TRICUSPID VALVE REPAIR USING TENSION

CROSS-REFERENCE TO RELATED APPLICATIONS

The present application claims priority from and is a continuation-in-part of US Application 12/692,061, filed January 22, 2010, entitled, "Tricuspid valve repair using
5 tension," which is assigned to the assignee of the present application and is incorporated herein by reference.

FIELD OF THE APPLICATION

Some applications of the present invention relate in general to valve repair. More specifically, some applications of the present invention relate to repair of a tricuspid valve
10 of a patient.

BACKGROUND OF THE APPLICATION

Functional tricuspid regurgitation (FTR) is governed by several pathophysiologic abnormalities such as tricuspid valve annular dilatation, annular shape, pulmonary hypertension, left or right ventricle dysfunction, right ventricle geometry, and leaflet
15 tethering. Treatment options for FTR are primarily surgical. The current prevalence of moderate-to-severe tricuspid regurgitation is estimated to be 1.6 million in the United States. Of these, only 8,000 patients undergo tricuspid valve surgeries annually, most of them in conjunction with left heart valve surgeries.

SUMMARY OF THE INVENTION

20 In some applications of the present invention, apparatus and methods are provided for repairing a tricuspid valve of a patient using tension. Typically, the apparatus and methods for repairing the tricuspid valve facilitate reducing of tricuspid valve regurgitation by altering the geometry of the tricuspid valve and/or by altering the geometry of the wall of the right atrium of the heart of the patient. In some applications
25 of the present invention, a first tissue-engaging element is implanted in a first portion of tissue that is upstream of the tricuspid valve of the patient. A second tissue-engaging element is then implanted in a second portion of tissue that is upstream of the tricuspid valve of the patient. Typically, following implantation of both the first and second tissue-engaging elements, a distance between the leaflets of the tricuspid valve is adjusted by

pulling a longitudinal member that connects the first and second tissue-engaging elements or by pulling at least one of the tissue-engaging elements. Alternatively or additionally, the longitudinal member is adjusted prior to implanting the second tissue-engaging element. For some applications, the longitudinal member is coupled at least in part to an
5 adjusting mechanism, and the longitudinal member is pulled or relaxed responsively to actuation of the adjusting mechanism.

In some applications of the present invention, apparatus and method are provided to achieve bicuspidization of the tricuspid valve. For such applications, typically, the anterior leaflet and the septal leaflet are drawn together to enhance coaptation.

10 For some applications, the first tissue-engaging element comprises a first stent which is expanded in a portion of an inferior vena cava. The second tissue engaging element comprises a second stent which is expanded in a portion of a superior vena cava. The distance between the first and second stents is then adjusted by pulling the longitudinal member, optionally while monitoring regurgitation of the tricuspid valve.
15 Responsively to the pulling of the longitudinal element, the geometry of the right atrium is altered, thereby drawing together the leaflets of the tricuspid valve.

For other applications, the first tissue-engaging element comprises a stent that is implanted in either the inferior or superior vena cava, and the second tissue-engaging element comprises a tissue anchor which punctures a portion of cardiac tissue of the
20 patient and is implanted at least in part in the portion of cardiac tissue. For some applications, a plurality of second tissue-engaging elements are provided (such as two or three), which are implanted in respective portions of cardiac tissue in a vicinity of the heart valve. For some applications, a longitudinal member is (a) directly coupled to the first tissue-engaging element, (b) directly coupled to one of the second tissue-engaging
25 elements, and (c) indirectly coupled to two others of the second tissue-engaging elements by a longitudinal sub-member.

For still other applications of the present invention, both the first and second tissue-engaging elements comprise respective first and second tissue anchors. Each tissue anchor punctures a respective portion of cardiac tissue of the patient and is implanted at
30 least in part in the respective portion of cardiac tissue. The tensioning element couples the first and second tissue anchors and is adjusted following implantation of the first and second tissue anchors by pulling or relaxing the tensioning element.

For some applications of the present invention, a rotation tool is provided for rotating a tissue anchor, so as to drive the anchor into tissue. The rotation tool comprises a rotation tube, a distal end of which is configured to removably engage a proximal coupling head of the anchor, such that rotation of the rotation tube rotates the anchor. For
5 some applications, the tool further comprises an elongated coupling element, which may comprise, for example, a string, a cable, or a wire. The anchor, such as the proximal coupling head thereof, is shaped so as to define a passage therethrough. The elongated coupling element is initially disposed so as to pass through the passage, such that both ends of the elongated coupling element extend in a proximal direction. When thus
10 positioned, the elongated coupling element couples the tool to the anchor. To decouple the tool from the anchor, one of the ends of the elongated coupling element is pulled until the elongated coupling element no longer passes through the passage.

For some applications of the present invention, a system for repairing a tricuspid valve comprises a tensioning device and a deployment tube. The tensioning device
15 comprises a tissue anchor, a radially-expandable anchor, and at least one flexible longitudinal member that connects the tissue and radially-expandable anchors. The radially-expandable anchor, when in a radially-expanded state, is configured to rest against a wall of a cardiac chamber and to not pass through a hole in the cardiac wall. For example, when in its radially-expanded state, the radially-expandable anchor may be
20 shaped like a flower or butterfly, and thus may be shaped so as to define a plurality of petals or wings. Typically, the radially-expandable anchor is configured to generally fall within exactly one plane when in its radially-expanded state.

The radially-expandable anchor defines an opening, through which the longitudinal member passes, such that the radially-expanded anchor is slidably coupled to
25 the longitudinal member. The radially-expandable anchor and the longitudinal member are configured such that the radially-expandable member is lockable to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the longitudinal member at least in a proximal direction toward the proximal end of the longitudinal member. For example, at least a portion of the longitudinal member may be
30 shaped so as to define ratchet teeth, which engage the radially-expandable anchor, thereby preventing the movement of the radially-expandable anchor with respect to the longitudinal member in the proximal direction. Alternatively or additionally, the radially-expandable anchor may be configured to be crimped to the longitudinal member, so as to

prevent the movement of the radially-expandable anchor with respect to the longitudinal member.

During a tricuspid valve repair procedure, the deployment tube is advanced into the left atrium. A hole is made in the interatrial septum. The deployment tube is
5 advanced from the left atrium through the hole, until a distal end of the deployment tube is positioned within the right atrium. The tissue anchor is deployed from the distal end of the deployment tube, and anchored to a portion of cardiac tissue in a vicinity of the tricuspid valve. The deployment tube is withdrawn into the left atrium, thereby releasing the radially-expandable anchor in the left atrium near the septum. The longitudinal
10 member is pulled in a proximal direction, while holding the radially-expandable anchor against a left-atrial side of the septum. The radially-expandable anchor is locked to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the longitudinal member at least in the proximal direction. Responsively, a distance between the leaflets of the tricuspid valve is adjusted to reduce and eliminate
15 regurgitation through the valve, and thereby, the valve is repaired. For some applications, a level of regurgitation of the tricuspid valve is monitored in conjunction with pulling the longitudinal member to adjust the distance between the anchors.

For some applications, the stents described hereinabove comprise a plurality of interconnected superelastic metallic struts. Alternatively or additionally, for some
20 applications, one or more of the stents may comprises one or more elongated members and two or more rings. The rings are typically coupled together by the one or more elongated members and by no other elements of the stent. Typically, the rings define respective planes that are generally perpendicular to the elongated members when the stent is in its expanded state. The longitudinal member connects the stent to the tissue
25 anchor(s).

For some applications, at least one of the tissue anchors described hereinabove is configured to radially contract and expand in a manner generally similar to that of an umbrella. The anchor is inserted into the tissue in a radially-contracted state, and is transitioned to a radially-expanded state in order to fix the anchor within the tissue. The
30 anchor comprises a distal tissue-piercing tip, which is fixed at a distal end of a post. The anchor further comprises a plurality of ribs, which are coupled to the anchor near the distal tip, such that the ribs can articulate with the post. The anchor further comprises a

runner, which is slidably coupled to the post, such that the runner can slide along the post. A plurality of stretchers are coupled to the runner and respective ones of the ribs, such that the stretchers can articulate with the runner and the respective ribs.

There is therefore provided, in accordance with some applications of the present invention, a method, including:

implanting at least a first tissue-engaging element in a first portion of tissue in a vicinity of a heart valve of a patient;

implanting at least a second tissue-engaging element in a portion of a blood vessel that is in contact with an atrium of a heart of the patient; and

drawing at least a first leaflet of the valve toward at least a second leaflet of the valve by adjusting a distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient.

In some applications of the present invention, adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient includes pulling a longitudinal member that connects the first and second tissue-engaging elements.

In some applications of the present invention, implanting the first tissue-engaging element includes implanting the first tissue-engaging element in the first portion of tissue of an annulus of the valve, and the method further includes: implanting, in a second portion of tissue of the annulus, a third tissue-engaging element that is connected to a fourth tissue-engaging element by a longitudinal sub-member; and implanting, in a third portion of tissue of the annulus, the fourth tissue-engaging element such that the longitudinal sub-member engages the longitudinal member at a junction therebetween.

In some applications of the present invention, adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient includes applying tension to one or more elements selected from the group consisting of the first tissue-engaging element and the second tissue-engaging element.

In some applications of the present invention, the method includes monitoring a level of regurgitation of the heart valve in conjunction with the adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient.

In some applications of the present invention, adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient includes pulling the first tissue-engaging element toward the portion of the blood vessel.

5 In some applications of the present invention, the heart valve includes a tricuspid valve, and adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient includes achieving bicuspidization of the tricuspid valve of the heart.

10 In some applications of the present invention, adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient includes actuating an adjusting mechanism that is coupled to a portion of a longitudinal member that connects the first and second tissue-engaging elements.

15 In some applications of the present invention, implanting the second tissue-engaging element in the portion of the blood vessel includes expanding a stent in the portion of the blood vessel.

In some applications of the present invention, the stent includes two or more rings coupled together by one or more elongated members and by no other elements of the stent, and implanting the second tissue-engaging element includes expanding the rings such that the rings anchor the stent to a wall of the blood vessel.

20 In some applications of the present invention, the method includes:
implanting a third tissue-engaging element in a second portion of tissue of the heart, the third tissue-engaging element being connected at a proximal end thereof to a distal end of a longitudinal member; and

engaging a proximal end portion of the longitudinal member with the stent.

25 In some applications of the present invention, the method includes applying tension to the third tissue-engaging element.

In some applications of the present invention, the blood vessel is selected from the group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.

30 In some applications of the present invention, implanting the first tissue-engaging element in the first portion of tissue in the vicinity of the heart valve of the patient includes engaging the first portion of tissue by performing one or more actions selected

from the group consisting of: puncturing and squeezing the first portion of tissue and advancing at least a portion of the first tissue-engaging element into the first portion of tissue.

In some applications of the present invention:

5 the first portion of tissue in the vicinity of the heart valve includes a portion of tissue of that is opposite the portion of the blood vessel of the patient,

engaging the first portion of tissue includes engaging the portion of tissue that is opposite the portion of the blood vessel of the patient, and

10 drawing the first leaflet of the valve toward the second leaflet of the valve includes adjusting a distance between the portion of the blood vessel of the patient and the portion of tissue that is opposite the portion of the blood vessel of the patient.

In some applications of the present invention, the first portion of tissue in the vicinity of the heart valve includes a portion of tissue of an annulus of the valve; and engaging the first portion of tissue includes engaging the portion of tissue of the annulus
15 of the valve.

In some applications of the present invention, the portion of tissue of the annulus of the valve includes a portion of tissue that is between a middle portion of an anterior leaflet of the valve and a middle portion of a posterior leaflet of the valve.

In some applications of the present invention, the first portion of tissue in the
20 vicinity of the heart valve includes a portion of tissue of a wall of the atrium of the heart above an annulus of the valve, and engaging the first portion of tissue includes engaging the portion of tissue of the wall of the atrium.

There is additionally provided, in accordance with some applications of the present invention, a method, including:

25 implanting at least a first tissue-engaging element in a first portion of tissue upstream of a tricuspid valve of a patient;

implanting at least a second tissue-engaging element in a second portion of tissue upstream of the tricuspid valve of the patient; and

30 altering a geometry of a wall of a right atrium of a heart of the patient by adjusting a distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient.

In some applications of the present invention, the method further includes implanting at least a third tissue-engaging element in a third portion of tissue upstream of the tricuspid valve of the patient, and altering the geometry of the wall of the right atrium includes altering the geometry of the wall by adjusting respective distances between the
5 first, the second, and the third portions of tissue upstream of the tricuspid valve.

In some applications of the present invention, adjusting the distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient includes adjusting a distance between the first tissue-engaging element and the second tissue-engaging element.

10 In some applications of the present invention, the first portion of tissue includes a first portion of the wall of the right atrium, and implanting the first tissue-engaging element in the first portion of tissue upstream of the tricuspid valve of the patient includes implanting the first tissue-engaging element in the first portion of the wall of the right atrium.

15 In some applications of the present invention, the second portion of tissue includes a second portion of the wall of the right atrium, and implanting the second tissue-engaging element in the second portion of tissue upstream of the tricuspid valve of the patient includes implanting the second tissue-engaging element in the second portion of the wall of the right atrium.

20 In some applications of the present invention, the method further includes implanting at least a third tissue-engaging element in a third portion of the wall of the right atrium, and altering the geometry of the wall of the right atrium includes altering the geometry of the wall by adjusting respective distances between the first, the second, and the third portions of the wall of the right atrium.

25 In some applications of the present invention, the method includes monitoring a level of regurgitation of the tricuspid valve in conjunction with the altering the geometry of the wall of the right atrium.

In some applications of the present invention, adjusting the distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion
30 of tissue upstream of the tricuspid valve of the patient includes pulling a longitudinal element that connects the first and second tissue-engaging elements.

In some applications of the present invention, adjusting the distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient includes actuating an adjusting mechanism that is coupled to a portion of a longitudinal element that connects the first
5 and second tissue-engaging elements.

In some applications of the present invention, altering the geometry of the wall of the right atrium of the heart of the patient includes drawing together at least a first leaflet of the tricuspid valve of the patient and at least a second leaflet of the tricuspid valve of the patient.

10 In some applications of the present invention,
implanting the first tissue-engaging element includes implanting the first tissue-engaging element with a longitudinal member coupled to the first tissue-engaging element;

the second tissue-engaging element is shaped so as to define a passage, and
15 implanting the second tissue-engaging element includes implanting the second tissue-engaging element with the longitudinal member passing through the passage, and

adjusting the distance includes pulling the longitudinal member in a proximal direction, so as to approximate the first and second tissue-engaging element.

In some applications of the present invention, pulling the longitudinal member
20 including pulling the longitudinal member until the first and second tissue-engaging elements become coupled together.

There is further provided, in accordance with some applications of the present invention, a method, including:

engaging at least a portion of at least a first tissue-engaging element in a portion of
25 tissue of a wall of an inferior vena cava of a patient;

engaging at least a portion of at least a second tissue-engaging element in a portion of tissue of a wall of a superior vena cava of the patient;

drawing at least a first leaflet of a heart valve toward at least a second leaflet of the valve by applying tension to one or more portions of tissue selected from the group
30 consisting of: the portion of tissue of the wall of the inferior vena cava of the patient and the portion of tissue of the wall of the superior vena cava of the patient; and

monitoring a level of regurgitation of a heart valve of the patient in conjunction

with the applying of the tension.

In some applications of the present invention, applying the tension includes applying the tension following the engaging of the at least first tissue-engaging element and the engaging of the at least second tissue-engaging element.

5 In some applications of the present invention, applying the tension includes adjusting a distance between the portion of tissue of the wall of the inferior vena cava of the patient and the portion of tissue of the wall of the superior vena cava of the patient.

In some applications of the present invention, adjusting the distance between the portion of tissue of the wall of the inferior vena cava of the patient and the portion of
10 tissue of the wall of the superior vena cava of the patient includes, by the applying of the tension, adjusting a distance between the first tissue-engaging element and the second tissue-engaging element.

In some applications of the present invention, engaging the portion of the at least first tissue-engaging element in the portion of tissue of the wall of the inferior vena cava
15 of the patient includes expanding a first stent in the inferior vena cava and contacting at least a portion of the first stent with the portion of the wall of the inferior vena cava.

In some applications of the present invention, engaging the portion of the at least second tissue-engaging element in the portion of tissue of the wall of the superior vena cava of the patient includes expanding a second stent in the inferior vena cava and
20 contacting at least a portion of the first stent with the portion of the wall of the inferior vena cava.

In some applications of the present invention, applying the tension includes altering a geometry of a wall of an atrium of a heart of the patient.

In some applications of the present invention, applying the tension includes
25 pulling a longitudinal member that connects the at least first tissue-engaging element and the at least second tissue-engaging element.

In some applications of the present invention, applying the tension includes actuating an adjusting mechanism that is coupled to a portion of a tensioning element that connects the first and second tissue-engaging elements.

30 There is still further provided, in accordance with some applications of the present

invention, apparatus including:

a stent;

a longitudinal member, which has a distal end that includes an annular loop that extends laterally from the longitudinal member; and

5 a tissue anchor, which is coupled to the annular loop, such that the anchor can rotate with respect to the annular loop, the longitudinal member, and the stent.

In some applications of the present invention, the apparatus further includes a tube, which is sized to pass through a lumen defined by the stent, and which is configured to be removably coupled to the tissue anchor, such that rotation of the tube rotates the
10 tissue anchor. In some applications of the present invention, the tissue anchor is shaped so as to define a passage therethrough, and the tube includes an elongated coupling element, which is initially disposed so as to pass through the passage, thereby coupling the tube to the anchor. In some applications of the present invention, when the tube is removably coupled to the tissue anchor, a longitudinal portion of the tube is positioned
15 alongside the longitudinal member, and no portion of the tube is positioned around the longitudinal member. In some applications of the present invention, the apparatus further includes an adapter holder, which is coupled to the tube, and which is shaped so as to define arms, which have a tendency to expand radially, and which couple the tube to the anchor when the arms are radially compressed. In some applications of the present
20 invention, the apparatus further includes a delivery tool overtube, which is sized to pass through the lumen defined by the stent, the tube is configured to pass through the delivery tool overtube, and the overtube is configured to radially compress the arms when positioned surrounding the arms. In some applications of the present invention, the apparatus further includes an adapter, which is shaped so as to define a cylindrical portion
25 that passes through the annular loop, and which has a distal end that is fixedly coupled to a proximal portion of the tissue anchor, and the tube is configured to be removably coupled to the adapter via the adapter holder when the arms are radially compressed, so as to be removably coupled to the tissue anchor.

In some applications of the present invention, the apparatus further includes an
30 adapter, which is shaped so as to define a cylindrical portion that passes through the annular loop, and which has a distal end that is fixedly coupled to a proximal portion of the tissue anchor, and the tube is configured to be removably coupled to the adapter, so as to be removably coupled to the tissue anchor.

In some applications of the present invention, the apparatus further includes a delivery tool overtube, which is sized to pass through the lumen defined by the stent, and the tube is configured to pass through the delivery tool overtube.

5 For any of the applications of the present invention described above, the apparatus may further include an adapter, which is shaped so as to define a cylindrical portion that passes through the annular loop, and which has a distal end that is fixedly coupled to a proximal portion of the tissue anchor.

For any of the applications of the present invention described above, the stent may include a plurality of interconnected superelastic metallic struts.

10 For any of the applications of the present invention described above, the stent may include one or more elongated members, and two or more rings coupled together by the one or more elongated members and by no other elements of the stent.

There is additionally provided, in accordance with some applications of the present invention, a method including:

15 providing (a) a stent, (b) a longitudinal member, which has a distal end that includes an annular loop that extends laterally from the longitudinal member, and (c) a tissue anchor, which is coupled to the annular loop;

positioning the stent in a blood vessel of a patient;

20 coupling the tissue anchor to tissue in a vicinity of a heart valve of the patient by rotating the anchor with respect to the annular loop, the longitudinal member, and the stent; and

after coupling the tissue anchor to the tissue, deploying the stent such that the stent expands and is implanted in the blood vessel at an implantation site.

25 In some applications of the present invention, the method further includes, after coupling the tissue anchor to the tissue and before deploying the stent, pulling the anchor toward the implantation site.

In some applications of the present invention, the blood vessel is selected from the group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.

30 In some applications of the present invention, rotating includes rotating the anchor using a tube, which passes through a lumen defined by the stent, and which is removably coupled to the tissue anchor. In some applications of the present invention, rotating the

anchor using a tube includes positioning a longitudinal portion of the tube alongside the longitudinal member, such that no portion of the tube is positioned around the longitudinal member. In some applications of the present invention, rotating includes rotating the anchor using the tube that is coupled to an adapter holder, which is shaped so
5 as to define arms, which have a tendency to expand radially, and which couple the tube to the anchor when the arms are radially compressed. In some applications of the present invention, the method further includes providing a delivery tool overtube, which is sized to pass through the lumen defined by the stent, the tube is configured to pass through the delivery tool overtube, and the overtube is configured to radially compress the arms when
10 positioned surrounding the arms.

In some applications of the present invention, the method further includes providing a delivery tool overtube, which is sized to pass through the lumen defined by the stent, and the tube is configured to pass through the delivery tool overtube.

There is yet additionally provided, in accordance with some applications of the
15 present invention, apparatus including:

a stent, which is configured to assume compressed and expanded states, and which includes:

one or more elongated members; and

two or more rings, which are coupled together by the one or more
20 elongated members and by no other elements of the stent, and which define respective planes that are generally perpendicular to the elongated members when the stent is in its expanded state;

a longitudinal member, having a proximal end and a distal end, which proximal end is coupled to the stent; and

25 a tissue anchor, which is coupled to the distal end of the longitudinal member.

In some applications of the present invention, the stent includes exactly two rings.

In some applications of the present invention, the stent includes exactly one elongated member.

For any of the applications of the present invention described above, the elongated
30 member may include two or more wires coupled to one another.

For any of the applications of the present invention described above, one of the

elongated members may be at least partially a continuation of the longitudinal member.

For any of the applications of the present invention described above, each of the rings may have an outer diameter of between 10 and 35 mm, when the stent is in its expanded state.

5 There is also provided, in accordance with some applications of the present invention, a method including:

 providing a (a) stent, which includes (i) one or more elongated members; and (ii) two or more rings, which are coupled together by the one or more elongated members and by no other elements of the stent, (b) a longitudinal member, having a proximal end and a
10 distal end, which proximal end is coupled to the stent, and (c) a tissue anchor, which is coupled to the distal end of the longitudinal member;

 positioning the stent in a blood vessel of a patient while the stent is in a compressed state;

 coupling the tissue anchor to tissue in a vicinity of a heart valve of the patient; and
15 transitioning the stent to an expanded state, such that the rings define respective planes that are generally perpendicular to the elongated members, and anchor the stent to a wall of the blood vessel.

 In some applications of the present invention, providing the stent includes providing the stent which includes exactly two rings.

20 In some applications of the present invention, providing the stent includes providing the stent which includes exactly one elongated member.

 In some applications of the present invention, providing the stent includes providing the stent in which one of the elongated members is at least partially a continuation of the longitudinal member.

25 In some applications of the present invention, positioning the stent in the blood vessel includes positioning the stent in a blood vessel selected from the group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.

 In some applications of the present invention, the method further includes monitoring a level of regurgitation of the heart valve in conjunction with the positioning
30 of the stent in the blood vessel.

There is further provided, in accordance with some applications of the present invention, apparatus including a tensioning device, which includes:

a radially-expandable anchor, which defines an opening;

a longitudinal member, having proximal and distal ends, which longitudinal member passes through the opening of the radially-expanded anchor, such that the radially-expanded anchor is slidably coupled to the longitudinal member; and

a tissue anchor, which is coupled to the distal end of the longitudinal member,

wherein the radially-expandable anchor and the longitudinal member are configured such that the radially-expandable member is lockable to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the longitudinal member at least in a proximal direction toward the proximal end of the longitudinal member.

In some applications of the present invention, at least a portion of the longitudinal member is shaped so as to define ratchet teeth, which engage the radially-expandable anchor, thereby preventing the movement of the radially-expandable anchor with respect to the longitudinal member in the proximal direction.

In some applications of the present invention, the radially-expandable anchor is configured to be crimped to the longitudinal member, so as to prevent the movement of the radially-expandable anchor with respect to the longitudinal member.

In some applications of the present invention, the radially-expandable anchor is configured to generally fall within exactly one plane when radially expanded.

In some applications of the present invention, the radially-expandable anchor, when radially expanded, is shaped so as to define at least one shape selected from the group consisting of: a petal and a wing.

For any of the applications of the present invention described above, the apparatus may further include a deployment tube, in which the tensioning device is initially positioned, with the radially-expandable anchor in a radially-compressed state.

There is still further provided, in accordance with some applications of the present invention, a method including:

providing a tensioning device initially positioned in a deployment tube, which tension device includes (a) a longitudinal member, (b) a radially-expanded anchor, which

is slidably coupled to the longitudinal member, and (c) a tissue anchor, which is coupled to a distal end of the longitudinal member;

advancing the deployment tube into a left atrium of a patient;

making a hole in an interatrial septum;

5 advancing the deployment tube from the left atrium through the hole, until a distal end of the deployment tube is positioned within a right atrium;

deploying the tissue anchor from the distal end of the deployment tube, and anchoring the tissue anchor to a portion of cardiac tissue in a vicinity of a tricuspid valve;

10 withdrawing the deployment tube into the left atrium, thereby releasing the radially-expandable anchor in the left atrium near the septum; and

pulling the longitudinal member in a proximal direction, while holding the radially-expandable anchor against a left-atrial side of the septum, and locking the radially-expandable anchor to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the longitudinal member at least in the
15 proximal direction.

In some applications of the present invention, at least a portion of the longitudinal member is shaped so as to define ratchet teeth, which engage the radially-expandable anchor, and locking the radially-expandable anchor to the longitudinal member includes using the ratchet teeth to prevent the movement of the radially-expandable anchor with
20 respect to the longitudinal member in the proximal direction.

In some applications of the present invention, locking the radially-expandable anchor to the longitudinal member includes crimping the radially-expandable anchor to the longitudinal member, so as to prevent the movement of the radially-expandable anchor with respect to the longitudinal member.

25 In some applications of the present invention, the radially-expandable anchor is configured to generally fall within exactly one plane when radially expanded.

In some applications of the present invention, the radially-expandable anchor, when radially expanded, is shaped so as to define at least one shape selected from the group consisting of: a petal and a wing.

30 In some applications of the present invention, the method further includes monitoring a level of regurgitation of the tricuspid valve in conjunction with the pulling the longitudinal member.

There is additionally provided, in accordance with some applications of the present invention, apparatus including a tissue anchor, which is configured to assume radially-contracted and radially-expanded states, and which includes:

5 a post, having a distal tissue-piercing tip, and a greatest diameter of no more than 1.8 mm;

a plurality of ribs, which are coupled to the anchor near the distal tip, such that the ribs can articulate with the post;

a runner, which is slidably coupled to the post, such that the runner can slide along the post; and

10 a plurality of stretchers, which are coupled to the runner and respective ones of the ribs, such that the stretchers can articulate with the runner and the respective ribs.

In some applications of the present invention, the apparatus further includes a catheter, in which the tissue anchor is initially positioned in the radially-contracted state. In some applications of the present invention, the apparatus further includes an inner tube
15 positioned within the catheter, and a proximal end of the runner is initially removably coupled to the inner tube.

For any of the applications of the present invention described above, an outer surface of a proximal end of the runner may be threaded.

For any of the applications of the present invention described above, the anchor
20 may at least partially include a shape-memory alloy.

The present invention will be more fully understood from the following detailed description of applications thereof, taken together with the drawings, in which:

BRIEF DESCRIPTION OF THE DRAWINGS

Figs. 1A-G are schematic illustrations of apparatus for reducing regurgitation of a
25 heart valve which comprises a stent, a tissue anchor, and a tensioning element that couples the stent and the tissue anchor, in accordance with some applications of the present invention;

Figs. 2A-B are schematic illustrations of apparatus for reducing regurgitation of the heart valve which comprises first and second stents, first and second tissue anchor,
30 and first and second tensioning elements, in accordance with some applications of the present invention;

Figs. 3A-C are schematic illustrations of apparatus for reducing regurgitation of the heart valve which comprises a single stent, first and second tissue anchor, and first and second tensioning elements, in accordance with some applications of the present invention;

5 Figs. 4A-C are schematic illustrations of apparatus for reducing regurgitation of a tricuspid valve which comprises first and second stents and first and a tensioning element that couples the first and second stents, in accordance with some applications of the present invention;

10 Figs. 5A-C are schematic illustrations of apparatus for reducing regurgitation of the heart valve which comprises two or three tissue anchors and a tensioning element that couples the tissue anchors, in accordance with some applications of the present invention;

15 Fig. 6 is a schematic illustration of apparatus for reducing regurgitation of the heart valve which comprises a first anchoring system in the inferior vena cava, a first tissue anchor implanted at the valve, and a second tissue anchor implanted in the papillary muscle;

Figs. 7A-D are schematic illustrations of a delivery system for a helical tissue anchor, in accordance with some applications of the present invention;

20 Figs. 8A-E and 9A-E are schematic illustrations of a system for repairing a tricuspid valve, using a superior vena cava approach and an inferior vena cava approach, respectively, in accordance with respective applications of the present invention;

Figs. 10A-B are schematic illustrations of a rotation tool, in accordance with an application of the present invention;

Figs. 11A-B are schematic illustration of another system for repairing a tricuspid valve, in accordance with some applications of the present invention;

25 Figs. 12A-D are schematic illustrations showing an exemplary procedure for deploying a tensioning device of the system of Figs. 11A-B, in accordance with respective applications of the present invention;

Figs. 13A-E are schematic illustration of tissue anchors, in accordance with respective applications of the present invention; and

30 Figs. 14A-D are schematic illustrations of apparatus for reducing regurgitation of a

heart valve which comprises two tissue anchors configured to be directly coupled to each other, and an exemplary deployment procedure, in accordance with some applications of the present invention.

DETAILED DESCRIPTION OF APPLICATIONS

5 Reference is now made to Figs. 1A-G, which are schematic illustrations of a system 20 comprising a first tissue-engaging element 60a and a second tissue-engaging element 60b for repairing a tricuspid valve 4 of a heart 2 of a patient, in accordance with some applications of the present invention. First tissue-engaging element 60a comprises a tissue anchor 40 which is designated for implantation at least in part in cardiac tissue at a first implantation site 30. It is to be noted that tissue anchor 40 comprises a helical tissue anchor by way of illustration and not limitation and that tissue anchor 40 may comprise any tissue anchor for puncturing or clamping cardiac tissue, including, but not limited to, the tissue anchors described hereinbelow with reference to Figs. 13A-E. Second tissue-engaging element 60b comprises a stent 50 which is designated for implantation in a portion of a blood vessel, e.g., a superior vena cava 10 (such as shown in Figs. 1E-G) or an inferior vena cava 8 (such as shown in Figs. 1A-D), at a second implantation site 52. First and second tissue-engaging elements 60a and 60b are coupled together by a flexible longitudinal member 42. Typically, a distance between first and second implantation sites 30 and 52 is adjusted by pulling to apply tension to or relaxing longitudinal member 42 and/or by applying tension to at least one of first and second tissue-engaging elements 60a and 60b. Responsively, a distance between the leaflets of tricuspid valve 4 is adjusted to reduce and eliminate regurgitation through valve 4, and thereby, valve 4 is repaired. For some applications, longitudinal member 42 is pulled or relaxed by manipulating second tissue-engaging element 60b, as is described hereinbelow.

25 For some applications, first and second tissue-engaging elements 60a and 60b and longitudinal member 42 are fabricated from the same material, e.g., nitinol, from a single piece. That is, first and second tissue-engaging elements 60a and 60b and longitudinal member 42 define a single continuous implant unit. For some applications, at least second tissue-engaging element 60b and longitudinal member 42 are fabricated from a single piece.

For other applications, longitudinal member 42 comprises a flexible and/or superelastic material, e.g., nitinol, polyester, stainless steel, cobalt chrome, PTFE, or

ePTFE. In some applications of the present invention, longitudinal member 42 comprises a braided polyester suture (e.g., Ticron). In other applications of the present invention, longitudinal member 42 is coated with polytetrafluoroethylene (PTFE). In some applications of the present invention, longitudinal member 42 comprises a plurality of
5 wires that are intertwined to form a rope structure. For some applications, at least a part of longitudinal member 42 comprises a tension spring and/or a plurality of coils.

For some applications, second tissue-engaging element 60b comprises a stent 50 which is advanced toward and expandable in a portion of inferior vena cava 8 (such as shown in Figs. 1A-D) or superior vena cava 10 (such as shown in Figs. 1E-G), i.e., a
10 blood vessel that is in direct contact with a right atrium 6 of heart 2 of the patient. Second tissue-engaging element 60b is implanted at second implantation site 52. As shown, first implantation site 30 comprises a portion of an annulus of tricuspid valve 4. Implantation site 30 typically comprises a portion of the annulus of valve 4 that is between (1) the middle of the junction between the annulus and anterior leaflet 14, and (2) the middle of
15 the junction between the annulus and posterior leaflet 16, e.g., between the middle of the junction between the annulus and anterior leaflet 14 and the commissure between the anterior and posterior leaflets. That is, anchor 40 is coupled to, e.g., screwed into, the fibrous tissue of the tricuspid annulus close to the commissure in between anterior leaflet 14 and posterior leaflet 16. Implantation site 30 is typically close to the mural side of
20 valve 4. For such applications, the drawing together of first and second implantation sites 30 and 52 cinches valve 4 and may create a bicuspidization of tricuspid valve 4, and thereby achieve stronger coaptation between anterior leaflet 14 and septal leaflet 12.

For some applications, first implantation site 30 may include a portion of tissue of a wall defining right atrium 6 of heart 2, typically in a vicinity of the annulus of valve 4.
25 For other applications, first implantation site 30 may include a portion of a wall of a right ventricle of heart 2, a ventricular portion of the annulus of valve 4, or a portion of a papillary muscle of the right ventricle of heart 2, as is shown hereinbelow in Fig. 6. First implantation site 30 is typically a distance away from, e.g., generally opposite, second implantation site 52 so that, following adjusting of longitudinal member 42, first and
30 second implantation sites 30 and 52 are drawn together, and thereby at least first and second leaflets, e.g., all three leaflets, of valve 4 are drawn toward each other. For applications in which first implantation site 30 includes a portion of tissue of the annulus, the adjusting of the distance between implantation sites 30 and 52 alters the geometry of

(i.e., changes the configuration of) the annulus of valve 4 and thereby draws together the leaflets of valve 4. For applications in which first implantation site 30 includes tissue of a portion of a wall that defines atrium 6, the adjusting of the distance between implantation sites 30 and 52 alters the geometry of (i.e., changes the configuration of) the wall of atrium 6 and thereby draws together the leaflets of valve 4.

Figs. 1A and 1E show the advancement of a catheter 22 toward atrium 6 of the patient until a distal end 23 of the catheter is disposed within atrium 6, as shown. The procedure is typically performed with the aid of imaging, such as fluoroscopy, transesophageal echo, and/or echocardiography. For some applications, the procedure begins by advancing a semi-rigid guidewire into right atrium 6 of the patient. The guidewire provides a guide for the subsequent advancement of a catheter 22 therealong and into the right atrium. Once distal end 23 of catheter 22 has entered right atrium 6, the guidewire is retracted from the patient's body. Catheter 22 typically comprises a 14-20 F sheath, although the size may be selected as appropriate for a given patient. Catheter 22 is advanced through vasculature into right atrium 6 using a suitable point of origin typically determined for a given patient. For example:

- catheter 22 may be introduced into the femoral vein of the patient, through inferior vena cava 8, and into right atrium 6;
- catheter 22 may be introduced into the basilic vein, through the subclavian vein through superior vena cava 10, and into right atrium 6; or
- catheter 22 may be introduced into the external jugular vein, through the subclavian vein through superior vena cava 10, and into right atrium 6.

As shown in Fig. 1A, catheter 22 is advanced through inferior vena cava 8 of the patient and into right atrium 6 using a suitable point of origin typically determined for a given patient. Alternatively, as shown in Fig. 1E, catheter 22 is advanced through superior vena cava 10 of the patient and into right atrium 6 using a suitable point of origin typically determined for a given patient.

Once distal end 23 of catheter 22 is disposed within atrium 6, an anchor-deployment tube 24 is extended from within catheter 22 beyond distal end 23 thereof and toward first implantation site 30. Anchor-deployment tube 24 holds tissue anchor 40 and a distal portion of longitudinal member 42. For some applications, tube 24 is steerable, as

is known in the catheter art, while for other applications, a separate steerable element may be coupled to anchor-deployment tube 24. Under the aid of imaging guidance, anchor-deployment tube 24 is advanced toward first implantation site 30 until a distal end thereof contacts cardiac tissue of heart 2 at first implantation site 30. Anchor-deployment tube 24 facilitates atraumatic advancement of first tissue-engaging element 60a toward first implantation site 30. For such applications in which anchor-deployment tube 24 is used, stent 50 is compressed within a portion of tube 24.

An anchor-manipulating tool (not shown for clarity of illustration), which is slidably disposed within anchor-deployment tube 24, is slid distally within tube 24 so as to push distally tissue anchor 40 of first tissue-engaging element 60a and expose tissue anchor 40 from within tube 24, as shown in Figs. 1B and 1E. For some applications of the present invention, the anchor-manipulating tool is reversibly coupled to anchor 40 and facilitates implantation of anchor 40 in the cardiac tissue. For applications in which anchor 40 comprises a helical tissue anchor, as shown, the operating physician rotates the anchor-manipulating tool from a site outside the body of the patient in order to rotate anchor 40 and thereby screw at least a portion of anchor 40 in the cardiac tissue.

Alternatively, system 20 is provided independently of the anchor-manipulating tool, and anchor-deployment tube 24 facilitates implantation of anchor 40 in the cardiac tissue. For applications in which anchor 40 comprises a helical tissue anchor, as shown, the operating physician rotates anchor-deployment tube 24 from a site outside the body of the patient in order to rotate anchor 40 and thereby screw at least a portion of anchor 40 in the cardiac tissue.

It is to be noted that for some applications of the present invention, anchor 40 comprises a clip, jaws, or a clamp which grips and squeezes a portion of cardiac tissue and does not puncture the cardiac tissue.

Following the implantation of anchor 40 at first implantation site 30, anchor-deployment tube 24 is retracted within catheter 22 in order to expose longitudinal member 42, as shown in Figs. 1C and 1F. Subsequently, longitudinal member 42 is pulled taut in order to repair tricuspid valve 4, as described hereinbelow.

For some applications, prior to pulling the portion of longitudinal member 42 that is disposed between anchor 40 and distal end 23 of catheter 22, a mechanism that facilitates the application of a pulling force to longitudinal member 42 is fixed in place, as

will be described hereinbelow. This fixing in place provides a reference force to system 20 while applying tension to longitudinal member 42 so as to ensure that during the pulling of longitudinal member 42, stent 50 is not pulled from within catheter 22. For some applications, distal end 23 of catheter 22 is fixed in place with respect to longitudinal member 42. Fixing in place catheter 22 stabilizes catheter 22 as longitudinal member 42 is pulled. This enables distal end 23 to remain in place and not slide distally toward implantation site 30 during the adjusting of longitudinal member 42. For some applications of the present invention, a proximal portion of catheter 22 and/or a proximal handle portion coupled to catheter 22 is anchored or otherwise fixed in place at its access location, e.g., by taping or plastering. Alternatively or additionally, a distal portion of catheter 22 comprises an inflatable element coupled to an inflation conduit which runs the length of catheter 22 from the distal portion thereof to a site outside the body of the patient. Prior to the adjusting of longitudinal member 42, the inflatable element is inflated such that it contacts tissue of the vasculature through which catheter 22 is advanced, and thereby catheter 22 is fixed in place. Typically, the inflatable element comprises an annular inflatable element, such that when inflated, the annular inflatable element functions as a seal to hold in place the distal portion of catheter 22.

Following the fixation of the mechanism that facilitates pulling of longitudinal member 42, the physician then pulls longitudinal member 42 and thereby draws together first and second implantation sites 30 and 52.

For some applications, catheter 22 is reversibly coupled to a proximal portion of longitudinal member 42 by being directly coupled to the proximal portion of member 42 and/or catheter 22 is reversibly coupled to second tissue-engaging element 60b. For example, catheter 22 may be reversibly coupled to stent 50 by the stent's application of a radial force against the inner wall of catheter 22 because of the tendency of stent 50 to expand radially. Following implantation of first tissue-engaging element 60a, catheter 22 (or an element disposed therein) is then pulled proximally to apply tension to longitudinal member 42, which, in such an application, functions as a tensioning element. For some applications, catheter 22 pulls on second tissue-engaging element 60b in order to pull longitudinal member 42. For other applications, catheter 22 pulls directly on longitudinal member 42. For yet other applications, a pulling mechanism pulls on longitudinal member 42, as is described hereinbelow with reference to Figs. 7A-D.

Pulling longitudinal member 42 pulls taut the portion of longitudinal member 42 that is disposed between anchor 40 and distal end 23 of catheter 22. Additionally, longitudinal member 42 may be pulled or relaxed in order to adjust the distance between first and second implantation sites 30 and 52. Responsively to the pulling of longitudinal member 42, at least the anterior and septal leaflets of tricuspid valve 4 are drawn together because the geometry of the annulus and/or of the wall of atrium 6 is altered in accordance with the pulling of longitudinal member 42 and depending on the positioning of first tissue-engaging element 60a. For some applications, during the pulling of longitudinal member 42 by catheter 22, a level of regurgitation of tricuspid valve 4 is monitored. Longitudinal member 42 is pulled until the regurgitation is reduced or ceases.

Once the physician determines that the regurgitation of valve 4 is reduced or ceases, and valve 4 has been repaired, the physician decouples catheter 22 from second tissue-engaging element 60b disposed therein and/or from longitudinal member 42, and then retracts catheter 22 in order to expose second tissue-engaging element 60b, i.e., stent 50. During the advancement of catheter 22 toward atrium 6, stent 50 is disposed within a distal portion of catheter 22 in a compressed state. Following initial retracting of catheter 22, stent 50 is exposed and is allowed to expand and contact a wall of inferior vena cava 8. Fig. 1F shows stent 50 partially exposed and partially expanded, and Figs. 1D and 1G show the stent fully exposed and fully expanded. Responsively to the expanding, stent 50 is implanted in second implantation site 52 and maintains the tension of longitudinal member 42 on anchor 40 and thereby on the portion of cardiac tissue to which anchor 40 is coupled.

Reference is now made to Figs. 1E-G. It is to be noted that catheter 22 may enter via superior vena cava 10, as described hereinabove. For such applications, first implantation site 30 may comprise an area of the annulus of valve 4, or a portion of the wall defining atrium 6 that is opposite superior vena cava 10.

Reference is again made to Figs. 1A-G. For some applications, following the implantation of first and second tissue-engaging elements 60a and 60b, a distance between first and second tissue-engaging elements 60a and 60b is adjusted by an adjustable mechanism, as described hereinbelow with reference to Figs. 5A-B or 5C. In such applications, a length of longitudinal member 42 between first and second tissue-engaging elements 60a and 60b may be adjusted by an adjusting mechanism 150, as

shown in Figs. 5A-B or 5C. Adjusting mechanism 150 typically comprises a mechanical element which shortens a distance of longitudinal member 42 between first and second tissue-engaging elements 60a and 60b. For some applications, adjustable mechanism 150 may be permanently coupled to longitudinal member 42 (not shown) and comprises an
5 adjusting element, e.g., a spool for looping portions of longitudinal member 42 therearound, a crimping bead for crimping and shortening a portion of longitudinal member 42, a ratchet element, or a deforming element which deforms a portion of longitudinal member 42 in order to shorten its length between first and second tissue-engaging elements 60a and 60b. For other applications, adjusting mechanism 150
10 comprises only an adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening a portion of longitudinal member 42, or a deforming element which deforms a portion of longitudinal member 42 in order to shorten its length between first and second tissue-engaging elements 60a and 60b. In either application, a level of regurgitation of
15 valve 4 may be monitored during the adjusting of the distance between first and second tissue-engaging elements 60a and 60b by adjusting mechanism 150.

For some applications, such as shown in Fig. 1D, stent 50 comprises a plurality of interconnected superelastic metallic struts, arranged so as to allow crimping the stent into a relatively small diameter (typically less than 8 mm) catheter, while allowing deployment
20 to a much larger diameter (typically more than 20 mm) in the vena cava, while still maintaining radial force against the vena cava tissue, in order to anchor stent 50 to the wall of the vena cava by friction. Alternatively or additionally, for some applications, such as shown in Figs. 1F-G, stent 50 comprises two or more rings 62, which are configured to expand in the superior or inferior vena cava, in order to anchor stent 50 to
25 the wall of the vena cava by friction. Typically, the rings are sized to push against and make small indentions in the wall of the vena cava. The rings may also reduce the risk of stent fatigue and stent fracture. Typically, the rings are configured to self-expand upon being released from catheter 22, and may, for example, comprise a shape-memory alloy, such as nitinol. For some applications, the rings are elliptical, such as circular, or have
30 other shapes.

Rings 62 are coupled together by one or more elongated members 64, such as exactly one elongated member 64 (as shown), or between two and four elongated members 64 (configurations not shown). Typically, no elements of stent 50, other than

elongated members 64, couple the rings together. Typically, each of elongated members 64 comprises one or more wires; for applications in which a plurality of wires is provided, the wires are typically tightly coupled to one another, such as by twisting (as shown), so as to define a single elongated member 64. Optionally, one of elongated members 64 is at least partially a continuation of longitudinal member 42 (e.g., one of the wires of elongated member 64 is a continuation of longitudinal member 42). For some applications, rings 62 and elongated members 64, and, optionally, longitudinal member 42, are fabricated from a single piece, such as shown in Fig. 1G. For some applications, stent 50 comprises exactly two rings (as shown), while for other applications, stent 50 comprises more than two rings 62, for example, between three and five rings (configuration not shown).

Typically, when stent 50 is in its expanded state, respective planes defined by rings 62 are generally perpendicular to elongated members 64, such that the rings, when positioned in the superior or inferior vena cava, are generally perpendicular to an axis of the vena cava, and thus make good contact with the wall of the vena cava.

Typically, rings 62 are sized in accordance with the patient's particular anatomy, so that when expanded, the rings are 10-25% larger than the nominal vena cava diameter. For example, for a patient who has a 20 mm vena cava, the surgeon may use rings with an outer diameter of 22-25 mm. For some applications, each of rings 62 has an outer diameter of at least 10 mm, no more than 35 mm, and/or between 10 and 35 mm, when stent 50 is in its expanded state. Typically, when the stent is in its expanded state, a distance between two of rings 62 that are longitudinally farthest from each other is at least 10 mm, no more than 40 mm, and/or between 10 and 40 mm (for applications in which stent 50 comprises exactly two rings, this distance is the distance between the two rings). For applications in which stent 50 comprises exactly two rings, a length of elongated members 64 equals the above-mentioned distance.

For some applications, such as those described with reference to Figs. 1A-D and 1E-F, longitudinal member 42 has a length of at least 10 mm, no more than 40 mm, and/or between 10 and 40 mm.

The configuration of stent 50 that is shown in Fig. 1D deployed in inferior vena cava 8 may instead be deployed in superior vena cava 10 (deployment not shown), and the configuration of stent 50 shown in Figs. 1F-G deployed in superior vena cava 10 may

instead be deployed in inferior vena cava 8 (deployment not shown). The configuration of stent 50 shown in Figs. 1F-G may be used in any of the stent configurations described herein, including those described hereinbelow with reference to Figs. 2A-B, 3A-B, 4A-C, 6, and/or 7A-D.

5 Reference is now made to Figs. 7A-D, which are schematic illustrations of a delivery tool system 200 for implanting anchor 40, in accordance with some applications of the present invention. Delivery tool system 200 may be used, for example, to rotate and implant an anchor in combination with the applications described herein with reference to Figs. 1A-G, 2A-B, 3A-C, 5A-C, 6, 8A-E, 9A-E, 11A-B, 12A-E, and/or 14A-D. Although longitudinal member is shown in Figs. 7A-D as being fixed to stent 50, this is not necessarily the case, and tool system 200 thus may also be used in combination with the applications that do not utilize stent 50, such as those described herein with reference to Figs. 3C, 5A-C, 11A-B, 12A-E, and/or 14A-D.

 Reference is now made to Figs. 1A-G and 7A-D. It is to be noted that anchor 40 may be implanted using delivery tool system 200. Fig. 7A shows an exploded view of the components of delivery tool system 200 and its spatial orientation relative to stent 50, longitudinal member 42, and anchor 40. In such an application, a distal end of longitudinal member 42 comprises an annular loop 216, through which a portion of anchor 40 is coupled to the distal end of longitudinal member 42. For some such applications, stent 50, longitudinal member 42, and anchor 40 are not fabricated from the same piece, as described hereinabove; rather, only stent 50, longitudinal member 42, and annular loop 216 are typically fabricated from a single piece, and anchor 40 is coupled to longitudinal member 42 via annular loop 216. Alternatively, as mentioned above, longitudinal member 42 is not coupled to stent 50, such as for applications in which stent 50 is not provided.

 System 200 typically comprises an adapter 218, which, for some applications, is shaped so as to define an annular proximal portion and a distal cylindrical portion having a distal end 220. During the manufacture of system 200, distal end 220 of the cylindrical portion of adapter 218 is slid through annular loop 218 at the distal end of longitudinal member 42, thereby coupling adapter 218 to the distal end of longitudinal member 42. Distal end 220 of adapter 218 is then welded or otherwise fixedly coupled to a proximal portion of an inner lumen of anchor 40, as shown in Fig. 7B. This coupling arrangement

of anchor 40 to annular loop 216 and adapter 218 enables anchor 40 to rotate about a central longitudinal axis of delivery system 200, freely within annular loop 216. That is, delivery tool system 200 rotates anchor 40 without rotating longitudinal member 42 and stent 50 (if provided), as described hereinbelow.

5 Delivery tool system 200 comprises a delivery tool overtube 202 having a distal end thereof. For application in which stent 50 is provided, delivery tool overtube 202 is housed within catheter 22 such that a distal portion thereof passes in part through the lumen of stent 50 and a distal end 204 thereof extends toward tissue anchor 40. During delivery of tissue anchor 40 and stent 50 toward their respective implantation sites, deliver
10 tool system 200 assumes the configuration shown in Fig. 7B. It is to be noted, however, that stent 50 is compressed around the portion of overtube 202 that extends through the lumen of stent 50 (not shown for clarity of illustration), and that catheter 22 (not shown for clarity of illustration) surrounds system 200 (and thereby compresses stent 50).

Reference is again made to Fig. 7A. Overtube 202 houses a torque-delivering and
15 an anchor-pulling tube 208 and facilitates slidable coupling of tube 208 to overtube 202. A distal end of torque-delivering and anchor-pulling tube 208 is coupled to a manipulator 206 which is shaped so as to define a coupling 210 which couples manipulator 206 to adapter 218, and thereby, to anchor 40. In order to rotate anchor 40, torque-delivering and anchor-pulling tube 208 is rotated. As torque-delivering and anchor-pulling tube 208
20 is rotated, manipulator 206 is rotated in order to screw anchor 40 into the cardiac tissue of the patient. As adapter 218 rotates, the cylindrical portion thereof rotates freely within annular loop 216. This coupling arrangement of adapter 218 (and thereby anchor 40) to loop 216 (and thereby longitudinal member 42) enables the physician to rotate and implant anchor 40 without rotating longitudinal member 42 and stent 50 (if provided).

25 Following rotation of anchor 40, torque-delivering and anchor-pulling tube 208 is pulled by the physician in order to pull on anchor 40 and thereby on the portion of cardiac tissue to which anchor 40 is implanted at first implantation site 30. Tube 208 is typically coupled at a proximal end thereof to a mechanical element, e.g., a knob, at the handle portion outside the body of the patient. The physician pulls on tube 208 by actuating the
30 mechanical element that is coupled to the proximal end of tube 208. This pulling of tube 208, and thereby of anchor 40 and of cardiac tissue at first implantation site 30, draws first implantation site toward second implantation site 52 and thereby draws at least anterior

leaflet 14 toward septal leaflet 12 in order to achieve coaptation of the leaflets and reduce regurgitation through valve 4.

For some applications in which stent 50 is provided, following the pulling of anchor 40, stent 50 is positioned at second implantation site 52. Catheter 22 is then
5 retracted slightly along tube 202 so as to pull taut longitudinal member 42 and to ensure that tension is maintained at first implantation site 30 and along longitudinal member 42. Stent 50 is then deployed when the physician holds torque-delivering and anchor-pulling tool 208 and then retracts proximally either (1) catheter 22 or (2) a sheath (i.e., that is disposed within catheter 22 and surrounds stent 50), around stent 50 so as to deploy stent
10 50 from within either (1) catheter 22 or (2) the sheath disposed within catheter 22.

It is to be noted that stent 50 is retrievable following at least partial deployment thereof, e.g., following deployment of up to 1/2 or up to 1/3 of stent 50. In such an application, following the initial retraction proximally of catheter 22 from around stent 50 in order to deploy at least a distal portion of stent 50, catheter 22 is advanceable distally
15 so as to compress and retrieve the at least partially-deployed stent back into the distal end portion of catheter 22. Alternatively, catheter 22 houses a sheath which compresses stent 50 during delivery of stent to second implantation site 52. During the initial retracting of catheter 22 proximally, the sheath surrounding stent 50 is also retracted in conjunction with the retracting of catheter 22. Following the at least partial deployment of stent 50 in
20 order to deploy at least a distal portion of stent 50, the sheath is advanceable distally (while catheter 22 remains in place) so as to compress and retrieve the at least partially-deployed stent back into the distal end portion of the sheath. The sheath is then retracted into catheter 22. For such applications of the present invention in which stent 50 is retrievable following at least partial deployment thereof, anchor 40 can then be unscrewed
25 from first implantation site 30 and the entire implant system may be extracted from the body, or repositioned in the heart, depending on the need of a given patient.

For applications in which stent 50 is retrievable, in order to retrieve stent 50 (i.e., prior to the decoupling of manipulator 206 from adapter 218 and thereby from anchor 40), the physician holds torque-delivering and anchor-pulling tool 208 and then advances
30 distally either (1) catheter 22 or (2) the sheath disposed within catheter 22, around stent 50 so as to compress stent 50 within either (1) catheter 22 or (2) the sheath disposed within catheter 22. Torque-delivering and anchor-pulling tool 208 may then be rotated in order

to unscrew anchor 40 from the tissue, and the entire system may be extracted from the body, or repositioned in the heart, depending on the need of a given patient.

Reference is again made to Figs. 7A-D. Figs. 7C-D show the decoupling and release of torque-delivering and anchor-pulling tube 208 and manipulator 206 from adapter 218 and anchor 40. This release occurs typically following the deployment of
 5 stent 50 (if provided), as described hereinabove. As shown in Fig. 7A, system 200 comprises a releasable adapter holder 212 which is shaped so as to define arms 214 which have a tendency to expand radially. Holder 212 surrounds manipulator 206, as shown in Fig. 7C. During the delivery of anchor 40 toward implantation site 30 and the subsequent
 10 rotation of anchor 40 to screw anchor 40 into tissue at site 30, a distal end 204 of overtube 202 is disposed adjacently to loop 216 such that a distal end portion of overtube 202 surrounds and compresses arms 214 of holder 212 (as shown in Fig. 7B). Following the pulling of anchor 40 by torque-delivering and anchor-pulling tube 208, overtube 202 is retracted slightly in order to expose arms 214 of holder 212. Responsively, arms 214
 15 expand radially (Fig. 7C) and release adapter 218 (and thereby anchor 40) from holder 212.

As shown in Fig. 7D, overtube 202 is held in place while the physician retracts tube 208 so as to collapse and draw arms 214 into the distal end portion of overtube 202. Overtube 202 is then slid proximally within catheter 22 leaving behind anchor 40, adapter
 20 218 coupled to anchor 40, loop 216, longitudinal member 42, and stent 50 (if provided). Catheter 22, that houses overtube 202 and the components disposed therein, is extracted from the body of the patient.

For some applications, such as those described hereinabove with reference to Figs. 7A-D, longitudinal member 42 has a length of at least 10 mm, no more than 40 mm,
 25 and/or between 10 and 40 mm.

Reference is again made to Figs. 1A-G. It is to be noted that tissue-engaging elements 60a and 60b may be implanted at their respective implantation sites 30 and 50, as described hereinabove, by advancing catheter 22 and tissue-engaging elements 60a and 60b through superior vena cava 10, *mutatis mutandis*.

30 Figs. 2A-B show a system 100 for repairing tricuspid valve 4 comprising first and second stents 50a and 50b, first and second longitudinal members 42a and 42b, and first and second tissue anchors 40a and 40b. First tissue anchor 40a defines first tissue-

engaging element 60a. First stent 50a defines second tissue-engaging element 60b. Second tissue anchor 40b defines a third tissue-engaging element 60c. Second stent 50b defines a fourth tissue-engaging element 60d. For some applications of the present invention, following the implantation of first tissue-engaging element 60a and second
5 tissue-engaging element 60b, such as described hereinabove with reference to Figs. 1A-G, third and fourth tissue-engaging elements 60c and 60d are then implanted. As described hereinabove, first implantation site 30, as shown, comprises a portion of tissue that is in a vicinity of the commissure between anterior leaflet 14 and posterior leaflet 16. First
10 implantation site 30 may comprise a portion of tissue that is between (1) the middle of the junction between the annulus and anterior leaflet 14, and (2) the middle of the junction between the annulus and posterior leaflet 16.

Following the implantation of first and second tissue-engaging elements 60a and 60b, catheter 22 is retracted from the body of the patient. Outside the body of the patient, catheter 22 is reloaded with third and fourth tissue-engaging elements 60c and 60d.
15 Catheter 22 is then reintroduced within the body of the patient and is advanced toward right atrium 6, as shown in Fig. 2A, such that distal end 23 thereof passes through first stent 50a and toward atrium 6. It is to be noted that a proximal end portion of longitudinal member 42a is coupled to second tissue-engaging element 60b and is not disposed within catheter 22.

20 Subsequently, a second tissue anchor 40b (i.e., an anchor that is similar to tissue anchor 40a, as described hereinabove) is implanted at a second portion of cardiac tissue at a third implantation site 32. Third implantation site 32 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4 (e.g., a second portion of tissue of the annulus of tricuspid valve 4, as shown). Third implantation site 32, as shown, comprises a portion of
25 tissue that is between (1) the middle of the junction between the annulus and anterior leaflet 14, and (2) the middle of the junction between the annulus and posterior leaflet 16. For some applications, third implantation site 32 may comprise a second portion of the wall that defines right atrium 6. For other applications, third implantation site 32 may comprise a portion of cardiac tissue in the right ventricle, e.g., a portion of the wall that
30 defines the right ventricle, a ventricular portion of the annulus of valve 4, or a portion of a papillary muscle of the right ventricle.

Following implantation of third tissue-engaging element 60c, catheter 22 is

retracted and tension is applied to third tissue-engaging element 60c in a manner as described hereinabove with reference to Figs. 1C-D with regard to the application of tension to implantation site 30. Additionally, tension is applied to a second longitudinal member 42b which couples third and fourth tissue-engaging elements 60c and 60d, e.g.,
5 in a manner as described hereinabove with regard to the pulling of first longitudinal member 42a, with reference to Fig. 1C. As described herein, a level of regurgitation of valve 4 may be monitored during the pulling tissue of third implantation site 32 toward second implantation site 52 and of second longitudinal member 42b.

Additionally, responsively to the pulling of tissue at first and third implantation
10 sites 30 and 32 toward second implantation site 52, anterior leaflet 14 is drawn toward septal leaflet 12, and bicuspidization is achieved. Also, responsively to the pulling, a portion of tissue that is between first and third implantation sites 30 and 32 is cinched.

Reference is now made to Fig. 2B. Once the physician determines that the regurgitation of valve 4 is reduced or ceases, and valve 4 has been repaired, catheter 22 is
15 decoupled from fourth tissue-engaging element 60d and/or from second longitudinal member 42b, and the physician retracts catheter 22 in order to expose fourth tissue-engaging element 60d, i.e., second stent 50b, as shown. During the advancement of catheter 22 toward atrium 6, second stent 50b is disposed within a distal portion of catheter 22 in a compressed state. Following initial retracting of catheter 22, second stent
20 50b is exposed and is allowed to expand within a lumen of first stent 50a, as shown, in order to contact a wall of inferior vena cava 8. Responsively to the expanding, second stent 50b is implanted in second implantation site 52 and maintains the tension of second longitudinal member 42b on second tissue anchor 40b and thereby on the portion of cardiac tissue to which anchor 40b is coupled.

25 It is to be noted that second stent 50b is implanted within the lumen of first stent 50a by way of illustration and not limitation, and that for some applications of the present invention, first and second stents 50a and 50b may be implanted coaxially at second implantation site 52.

It is to be noted that third and fourth tissue-engaging elements 60c and 60d and
30 second longitudinal member 42b are typically fabricated from the same material, e.g., nitinol, from a single piece. That is, third and fourth tissue-engaging elements 60c and 60d and second longitudinal member 42b typically define a single continuous implant

unit.

Reference is now made to Figs. 3A-C, which are schematic illustrations of a system 110 for repairing tricuspid valve 4, which comprises first, second, and third tissue-engaging elements 60a, 60b, and 60c, and first and second longitudinal members 42a and 42b, in accordance with some applications of the present invention. System 110 is similar to system 100 described hereinabove with reference to Figs. 2A-B, with the exception that system 110 does not comprise second stent 50b; rather, as shown in Figs. 3B-C, a proximal end portion 112 of second longitudinal member 42b is shaped so as to define one or more engaging elements 114 (e.g., hooks or barbs, as shown). Following the implanting of third tissue-engaging element 60c and the subsequent pulling of second longitudinal member 42b, catheter 22 facilitates coupling of engaging elements 114 with the struts of stent 50 (as shown in Fig. 3C which is an enlarged image of stent 50 and the proximal portion of second longitudinal member 42b of Fig. 3B). The coupling of engaging elements 114 to stent 50 maintains the tension applied to longitudinal member 42, and thereby maintains the tension on third tissue-engaging element 60c in order to maintain the remodeled state of tricuspid valve 4.

It is to be noted that third tissue-engaging element 60c, second longitudinal member 42b, and engaging elements 114 and proximal end portion 112 of second longitudinal member 42b are typically fabricated from the same material, e.g., nitinol, from a single piece. That is, third tissue-engaging element 60c, second longitudinal member 42b, and engaging elements 114 and proximal end portion 112 of second longitudinal member 42b typically define a single continuous implant unit.

Reference is now made to Figs. 2A-B and 3A-C. For some applications, following the implantation the tissue-engaging elements at their respective implantation sites, as described hereinabove, a length of each one of first and second longitudinal members 42a and 42b is adjusted by an adjustable mechanism, as described hereinbelow with reference to Figs. 5A-B or 5C. Adjusting mechanism 150 typically comprises a mechanical element which shortens a length of each one of first and second longitudinal members 42a and 42b. For some applications, a respective adjustable mechanism 150 may be permanently coupled to each one of first and second longitudinal members 42a and 42b (not shown); each mechanism 150 comprises an adjusting element, e.g., a spool for looping respective portions of longitudinal members 42a and 42b therearound, a crimping bead for crimping

and shortening respective portions of longitudinal members 42a and 42b, a ratchet element, or a deforming element which deforms respective portions of longitudinal members 42a and 42b. For other applications, adjusting mechanism 150 comprises only adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may
5 comprise an adjusting element, e.g., a crimping bead for crimping and shortening respective portions of longitudinal members 42a and 42b, or a deforming element which deforms respective portions of longitudinal members 42a and 42b. In either application, a level of regurgitation of valve 4 may be monitored during the adjusting of the respective lengths of first and second longitudinal members 42a and 42b.

10 Figs. 4A-C show a system 120 for repairing tricuspid valve 4 comprising first and second stents 130 and 132 implanted in superior vena cava 10 and inferior vena cava, respectively, in accordance with some applications of the present invention. A catheter 122 is advanced through vasculature of the patient such that a distal end 124 of catheter 122 toward superior vena cava 10, as shown in Fig. 4A. Catheter 122 is advanced from a
15 suitable access location, e.g., catheter 122 may be introduced into the femoral vein of the patient, through inferior vena cava 8, and toward superior vena cava 10. During the advancement of catheter 122 toward superior vena cava 10 and inferior vena cava 8, stents 130 and 132 are disposed within a distal portion of catheter 122 in a compressed state.

20 In Fig. 4B, first stent 130 is deployed from within catheter 122 and expands to contact tissue of a wall of superior vena cava 10. This portion of the wall of the superior vena cava defines first implantation site 30 in such applications of the present invention. Additionally, first stent member 130 defines first tissue-engaging element 60a in such applications of the present invention. It is to be noted that the portion of superior vena
25 cava 10 in which stent 130 is implanted defines a portion of tissue that is in the vicinity of valve 4.

Catheter 122 is then retracted so as to pull and apply tension to longitudinal member 42. Longitudinal member 42 is pulled directly by catheter 122 and/or indirectly by pulling stent member 132 disposed within catheter 122. For some applications, during
30 the pulling, a level of regurgitation of tricuspid valve 4 may be monitored, because responsively to the pulling, the geometry of the wall of atrium 6 is altered and the leaflets of tricuspid valve 4 are drawn together so as to reduce and eliminate regurgitation of

valve 4.

Once the physician determines that the regurgitation of valve 4 is reduced or ceases, and valve 4 has been repaired, the physician decouples catheter 122 from second stent member 132 disposed therein and/or from longitudinal member 42, and then retracts
5 catheter 122 in order to expose second tissue-engaging element 60b, i.e., second stent member 132, as shown. Following initial retracting of catheter 122, second stent member 132 is exposed and is allowed to expand and contact a wall of inferior vena cava 8, as shown in Fig. 4C. Responsively to the expanding, second stent member 132 is implanted in second implantation site 52 and maintains the tension of longitudinal member 42 on
10 first stent member 130 and thereby maintains the altered geometry of the wall of atrium 6 and of the leaflets of tricuspid valve 4.

Reference is again made to Figs. 4A-C. For some applications, following the deploying of first and second tissue-engaging elements 60a and 60b (i.e., first and second stents 130 and 132, respectively), a distance between first and second tissue-engaging
15 elements 60a and 60b is adjusted by an adjustable mechanism, as described hereinbelow with reference to Figs. 5A-B or 5C. In such applications, a length of longitudinal member 42 between first and second stents 130 and 132 may be adjusted by an adjusting mechanism 150, as shown in Figs. 5A-B or 5C. Adjusting mechanism 150 typically comprises a mechanical element which shortens a distance of longitudinal member 42
20 between first and second stents 130 and 132. For some applications, adjustable mechanism 150 may be permanently coupled to longitudinal member 42 (not shown) and comprises an adjusting element, e.g., a spool for looping portions of longitudinal member 42 therearound, a crimping bead for crimping and shortening a portion of longitudinal member 42, a ratchet element, or a deforming element which deforms a portion of
25 longitudinal member 42 in order to shorten its length between first and second stents 130 and 132. For other applications, adjusting mechanism 150 comprises only adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening a portion of longitudinal member 42, or a deforming element which deforms a portion of longitudinal
30 member 42 in order to shorten its length between first and second stents 130 and 132. In either application, a level of regurgitation of valve 4 may be monitored during the adjusting of the distance between first and second tissue-engaging elements 60a and 60b by adjusting mechanism 150.

It is to be noted that first and second stents 130 and 132 and longitudinal member 42 are typically fabricated from the same material, e.g., nitinol, from a single piece. That is, first and second stents 130 and 132 and longitudinal member 42 typically define a single continuous implant unit.

5 Reference is yet again made to Figs. 4A-C. It is to be noted that distal end 124 of catheter 122 may first be advanced toward inferior vena cava, and not first toward superior vena cava, as shown in Fig. 4A. In such an embodiment, catheter 122 may be introduced into the external jugular vein, through the subclavian vein, through superior vena cava 10, and toward inferior vena cava 8. Alternatively, catheter 122 may be
10 introduced into the basilic vein, through the subclavian vein, through superior vena cava 10 and toward inferior vena cava 8. It is to be noted that any suitable access location may be used to introduce catheter 122 into the vasculature of the patient.

Reference is still made to Figs. 4A-C. For some applications, one or both of stents 130 and/or 132 comprise a plurality of interconnected superelastic metallic struts, such as
15 described hereinabove with reference to Fig. 1D. Alternatively or additionally, for some applications, one or both of stents 130 and/or 132 comprise two or more rings 62, configured as described hereinabove with reference to Figs. 1E-G.

Reference is now made to Figs. 5A-B, which are schematic illustrations of a system 140 for repairing tricuspid valve 4 comprising first and second tissue anchors 40a
20 and 40b coupled together by longitudinal member 42, in accordance with some applications of the present invention. In such applications, first tissue anchor 40a defines first tissue-engaging element 60a, and second tissue anchor 40b defines second tissue-engaging element 60b. Tissue anchors 40a and 40b may comprise any suitable anchor for puncturing, squeezing, or otherwise engaging cardiac tissue of the patient. As shown by
25 way of illustration and not limitation, tissue anchors 40a and 40b comprise helical tissue anchors which puncture and screw into the cardiac tissue. It is to be noted that first and second tissue-engaging elements 60a and 60b (i.e., first and second tissue anchors 40a and 40b) and longitudinal member 42 are fabricated from the same material, e.g., nitinol, from a single piece. That is, first and second tissue-engaging elements 60a and 60b and
30 longitudinal member 42 define a single continuous implant unit.

Catheter 142 is advanced through vasculature of the patient, in manner as described hereinabove with regard to catheter 22 with reference to Fig. 1A. Catheter 142

is advanced toward first implantation site 30 and facilitates implantation of first tissue anchor 40a in the cardiac tissue. As shown, first implantation site 30 includes a first portion of tissue of the annulus of valve 4 at the mural side of valve 4, by way of illustration and not limitation. For some applications, first implantation site 30 may include a first portion of the wall of atrium 6 of heart 2. As shown by way of illustration and not limitation, first implantation site 30 includes a portion of tissue of the annulus at the commissure between anterior leaflet 14 and posterior leaflet 16. It is to be noted that first implantation site 30 may be implanted at any suitable location along and in the vicinity of the annulus of valve 4.

10 Catheter 142 is then advanced toward second implantation site 52 and facilitates implantation of second tissue anchor 40b in the cardiac tissue. For some applications, as catheter 142 is advanced toward second implantation site, longitudinal member 42 is pulled to draw together the leaflets of valve 4, while a level of regurgitation of valve 4 is monitored. As shown, second implantation site 52 includes a second portion of tissue of
15 the annulus of valve 4 at the septal side of valve 4, by way of illustration and not limitation. For some applications, second implantation site 52 may include a second portion of the wall of atrium 6 of heart 2. As shown by way of illustration and not limitation, second implantation site 52 includes a portion of tissue of the annulus inferior of the middle of septal leaflet 12. It is to be noted that first implantation site 30 may be
20 implanted at any suitable location along and in the vicinity of the annulus of valve 4, e.g., at the commissure between posterior leaflet 16 and septal leaflet 12.

For such an application, by applying tension to longitudinal member 42, anterior leaflet 14 and septal leaflet 12 are drawn together, and bicuspidization of valve 4 is achieved. For some applications, during the adjusting of mechanism 150, a retrievable
25 stent may be deployed in inferior vena cava 8 so as to stabilize system 140 during the adjusting of adjusting mechanism 150. It is to be further noted that tissue-engaging elements 60a and 60b and catheter 142 may be advanced toward atrium 6 through superior vena cava, *mutatis mutandis*.

For some applications of the present invention, system 140 comprises one or more
30 anchor-manipulating tools (not shown for clarity of illustration), that is slidably disposed within catheter 142. The anchor-manipulating tool is slid distally with within catheter 142 so as to push distally tissue anchors 40a and 40b and expose tissue anchors 40a and 40b

from within catheter 142. For some applications of the present invention, the anchor-manipulating tool(s) is(/are) reversibly couplable to anchors 40a and 40b, and facilitate(s) implantation of anchors 40a and 40b in the cardiac tissue. For applications in which anchors 40a and 40b comprises respective helical tissue anchor, as shown, the operating physician rotates the anchor-manipulating tool(s) from a site outside the body of the patient in order to rotate anchors 40a and 40b, and thereby screw at least respective distal portions of anchors 40a and 40b in the cardiac tissue.

Reference is again made to Figs. 5A-B. It is to be noted that first and second implantation sites 30 and 52 include cardiac tissue that is upstream of valve 4 by way of illustration and not limitation, and that either or both first and second implantation sites may include cardiac tissue that is downstream of valve 4.

Typically, following implantation of first and second tissue anchors 40a and 40b, a length of longitudinal member 42, that is disposed between first and second tissue anchors 40a and 40b, is adjusted by adjusting mechanism 150. Adjusting mechanism 150 typically comprises a mechanical element which shortens a distance of longitudinal member 42 between first and second tissue-engaging elements 60a and 60b. For some applications, adjustable mechanism 150 may be permanently coupled to longitudinal member 42 (as shown in Fig. 5B) and comprises an adjusting element, e.g., a spool for looping portions of longitudinal member 42 therearound, a crimping bead for crimping and shortening a portion of longitudinal member 42, a ratchet element, or a deforming element which deforms a portion of longitudinal member 42 in order to shorten its length between first and second tissue-engaging elements 60a and 60b.

For other applications, adjusting mechanism 150 comprises only adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening a portion of longitudinal member 42, or a deforming element which deforms a portion of longitudinal member 42 in order to shorten its length between first and second tissue-engaging elements 60a and 60b.

In either application, a level of regurgitation of valve 4 may be monitored during the adjusting of the distance between first and second tissue-engaging elements 60a and 60b by adjusting mechanism 150.

Following the adjusting of the distance between first and second implantation sites

30 and 52, adjusting tool 144 and catheter 142 are decoupled from longitudinal member 42 and are extracted from the body of the patient.

Reference is now made to Fig. 5C, which is a schematic illustration of another configuration of system 140, in accordance with some applications of the present invention. This configuration of system 140 is generally similar to the configuration described above with reference to Figs. 5A-B, except that the system comprises a third tissue-engaging element 60c (i.e., a third tissue anchor), in addition to first and second tissue-engaging elements 60a and 60b. Third tissue-engaging element 60c is implanted at third implantation site 32, such as using the techniques described hereinabove with reference to Figs. 5A-B. For some applications, third implantation site 32 may include a third portion of the wall of atrium 6. By way of illustration and not limitation, the three implantation sites may include portions of tissue of the annulus of the three leaflets of the valve, such as at the middle of the leaflets.

Tissue-engaging elements 60a, 60b, and 60c are coupled to longitudinal members 42a, 42b, and 42c, respectively. The longitudinal members are coupled together by adjusting mechanism 150. For some applications, adjusting mechanism 150 comprises a spool for looping portions of the longitudinal members therearound, and a ratchet element which allows the spool to rotate in only one direction. Rotation of the spool loops the longitudinal member therearound, thereby shortening the effective lengths of the members and applying tension thereto, to draw the leaflets toward one another, such as described hereinabove with reference to Figs. 5A-B. As a result, a geometry of the wall of the right atrium may be altered.

Reference is now made to Fig. 6 which is a schematic illustration of a system 700 for repairing tricuspid valve 4 comprising first tissue-engaging element 60a implanted at a portion of the annulus of valve 4 and a third tissue-engaging element 60c implanted at a portion of a papillary muscle 72 in the right ventricle of the patient, in accordance with some applications of the present invention. It is to be noted that third implantation site 32 comprises papillary muscle 72 by way of illustration and not limitation, and that third implantation site 32 may comprise any portion of a wall of the right ventricle (e.g., a portion of tissue of the annulus at the ventricular surface of valve 4, a portion of the wall of the ventricle in the vicinity of valve 4, a portion of tissue in the vicinity of the apex of heart 2, or any other suitable portion of the wall of the ventricle).

Reference is now made to Figs. 2A-B and 6. First, second, and third tissue-engaging elements 60a-c of Fig. 6 are implanted in cardiac tissue in a manner as described hereinabove with reference to Figs. 2A-B, with the exception that, in order to implant third tissue-engaging element 60c, catheter 22 passes through the leaflets of valve 4 into the right ventricle and implants third tissue-engaging element 60c in tissue of the ventricle. Following coupled of third tissue-engaging element 60c in Fig. 6, second stent 50b is deployed in second implantation site 52 in inferior vena cava 8, as described hereinabove with reference to Fig. 2B.

Reference is now made to Figs. 3A-C and 6. It is to be noted, that for some applications, second longitudinal member 42b is coupled at a proximal end thereof to one or more barbs 114 (i.e., and is not connected to second stent 50, as shown). Barbs 114 enable second longitudinal member 42b to be coupled to stent 50 that is in connection with first longitudinal member 42a, and thereby maintain tension on third implantation site 32 and maintain coaptation of at least anterior leaflet 14 and septal leaflet 12.

Reference is again made to Fig. 6. Such an application of at least one tissue-engaging element 60 in a portion of tissue of the ventricle of heart 2, in some applications, facilitates independent adjustment of valve 4 and a portion of the ventricle wall of heart 2. That is, for some application, geometric adjustment of the right ventricle to improve its function is achieved.

For some applications, following the deploying of first, second, third, and fourth tissue-engaging elements 60a-d (i.e., first and second anchors 40a and 40b, and first and second stents 50a and 50b), (1) a distance between first and second tissue-engaging elements 60a and 60b is adjustable by first adjustable mechanism, and (2) a distance between third and fourth tissue-engaging elements 60c and 60d is adjustable by a second adjustable mechanism, as described hereinbelow with reference to Figs. 5A-B or 5C. In such applications, (1) a length of first longitudinal member 42a between first and second tissue-engaging elements 60a and 60b may be adjusted by a first adjusting mechanism 150, as shown in Figs. 5A-B or 5C, and (2) a length of second longitudinal member 42b between third and fourth tissue-engaging elements 60c and 60d may be adjusted by a second adjusting mechanism 150, as shown in Figs. 5A-B or 5C. Adjusting mechanisms 150 typically each comprise a mechanical element which shortens a distance of respective longitudinal members 42a and 42b. For some applications, adjustable mechanisms 150

may be permanently coupled to respective longitudinal members 42a and 42b (not shown) and each comprise an adjusting element, e.g., a spool for looping portions of longitudinal members 42a and 42b therearound, a crimping bead for crimping and shortening respective portions of longitudinal members 42a and 42b, a ratchet element, or a
5 deforming element which deforms respective portions of longitudinal members 42a and 42b in order to shorten its length between the respective tissue-engaging elements 60. For other applications, adjusting mechanisms 150 each comprise only adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening respective portions of
10 longitudinal members 42a and 42b, or a deforming element which deforms respective portions of longitudinal members 42a and 42b. In either application, a level of regurgitation of valve 4 may be monitored and the adjustment of the geometry of the right ventricle is monitored during (1) the adjusting of the distance between first and second implantation sites 30 and 52, and (2) the adjusting of the distance between third and
15 second implantation sites 32 and 52, respectively.

Reference is now made to Figs. 8A-E and 9A-E, which are schematic illustrations of a system 800 for repairing tricuspid valve 4, in accordance with respective applications of the present invention. As perhaps best seen in Figs. 8E and 9E, system 800 comprises first, second, third, and fourth tissue-engaging elements 60a, 60b, 60c, and 60d. System
20 800 is similar in some respects to system 110 described hereinabove with reference to Figs. 3A-B, with the exception that system 800 typically comprises only exactly one longitudinal member 42. Typically, longitudinal member 42 is directly coupled to first tissue-engaging element 60a, and indirectly coupled to tissue-engaging elements 60c and 60d by a longitudinal sub-member 802. Typically, one end of longitudinal sub-member
25 802 is coupled to tissue-engaging element 60c, and the other end of the sub-member is coupled to tissue-engaging element 60d. For some applications, as shown, longitudinal member 42 is not fixed to longitudinal sub-member 802; instead, longitudinal sub-member 802 engages, e.g., is hooked on or looped over, longitudinal member 42, at a junction 804 during deployment of the longitudinal sub-member, as described
30 hereinbelow with reference to Figs. 8C-E and 9C-E. Alternatively, a ring is provided that couples the longitudinal sub-member to the longitudinal member (configuration not shown).

Figs. 8A-E illustrate a superior vena cava approach, in which tissue-engaging

elements 60a, 60c, and 60d are advanced into atrium 6 via superior vena cava 10, and tissue-engaging element 60b is deployed in the superior vena cava. Figs. 9A-E illustrate an inferior vena cava approach, in which tissue-engaging elements 60a, 60c, and 60d are advanced into atrium 6 via inferior vena cava 8, and tissue-engaging element 60b is
5 deployed in the inferior vena cava. Typically, one of tissue-engaging elements 60a, 60c, and 60d is deployed at the septal side of tricuspid valve 4 in the caudal part of the base of the septal leaflet, and the other two of tissue-engaging elements 60a, 60c, and 60d are deployed at the mural side of the valve, dividing the entire mural side in three equal spaces, generally at the middle of anterior leaflet and the commissure between the anterior
10 and posterior leaflets. For some applications, yet another tissue-engaging element is deployed at the mural side of the valve (configuration not shown).

As shown in Figs. 8A and 9A, anchor-deployment tube 24 is deployed into atrium 6, for example, using techniques described hereinabove with reference to Fig. 1A. First tissue-engaging element 60a is deployed at first implantation site 30, such as using
15 anchoring techniques described herein. First implantation site 30 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4 (e.g., a first portion of tissue of the annulus of tricuspid valve 4, as shown). For example, in the approach shown in Fig. 8A, first implantation site 30 may be on the mural side of the annulus of the valve (e.g., at anterior leaflet 14), approximately centered between two of the commissures of the valve.
20 In the approach shown in Fig. 9A, first implantation site 30 may be on the mural side of the annulus (e.g., at posterior leaflet 16), approximately centered between two of the commissures of the valve. Alternatively, although typically less desirable, first implantation site 30 may be approximately at a commissure of the valve.

As shown in Figs. 8B and 9B, the distal end of anchor-deployment tube 24 is
25 advanced to third implantation site 32. Third tissue-engaging element 60c is deployed at third implantation site 32, such as using anchoring techniques described herein. Third implantation site 32 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4 (e.g., a second portion of tissue of the annulus of tricuspid valve 4, as shown). For example, in the approach shown in Fig. 8B, third implantation site 32 may be on the
30 mural side of the annulus of the valve (e.g., at posterior leaflet 16), approximately centered between two of the commissures of the valve. In the approach shown in Fig. 9B, third implantation site 32 may be on the mural side of the annulus of the valve (e.g., at anterior leaflet 14), approximately centered between two of the commissures of the valve.

Alternatively, although typically less desirable, third implantation site 32 may be approximately at a commissure of the valve.

As shown in Figs. 8C and 9C, the distal end of anchor-deployment tube 24 is advanced to a fourth implantation site 34. As mentioned above, longitudinal sub-member 802 extends between tissue-engaging elements 60c and 60d. As fourth tissue-engaging element 60d is brought to fourth implantation site 34, longitudinal sub-member 802 engages, e.g., becomes hooked on or looped over, longitudinal member 42 at junction 804. Fourth tissue-engaging element 60d is deployed at fourth implantation site 34, such as using anchoring techniques described herein. Fourth implantation site 34 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4 (e.g., a second portion of tissue of the annulus of tricuspid valve 4, as shown). For example, in the approaches shown in Figs. 8C and 9C, fourth implantation site 34 may be on septal side of the annulus of the valve (e.g., at the caudal part of the base of septal leaflet 12, approximately centered between two of the commissures of the valve). Alternatively, although typically less desirable, fourth implantation site 34 may be approximately at a commissure of the valve.

As shown in Figs. 8D and 9D, anchor-deployment tube 24 is withdrawn into the vena cava. Second tissue-engaging element 60b (stent 50) pulls on longitudinal member 42, which directly pulls on first tissue-engaging element 60a, and indirectly pulls on tissue-engaging elements 60c and 60d via longitudinal sub-member 802. Responsively, a distance between the leaflets of tricuspid valve 4 is adjusted to reduce and eliminate regurgitation through valve 4, and thereby, valve 4 is repaired. For some applications, during the pulling of longitudinal member 42, a level of regurgitation of tricuspid valve 4 is monitored. Longitudinal member 42 is pulled until the regurgitation is reduced or ceases. Once the physician determines that the regurgitation of valve 4 is reduced or ceases, and valve 4 has been repaired, second tissue-engaging element 60b (e.g., stent 50) is deployed from anchor-deployment tube 24 in the vena cava, such as described hereinabove, thereby implanting the tissue-engaging element at second implantation site 52, as shown in Figs. 8E and 9E.

For some applications, stent 50 comprises a plurality of interconnected superelastic metallic struts, such as described hereinabove with reference to Fig. 1D. Alternatively or additionally, for some applications, stent 50 comprise two or more rings 62, configured as described hereinabove with reference to Figs. 1E-G.

For some applications, following the implantation the tissue-engaging elements at their respective implantation sites, as described hereinabove, a length of longitudinal member 42 is adjusted by an adjustable mechanism, as described hereinabove with reference to Figs. 5A-B or 5C. Adjusting mechanism 150 typically comprises a mechanical element which shortens a length of longitudinal member 42. For some applications, adjustable mechanism 150 may be permanently coupled to longitudinal member 42; mechanism 150 comprises an adjusting element, e.g., a spool for looping a portion of longitudinal member 42 therearound, a crimping bead for crimping and shortening the portion of longitudinal member 42, a ratchet element, or a deforming element which deforms the portion of longitudinal member 42. For other applications, adjusting mechanism 150 comprises only adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening the portion of longitudinal member 42, or a deforming element which deforms the portion of longitudinal member 42. In either application, a level of regurgitation of valve 4 may be monitored during the adjusting of the length of longitudinal member 42.

Reference is now made to Figs. 10A-B, which are schematic illustrations of a rotation tool 900, in accordance with an application of the present invention. Tool 900 may be used to rotate a tissue anchor for driving the anchor into tissue. Tool 900 may be used, for example, to rotate and implant an anchor in combination with the applications described herein with reference to Figs. 1A-G, 2A-B, 3A-C, 5A-C, 6, 8A-E, 9A-E, 11A-B, 12A-D, and/or 14A-D. Tool 900 is similar in some respect to delivery tool system 200, described hereinabove with reference to Figs. 7A-D, and may optionally implement various features of system 200, and/or be utilized in a manner similar to system 200.

Tool 900 comprises a rotation tube 902, a distal end 904 of which is configured to removably engage a proximal coupling head 906 of anchor 40. Rotation of rotation tube 902 rotates the anchor. For example, distal end 904 may be shaped so as to define a female coupling member (which may, for example, be hexagonal or square), and proximal coupling head 906 may be shaped so as to define a male coupling element (which may, for example, be hexagonal or square). For some applications, rotation tube 902 comprises a braided or woven material, which may comprise, for example, a metal, such as stainless steel.

For some applications, such as described hereinabove with reference to Figs. 7A-D, a distal end of longitudinal member 42 comprises annular loop 216, through which a portion of anchor 40 is coupled to the distal end of longitudinal member 42. This coupling arrangement of anchor 40 to annular loop 216 enables anchor 40 to rotate about
5 a central longitudinal axis of rotation tool 900, freely within annular loop 216. That is, rotation tool 900 rotates anchor 40 without rotating longitudinal member 42 and stent 50 (if provided, such as described with reference to Figs. 7A-D).

For some applications, tool 900 further comprises an elongated coupling element 910, which may comprise, for example, a string, cable, or wire. Anchor 40, such as
10 proximal coupling head 906 thereof, is shaped so as to define a passage 912 therethrough. Elongated coupling element 910 is initially disposed so as to pass through passage 912, such that both ends 914 of the elongated coupling element extend in a proximal direction. When thus positioned, the elongated coupling element couples the tool to the anchor. To
15 decouple the tool from the anchor, one of ends 914 is pulled until the elongated coupling element no longer passes through passage 912.

Reference is now made to Figs. 11A-B and 12A-D, which are schematic illustrations of a system 950 for repairing tricuspid valve 4, in accordance with some applications of the present invention. System 950 typically comprises a tensioning device 952 and a deployment tube 954. For some applications, tube 954 is steerable, as is known
20 in the catheter art, while for other applications, a separate steerable element may be coupled to tube 954. Figs. 11A-B show system 950 with tensioning device 952 partially and fully deployed from deployment of deployment tube 954, respectively, and Figs. 12A-B and 12C-D show two exemplary procedures for deploying tensioning device 952.

As shown in Figs. 11A-B, tensioning device 952 comprises a first distal tissue-
25 engaging element 60a and a second proximal tissue-engaging element 60b, and at least one flexible longitudinal member 42 that connects the tissue-engaging elements. First tissue-engaging element comprises tissue anchor 40, which is shown, by way of illustration, as comprising a helical tissue anchor. Anchor 40 may comprise any tissue
30 anchors described hereinbelow with reference to Figs. 13A-E. Second tissue-engaging element 60b comprises a radially-expandable anchor 956 that is configured to assume radially-compressed and radially-expanded state. When in its radially-expanded state,

such as shown in Fig. 11B, anchor 956 is configured to rest against a wall of a cardiac chamber and to not pass through a hole in the cardiac wall. For example, when in its radially-expanded state, anchor 956 may be shaped like a flower or butterfly, and thus may be shaped so as to define a plurality of petals or wings. Typically, anchor 956 is
5 configured to generally fall within exactly one plane when in its radially-expanded state.

Longitudinal member 42 passes through an opening defined by anchor 956, such that anchor 956 is slidably coupled to longitudinal member 42. Typically, a distance between first and second tissue-engaging elements 60a and 60b is adjusted by pulling longitudinal member 42 through the opening of anchor 956, which opening is typically
10 positioned at a radial center of the anchor.

Once a desired distance has been obtained, the distance is maintained by locking anchor 956 to longitudinal member 42, so as to prevent movement of anchor 956 with respect to longitudinal member 42 at least in a proximal direction (away from distal tissue-engaging element 60a). For some applications, such as for deployment as
15 described hereinbelow with reference to Figs. 12C-D, at least a portion of longitudinal member 42 is shaped so as to define ratchet teeth 958, which engage anchor 956 so as to allow movement of anchor 956 with respect to longitudinal member 42 in a distal direction (toward first distal tissue-engaging element 60a), while preventing movement of anchor 956 with respect to longitudinal member 42 in a proximal direction (away from
20 distal tissue-engaging element 60a). For other applications, such as for deployment as described hereinbelow with reference to Figs. 12C-D, longitudinal member 42 is configured to move bidirectionally through anchor 956, and anchor 956 is configured to crimp longitudinal member 42 in place after the desired distance has been obtained, in order to lock anchor 956 to longitudinal member 42. For still other applications, such as
25 for deployment as described hereinbelow with reference to Figs. 12A-B, longitudinal member 42 is fixed to anchor 956, such as shown in Fig. 12B.

For some applications, first tissue-engaging element 60a and longitudinal member 42 are fabricated from the same material, e.g., nitinol, from a single piece. Typically, second tissue-engaging element 60b is fabricated from a second piece, and may comprise
30 a shape-memory alloy, such as nitinol.

Reference is again made to Figs. 12A-B, which illustrate a procedure for deploying tensioning device via a vena cava, such as superior vena cava 10 (as shown), or

inferior vena cava 8 (approach not shown). Tensioning device 952 is initially positioned within deployment tube 954. For some applications, as shown in Fig. 12A, during an implantation procedure, deployment tube 954 is advanced into right atrium 6.

As shown in Fig. 12A, first distal tissue-engaging element 60a is deployed at first
5 implantation site 30, such as using anchoring techniques described herein. First
implantation site 30 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4
(e.g., a first portion of tissue of the annulus of tricuspid valve 4, as shown). For example,
first implantation site 30 may be on the mural side of the annulus (e.g., at posterior leaflet
16), approximately centered between two of the commissures of the valve. Alternatively,
10 first implantation site 30 may be approximately at a commissure of the valve.

Prior to introducing the device, a hole is made in interatrial septum 362, typically
using a separate perforation tool, such as a standard transeptal needle and kit.
Deployment tube 954 is advanced to the right-atrial side of the hole (or, optionally,
slightly through the hole), and second proximal tissue-engaging element 60b in the left
15 atrium near septum 362, as shown in Fig. 12B. Typically, anchor 956 of second tissue-
engaging element 60b self-expands upon being released from the deployment tube.

A distance between first and second implantation sites 30 and 52 is adjusted, such
as by pulling longitudinal member 42 in a proximal direction (toward the vena cava). The
decreased distance, and resulting increased tension, is maintained, such as using a locking
20 mechanism 962. (For example, longitudinal member 42 may be tensioned by depressing
a button of the locking mechanism and pulling the longitudinal member from the side of
anchor 40; a spring may hold the button in a locked position when the button is not
depressed.) Responsively, a distance between the leaflets of tricuspid valve 4 is adjusted
to reduce and eliminate regurgitation through valve 4, and thereby, valve 4 is repaired.
25 Optionally, a level of regurgitation of valve 4 may be monitored during the adjusting of
the distance. Deployment tube 954 is withdrawn from the left atrium and the patient's
body.

Alternatively, for some applications, a length of longitudinal member 42 is
adjusted by an adjustable mechanism, as described hereinabove with reference to Figs.
30 5A-B or 5C. Adjusting mechanism 150 typically comprises a mechanical element which
shortens a length of longitudinal member 42. For some applications, adjustable
mechanism 150 may be permanently coupled to longitudinal member 42; mechanism 150

comprises an adjusting element, e.g., a spool for looping a portion of longitudinal member 42 therearound, a crimping bead for crimping and shortening the portion of longitudinal member 42, a ratchet element, or a deforming element which deforms the portion of longitudinal member 42. For other applications, adjusting mechanism 150 comprises only
5 adjusting tool 144, as shown in Fig. 5A. In such applications, adjusting tool 144 may comprise an adjusting element, e.g., a crimping bead for crimping and shortening the portion of longitudinal member 42, or a deforming element which deforms the portion of longitudinal member 42.

Alternatively, second proximal tissue-engaging element 60b is deployed before
10 first distal tissue-engaging element 60a.

Reference is again made to Figs. 12C-D, which illustrate a procedure for deploying tensioning device via a left atrium 960. Tensioning device 952 is initially positioned within deployment tube 954, such that first distal tissue-engaging element 60a is positioned near a distal end 959 of tube 954 and second proximal tissue-engaging
15 element 60b is positioned more proximally within the tube, farther from the distal end thereof. For some applications, as shown in Fig. 12C, during an implantation procedure, deployment tube 954 is advanced into a left atrium 960. For example, the tube may be advanced to the left atrium via the aorta and left ventricle, as shown in the figure (the aorta may be accessed from the femoral artery or subclavian artery, for example).
20 Alternatively, the tube may be advanced to the left atrium using a transapical approach through the left ventricle, as is known in the art.

Prior to introducing the device, a hole is made in interatrial septum 362, typically using a separate perforation tool, such as a standard transeptal needle and kit. Deployment tube 954 is advanced through the hole, until distal end 959 of the tube is
25 positioned within right atrium 6, as shown in Fig. 12C.

As also shown in Fig. 12C, first distal tissue-engaging element 60a is deployed at first implantation site 30, such as using anchoring techniques described herein. First implantation site 30 includes a portion of cardiac tissue in the vicinity of tricuspid valve 4 (e.g., a first portion of tissue of the annulus of tricuspid valve 4, as shown). For example,
30 first implantation site 30 may be on the mural side of the annulus (e.g., at posterior leaflet 16), approximately centered between two of the commissures of the valve. Alternatively, first implantation site 30 may be approximately at a commissure of the valve.

Deployment tube 954 is withdrawn proximally into left atrium 960, thereby releasing second proximal tissue-engaging element 60b in the left atrium near septum 362, as shown in Fig. 12D. Typically, anchor 956 of second tissue-engaging element 60b self-expands upon being released from the deployment tube. Anchor 956 of second tissue-engaging element 60b is held, such as using distal end 959 of deployment tube 954, at second implantation site 52 against the left-atrial side of septum 362 around the hole previously made in the septum. A distance between first and second implantation sites 30 and 52 is adjusted by pulling longitudinal member 42 in a proximal direction (toward left atrium 960), while holding anchor 956 against the left-atrial side of the septum, such as using distal end 959 of deployment tube 954. The decreased distance, and resulting increased tension, is maintained, such as described hereinabove with reference to Figs. 11A-B. Responsively, a distance between the leaflets of tricuspid valve 4 is adjusted to reduce and eliminate regurgitation through valve 4, and thereby, valve 4 is repaired. Optionally, a level of regurgitation of valve 4 may be monitored during the adjusting of the distance. Deployment tube 954 is withdrawn from the left atrium and the patient's body.

Reference is now made to Figs. 13A-E, which are schematic illustration of tissue anchors 40, in accordance with respective applications of the present invention. One or more of these anchors may be used as anchors 40 in the applications described hereinabove with reference to Figs. 1A-G, 2A-B, 3A-C, 5A-C, 6, 8A-E, 9A-E, 10A-B, 11A-B, 12A-D, and/or 14A-D.

In the configuration shown in Fig. 13A, anchor 40 comprises a helical tissue-coupling element 970 fixed to coupling head 906. Optionally, anchor 40, such as coupling head 906, is shaped so as to define passage 912, such as for use with the techniques described hereinabove with reference to Figs. 10A-B. For some applications, a length L1 of tissue-coupling element 970 is at least 5 mm, no more than 30 mm, and/or between 5 and 30 mm, such as 10 mm.

In the configuration shown in Fig. 13B, anchor 40 comprises a distal tissue-piercing tip 972 fixed to a plurality of arms 974, which extend from tip 972 in respective generally distal and radially-outward directions. The arms are inserted entirely into the tissue, thereby helping to couple the anchor to the tissue. For some applications, a greatest width W1 of anchor 40 is at least 6.5 mm, no more than 39 mm, and/or between

6.5 and 39 mm, such as 13 mm. For some applications, a length L2 of anchor 40, measured along an axis of the anchor from tips of arms 974 to the end of tip 972 of the anchor, is at least 5 mm, no more than 30 mm, and/or between 5 and 30 mm, such as 10 mm. For some applications, a greatest diameter D1 of tip 972 is at least 1 mm, no more than 6 mm, and/or between 1 and 6 mm, such as 2 mm.

In the configurations shown in Fig. 13C and 13D, anchor 40 is configured to radially contract and expand in a manner generally similar to that of an umbrella (but without the umbrella cloth). The anchor is inserted into the tissue in a radially-contracted (closed) state, and is transitioned to a radially-expanded (open) state, either automatically or by the surgeon, in order to fix the anchor within the tissue. For some applications, such as shown in Fig. 13C, the anchor is configured to assume the radially-expanded state when resting; the anchor is held in a radially-contracted state during deployment, and transitions to the radially-expanded state upon being released. For other applications, such as shown in Fig. 13D, the anchor is configured to assume the radially-contracted state when resting; the anchor is deployed in the radially-contracted state, and is actively transitioned to the radially-expanded state by the surgeon after being inserted into the tissue.

Anchor 40 comprises distal tissue-piercing tip 972, which is fixed at a distal end of a post 976 (which typically comprises a tube). The anchor further comprises a plurality of ribs 978 (e.g., three or four). Ribs 978 are coupled to the anchor near distal tip 972, such that the ribs can articulate with post 976, thereby changing respective angles between the ribs and the post. The anchor further comprises a runner 980 (which typically comprises a tube), which is slidably coupled to post 976, such that the runner can slide along the post. A plurality of stretchers 982 are coupled to runner 980 and respective ones of the ribs, such that stretchers can articulate with the runner and the respective ribs. Each of the stretchers may comprise one or more elongated elements; by way of example, each of the stretchers is shown comprising two elongated elements. Typically, tips 984 of ribs 978 (i.e., at the ends not coupled to the anchor) are blunt.

For some applications, such as the configuration shown in Fig. 13C, the anchor at least partially comprises a shape-memory alloy (e.g., nitinol), and the anchor's natural, resting state is the radially-expanded (open) state. The anchor is crimped inside a catheter so that it remains radially-contracted (closed) until deployed. Once deployed into the

tissue, the catheter is pulled back and the anchor is allowed to open (i.e., automatically transition to the radially-expanded state).

For some applications, in order to allow retraction of the anchor (such as if the anchor has been improperly positioned, or needs to be removed for another reason), the proximal end of runner 980 (i.e., the end farther from tip 972) is removably coupled to an inner tube positioned within the catheter. For example, an outer surface of the proximal end of runner 980 and an inner surface of the inner tube near a distal end thereof may be threaded, to enable the removable coupling. Runner 980 thus remains coupled to the inner tube until released, such as by rotating the inner tube with respect to the runner (the tissue prevents the runner from also rotating). In order to retract the anchor, post 976 is pushed in a distal direction while the runner is still coupled to the inner tube, thereby moving post 976 with respect to runner 980 and transitioning the anchor back to its radially-contracted (closed) state. The anchor can thus be withdrawn into the catheter, repositioned, and deployed again at a different location. The surgeon rotates the inner tube to decouple the anchor once the location of the anchor has been finalized.

For some applications, in the configuration shown in Fig. 13D, anchor 40 further comprises a tube positioned around post 976, proximal to runner 980 (i.e., farther from tip 972). The tube is used to push runner 980 in a distal direction (toward the tip), in order to open the umbrella.

For some applications, a greatest width W2 of anchor 40, when radially expanded, is at least 6.5 mm, no more than 39 mm, and/or between 6.5 and 39 mm, such as 13 mm. For some applications, a length L3 of anchor 40, measured along an axis of the anchor from tips 984 of ribs 978 to the end of tip 972 of the anchor when the anchor is radially expanded, is at least 5 mm, no more than 30 mm, and/or between 5 and 30 mm, such as 10 mm. For some applications, a greatest diameter D2 of tip 972 is at least 0.4 mm, no more than 2.4 mm, and/or between 0.4 and 2.4 mm, such as 0.8 mm. For some applications, a greatest diameter D3 of post 976 is at least 0.3 mm, no more than 1.8 mm, and/or between 0.3 and 1.8 mm, such as 0.6 mm. For some applications, each of ribs 978 has a length of at least 6 mm, no more than 20 mm, and/or between 6 and 20 mm, such as 10 mm.

In the configuration shown in Fig. 13E, anchor 40 is barbed. For example, the anchor may be generally flat, and is shaped so as to define one or more barbs 990, which

typically extend from both sides of the anchor. The barbs help couple the anchor to the tissue. For some applications, a greatest width W3 of anchor 40, excluding barbs 990, is at least 0.85 mm, no more than 5.1 mm, and/or between 0.85 and 5.1 mm, such as 1.7 mm. For some applications, a greatest width W4 of anchor 40, including barbs 990, is at least 1.25 mm, no more than 7.5 mm, and/or between 1.25 and 7.5 mm, such as 2.5 mm. For some applications, a length L4 of anchor 40, measured along an axis of the anchor from a distal end of the barbed portion to the proximal tip of the anchor, is at least 5 mm, no more than 30 mm, and/or between 5 and 30 mm, such as 9.5 mm. For some applications, a greatest thickness T of anchor 40 is at least 0.1 mm, no more than 0.6 mm, and/or between 0.1 and 0.6 mm, such as 0.2 mm.

Reference is now made to Figs. 14A-D, which are schematic illustrations of a system 1000 for reducing regurgitation of a heart valve, such as tricuspid valve 4, and an exemplary deployment procedure, in accordance with some applications of the present invention. System 1000 comprises first and second tissue-engaging elements 60a and 60b, which comprise first and second tissue anchors 40a and 40b, respectively. It is to be noted that tissue anchors 40a and 40b comprise a helical tissue anchors by way of illustration and not limitation and that tissue anchors 40a and 40b may comprise any tissue anchor for puncturing or clamping cardiac tissue, including, but not limited to, the tissue anchors described hereinbelow with reference to Figs. 13A-E, modified as described hereinbelow. First and second tissue anchors 40a and 40b are configured to be directly coupled to each other during an implantation procedure. For example, one of the tissue anchors (e.g., first tissue anchor 40a) may comprise a male coupling element 1002, and the other (e.g., second tissue anchor 40b) may comprise a female coupling element 1004 (shown in Fig. 14D).

Fig. 14A shows the advancement of catheter 22 toward atrium 6 until distal end of the catheter is disposed within atrium 6. This portion of the procedure may be performed using techniques described hereinabove with reference to Figs. 1A and 1E. Although the catheter is shown advanced through superior vena cava 10, the catheter may also be introduced through inferior vena cava 8. Once the distal end of catheter 22 is disposed within atrium 6, anchor-deployment tube 24 is extended from within catheter 22 toward first implantation site 30. Anchor-deployment tube 24 holds first tissue anchor 40a and at least a portion of a longitudinal member 1010, such as a wire, which is coupled to the anchor, typically removably. For some applications, tube 24 is steerable, as is known in

the catheter art, while for other applications, a separate steerable element may be coupled to anchor-deployment tube 24. Under the aid of imaging guidance, anchor-deployment tube 24 is advanced toward first implantation site 30 until a distal end thereof contacts cardiac tissue of heart 2 at first implantation site 30. Anchor-deployment tube 24 facilitates atraumatic advancement of first tissue-engaging element 60a toward first implantation site 30.

First implantation site 30 is typically on the annulus of the valve. For example, first implantation site 30 may be on the annulus in the area between the coronary sinus and the base of septal leaflet 12, as shown. Alternatively, for example, first implantation site 30 may be on the annulus in the area of the antero-posterior commissure. Anchor 40a is fixed to the cardiac tissue, such as using techniques described hereinabove with reference to Figs. 1B and 1E. Longitudinal member 1010 is typically removably coupled to anchor 40a, typically extending from male coupling element 1010, as shown in Fig. 14A.

Anchor-deployment tube 24 is withdrawn from the atrium, as shown in Fig. 14B, leaving first tissue anchor 40a implanted in the annulus.

Second tissue anchor 40b is threaded onto longitudinal member 1010, by passing a proximal end of the longitudinal member (not shown) through a passage 1012 defined by anchor 40b. For some applications, a portion of passage 1012 is shaped so as to define female coupling element 1004. Second anchor 40b is loaded in anchor-deployment tube 24, or another anchor-deployment tube similar to anchor-deployment tube 24, which is advanced toward second implantation site 52 until a distal end thereof contacts cardiac tissue of heart 2 at first implantation site 52.

Second implantation site 52 is typically on the annulus of the valve. For example, second implantation site 52 may be on the annulus in the area of the antero-posterior commissure, as shown. Alternatively, for example, second implantation site 52 may be on the annulus in the area between the coronary sinus and the base of septal leaflet 12. As shown in Fig. 14C, second anchor 40b is fixed to the cardiac tissue, such as using techniques described hereinabove with reference to Figs. 1B and 1E.

Tension is applied to longitudinal member 1010, by pulling the longitudinal member in a proximal direction, as schematically indicated by arrows 1014 in the blow-up in Fig. 14C. The resulting tension approximates first and second anchors 40a and 40b, as

shown in blow-ups "A" in Fig. 14D, until the anchors are brought together, as shown in blow-ups "B" in Fig. 14D. Bringing the anchors together causes male coupling element 1002 of first anchor 40a to engage female coupling element 1004 of second anchor 40b, thereby directly coupling (i.e., locking) the anchors to each other. Drawing the anchors
 5 together draws the portions of the annulus to which they are coupled together, thereby achieving bicuspidization. For example, as shown in Fig. 14D, septal leaflet 12 and posterior leaflet 16 are drawn together. Typically, as shown in blow-ups "B" in Fig. 14D, longitudinal member 1010 is decoupled from first anchor 40a, such as by unscrewing the longitudinal member from the anchor, or using another decoupling technique.
 10 Alternatively, the longitudinal member is left coupled to the first anchor, and is cut off in the atrium.

Reference is now made to Figs. 1A-G, 2A-B, 3A-C, 4A-C, 5A-C, 6, 7A-D, 8A-E, 9A-E, 10A-B, 11A-B, 12A-D, 13A-E, and 14A-D. It is to be noted that apparatus and methods described herein for repairing tricuspid valve 4 may also be applied to repair any
 15 other heart valve of the patient, e.g., a mitral valve, a pulmonary valve, or an aortic valve. For such applications, second implantation site 52 may include a portion of a blood vessel that is in contact with the left atrium of the patient, e.g., a pulmonary vein, a portion of the wall of the left atrium, a portion of the annulus of the mitral valve, or a portion of the left ventricle of the heart of the patient, and first implantation site 30 may include a portion of
 20 the wall of the left atrium, a portion of the annulus of the mitral valve, or a portion of the left ventricle of the heart of the patient.

Reference is again made to Figs. 1A-G, 2A-B, 3A-C, 4A-C, 5A-C, 6, 7A-D, 8A-E, 9A-E, 10A-B, 11A-B, 12A-D, 13A-E, and 14A-D. It is to be noted that any suitable number of tissue-engaging elements 60 may be implanted in and/or grasp cardiac tissue,
 25 depending on the needs of a given patient. Typically, one or more tissue-engaging elements 60 is/are implanted in cardiac tissue (e.g., tissue of the annulus, tissue of the wall of the atrium adjacent the valve, or tissue of the wall of the ventricle adjacent the valve) in a vicinity of the valve that is between the middle of the anterior leaflet and the middle of the posterior leaflet, e.g., at the commissure between the middle of the anterior leaflet and
 30 the middle of the posterior leaflet. For such an application, pulling together implantation sites 30 and 52 pulls anterior leaflet 14 toward septal leaflet 12 and thereby achieves bicuspidization of tricuspid valve 4. It is to be noted, however, that tissue engaging elements 60 may be implanted in portions of tissue in the vicinity of any portion of the

annulus of valve 4.

Reference is yet again made to Figs. 1A-G, 2A-B, 3A-C, 4A-C, and 5A-C, 6, 7A-D, 8A-E, 9A-E, 10A-B, 11A-B, 12A-D, 13A-E, and 14A-D. It is to be noted that the adjustment of the distance between the respective implantation sites of the tissue-engaging elements 60 is facilitated by adjusting mechanism 150 following initial
5 implantation of the tissue-engaging elements 60 and the repair of the valve and/or the adjustment of the heart wall geometry.

For some applications, techniques described herein are practiced in combination with techniques described in one or more of the references cited in the Background
10 section of the present patent application.

It will be appreciated by persons skilled in the art that the present invention is not limited to what has been particularly shown and described hereinabove. Rather, the scope of the present invention includes both combinations and subcombinations of the various features described hereinabove, as well as variations and modifications thereof that are
15 not in the prior art, which would occur to persons skilled in the art upon reading the foregoing description.

CLAIMS

1. A method, comprising:
 - implanting at least a first tissue-engaging element in a first portion of tissue in a vicinity of a heart valve of a patient;
 - 5 implanting at least a second tissue-engaging element in a portion of a blood vessel that is in contact with an atrium of a heart of the patient; and
 - drawing at least a first leaflet of the valve toward at least a second leaflet of the valve by adjusting a distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient.
- 10 2. The method according to claim 1, wherein adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient comprises pulling a longitudinal member that connects the first and second tissue-engaging elements.
3. The method according to claim 2,
 - 15 wherein implanting the first tissue-engaging element comprises implanting the first tissue-engaging element in the first portion of tissue of an annulus of the valve, and
 - wherein the method further comprises:
 - implanting, in a second portion of tissue of the annulus, a third tissue-engaging element that is connected to a fourth tissue-engaging element by a
 - 20 longitudinal sub-member; and
 - implanting, in a third portion of tissue of the annulus, the fourth tissue-engaging element such that the longitudinal sub-member engages the longitudinal member at a junction therebetween.
4. The method according to claim 1, wherein adjusting the distance between the
 - 25 portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient comprises applying tension to one or more elements selected from the group consisting of the first tissue-engaging element and the second tissue-engaging element.
5. The method according to claim 1, further comprising monitoring a level of regurgitation of the heart valve in conjunction with the adjusting the distance between the
 - 30 portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient.

6. The method according to claim 1, wherein adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient comprises pulling the first tissue-engaging element toward the portion of the blood vessel.
- 5 7. The method according to claim 1, wherein the heart valve includes a tricuspid valve, and wherein adjusting the distance between the portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient comprises achieving bicuspidization of the tricuspid valve of the heart.
8. The method according to claim 1, wherein adjusting the distance between the
10 portion of the blood vessel and the first portion of tissue in the vicinity of the heart valve of the patient comprises actuating an adjusting mechanism that is coupled to a portion of a longitudinal member that connects the first and second tissue-engaging elements.
9. The method according to claim 1, wherein implanting the second tissue-engaging element in the portion of the blood vessel comprises expanding a stent in the portion of
15 the blood vessel.
10. The method according to claim 9, wherein the stent includes two or more rings coupled together by one or more elongated members and by no other elements of the stent, and wherein implanting the second tissue-engaging element comprises expanding the rings such that the rings anchor the stent to a wall of the blood vessel.
- 20 11. The method according to claim 9, further comprising:
implanting a third tissue-engaging element in a second portion of tissue of the heart, the third tissue-engaging element being connected at a proximal end thereof to a distal end of a longitudinal member; and
engaging a proximal end portion of the longitudinal member with the stent.
- 25 12. The method according to claim 11, further comprising applying tension to the third tissue-engaging element.
13. The method according to claim 1, wherein the blood vessel is selected from the group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.
14. The method according to claim 1, wherein implanting the first tissue-engaging
30 element in the first portion of tissue in the vicinity of the heart valve of the patient comprises engaging the first portion of tissue by performing one or more actions selected

from the group consisting of: puncturing and squeezing the first portion of tissue and advancing at least a portion of the first tissue-engaging element into the first portion of tissue.

15. The method according to claim 14, wherein:

5 the first portion of tissue in the vicinity of the heart valve includes a portion of tissue of that is opposite the portion of the blood vessel of the patient,

engaging the first portion of tissue comprises engaging the portion of tissue that is opposite the portion of the blood vessel of the patient, and

10 drawing the first leaflet of the valve toward the second leaflet of the valve comprises adjusting a distance between the portion of the blood vessel of the patient and the portion of tissue that is opposite the portion of the blood vessel of the patient.

16. The method according to claim 14, wherein the first portion of tissue in the vicinity of the heart valve includes a portion of tissue of a wall of the atrium of the heart above an annulus of the valve, and wherein engaging the first portion of tissue comprises
15 engaging the portion of tissue of the wall of the atrium.

17. The method according to claim 14, wherein the first portion of tissue in the vicinity of the heart valve includes a portion of tissue of an annulus of the valve, and wherein engaging the first portion of tissue comprises engaging the portion of tissue of the annulus of the valve.

20 18. The method according to claim 17, wherein the portion of tissue of the annulus of the valve includes a portion of tissue that is between a middle portion of an anterior leaflet of the valve and a middle portion of a posterior leaflet of the valve.

19. A method, comprising:

25 implanting at least a first tissue-engaging element in a first portion of tissue upstream of a tricuspid valve of a patient;

implanting at least a second tissue-engaging element in a second portion of tissue upstream of the tricuspid valve of the patient; and

30 altering a geometry of a wall of a right atrium of a heart of the patient by adjusting a distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient.

20. The method according to claim 19, further comprising implanting at least a third

tissue-engaging element in a third portion of tissue upstream of the tricuspid valve of the patient, wherein altering the geometry of the wall of the right atrium comprises altering the geometry of the wall by adjusting respective distances between the first, the second, and the third portions of tissue upstream of the tricuspid valve.

5 21. The method according to claim 19, wherein adjusting the distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient comprises adjusting a distance between the first tissue-engaging element and the second tissue-engaging element.

10 22. The method according to claim 19, wherein the first portion of tissue includes a first portion of the wall of the right atrium, and wherein implanting the first tissue-engaging element in the first portion of tissue upstream of the tricuspid valve of the patient comprises implanting the first tissue-engaging element in the first portion of the wall of the right atrium.

15 23. The method according to claim 22, wherein the second portion of tissue includes a second portion of the wall of the right atrium, and wherein implanting the second tissue-engaging element in the second portion of tissue upstream of the tricuspid valve of the patient comprises implanting the second tissue-engaging element in the second portion of the wall of the right atrium.

20 24. The method according to claim 23, further comprising implanting at least a third tissue-engaging element in a third portion of the wall of the right atrium, wherein altering the geometry of the wall of the right atrium comprises altering the geometry of the wall by adjusting respective distances between the first, the second, and the third portions of the wall of the right atrium.

25 25. The method according to claim 19, further comprising monitoring a level of regurgitation of the tricuspid valve in conjunction with the altering the geometry of the wall of the right atrium.

30 26. The method according to claim 19, wherein adjusting the distance between the first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient comprises pulling a longitudinal element that connects the first and second tissue-engaging elements.

27. The method according to claim 19, wherein adjusting the distance between the

first portion of tissue upstream of the tricuspid valve of the patient and the second portion of tissue upstream of the tricuspid valve of the patient comprises actuating an adjusting mechanism that is coupled to a portion of a longitudinal element that connects the first and second tissue-engaging elements.

5 28. The method according to claim 19, wherein altering the geometry of the wall of the right atrium of the heart of the patient comprises drawing together at least a first leaflet of the tricuspid valve of the patient and at least a second leaflet of the tricuspid valve of the patient.

29. The method according to claim 19,
10 wherein implanting the first tissue-engaging element comprises implanting the first tissue-engaging element with a longitudinal member coupled to the first tissue-engaging element,

wherein the second tissue-engaging element is shaped so as to define a passage, and wherein implanting the second tissue-engaging element comprises implanting the
15 second tissue-engaging element with the longitudinal member passing through the passage, and

wherein adjusting the distance comprises pulling the longitudinal member in a proximal direction, so as to approximate the first and second tissue-engaging element.

30. The method according to claim 29, wherein pulling the longitudinal member
20 comprising pulling the longitudinal member until the first and second tissue-engaging elements become coupled together.

31. A method, comprising:

engaging at least a portion of at least a first tissue-engaging element in a portion of tissue of a wall of an inferior vena cava of a patient;

25 engaging at least a portion of at least a second tissue-engaging element in a portion of tissue of a wall of a superior vena cava of the patient;

drawing at least a first leaflet of a heart valve toward at least a second leaflet of the valve by applying tension to one or more portions of tissue selected from the group consisting of: the portion of tissue of the wall of the inferior vena cava of the patient and
30 the portion of tissue of the wall of the superior vena cava of the patient; and

monitoring a level of regurgitation of a heart valve of the patient in conjunction with the applying of the tension.

32. The method according to claim 31, wherein applying the tension comprises applying the tension following the engaging of the at least first tissue-engaging element and the engaging of the at least second tissue-engaging element.

33. The method according to claim 31, wherein applying the tension comprises
5 adjusting a distance between the portion of tissue of the wall of the inferior vena cava of the patient and the portion of tissue of the wall of the superior vena cava of the patient.

34. The method according to claim 33, wherein adjusting the distance between the portion of tissue of the wall of the inferior vena cava of the patient and the portion of tissue of the wall of the superior vena cava of the patient comprises, by the applying of the
10 tension, adjusting a distance between the first tissue-engaging element and the second tissue-engaging element.

35. The method according to claim 31, wherein engaging the portion of the at least first tissue-engaging element in the portion of tissue of the wall of the inferior vena cava of the patient comprises expanding a first stent member in the inferior vena cava and
15 contacting at least a portion of the first stent member with the portion of the wall of the inferior vena cava.

36. The method according to claim 31, wherein engaging the portion of the at least second tissue-engaging element in the portion of tissue of the wall of the superior vena cava of the patient comprises expanding a second stent member in the inferior vena cava and contacting at least a portion of the first stent member with the portion of the wall of
20 the inferior vena cava.

37. The method according to claim 31, wherein applying the tension comprises altering a geometry of a wall of an atrium of a heart of the patient.

38. The method according to claim 31, wherein applying the tension comprises pulling
25 a longitudinal member that connects the at least first tissue-engaging element and the at least second tissue-engaging element.

39. The method according to claim 31, wherein applying the tension comprises actuating an adjusting mechanism that is coupled to a portion of a tensioning element that connects the first and second tissue-engaging elements.

30 40. Apparatus comprising:
a stent;

a longitudinal member, which has a distal end that comprises an annular loop that extends laterally from the longitudinal member; and

a tissue anchor, which is coupled to the annular loop, such that the anchor can rotate with respect to the annular loop, the longitudinal member, and the stent.

5 41. The apparatus according to claim 40, further comprising a tube, which is sized to pass through a lumen defined by the stent, and which is configured to be removably coupled to the tissue anchor, such that rotation of the tube rotates the tissue anchor.

42. The apparatus according to claim 41, wherein the tissue anchor is shaped so as to define a passage therethrough, and wherein the tube comprises an elongated coupling
10 element, which is initially disposed so as to pass through the passage, thereby coupling the tube to the anchor.

43. The apparatus according to claim 41, wherein, when the tube is removably coupled to the tissue anchor, a longitudinal portion of the tube is positioned alongside the longitudinal member, and no portion of the tube is positioned around the longitudinal
15 member.

44. The apparatus according to claim 41, further comprising an adapter holder, which is coupled to the tube, and which is shaped so as to define arms, which have a tendency to expand radially, and which couple the tube to the anchor when the arms are radially compressed.

20 45. The apparatus according to claim 44, further comprising a delivery tool overtube, which is sized to pass through the lumen defined by the stent, wherein the tube is configured to pass through the delivery tool overtube, and wherein the overtube is configured to radially compress the arms when positioned surrounding the arms.

46. The apparatus according to claim 44, further comprising an adapter, which is
25 shaped so as to define a cylindrical portion that passes through the annular loop, and which has a distal end that is fixedly coupled to a proximal portion of the tissue anchor, wherein the tube is configured to be removably coupled to the adapter via the adapter holder when the arms are radially compressed, so as to be removably coupled to the tissue anchor.

30 47. The apparatus according to claim 41, further comprising an adapter, which is shaped so as to define a cylindrical portion that passes through the annular loop, and

which has a distal end that is fixedly coupled to a proximal portion of the tissue anchor, wherein the tube is configured to be removably coupled to the adapter, so as to be removably coupled to the tissue anchor.

48. The apparatus according to claim 41, further comprising a delivery tool overtube,
5 which is sized to pass through the lumen defined by the stent, wherein the tube is configured to pass through the delivery tool overtube.

49. The apparatus according to any one of claims 40-48, further comprising an adapter, which is shaped so as to define a cylindrical portion that passes through the annular loop, and which has a distal end that is fixedly coupled to a proximal portion of
10 the tissue anchor.

50. The apparatus according to any one of claims 40-48, wherein the stent comprises a plurality of interconnected superelastic metallic struts.

51. The apparatus according to any one of claims 40-48, wherein the stent comprises one or more elongated members, and two or more rings coupled together by the one or
15 more elongated members and by no other elements of the stent.

52. A method comprising:

providing (a) a stent, (b) a longitudinal member, which has a distal end that includes an annular loop that extends laterally from the longitudinal member, and (c) a tissue anchor, which is coupled to the annular loop;

20 positioning the stent in a blood vessel of a patient;

coupling the tissue anchor to tissue in a vicinity of a heart valve of the patient by rotating the anchor with respect to the annular loop, the longitudinal member, and the stent; and

after coupling the tissue anchor to the tissue, deploying the stent such that the stent
25 expands and is implanted in the blood vessel at an implantation site.

53. The method according to claim 52, further comprising, after coupling the tissue anchor to the tissue and before deploying the stent, pulling the anchor toward the implantation site.

54. The method according to claim 52, wherein the blood vessel is selected from the
30 group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.

55. The method according to claim 52, wherein rotating comprises rotating the anchor

using a tube, which passes through a lumen defined by the stent, and which is removably coupled to the tissue anchor.

56. The method according to claim 55, wherein rotating the anchor using a tube comprises positioning a longitudinal portion of the tube alongside the longitudinal member, such that no portion of the tube is positioned around the longitudinal member.

57. The method according to claim 55, wherein rotating comprises rotating the anchor using the tube that is coupled to an adapter holder, which is shaped so as to define arms, which have a tendency to expand radially, and which couple the tube to the anchor when the arms are radially compressed.

58. The method according to claim 57, further comprising providing a delivery tool overtube, which is sized to pass through the lumen defined by the stent, wherein the tube is configured to pass through the delivery tool overtube, and wherein the overtube is configured to radially compress the arms when positioned surrounding the arms.

59. The method according to claim 55, further comprising providing a delivery tool overtube, which is sized to pass through the lumen defined by the stent, wherein the tube is configured to pass through the delivery tool overtube.

60. Apparatus comprising:

a stent, which is configured to assume compressed and expanded states, and which comprises:

one or more elongated members; and

two or more rings, which are coupled together by the one or more elongated members and by no other elements of the stent, and which define respective planes that are generally perpendicular to the elongated members when the stent is in its expanded state;

a longitudinal member, having a proximal end and a distal end, which proximal end is coupled to the stent; and

a tissue anchor, which is coupled to the distal end of the longitudinal member.

61. The apparatus according to claim 60, wherein the stent comprises exactly two rings.

62. The apparatus according to claim 60, wherein the stent comprises exactly one elongated member.

63. The apparatus according to claim 62, wherein the elongated member comprises two or more wires coupled to one another.
64. The apparatus according to any one of claims 60-63, wherein one of the elongated members is at least partially a continuation of the longitudinal member.
- 5 65. The apparatus according to any one of claims 60-63, wherein each of the rings has an outer diameter of between 10 and 35 mm, when the stent is in its expanded state.
66. A method comprising:
providing a (a) stent, which includes (i) one or more elongated members; and (ii) two or more rings, which are coupled together by the one or more elongated members and
10 by no other elements of the stent, (b) a longitudinal member, having a proximal end and a distal end, which proximal end is coupled to the stent, and (c) a tissue anchor, which is coupled to the distal end of the longitudinal member;
positioning the stent in a blood vessel of a patient while the stent is in a compressed state;
15 coupling the tissue anchor to tissue in a vicinity of a heart valve of the patient; and
transitioning the stent to an expanded state, such that the rings define respective planes that are generally perpendicular to the elongated members, and anchor the stent to a wall of the blood vessel.
67. The method according to claim 66, wherein providing the stent comprises
20 providing the stent which includes exactly two rings.
68. The method according to claim 66, wherein providing the stent comprises providing the stent which includes exactly one elongated member.
69. The method according to claim 66, wherein providing the stent comprises providing the stent in which one of the elongated members is at least partially a
25 continuation of the longitudinal member.
70. The method according to claim 66, wherein positioning the stent in the blood vessel comprises positioning the stent in a blood vessel selected from the group of blood vessels consisting of: a superior vena cava, and an inferior vena cava.
71. The method according to claim 66, further comprising monitoring a level of
30 regurgitation of the heart valve in conjunction with the positioning of the stent in the blood vessel.

72. Apparatus comprising a tensioning device, which comprises:
a radially-expandable anchor, which defines an opening;
a longitudinal member, having proximal and distal ends, which longitudinal member passes through the opening of the radially-expanded anchor, such that the
5 radially-expanded anchor is slidably coupled to the longitudinal member; and
a tissue anchor, which is coupled to the distal end of the longitudinal member,
wherein the radially-expandable anchor and the longitudinal member are configured such that the radially-expandable member is lockable to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the
10 longitudinal member at least in a proximal direction toward the proximal end of the longitudinal member.
73. The apparatus according to claim 72, wherein at least a portion of the longitudinal member is shaped so as to define ratchet teeth, which engage the radially-expandable anchor, thereby preventing the movement of the radially-expandable anchor with respect
15 to the longitudinal member in the proximal direction.
74. The apparatus according to claim 72, wherein the radially-expandable anchor is configured to be crimped to the longitudinal member, so as to prevent the movement of the radially-expandable anchor with respect to the longitudinal member.
75. The apparatus according to claim 72, wherein the radially-expandable anchor is
20 configured to generally fall within exactly one plane when radially expanded.
76. The apparatus according to claim 72, wherein the radially-expandable anchor, when radially expanded, is shaped so as to define at least one shape selected from the group consisting of: a petal and a wing.
77. The apparatus according to any one of claims 72-76, further comprising a
25 deployment tube, in which the tensioning device is initially positioned, with the radially-expandable anchor in a radially-compressed state.
78. A method comprising:
providing a tensioning device initially positioned in a deployment tube, which tension device includes (a) a longitudinal member, (b) a radially-expanded anchor, which
30 is slidably coupled to the longitudinal member, and (c) a tissue anchor, which is coupled to a distal end of the longitudinal member;

advancing the deployment tube into a left atrium of a patient;

making a hole in an interatrial septum;

advancing the deployment tube from the left atrium through the hole, until a distal end of the deployment tube is positioned within a right atrium;

5 deploying the tissue anchor from the distal end of the deployment tube, and anchoring the tissue anchor to a portion of cardiac tissue in a vicinity of a tricuspid valve;

 withdrawing the deployment tube into the left atrium, thereby releasing the radially-expandable anchor in the left atrium near the septum; and

 pulling the longitudinal member in a proximal direction, while holding the
10 radially-expandable anchor against a left-atrial side of the septum, and locking the radially-expandable anchor to the longitudinal member, so as to prevent movement of the radially-expandable anchor with respect to the longitudinal member at least in the proximal direction.

79. The method according to claim 78, wherein at least a portion of the longitudinal
15 member is shaped so as to define ratchet teeth, which engage the radially-expandable anchor, and wherein locking the radially-expandable anchor to the longitudinal member comprises using the ratchet teeth to prevent the movement of the radially-expandable anchor with respect to the longitudinal member in the proximal direction.

80. The method according to claim 78, wherein locking the radially-expandable
20 anchor to the longitudinal member comprises crimping the radially-expandable anchor to the longitudinal member, so as to prevent the movement of the radially-expandable anchor with respect to the longitudinal member.

81. The method according to claim 78, wherein the radially-expandable anchor is configured to generally fall within exactly one plane when radially expanded.

25 82. The method according to claim 78, wherein the radially-expandable anchor, when radially expanded, is shaped so as to define at least one shape selected from the group consisting of: a petal and a wing.

83. The method according to claim 78, further comprising monitoring a level of
30 regurgitation of the tricuspid valve in conjunction with the pulling the longitudinal member.

84. Apparatus comprising a tissue anchor, which is configured to assume radially-

contracted and radially-expanded states, and which comprises:

a post, having a distal tissue-piercing tip, and a greatest diameter of no more than 1.8 mm;

a plurality of ribs, which are coupled to the anchor near the distal tip, such that the
5 ribs can articulate with the post;

a runner, which is slidably coupled to the post, such that the runner can slide along the post; and

a plurality of stretchers, which are coupled to the runner and respective ones of the ribs, such that the stretchers can articulate with the runner and the respective ribs.

10 85. The apparatus according to claim 84, further comprising a catheter, in which the tissue anchor is initially positioned in the radially-contracted state.

86. The apparatus according to claim 85, further comprising an inner tube positioned within the catheter, wherein a proximal end of the runner is initially removably coupled to the inner tube.

15 87. The apparatus according to any one of claims 84-86, wherein an outer surface of a proximal end of the runner is threaded.

88. The apparatus according to any one of claims 84-86, wherein the anchor at least partially comprises a shape-memory alloy.
