or CAR-T cytotoxicity. Thus, apoptotic cells decreased pro-inflammatory cytokines that originate from innate immunity and inhibit IFN- γ effect without harming IFN- γ levels and CAR-T cytotoxicity.

These results support the safe use of ApoCells for the prevention of CRS in clinical studies using CAR-T cell therapy.

[0772] While certain features disclosed herein have been illustrated and described herein, many modifications, substitutions, changes, and equivalents will now occur to those of ordinary skill in the art. It is, therefore, to be understood that the appended claims are intended to cover all such modifications and changes as fall within the true spirit disclosed herein.

CLAIMS

1. A method of maintaining or increasing the proliferation rate of chimeric antigen receptor-expressing T-cells (CAR T-cell) during CAR T-cell cancer therapy, the method comprising a step of administering a composition comprising apoptotic cells or an apoptotic cell supernatant to a subject undergoing CAR T-cell cancer therapy, wherein said proliferation rate is maintained or increased in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.
2. The method of claim 1, wherein the method does not reduce or inhibit the efficacy of said CAR T-cell cancer therapy.
3. The method of claim 1, wherein the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject not administered said apoptotic cells or said apoptotic cell supernatant.
4. The method of claim 1, wherein administration of said composition comprising said apoptotic cells or said apoptotic cell supernatant occurs prior to, concurrent with, or following the CAR T-cell therapy.
5. The method of claim 1, wherein said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with said apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant, and said white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.
6. The method of claim 1, wherein said method maintains or increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.
7. A method of increasing the efficacy of chimeric antigen receptor T-cell (CAR T-cell) cancer therapy, the method comprising a step of administering CAR T-cells and an additional agent selected from the group comprising apoptotic cells, an apoptotic cell supernatant, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said efficacy of said CAR T-cell cancer therapy is

increased in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said additional agent.

8. The method of claim 7, wherein the level of production of at least one pro-inflammatory cytokine is reduced compared with the level of said pro-inflammatory cytokine in a subject received CAR T-cell cancer therapy and not administered a composition comprising said agent.
9. The method of claim 8, wherein said pro-inflammatory cytokine comprises IL-6.
10. The method of claim 7, wherein when apoptotic cells or an apoptotic cell supernatant is administered, said method maintains or increases the levels of IL-2 in the subject compared with a subject undergoing CAR T-cell cancer therapy and not administered said apoptotic cells or said apoptotic cell supernatant.
11. The method of claim 7, wherein the incidence of cytokine release syndrome (CRS) or a cytokine storm in said subject is inhibited or reduced compared with a subject not administered said additional agent.
12. The method of claim 7, wherein said CAR T-cells and said additional agent or any combination thereof, are comprised in a single composition or in at least two compositions, and when the additional agent or combination of agents thereof are comprised in a composition not including said CAR T-cells, the administration of said composition comprising said agent or agents occurs prior to, concurrent with, or following administration of said CAR T-cells.
13. The method of claim 7, wherein said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with said apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant, and said white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.
14. A method of treating, preventing, inhibiting, reducing the incidence of, ameliorating, or alleviating a cancer or a tumor in a subject, comprising a step of administering chimeric antigen receptor-expressing T-cells (CAR T-cell) and an additional agent, said additional agent comprising apoptotic cells, apoptotic cell supernatants, a CTLA-4 blocking agent, an alpha-1 anti-trypsin or fragment thereof or analogue thereof, a tellurium-based compound, or an immune modulating agent, or any combination thereof, wherein said

method treats, prevents, inhibits, reduces the incidence of, ameliorates or alleviates a cancer or a tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.

15. The method of claim 14, wherein said method has increased efficacy treating, preventing, inhibiting, reducing the incidence of, ameliorating or alleviating said cancer or said tumor in said subject compared with a subject administered CAR T-cells and not administered said additional agent.
16. The methods of claim 14, wherein the level of production of at least one pro-inflammatory cytokine is reduced compared with the level of said pro-inflammatory cytokine in a subject administered said CAR T-cells and not administered a composition comprising said agent.
17. The method of claim 16, wherein said pro-inflammatory cytokine comprises IL-6.
18. The method of claim 14, wherein when said additional agent comprises apoptotic cells or an apoptotic cell supernatant, and said method increases the levels of IL-2 in the subject compared with a subject administered said CAR T-cells and not administered said apoptotic cells or said apoptotic cell supernatant.
19. The method of claim 14, wherein said CAR T-cells and said additional agent or any combination thereof are comprised in a single composition or in at least two compositions, and when the additional agent or combination of agents thereof are comprised in a composition not including said CAR T-cells, the administration of said composition comprising said agent or agents occurs prior to, concurrent with, or following administration of said CAR T-cells.
20. The method of claim 14, wherein said apoptotic cell supernatant is an apoptotic cell-white blood cell supernatant, wherein white blood cells are co-cultured with said apoptotic cells prior to collection of the apoptotic cell-white blood cell supernatant, and said white blood cells are selected from the group consisting of phagocytes, macrophages, dendritic cells, monocytes, B cells, T cells, and NK cells.
