INTRODUCTION

[0004] Coupling biomolecules to target molecules, to generate conjugates, while preserving the function of the biomolecule and the target molecule, has long been a goal of chemical biology and biopharmaceutical research. Examples of conjugates include protein-peptide conjugates for vaccine development, antibody-drug, and antibody-protein conjugates for immunotherapeutics.

[0005] While many techniques have been developed to allow for attachment of moderately sized molecules to proteins, it has been challenging to develop a simple biomolecule modification procedure that can attach proteins or biomolecules in a site-specific manner to any position on a protein's surface.

[0006] There is a need for improved target molecule modification procedures that can modify a target molecule in a simple yet site specific manner.

SUMMARY

[0007] The present disclosure provides a method for chemoselective modification of a target molecule. A subject method includes contacting a target molecule comprising a thiol moiety with a biomolecule comprising a reactive moiety, wherein the reactive moiety is generated by reaction of a biomolecule comprising a phenol moiety or a catechol with an enzyme capable of oxidizing the phenol or the catechol moiety. The contacting is carried out under conditions sufficient for

conjugation of the target molecule to the biomolecule, thereby producing a modified target molecule. The present disclosure provides compositions comprising a subject target molecule comprising a thiol moiety, and a biomolecule comprising a phenol moiety or a catechol moiety. The present disclosure provides kits for carrying out a subject method. The present disclosure also provides modified target molecules and methods for using same.

BRIEF DESCRIPTION OF THE DRAWINGS

[0008] The invention is best understood from the following detailed description when read in conjunction with the accompanying figures. It is emphasized that, according to common practice, the various features of the figures are not to-scale. On the contrary, the dimensions of the various features are arbitrarily expanded or reduced for clarity. Included in the drawings are the following figures. It is understood that the figures, described below, are for illustration purposes only. The figures are not intended to limit the scope of the present teachings in any way.

[0009] **FIG. 1A** illustrates activation of phenol and catechol moieties with a tyrosinase enzyme to provide a quinone intermediate, and subsequent reaction of the quinone intermediate with potential nucleophiles.

[0010] **FIG. 1B** illustrates an exemplary subject chemoselective modification reaction of a target protein with solvent exposed thiol (A) with a tyrosine/phenol containing coupling partner (B) to provide a covalently bound conjugation product (C).

[0011] **FIG. 2, panel A** depicts ESI-TOF data showing MS2 N87C modified with alpha-endorphin peptide, as well as maleimide blocking experiments, illustrating that capping the thiols via a maleimide on the protein blocks addition via tyrosinase catalyzed reaction, and that where tyrosinase is performed first this also blocks the reaction of maleimide. This Figure demonstrates that the surface cysteines are the residues being modified. **FIG. 2, panel B** depicts stability studies for protein-peptide conjugates under various conditions. All samples were stored in 50 mM phosphate buffer at the stated conditions.

[0012] **FIG. 3** illustrates exemplary examples of biomolecules comprising a phenol moiety compatible in the subject methods.

[0013] **FIG. 4** illustrates ESI-TOF data showing coupling of various peptides to cysteine-containing mutants of the MS2 viral capsid. The peptides consisted of the following sequences with acylated N-termini: 2NLS: Ac-YGPKKKRKVGGSPKKKRKV (SEQ ID NO: 943); IL13: Ac-GYACGEMGWVRCGGSK (SEQ ID NO: 944); R8: Ac-YGRRRRRRRR (SEQ ID NO: 945); and HIV-Tat: Ac-YGRKKRRQRRRPPQ (SEQ ID NO: 946).

[0014] **FIG. 5, panel A** illustrates ESI-TOF data showing Cas9 (C80, C574) is modified twice by endorphin. **FIG. 5, panel B** depicts an in vitro DNA cleavage assay, demonstrating that Cas9 (RNP) modified with peptide (End) retains cleavage activity even if modified prior to addition to guide RNA (apo). For each treatment RNP was added across a concentration gradient to determine activity on target DNA strands. **FIG. 5, panel C** illustrates ESI-TOF data showing successful Cas9-GFP conjugation. The sequences are set forth as follows: GYGGS (SEQ ID NO: 1021), MYGGS (SEQ ID NO: 1022). **FIG. 5, panel D** depicts an in vitro cleavage assay, showing that Cas9 modified with GFP retains activity compared to controls. The sequences are set forth as follows: MYGGS (SEQ ID NO: 1022), SGGGGY (SEQ ID NO: 1040).

[0015] **FIG. 6** illustrates that Cas9 modified by peptides containing two copies of the SV40 nuclear localization sequence were able to enter and edit neural progenitor cells, allowing for a 20-fold increase in editing efficiency.

[0016] **FIG. 7** illustrates ESI-TOF data showing modification of a phenol containing protein with small molecule thiols.

[0017] **FIGS. 8 and 9** provide mushroom tyrosinase amino acid sequences. The sequence of FIG. 8 is set forth in SEQ ID NO: 971. The sequence of FIG. 9 is set forth in SEQ ID NO: 972.

[0018] **FIGS. 10A-10Z** and **10AA-10VV** provide *Bacillus megaterium* tyrosinase amino acid sequences. The sequences of FIGs. 10A-10Z are set forth in SEQ ID NOs: 973-998. The sequences of FIGs. 10AA-10VV are set forth in SEQ ID NOs: 999-1020.

The upper and lower limits of these smaller ranges may independently be included in the smaller ranges, and are also encompassed within the invention, subject to any specifically excluded limit in the stated range. Where the stated range includes one or both of the limits, ranges excluding either or both of those included limits are also included in the invention.

[0055] Unless defined otherwise, all technical and scientific terms used herein have the same meaning as commonly understood by one of ordinary skill in the art to which this invention belongs. Although any methods and materials similar or equivalent to those described herein can also be used in the practice or testing of the present invention, the preferred methods and materials are now described. All publications mentioned herein are incorporated herein by reference to disclose and describe the methods and/or materials in connection with which the publications are cited.

[0056] It must be noted that as used herein and in the appended claims, the singular forms "a," "an," and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "a thiol group" includes a plurality of such thiol groups and reference to "the thiol group" includes reference to one or more thiol groups and equivalents thereof known to those skilled in the art, and so forth. It is further noted that the claims may be drafted to exclude any optional element. [0059] As used herein, the term "affinity tag" refers to a member of a specific binding pair, i.e. two molecules where one of the molecules through chemical or physical means specifically binds to the other molecule. The complementary member of the affinity tag may be immobilized (e.g., to a chromatography support, a bead or a planar surface) to produce an affinity chromatography support that specifically binds the affinity tag. Tagging a compound of interest with an affinity tag allows the compound to be separated from a mixture of untagged compounds by affinity, e.g., using affinity chromatography. Examples of specific binding pairs include biotin and streptavidin (or avidin), and antigen and antibody, although binding pairs, e.g., nucleic acid hybrids, polyhistidine and nickel, and azido and alkynyl (e.g., cyclooctynyl) or phosphino groups are also envisioned. The specific binding pairs may include analogs, derivatives and fragments of the original specific binding members.

[0060] As used herein, the term “biotin moiety” refers to an affinity tag that includes biotin or a biotin analogue such as desthiobiotin, oxybiotin, 2’-iminobiotin, diaminobiotin, biotin sulfoxide, biocytin, etc. Biotin moieties bind to streptavidin with an affinity of at least 10^{-8}M. A biotin moiety may also include a linker, e.g., —LC-biotin, —LC-LC-Biotin, —SLC-Biotin or —PEG_{n^1}-Biotin where n^1 is 3-12.

[0061] By "linking" or "linker" as in "linking group," "linker moiety," etc., is meant a linking moiety that connects two groups via covalent bonds. The linker may be linear, branched, cyclic or a single atom. Examples of such linking groups include alkyl, alkenylene, alkynylene, arylene, alkarylene, aralkylene, and linking moieties containing functional groups including, without limitation: amido (-NH-CO-), ureylene (-NH-CO-NH-), imide (-CO-NH-CO-) , epoxy (-O-), epithio (-S-), epidioxy (-O-O-), epidithio (-S-S-), carbonyldioxy (-O-CO-O-), alkyldioxy (-O-(CH2)n-O-), epoxyimino (-O-NH-), epimino (-NH-), carbonyl (-CO-), etc. In certain cases, one, two, three, four or five or more carbon atoms of a linker backbone may be optionally substituted with a sulfur, nitrogen or oxygen heteroatom. The bonds between backbone atoms may be

saturated or unsaturated, usually not more than one, two, or three unsaturated bonds will be present in a linker backbone. The linker may include one or more substituent groups, for example with an alkyl, aryl or alkenyl group. A linker may include, without limitations, poly(ethylene glycol) unit(s) (e.g., -(CH_2-CH_2-O)-); ethers, thioethers, amines, alkyls (e.g., (C_1-C_{12})alkyl) , which may be straight or branched, e.g., methyl, ethyl, n-propyl, 1-methylethyl (iso-propyl), n-butyl, n-pentyl, 1,1-dimethylethyl (t-butyl), and the like. The linker backbone may include a cyclic group, for example, an aryl, a heterocycle or a cycloalkyl group, where 2 or more atoms, e.g., 2, 3 or 4 atoms, of the cyclic group are included in the backbone. A linker may be cleavable or non-cleavable. Any convenient orientation and/or connections of the linkers to the linked groups may be used.

[0072] It is understood that in all substituted groups defined above, polymers arrived at by defining substituents with further substituents to themselves (e.g., substituted aryl having a substituted aryl group as a substituent which is itself substituted with a substituted aryl group, which is further substituted by a substituted aryl group, etc.) are not intended for inclusion herein. In such cases, the maximum number of such substitutions is three. For example, serial substitutions of

substituted aryl groups specifically contemplated herein are limited to substituted aryl-(substituted aryl)-substituted aryl.

[0073] As to any of the groups disclosed herein which contain one or more substituents, it is understood, of course, that such groups do not contain any substitution or substitution patterns which are sterically impractical and/or synthetically non-feasible. In addition, the subject compounds include all stereochemical isomers arising from the substitution of these compounds.

[0074] In certain embodiments, a substituent may contribute to optical isomerism and/or stereo isomerism of a compound. Salts, solvates, hydrates, and prodrug forms of a compound are also of interest. All such forms are embraced by the present disclosure. Thus the compounds described herein include salts, solvates, hydrates, prodrug and isomer forms thereof, including the pharmaceutically acceptable salts, solvates, hydrates, prodrugs and isomers thereof. In certain embodiments, a compound may be a metabolized into a pharmaceutically active derivative.

[0076] As used herein, the term "cleavable linker" or "cleavably linked" refers to a linker or a linkage that is selectively breakable using a stimulus (e.g., a physical, chemical or enzymatic stimulus) that leaves the moieties to which the linkages joins intact. Several cleavable linkages have been described in the literature (e.g., Brown (1997) Contemporary Organic Synthesis 4(3); 216-237). And Guillier et al (Chem. Rev. 2000 1000:2091-2157). A disulfide bond (which can be broken by DDT) and a photo-cleavable linker are examples of cleavable linkages.

[0077] The term "fluorophore" refers to any molecular entity that is capable of absorbing energy of a first wavelength and re-emit energy at a different second wavelength. In certain embodiments, the subject biomolecule includes a fluorophore attached to one end of the biomolecule or at a central position. In some embodiments, the fluorophore may be attached to one end of the biomolecule. The fluorophore attached to the biomolecule need not be a single molecule, but may include multiple molecules.

[0078] The fluorophore may be synthetic or biological in nature, as known to those of skill in the art. More generally, any fluorophore can be used that is stable under coupling conditions and that can be sufficiently suppressed when in close proximity to the quencher such that a significant change in the intensity of fluorescence of the fluorophore is detectable in response to target specifically binding the probe. Examples of suitable fluorophores include, but are not limited to Oregon Green 488 dye, rhodamine and rhodamine derivatives, fluorescein isothiocyanate,

fluorescein, 6-carboxyfluorescein (6-FAM), coumarin and coumarin derivatives, cyanine and cyanine derivatives, Alexa Fluors, DyLight Fluors, and the like.

[0079] In certain embodiments, the biomolecule includes a metal-chelating agent. A "chelate" as used herein in reference to a complex between a metal and a chelating ligand, refers to a combination of a metallic ion bonded to one or more ligands to form a heterocyclic ring structure. Chelate formation through neutralization of the positive charge(s) of the metal ion may be through the formation of ionic, covalent or coordinate covalent bonding. In certain embodiments, the metal-chelating agent is includes, but are not limited to, 1,4,7,10-Tetraazacyclododecane-1,4,7,10-tetraacetic acid (also referred to as, DOTA, or tetraxetan).

[0080] The terms "polynucleotide" and "nucleic acid," used interchangeably herein, refer to a polymeric form of nucleotides of any length, either ribonucleotides or deoxyribonucleotides. Thus, this term includes, but is not limited to, single-, double-, or multi-stranded DNA or RNA, genomic DNA, cDNA, DNA-RNA hybrids, or a polymer comprising purine and pyrimidine bases or other natural, chemically or biochemically modified, non-natural, or derivatized nucleotide bases.

[0081] The terms "polypeptide" and "protein", used interchangeably herein, refer to a polymeric form of amino acids of any length, which can include coded and non-coded amino acids, chemically or biochemically modified or derivatized amino acids, and polypeptides having modified peptide backbones. The term "fusion protein" or grammatical equivalents thereof is meant to include a protein composed of a plurality of polypeptide components, that while typically unjoined in their native state, typically are joined by their respective amino and carboxyl termini through a peptide linkage to form a single continuous polypeptide. Fusion proteins may be a combination of two, three or even four or more different proteins.

[0082] In general, polypeptides may be of any length, e.g., 2 or greater amino acids, greater than 4 amino acids, greater than about 10 amino acids, greater than about 20 amino acids, greater than about 50 amino acids, greater than about 100 amino acids, greater than about 300 amino acids, usually up to about 500 or 1000 or more amino acids. "Peptides" are generally 2 or greater amino acids in length, such as greater than 4 amino acids, greater than about 10 amino acids, greater than about 20 amino acids, usually up to about 50 amino acids. In some embodiments, peptides are between 2 and 30 amino acids in length.

[0083] As used herein, the term "a target protein" refers to all members of the target family, and fragments and enantiomers thereof, and protein mimics thereof. The target proteins of interest that are described herein are intended to include all members of the target family, and fragments and enantiomers thereof, and protein mimics thereof, unless explicitly described otherwise. The target protein may be any protein of interest, such as a therapeutic or diagnostic target, including

but not limited to: hormones, growth factors, receptors, enzymes, cytokines, osteoinductive factors, colony stimulating factors and immunoglobulins. The term "target protein" is intended to include recombinant and synthetic molecules, which can be prepared using any convenient recombinant expression methods or using any convenient synthetic methods, or purchased commercially, as well as fusion proteins containing a target molecule.

[0084] The term "physiological conditions" is meant to encompass those conditions compatible with living cells, *e.g.*, predominantly aqueous conditions of a temperature, pH, salinity, *etc.* that are compatible with living cells.

[0085] "Solid support", "support", and "solid phase support" are used interchangeably and refer to a material or group of materials having a rigid or semi-rigid surface or surfaces. In many embodiments, at least one surface of the solid support will be substantially flat, although in some embodiments it may be desirable to physically separate synthesis regions for different compounds with, for example, wells, raised regions, pins, etched trenches, or the like. According to other embodiments, the solid support(s) will take the form of beads, resins, gels, microspheres, or other geometric configurations.

[0086] The terms "antibodies" and "immunoglobulin" include antibodies or immunoglobulins of any isotype, fragments of antibodies that retain specific binding to antigen, including, but not limited to, Fab, Fv, scFv, and Fd fragments, chimeric antibodies, humanized antibodies, single-chain antibodies (scAb), single domain antibodies (dAb), single domain heavy chain antibodies, a single domain light chain antibodies, nanobodies, bi-specific antibodies, multi-specific antibodies, and fusion proteins comprising an antigen-binding (also referred to herein as antigen binding) portion of an antibody and a non-antibody protein. The antibodies can be detectably labeled, *e.g.*, with a radioisotope, an enzyme that generates a detectable product, a fluorescent protein, and the like. The antibodies can be further conjugated to other moieties, such as members of specific binding pairs, *e.g.*, biotin (member of biotin-avidin specific binding pair), and the like. The antibodies can also be bound to a solid support, including, but not limited to, polystyrene plates or beads, and the like. Also encompassed by the term are Fab', Fv, $F(ab')_2$, and or other antibody fragments that retain specific binding to antigen, and monoclonal antibodies. As used herein, a monoclonal antibody is an antibody produced by a group of identical cells, all of which were produced from a single cell by repetitive cellular replication. That is, the clone of cells only produces a single antibody species. While a monoclonal antibody can be produced using hybridoma production technology, other production methods known to those skilled in the art can also be used (e.g., antibodies derived from antibody phage display libraries). An antibody can be monovalent or bivalent. An antibody can be an Ig monomer,

which is a "Y-shaped" molecule that consists of four polypeptide chains: two heavy chains and two light chains connected by disulfide bonds.

[0087] The term "humanized immunoglobulin" as used herein refers to an immunoglobulin comprising portions of immunoglobulins of different origin, wherein at least one portion comprises amino acid sequences of human origin. For example, the humanized antibody can comprise portions derived from an immunoglobulin of nonhuman origin with the requisite specificity, such as a mouse, and from immunoglobulin sequences of human origin (e.g., chimeric immunoglobulin), joined together chemically by conventional techniques (e.g., synthetic) or prepared as a contiguous polypeptide using genetic engineering techniques (e.g., DNA encoding the protein portions of the chimeric antibody can be expressed to produce a contiguous polypeptide chain). Another example of a humanized immunoglobulin is an immunoglobulin containing one or more immunoglobulin chains comprising a complementarity-determining region (CDR) derived from an antibody of nonhuman origin and a framework region derived from a light and/or heavy chain of human origin (e.g., CDR-grafted antibodies with or without framework changes). Chimeric or CDR-grafted single chain antibodies are also encompassed by the term humanized immunoglobulin. See, e.g., Cabilly et al., U.S. Pat. No. 4,816,567; Cabilly et al., European Patent No. 0,125,023 B1; Boss et al., U.S. Pat. No. 4,816,397; Boss et al., European Patent No. 0,120,694 B1; Neuberger, M. S. et al., WO 86/01533; Neuberger, M. S. et al., European Patent No. 0,194,276 B1; Winter, U.S. Pat. No. 5,225,539; Winter, European Patent No. 0,239,400 B1; Padlan, E. A. et al., European Patent Application No. 0,519,596 A1. See also, Ladner et al., U.S. Pat. No. 4,946,778; Huston, U.S. Pat. No. 5,476,786; and Bird, R. E. et al., Science, 242: 423-426 (1988)), regarding single chain antibodies.

[0088] The term "nanobody" (Nb), as used herein, refers to the smallest antigen binding fragment or single variable domain (V_{HH}) derived from naturally occurring heavy chain antibody and is known to the person skilled in the art. They are derived from heavy chain only antibodies, seen in camelids (Hamers-Casterman et al., (1993) *Nature* 363:446; Desmyter et al., (1996) *Nature Struct. Biol.* 3:803). In the family of "camelids" immunoglobulins devoid of light polypeptide chains are found. "Camelids" comprise old world camelids (*Camelus bactrianus* and *Camelus dromedarius*) and new world camelids (for example, *Llama paccos*, *Llama glama*, *Llama guanicoe* and *Llama vicugna*). A single variable domain heavy chain antibody is referred to herein as a nanobody or a V_{HH} antibody.

[0089] "Antibody fragments" comprise a portion of an intact antibody, for example, the antigen binding or variable region of the intact antibody. Examples of antibody fragments include Fab, Fab', $F(ab')_2$, and Fv fragments; diabodies; linear antibodies (Zapata et al., Protein Eng. 8(10): 1057-1062 (1995)); domain antibodies (dAb; Holt et al. (2003) *Trends Biotechnol.* 21:484); single-

chain antibody molecules; and multi-specific antibodies formed from antibody fragments. Papain digestion of antibodies produces two identical antigen-binding fragments, called "Fab" fragments, each with a single antigen-binding site, and a residual "Fc" fragment, a designation reflecting the ability to crystallize readily. Pepsin treatment yields an $F(ab')_2$ fragment that has two antigen combining sites and is still capable of cross-linking antigen.

[0090] "Fv" is the minimum antibody fragment that contains a complete antigen-recognition and -binding site. This region consists of a dimer of one heavy- and one light-chain variable domain in tight, non-covalent association. It is in this configuration that the three CDRS of each variable domain interact to define an antigen-binding site on the surface of the V_H-V_L dimer. Collectively, the six CDRs confer antigen-binding specificity to the antibody. However, even a single variable domain (or half of an Fv comprising only three CDRs specific for an antigen) has the ability to recognize and bind antigen, although at a lower affinity than the entire binding site.

[0091] The “Fab” fragment also contains the constant domain of the light chain and the first constant domain (CH_1) of the heavy chain. Fab fragments differ from Fab' fragments by the addition of a few residues at the carboxyl terminus of the heavy chain CH_1 domain including one or more cysteines from the antibody hinge region. Fab'-SH is the designation herein for Fab' in which the cysteine residue(s) of the constant domains bear a free thiol group. $F(ab')_2$ antibody fragments originally were produced as pairs of Fab' fragments which have hinge cysteines between them. Other chemical couplings of antibody fragments are also known.

[0092] The "light chains" of antibodies (immunoglobulins) from any vertebrate species can be assigned to one of two clearly distinct types, called kappa and lambda, based on the amino acid sequences of their constant domains. Depending on the amino acid sequence of the constant domain of their heavy chains, immunoglobulins can be assigned to different classes. There are five major classes of immunoglobulins: IgA, IgD, IgE, IgG, and IgM, and several of these classes can be further divided into subclasses (isotypes), e.g., IgG1, IgG2, IgG3, IgG4, IgA, and IgA2. The subclasses can be further divided into types, e.g., IgG2a and IgG2b.

[0093] "Single-chain Fv" or "sFv" or “scFv” antibody fragments comprise the V_H and V_L domains of antibody, wherein these domains are present in a single polypeptide chain. In some embodiments, the Fv polypeptide further comprises a polypeptide linker between the V_H and V_L domains, which enables the sFv to form the desired structure for antigen binding. For a review of sFv, see *Pluckthun in The Pharmacology of Monoclonal Antibodies, vol. 113, Rosenburg and Moore eds., Springer-Verlag, New York, pp. 269-315 (1994)*.

[0094] The term "diabodies" refers to small antibody fragments with two antigen-binding sites, which fragments comprise a heavy-chain variable domain (V_H) connected to a light-chain variable

domain (V_L) in the same polypeptide chain (V_H-V_L). By using a linker that is too short to allow pairing between the two domains on the same chain, the domains are forced to pair with the complementary domains of another chain and create two antigen-binding sites. Diabodies are described more fully in, for example, EP 404,097; WO 93/11161; and Hollinger et al. (1993) *Proc. Natl. Acad. Sci. USA* 90:6444-6448.

[0095] As used herein, the term "affinity" refers to the equilibrium constant for the reversible binding of two agents (e.g., an antibody and an antigen) and is expressed as a dissociation constant (K_D). Affinity can be at least 1-fold greater, at least 2-fold greater, at least 3-fold greater, at least 4-fold greater, at least 5-fold greater, at least 6-fold greater, at least 7-fold greater, at least 8-fold greater, at least 9-fold greater, at least 10-fold greater, at least 20-fold greater, at least 30-fold greater, at least 40-fold greater, at least 50-fold greater, at least 60-fold greater, at least 70-fold greater, at least 80-fold greater, at least 90-fold greater, at least 100-fold greater, or at least 1,000-fold greater, or more, than the affinity of an antibody for unrelated amino acid sequences. Affinity of an antibody to a target protein can be, for example, from about 100 nanomolar (nM) to about 0.1 nM, from about 100 nM to about 1 picomolar (pM), or from about 100 nM to about 1 femtomolar (fM) or more. As used herein, the term “avidity” refers to the resistance of a complex of two or more agents to dissociation after dilution. The terms “immunoreactive” and “preferentially binds” are used interchangeably herein with respect to antibodies and/or antigen-binding fragments.

[0096] The term “binding” refers to a direct association between two molecules, due to, for example, covalent, electrostatic, hydrophobic, and ionic and/or hydrogen-bond interactions, including interactions such as salt bridges and water bridges. “Specific binding” refers to binding with an affinity of at least about 10^{-7} M or greater, e.g., 5x 10^{-7} M, 10^{-8} M, 5 x 10^{-8} M, and greater. “Non-specific binding” refers to binding with an affinity of less than about 10^{-7} M, e.g., binding with an affinity of 10^{-6} M, 10^{-5} M, 10^{-4} M, etc.

[0097] An "isolated" polypeptide is one that has been identified and separated and/or recovered from a component of its natural environment. Contaminant components of its natural environment are materials that would interfere with diagnostic or therapeutic uses for the polypeptide, and may include enzymes, hormones, and other proteinaceous or nonproteinaceous solutes. In some embodiments, the polypeptide will be purified (1) to greater than 90%, greater than 95%, or greater than 98%, by weight of protein as determined by the Lowry method, for example, more than 99% by weight, (2) to a degree sufficient to obtain at least 15 residues of N-terminal or internal amino acid sequence by use of a spinning cup sequenator, or (3) to homogeneity by sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) under reducing or nonreducing conditions using Coomassie blue or silver stain. Isolated polypeptide includes the

polypeptide in situ within recombinant cells since at least one component of the polypeptide's natural environment will not be present. In some instances, isolated polypeptide will be prepared by at least one purification step.

[0098] As will be apparent to those of skill in the art upon reading this disclosure, each of the individual embodiments described and illustrated herein has discrete components and features which may be readily separated from or combined with the features of any of the other several embodiments without departing from the scope or spirit of the present invention. Any recited method can be carried out in the order of events recited or in any other order which is logically possible.

The upper and lower limits of these smaller ranges may independently be included in the smaller ranges, and are also encompassed within the invention, subject to any specifically excluded limit in the stated range. [00101] It must be noted that as used herein and in the appended claims, the singular forms "a," "an," and "the" include plural referents unless the context clearly dictates otherwise. Thus, for example, reference to "a target molecule" includes a plurality of such target molecules and reference to "the biomolecule" includes reference to one or more biomolecules and equivalents thereof known to those skilled in the art, and so forth. It is further noted that the claims may be drafted to exclude any optional element. As such, this statement is intended to serve as antecedent basis for use of such exclusive terminology as "solely," "only" and the like in connection with the recitation of claim elements, or use of a "negative" limitation.

DETAILED DESCRIPTION

[00104] The present disclosure provides a method for chemoselective modification of a target molecule. The present disclosure provides compositions comprising a subject target molecule comprising a thiol moiety, and a biomolecule comprising a phenol moiety or a catechol moiety. The present disclosure provides kits providing a first container including a subject composition, and a second container including an enzyme capable of oxidizing the phenol moiety or the catechol moiety. The present disclosure also provides modified target molecules, that may find use in the delivery of biomolecules for gene therapy, novel immunotherapies through antibody conjugates, biomaterial construction and vaccine development.

METHODS

[00105] As summarized above, aspects of the present disclosure include a method for chemoselective modification of a target molecule. The subject method includes contacting a target molecule comprising a thiol moiety with a biomolecule comprising a reactive moiety, wherein the reactive moiety is generated by reaction of a biomolecule comprising a phenol moiety or a catechol moiety with an enzyme capable of oxidizing the phenol moiety or the catechol moiety. The contacting is carried out under conditions sufficient for conjugation of the target molecule to the biomolecule, thereby producing a modified target molecule.

[00106] In some cases, a subject method for chemoselective modification of a target molecule comprises contacting: i) a target molecule comprising a thiol moiety; ii) a biomolecule comprising a phenol moiety or a catechol moiety; and iii) an enzyme capable of oxidizing the phenol or catechol moiety; wherein the enzyme oxidizes the phenol or catechol moiety of the

biomolecule to generate a reactive moiety, thereby generating a biomolecule comprising the reactive moiety, and wherein the reactive moiety reacts with the thiol moiety, thereby conjugating the target molecule and the biomolecule to one another, thereby producing a modified target molecule. In some cases, the target molecule comprises a single thiol moiety. In some cases, the target molecule comprises two thiol moieties.

[00107] The target molecule can be any of a variety of molecules (e.g., polypeptides; nucleic acids; small molecules; etc.). Similarly, the biomolecule can be any of a variety of molecules (e.g., polypeptides; nucleic acids; small molecules; etc.). In some cases, the target molecule is a polypeptide; and the biomolecule is a nucleic acid. In some cases, the target molecule is a nucleic acid; and the biomolecule is a polypeptide. In some cases, the target molecule is a polypeptide; and the biomolecule is a small molecule (e.g., a cancer chemotherapeutic agent). In some cases, the target molecule is a first polypeptide; and the biomolecule is a second polypeptide, where the first polypeptide and the second polypeptide can be the same or different.

[00108] The subject methods provide a simple coupling procedure that can attach biomolecules of interest in a site-specific manner to any position on the surface of a target molecule, thereby producing a modified target molecule of interest. In some embodiments, the target molecule is a second biomolecule (e.g., as described herein). In some embodiments, the second biomolecule is a polypeptide.

[00109] Biomolecules of interest include, but are not limited to, polypeptides, polynucleotides, carbohydrates, lipids, fatty acids, steroids, purines, pyrimidines, derivatives, structural analogs thereof and combinations thereof. In certain instances, the biomolecule of interest is an antibody. In some instances, the biomolecule of interest is an antibody fragment or binding derivative thereof. In some cases, the antibody fragment or binding derivative thereof is selected from the group consisting of a Fab fragment, a F(ab')2 fragment, a single-chain Fv (scFv), a diabody, a nanobody, and a triabody. Suitable biomolecules include, e.g., small molecules (e.g., cancer chemotherapeutic agents, etc.), cytokines, hormones, immunomodulatory polypeptides, and the like. In some cases, the biomolecule is a nucleic acid; and the target molecule is an antibody (e.g., a scFv; a nanobody; and the like). In some cases, the biomolecule is a small molecule (e.g., a cancer chemotherapeutic agent); and the target molecule is an antibody (e.g., a scFv; a nanobody; and the like). In some cases, e.g., where the target molecule is an antibody, the biomolecule is attached to the Fc portion of the target molecule. In some cases, the target molecule is an immunoglobulin (Ig) Fc polypeptide.

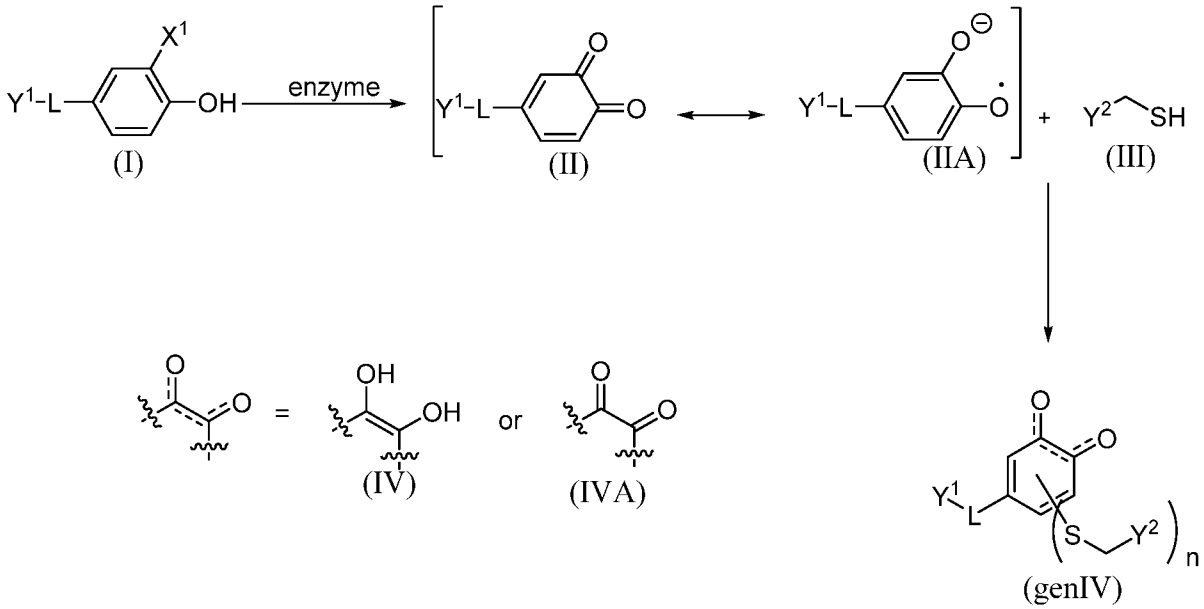
[00110] In certain embodiments, the biomolecule comprising a phenol or catechol moiety further comprises, one or more moieties selected from a fluorophore, an active small molecule, an affinity tag, and a metal-chelating agent (e.g., as described herein). In certain instances, the

biomolecule of interest is a fluorescent protein. In certain cases, the fluorescent protein is a green fluorescent protein (GFP). In certain cases, the biomolecule is an enzyme. In certain cases, the biomolecule is a ligand for a receptor. In certain cases, the biomolecule is a receptor.

[00111] In some embodiments, the enzyme capable of oxidizing the phenol moiety or the catechol moiety is a phenol oxidase or a catechol oxidase. In certain cases, the enzyme is a tyrosinase.

[00112] The term "tyrosinase" is used herein to refer to monophenol monooxygenase (EC 1.14.18.1; CAS number: 9002-10-2), an enzyme that catalyses the oxidation of phenols (such as tyrosine). It is a copper-containing enzyme present in plant and animal tissues that catalyzes the production of melanin and other pigments from tyrosine by oxidation. Aall tyrosinases have in common a binuclear type 3 copper center within their active site. Here two copper atoms are each coordinated with three histidine residues. Matoba et al., "Crystallographic evidence that the dinuclear copper center of tyrosinase is flexible during catalysis," J Biol Chem. 2006 Mar 31;281(13):8981-90. Epub 2006 Jan 25, disclose a three dimensional model of a tyrosinase catalytic center.

[00113] In certain embodiments, the subject enzyme is affixed to a solid support system, such as beads, resins, gels, microspheres, or other geometric configurations. In certain cases, the solid support is a glass bead. In some cases, the solid support is a resin bead. Use of an enzyme affixed to a solid support system can allow for multiple use of the subject enzyme, and can facilitate purification of the subject target molecules by allowing for the enzyme to be easily removed from the reaction mixture. In certain embodiments, the subject enzyme affixed to a solid support system can allow for the subject methods to be carried out in a continuous flow system. In certain embodiments, the subject enzyme affixed to a solid support system can facilitate large batch processing of the subject methods.



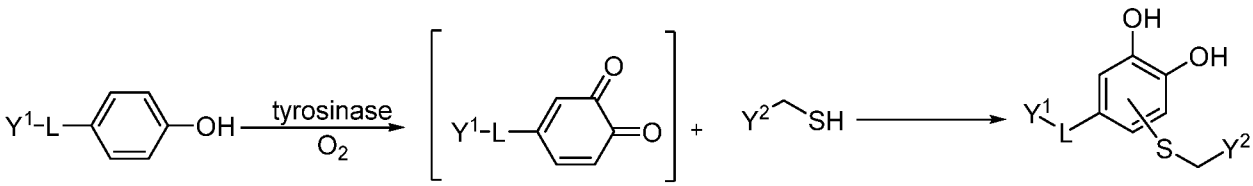
[00114] In certain cases, the subject phenol moiety is present in a tyrosine residue. In certain cases, the tyrosine residue is part of the biomolecule of interest. In certain cases, the tyrosine residue is synthetically introduced into the biomolecule of interest. In some other cases, the tyrosine residue is linked to the biomolecule of interest via a linker (e.g., as described herein). A tyrosine residue can be introduced using standard recombinant techniques, e.g., by modifying a nucleotide sequence encoding a polypeptide biomolecule such that a tyrosine residue is introduced into the polypeptide biomolecule.

[00115] In some cases, a phenol or catechol moiety is part of an unnatural (non-genetically encoded) amino acid that is introduced into a biomolecule of interest. For example, amber codon (TAG) suppression can be used to incorporate a non-genetically encoded amino acid residue that

comprises a phenol moiety or a catechol moiety. See, e.g., Chin et al. (2002) *J. Am. Chem. Soc.* 124:9026; Chin and Schultz (2002) *Chem. Biol. Chem.* 3:1135; Chin et al. (2002) *Proc. Natl. Acad. Sci. USA* 99:11020; U.S. 2015/0240249; and US 2018/0171321. As another example, an orthogonal RNA synthetase and/or an orthogonal tRNA can be used for introducing a non-genetically encoded amino acid into a biomolecule, where the non-genetically encoded amino acid comprises a phenol moiety or a catechol moiety.

[00116] In some embodiments of the subject methods, the thiol moiety present in the target molecule is part of a cysteine residue. In certain cases, the cysteine residue is a native cysteine residue. In certain cases, the cysteine residue is a residue synthetically introduced into the target molecule.

[00117] In certain embodiments, the reactive moiety is an orthoquinone or a semi-quinone radical, or a combination thereof. In certain embodiments, the subject methods provide a reaction between an orthoquinone reactive intermediate and a thiol moiety, as depicted in Scheme 1 below:



Scheme 1

where Y^1 is any convenient biomolecule optionally comprising one or more moieties selected from, an active small molecule, a cleavable probe, a fluorophore, and a metal chelator; L is an optional linker (e.g., as described herein); X^1 is selected from hydrogen and hydroxyl; Y^2 is any convenient biomolecule; and n is an integer from 1 to 3.

[00118] As depicted in Scheme 1, in certain embodiments, a biomolecule comprising a phenol or catechol moiety (e.g., of formula (I)), undergoes activation with an enzyme capable of oxidizing the phenol or catechol moiety. In some cases, activation is achieved with a tyrosinase enzyme in

the presence of oxygen to generate an intermediate comprising a reactive moiety (e.g., orthoquinone of formula (II) and/or semi-quinone radical of formula (IIA)), and the said reactive moiety reacts with a target molecule comprising a thiol based nucleophile (e.g., of formula (III)), to result in conjugation of the target molecule to the biomolecule, thereby producing a modified target molecule (e.g., of formula (genIV)). In certain embodiments, a target molecule of formula (III) may comprise any convenient biomolecule, e.g., as described herein. In certain cases, Y^2 in formula (III) is a polypeptide. In certain cases, the modified molecule is described by the formula (IV). In some cases, the modified target molecule is described by the formula (IVA). In certain cases, the modified target molecule is described by any one of formulae (IV)-(IVL), as described herein.

[00119] In certain embodiments, the subject methods provide a reaction between an orthoquinone reactive intermediate and a thiol moiety, as depicted in Scheme 2 below:

(IB) (II) (III) (IVM)

[00120] As depicted in Scheme 2, in certain embodiments, a biomolecule comprising a phenol moiety (e.g., of formula (IB)) undergoes activation with a tyrosinase enzyme in the presence of oxygen to generate an intermediate comprising a reactive moiety (e.g., orthoquinone of formula (II)), and the said reactive moiety reacts with a target molecule comprising a thiol based nucleophile (e.g., of formula (III)), to result in conjugation of the target molecule to the biomolecule, thereby producing a modified target molecule (e.g., of formula (IVM). In certain embodiments, a target molecule of formula (III) may comprise any convenient biomolecule, e.g., as described herein. In certain cases, Y^2 in formula (III) is a polypeptide. In certain cases of the modified molecule of formula (IVM), the thiol group is at the 3-position of the catechol ring. In certain cases of the modified molecule of formula (IVM), the thiol group is at the 5-position of the catechol ring. In certain cases of the modified molecule of formula (IVM), the thiol group is at the 6-position of the catechol ring.

[00121] In certain embodiments, the biomolecule of formula (I) may be any one of formulae (IA)-(IDb), e.g., as described herein and discussed in more detail below. In certain embodiments, the modified target molecule may be of any one of formulae (IV)-(IVL), e.g., as described herein and discussed in more detail below. In certain embodiments, the modified target molecule is a product of a single conjugation, e.g., as shown in formulae (IV1)-(IV3), (IVA1)-(IVA3), (IVB1)-(IVB3), (IVC1)-(IVC3), (IVD1)-(IVD3), (IVE1)-(IVE3), (IVF1)-

(IVF3), (IVG1)-(IVG3), (IVH1)-(IVH3) and (IVJ1)-(IVJ3). In certain cases, the modified target molecule is a product of double conjugation, e.g., as shown in formulae (IV4)-(IV5), (IVA4)-(IVA5), (IVB4)-(IVB5), (IVC4)-(IVC5), (IVD4)-(IVD5), (IVE4)-(IVE5), (IVF4)-(IVF5), (IVG4)-(IVG5), (IVH4)-(IVH5) and (IVJ4)-(IVJ5).

[00122] In certain embodiments, the subject method is carried out at a pH from 4 to 9, such as 4.2, 4.5, 4.8, 5.0, 5.2, 5.5, 5.8, 6.0, 6.2, 6.5, 6.8, 7.0, 7.2, 7.5, 7.8, 8.0, 8.2, 8.5, 8.8 or 9. In certain embodiments, the subject method is carried out at a pH of from 5 to 8, such as 5.2, 5.5, 5.8, 6.0, 6.2, 6.5, 6.8, 7.0, 7.2, 7.5, 7.8 or 8.0. In certain cases, the subject method is carried out at a pH of 6 to 7.5, such as 6.0, 6.3, 6.4, 6.5, 6.6, 6.8, 7.0, 7.2, 7.4, or 7.5. In certain embodiments, the subject method is carried out at neutral pH. As used herein, the expression "neutral pH" means a pH of about 7.0 to about 7.4. The expression "neutral pH" includes pH values of about 7.0, 7.05, 7.1, 7.15, 7.2, 7.25, 7.3, 7.35, and 7.4.

[00123] In certain embodiments, the subject methods may be carried out under physiological conditions. In some embodiments, the method is carried out on living cells *in vitro*. In other embodiments, the method is carried out on living cells *ex vivo*.

[00124] In certain embodiments, the subject methods may be carried out in aqueous media in the presence of one or more buffers. Buffers of interest include, but are not limited to, a phosphate buffer, 2-amino-2-(hydroxymethyl)propane-1,3-diol (TRIS), 4-[4-(2-hydroxyethyl)piperzin-1-yl]ethanesulfonic acid (HEPES), and the like. In certain embodiments, the subject methods may be carried out in an organic solvent. In certain cases, the organic solvent is a water miscible solvent. In certain cases, the organic solvent is a dipolar aprotic solvent. In certain cases, the organic solvent is selected from acetonitrile, dimethyl formamide, methanol and acetone. In certain cases, the organic solvent is present in an amount from 1 to 20%, relative to water, such as 2%, 5%, 10%, 15% or 20%. In some cases, the subject method is carried out in from 1% to 20% acetonitrile, such as 5%, 10%, 15% or 20%. In some cases, the subject method is carried out in from 1% to 20% dimethyl formamide, such as 5%, 10%, 15%, or 20%. In some cases, the subject method is carried out in from 1% to 20% methanol, such as 5%, 10%, 15%, or 20%. In some cases, the subject method is carried out in from 1% to 20% acetone, such as 5%, 10%, 15%, or 20%.

[00125] In certain embodiments of the subject methods, the modified target molecule is a product of double or triple conjugation (e.g., referring to formula (IV), when n is 2 or 3, referred to collectively herein as "multiple conjugation products"). In certain embodiments of the subject methods, multiple conjugation products are present in less than 1 part in 10 by weight of one or more multiple conjugation products relative to the single conjugation product (e.g., referring to formula (IV), when n is 1), such as less than 1 part in 20, less than 1 part in 25, less than 1 part in

50, less than 1 part in 75, less than 1 part in 100, or even less. In certain embodiments of the subject methods, no multiple conjugation products are observed.

[00126] In certain embodiments of the methods, the modified target molecule is stable at a range of pH and temperature values and in the presence of a number of additional molecules. In some cases, the modified target molecule is stable from 0 °C to 50 °C, such as 4 °C to 40 °C, such as 4 °C to 37 °C. In certain cases, the modified target molecule is stable over a pH range of 4 to 9, such as at pH 4, 4.5, 5, 5.5, 6, 6.5, 7, 7.5, 8, 8.5 or 9. In certain cases, the modified target molecule is stable in the presence of biologically relevant molecules. In certain cases, the modified target molecule is stable in the presence of molecules such as, the guanidinium group of an arginine residue, the primary amine of a lysine residue, and aniline moieties. In some cases, the modified target molecule is stable in physiological conditions; for example, in some cases, the modified target molecule is stable in human serum. In some cases, the modified target molecule (also referred to herein as a "target molecule-biomolecule conjugate") is stable in human serum at 37°C for a period of time of at least 2 days, at least 3 days, at least 4 days, at least 5 days, at least 6 days, at least 7 days, at least 10 days, or at least 14 days. In some cases, the modified target molecule (also referred to herein as a "target molecule-biomolecule conjugate") is stable in human serum at 37°C for a period of time of from about 2 days to about 7 days, from about 7 days to about 10 days, or from about 10 days to about 14 days.

[00127] As noted above, in some cases, the target molecule includes a single thiol moiety. In other instances, the target molecule includes two thiol moieties. In addition to being competent in an initial oxidative coupling reaction, a nucleophile bearing a second thiol in proximity to the newly-formed catechol could add in a second time in the event of re-oxidation. The intramolecular nature of the second addition could prevent or minimize secondary addition by glutathione or other molecules bearing a free thiol in a biological milieu. An example of the use of a di-thiol nucleophile (di-thiol target molecule) is depicted schematically in FIG. 44A.

[00128] Another embodiment of this strategy could be protein coupling partners with two cysteine residues. The cysteine residues could be in close proximity to one another by virtue of their position in the amino acid sequence of the protein or they could be in close spatial proximity by virtue of their position in the three-dimensional structure of the protein. A polypeptide can include a di-thiol, where the polypeptide comprises, e.g.: a CC, a CGC, a CGGC (SEQ ID NO: 1055), or a CGGGC (SEQ ID NO: 1056) sequence. For example, a polypeptide can comprise an amino acid sequence of the general formula: $X_{n1}C(X)_{n2}CX_{n3}$ (SEQ ID NO: 1057), where X is any natural (coded) or unnatural (non-coded) amino acid, n1 and n3 are each independently zero or an integer from 1 to 5000 (or more than 5000), and n2 is zero or an integer

from 1 to about 10. An example of the use of such a di-thiol target molecule is depicted schematically in FIG. 44B.

Tyrosinase polypeptides

[00129] Tyrosinase polypeptides that are suitable for use in generating a reactive moiety (e.g., an orthoquinone) include a tyrosinase polypeptide having at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to any one of the tyrosinase amino acid sequences set forth in FIG. 8, FIG. 9, FIG. 10A-10Z, and FIG. 10AA-10VV. In some cases, the tyrosinase polypeptide is an *Agricus bisporus* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Bacillus megaterium* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Streptomyces castaneoglobisporus* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Citrobacter freundii* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Homo sapiens* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Malus domestica* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is an *Aspergillus oryzae* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Solanum lycopersicum* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Burkholderia thailandensis* tyrosinase polypeptide. In some cases, the tyrosinase polypeptide is a *Juglans regia* tyrosinase polypeptide. See, e.g., Pretzler et al. Sci. Rep. 2017, 7 (1), 1810; Ren et al. BMC Biotechnol. 2013, 13, 18; Faccio et al. Process Biochem. 2012, 47 (12), 1749–1760; Fairhead et al. FEBS J. 2010, 277 (9), 2083–2095; Do et al. Sci. Rep. 2017, 7 (1), 17267; Elsayed and Danial J. Appl. Pharm. Sci. 2018, 8 (09), 93–101; Lopez-Tejedor and Palomo Protein Expr. Purif. 2018, 145, 64–70; and Fairhead et al. Nature Biotechnol. 2012, 29 (2), 183–191.

[00130] In some cases, the tyrosinase polypeptide selectively acts on (e.g., generates a reactive moiety such as an orthoquinone) a substrate (a biomolecule) comprising a phenol moiety (e.g., a tyrosine) or a catechol moiety, where the substrate is neutral or positively charged within 50 Å (e.g., within 50 Å, within 40 Å, within 30 Å, or within 20 Å) of the phenol or the catechol moiety. For example, a tyrosinase having at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to any one of the tyrosinase amino acid sequences set forth in FIG. 8 or FIG. 9 can selectively modify a phenol or catechol moiety on a substrate, where the substrate is neutral or positively charged within 50 Å (e.g., within 50 Å, within 40 Å, within 30 Å, or within 20 Å) of the phenol or the catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises at least 2 neutral or positively charged amino acids within 10 amino acids of the phenol moiety (e.g., a tyrosine) or a catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises 2, 3, 4, 5, 6, 7, 8, 9, or 10 neutral or

positively charged amino acids within 10 amino acids of the phenol moiety (e.g., a tyrosine) or a catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises the amino acid sequence RRRY (SEQ ID NO: 949), YRRR (SEQ ID NO: 950), RRRRY (SEQ ID NO: 951), or YRRRR (SEQ ID NO: 952).

[00131] In some cases, the tyrosinase polypeptide selectively acts on (e.g., generates a reactive moiety such as an orthoquinone) a substrate (a biomolecule) comprising a phenol moiety (e.g., a tyrosine) or a catechol moiety, where the substrate is negatively charged within 50 Å (e.g., within 50 Å, within 40 Å, within 30 Å, or within 20 Å) of the phenol or the catechol moiety. For example, a tyrosinase having at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to any one of the tyrosinase amino acid sequences set forth in FIG. 10A-10Z and FIG. 10AA-10VV can selectively modify a phenol or catechol moiety on a substrate, where the substrate is negatively charged within 50 Å (e.g., within 50 Å, within 40 Å, within 30 Å, or within 20 Å) of the phenol or the catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises at least 2 negatively charged amino acids within 10 amino acids of the phenol moiety (e.g., a tyrosine) or a catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises 2, 3, 4, 5, 6, 7, 8, 9, or 10 negatively charged amino acids within 10 amino acids of the phenol moiety (e.g., a tyrosine) or a catechol moiety. For example, where the biomolecule is a polypeptide, in some cases, the biomolecule comprises the amino acid sequence EEEY (SEQ ID NO: 953), YEEE (SEQ ID NO: 954), EEEEY (SEQ ID NO: 955), or YEEEE (SEQ ID NO: 956).

Cell surface modification

[00134] In some embodiments, a subject method is used to modify the surface of a cell. Thus, in one aspect, the invention features a method of modifying the surface of cell *in vitro*. The method generally involves reacting a thiol group in a target molecule with a biomolecule comprising a reactive moiety to provide for chemoselective conjugation at the cell surface. In some embodiments, the method comprises modifying a target molecule on a cell surface with a thiol moiety; and reacting the thiol moiety in the target molecule with a biomolecule comprising a reactive moiety (e.g., an orthoquinone moiety). In other embodiments, the method comprises activation of a biomolecule comprising a phenol moiety on a cell surface to generate a biomolecule comprising a reactive moiety; and reacting the reactive moiety in the biomolecule with a target molecule comprising a thiol moiety.

Modification of a target molecule with detectable labels, drugs, and other molecules

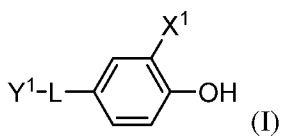
[00135] In some embodiments, the present disclosure provides for attachment of a biomolecule of interest to a target molecule comprising a thiol moiety. The methods generally involve reacting thiol containing target molecules with a subject biomolecule comprising a reactive moiety (e.g., an orthoquinone moiety). Target molecules and biomolecules of interest include, but are not limited to, polypeptides, polynucleotides, carbohydrates, fatty acids, steroids, purines, pyrimidines, derivatives; and the like.

Attachment of biomolecule of interest to a support

[00136] The biomolecule comprising the reactive moiety can also comprise one or more hydrocarbon linkers (*e.g.*, an alkyl group or derivative thereof such as an alkyl ester or PEG) conjugated to a moiety providing for attachment to a solid substratum (*e.g.*, to facilitate assays), or to a moiety providing for easy separation (e.g., a hapten recognized by an antibody bound to a magnetic bead). In one embodiment, the methods of the invention are used to provide for attachment of a protein (or other molecule that contains or can be modified to contain a thiol) to a chip in a defined orientation. For example, the methods and compositions of the disclosure can be used to deliver a tag or other moiety (e.g., as described herein) to the thiol of a target molecule, e.g., a polypeptide having a thiol moiety at a selected site (*e.g.*, at or near the N-terminus). The tag or other moiety can then be used as the attachment site for affixing the molecule to a support (*e.g.*, solid or semi-solid support, e.g., a support suitable for use as a microchip in high-throughput assays).

Attachment of biomolecules for delivery to a target site

[0001] The biomolecule comprising a reactive moiety will in some embodiments comprise a small molecule drug, toxin, or other molecule for delivery to a cell. The small molecule drug, toxin, or other molecule will in some embodiments provide for a pharmacological activity. The small molecule drug, toxin, or other molecule will in some embodiments serve as a target for delivery of other molecules.



[0002] Small molecule drugs may be small organic or inorganic compounds having a molecular weight of more than 50 and less than about 2,500 daltons. Small molecule drugs may comprise functional groups necessary for structural interaction with proteins, particularly hydrogen bonding, and may include at least an amine, carbonyl, hydroxyl or carboxyl group, and may contain at least two of the functional chemical groups. The drugs may comprise cyclical carbon or heterocyclic structures and/or aromatic or polyaromatic structures substituted with one or more of the above functional groups. Small molecule drugs are also found among biomolecules including peptides, saccharides, fatty acids, steroids, purines, pyrimidines, derivatives, structural analogs or combinations thereof.

[00137] In another embodiment, a subject biomolecule comprising a reactive moiety comprises one of a pair of binding partners (*e.g.*, a ligand; a ligand-binding portion of a receptor; an antibody; an antigen-binding fragment of an antibody; an antigen; a hapten; a lectin; a lectin-binding carbohydrate; *etc.*). For example, the biomolecule can comprise a polypeptide that serves as a viral receptor and, upon binding with a viral envelope protein or viral capsid protein, facilitates attachment of virus to the cell surface on which the biomolecule is displayed. Alternatively, the biomolecule comprises an antigen that is specifically bound by an antibody (*e.g.*, monoclonal antibody), to facilitate detection and/or separation of host cells displaying the antigen on the cell surface. In another example, the biomolecule comprises a ligand binding portion of a receptor, or a receptor-binding portion of a ligand.

[00152] Compounds of any of formula (ID)-(IDb) may be prepared by reacting tyramine, or a corresponding phenol or catechol containing amine, to a biomolecule including a N-hydroxysuccinimide (NHS) ester or maleimide group in a suitable solvent. For example, a

[00153] It will be understood that the biomolecule comprising a phenol moiety or a catechol moiety (e.g., of any of formulae (I)-(IDb)) may be prepared by any convenient methods. Many general references providing commonly known chemical synthetic schemes and conditions useful for synthesizing the subject phenol and catechol containing moieties are available (see, e.g., Smith and March, March's Advanced Organic Chemistry: Reactions, Mechanisms, and Structure, Fifth Edition, Wiley-Interscience, 2001; or Vogel, A Textbook of Practical Organic Chemistry, Including Qualitative Organic Analysis, Fourth Edition, New York: Longman, 1978). As disclosed herein, in certain cases the subject phenol moiety is present in a tyrosine residue. The tyrosine residue may be part of the biomolecule of interest. In other cases, the tyrosine moiety may be synthetically introduced into the biomolecule of interest. For example, where the biomolecule is a peptide or a polypeptide, the tyrosine residue may be introduced by standard solid-phase Fmoc peptide chemistry (Fields GB, Noble RL. Solid phase peptide synthesis utilizing 9-fluorenylmethoxycarbonyl amino acids. Int J Pept Protein Res 35: 161–214, 1990). In some cases, a phenol or catechol moiety is part of an unnatural (non-genetically encoded) amino acid that is introduced into a biomolecule of interest. For example, amber codon (TAG) suppression can be used to incorporate a non-genetically encoded amino acid residue that comprises a phenol moiety or a catechol moiety. See, e.g., Chin et al. (2002) *J. Am. Chem. Soc.* 124:9026; Chin and Schultz (2002) *Chem. Biol. Chem.* 3:1135; Chin et al. (2002) *Proc. Natl. Acad. Sci. USA* 99:11020; U.S. 2015/0240249; and US 2018/0171321. As another example, an orthogonal RNA synthetase and/or an orthogonal tRNA can be used for introducing a non-genetically encoded amino acid into a biomolecule, where the non-genetically encoded amino acid comprises a phenol moiety or a catechol moiety.

[00154] In some embodiments of any one of formulae (I)-(IDb), the biomolecule of interest comprises one or more groups selected from an active small molecule, an affinity tag, a fluorophore, and a metal-chelating agent. 1,4,7,10-tetraacetic acid (also referred to as, DOTA, or tetraxetan). In certain cases, the affinity tag is a biotin moiety (e.g., as described herein).

[00155] In certain cases, the biomolecule comprising a phenol moiety is described by a structure as depicted in FIG. 3.

Target molecule comprising a thiol moiety

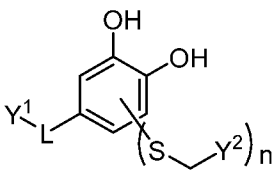
[00156] Molecules comprising a thiol moiety and suitable for use in the subject methods, as well as methods for producing thiol-comprising molecules suitable for use in the subject methods, are well known in the art.

[00157] The target molecules can be naturally occurring, or may be synthetically or recombinantly produced, and may be isolated, substantially purified, or present within the native milieu of the unmodified molecule upon which the thiol-containing target molecule is based (*e.g.*, on a cell surface or within a cell, including within a host animal, *e.g.*, a mammalian animal, such as a murine host (*e.g.*, rat, mouse), hamster, canine, feline, bovine, swine, and the like). In some embodiments, the target molecule is present *in vitro* in a cell-free reaction. In other embodiments, the target molecule is present in a cell and/or displayed on the surface of a cell. In many embodiments of interest, the target molecule is in a living cell; on the surface of a living cell; in a living organism, e.g., in a living multicellular organism. Suitable living cells include cells that are part of a living multicellular organism; cells isolated from a multicellular organism; immortalized cell lines; and the like.

[00158] The target molecule may be composed of D-amino acids, L-amino acids, or both, and may be further modified, either naturally, synthetically, or recombinantly, to include other moieties. For example, the target molecule may be a lipoprotein, a glycoprotein, or other such modified protein.

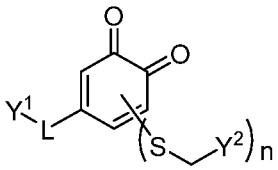
[00159] In general, the target molecule comprises at least one thiol moiety for reaction with a biomolecule comprising a reactive moiety according to the invention, but may comprise 2 or more, 3 or more, 5 or more, 10 or more thiol moieties. The number of thiol moieties that may be present in a target molecule will vary according to the intended application of the modified target molecule of the reaction, the nature of the target molecule itself, and other considerations which will be readily apparent to the ordinarily skilled artisan in practicing the methods as disclosed herein.

[00160] The target molecule can be modified to comprise a thiol moiety at the point at which linkage to the biomolecule comprising a reactive moiety is desired. For example, when the target molecule is a peptide or a polypeptide, the target molecule substrate may be modified to contain an N-terminal thiol moiety, thereby producing a subject target peptide or polypeptide



comprising a thiol moiety. It will be understood that any convenient location on a peptide or a polypeptide substrate may be modified to contain a thiol moiety and thereby produce a target peptide or polypeptide for use in the subject methods.

[00161] In certain embodiments, the target molecule comprising a thiol moiety is a CRISPR-Cas effector polypeptide.



[00162] In certain cases, the thiol moiety is present in a cysteine residue. In certain cases, the cysteine residue is native to the CRISPR-Cas effector polypeptide. In other cases, the cysteine residue is introduced into the CRISPR-Cas effector polypeptide. For example, the cysteine residue may be introduced by standard solid-phase Fmoc peptide chemistry (Fields GB, Noble RL. Solid phase peptide synthesis utilizing 9-fluorenylmethoxycarbonyl amino acids. Int J Pept Protein Res 35: 161–214, 1990).

In some cases, a CRISPR-Cas effector polypeptide is a class 2 type V CRISPR-Cas effector polypeptide (e.g., a Cpf1 protein, a C2c1 protein, or a C2c3 protein). In some cases, a suitable CRISPR-Cas effector polypeptide is a class 2 type VI CRISPR-Cas effector polypeptide (e.g., a C2c2 protein; also referred to as a "Cas13a" protein). Also suitable is a CasX protein. Also suitable is a CasY protein.

[00274] In some cases, the CRISPR/Cas effector polypeptide is a Type II CRISPR/Cas effector polypeptide. In some cases, the CRISPR/Cas effector polypeptide is a Cas9 polypeptide. The Cas9 protein is guided to a target site (e.g., stabilized at a target site) within a target nucleic acid sequence (e.g., a chromosomal sequence or an extrachromosomal sequence, e.g., an episomal sequence, a minicircle sequence, a mitochondrial sequence, a chloroplast sequence, etc.) by virtue of its association with the protein-binding segment of the Cas9 guide RNA. In some cases, a Cas9 polypeptide comprises an amino acid sequence having at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, at least 95%, at least 98%, at least 99%, or more than 99%, amino acid sequence identity to the *Streptococcus pyogenes* Cas9 set forth in SEQ ID NO:753.

In some cases, a Cas9 polypeptide comprises the amino acid sequence set forth in any one of SEQ ID NOs:5-816. In some cases, a Cas9 polypeptide comprises an amino acid sequence having at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, at least 95%, at least 98%, at least 99%, or more than 99%, amino acid sequence identity to the amino acid sequence set forth in any one of SEQ ID NOs:5-816.

[00275] In some cases, the Cas9 polypeptide is a *Staphylococcus aureus* Cas9 (saCas9) polypeptide. In some cases, the saCas9 polypeptide comprises an amino acid sequence having at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the saCas9 amino acid sequence set forth in SEQ ID NO:249.

[00276] In some cases, the Cas9 polypeptide is a *Campylobacter jejuni* Cas9 (CjCas9) polypeptide. CjCas9 recognizes the 5′-NNNVRYM-3′ as the protospacer-adjacent motif (PAM). The amino acid sequence of CjCas9 is set forth in SEQ ID NO:55. In some cases, a suitable Cas9 polypeptide comprises an amino acid sequence having at least 50%, at least 60%, at least 70%, at least 80%, at least 90%, at least 95%, at least 98%, at least 99%, or more than 99%, amino acid sequence identity to the CjCas9 amino acid sequence set forth in SEQ ID NO:55.

[00277] In some cases, a suitable Cas9 polypeptide is a high-fidelity (HF) Cas9 polypeptide. Kleinstiver et al. (2016) *Nature* 529:490. For example, amino acids N497, R661, Q695, and Q926 of a *Streptococcus pyogenes* Cas9 amino acid sequence (e.g., SEQ ID NO:5) are substituted, e.g., with alanine. For example, an HF Cas9 polypeptide can comprise an amino acid sequence having at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to a *Streptococcus pyogenes* Cas9 (e.g., SEQ ID NO:5), where amino acids N497, R661, Q695, and Q926 are substituted, e.g., with alanine. In some cases, a suitable Cas9 polypeptide exhibits altered PAM specificity. See, e.g., Kleinstiver et al. (2015) *Nature* 523:481.

[00278] In some cases, a suitable Cas9 polypeptide comprises an amino acid sequence having at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the following Cas9-HF1 sequence:

[00279] In some cases, a suitable CRISPR/Cas effector polypeptide is a type V CRISPR/Cas effector polypeptide. In some cases, a type V CRISPR/Cas effector polypeptide is a Cpf1 protein. In some cases, a Cpf1 protein comprises an amino acid sequence having at least 30%, at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, at least 90%, or 100%, amino acid sequence identity to the Cpf1 amino acid sequence set forth in any one of SEQ ID NOs:818-822.

[00280] In some cases, a suitable CRISPR/Cas effector polypeptide is a CasX or a CasY polypeptide. CasX and CasY polypeptides are described in Burstein et al. (2017) *Nature* 542:237.

[00281] In some cases, a suitable CRISPR/Cas effector polypeptide is a fusion protein comprising a CRISPR/Cas effector polypeptide that is fused to a heterologous polypeptide (also referred to as a "fusion partner"). In some cases, a CRISPR/Cas effector polypeptide is fused to an amino acid sequence (a fusion partner) that provides for subcellular localization, i.e., the fusion partner is a subcellular localization sequence (e.g., one or more nuclear localization signals (NLSs) for targeting to the nucleus, two or more NLSs, three or more NLSs, etc.).

[00282] A nucleic acid that binds to a class 2 CRISPR/Cas effector polypeptide (e.g., a Cas9 protein; a type V or type VI CRISPR/Cas protein; a Cpf1 protein; etc.) and targets the complex to a specific location within a target nucleic acid is referred to herein as a "guide RNA" or "CRISPR/Cas guide nucleic acid" or "CRISPR/Cas guide RNA." A guide RNA provides target

specificity to the complex (the RNP complex) by including a targeting segment, which includes a guide sequence (also referred to herein as a targeting sequence), which is a nucleotide sequence that is complementary to a sequence of a target nucleic acid.

[00283] In some cases, a guide RNA includes two separate nucleic acid molecules: an "activator" and a "targeter" and is referred to herein as a "dual guide RNA", a "double-molecule guide RNA", a "two-molecule guide RNA", or a "dgRNA." In some cases, the guide RNA is one molecule (e.g., for some class 2 CRISPR/Cas proteins, the corresponding guide RNA is a single molecule; and in some cases, an activator and targeter are covalently linked to one another, e.g., via intervening nucleotides), and the guide RNA is referred to as a "single guide RNA", a "single-molecule guide RNA," a "one-molecule guide RNA", or simply "sgRNA."

Class 2 CRISPR/Cas effector polypeptides

[00284] In class 2 CRISPR systems, the functions of the effector complex (e.g., the cleavage of target DNA) are carried out by a single endonuclease (e.g., see Zetsche et al., Cell. 2015 Oct 22;163(3):759-71; Makarova et al., Nat Rev Microbiol. 2015 Nov;13(11):722-36; Shmakov et al., Mol Cell. 2015 Nov 5;60(3):385-97); and Shmakov et al. (2017) *Nature Reviews Microbiology* 15:169. As such, the term "class 2 CRISPR/Cas protein" is used herein to encompass the CRISPR/Cas effector polypeptide (e.g., the target nucleic acid cleaving protein) from class 2 CRISPR systems. Thus, the term "class 2 CRISPR/Cas effector polypeptide" as used herein encompasses type II CRISPR/Cas effector polypeptides (e.g., Cas9); type V-A CRISPR/Cas effector polypeptides (e.g., Cpf1 (also referred to a "Cas12a")); type V-B CRISPR/Cas effector polypeptides (e.g., C2c1 (also referred to as "Cas12b")); type V-C CRISPR/Cas effector polypeptides (e.g., C2c3 (also referred to as "Cas12c")); type V-U1 CRISPR/Cas effector polypeptides (e.g., C2c4); type V-U2 CRISPR/Cas effector polypeptides (e.g., C2c8); type V-U5 CRISPR/Cas effector polypeptides (e.g., C2c5); type V-U4 CRISPR/Cas proteins (e.g., C2c9); type V-U3 CRISPR/Cas effector polypeptides (e.g., C2c10); type VI-A CRISPR/Cas effector polypeptides (e.g., C2c2 (also known as "Cas13a")); type VI-B CRISPR/Cas effector polypeptides (e.g., Cas13b (also known as C2c4)); and type VI-C CRISPR/Cas effector polypeptides (e.g., Cas13c (also known as C2c7)). To date, class 2 CRISPR/Cas effector polypeptides encompass type II, type V, and type VI CRISPR/Cas effector polypeptides, but the term is also meant to encompass any class 2 CRISPR/Cas effector polypeptide suitable for binding to a corresponding guide RNA and forming an RNP complex.

Type II CRISPR/Cas endonucleases (e.g., Cas 9)

[00285] In natural Type II CRISPR/Cas systems, Cas9 functions as an RNA-guided endonuclease that uses a dual-guide RNA having a crRNA and *trans*-activating crRNA (tracrRNA) for target recognition and cleavage by a mechanism involving two nuclease active sites in Cas9 that

together generate double-stranded DNA breaks (DSBs), or can individually generate single-stranded DNA breaks (SSBs). The Type II CRISPR endonuclease Cas9 and engineered dual- (dgRNA) or single guide RNA (sgRNA) form a ribonucleoprotein (RNP) complex that can be targeted to a desired DNA sequence. Guided by a dual-RNA complex or a chimeric single-guide RNA, Cas9 generates site-specific DSBs or SSBs within double-stranded DNA (dsDNA) target nucleic acids, which are repaired either by non-homologous end joining (NHEJ) or homology-directed recombination (HDR).

[00286] A type II CRISPR/Cas effector polypeptide is a type of class 2 CRISPR/Cas endonuclease. In some cases, the type II CRISPR/Cas endonuclease is a Cas9 protein. A Cas9 protein forms a complex with a Cas9 guide RNA. The guide RNA provides target specificity to a Cas9-guide RNA complex by having a nucleotide sequence (a guide sequence) that is complementary to a sequence (the target site) of a target nucleic acid (as described elsewhere herein). The Cas9 protein of the complex provides the site-specific activity. In other words, the Cas9 protein is guided to a target site (e.g., stabilized at a target site) within a target nucleic acid sequence (e.g. a chromosomal sequence or an extrachromosomal sequence, e.g., an episomal sequence, a minicircle sequence, a mitochondrial sequence, a chloroplast sequence, etc.) by virtue of its association with the protein-binding segment of the Cas9 guide RNA.

[00287] A Cas9 protein can bind and/or modify (e.g., cleave, nick, methylate, demethylate, etc.) a target nucleic acid and/or a polypeptide associated with target nucleic acid (e.g., methylation or acetylation of a histone tail)(e.g., when the Cas9 protein includes a fusion partner with an activity). In some cases, the Cas9 protein is a naturally-occurring protein (e.g., naturally occurs in bacterial and/or archaeal cells). In other cases, the Cas9 protein is not a naturally-occurring polypeptide (e.g., the Cas9 protein is a variant Cas9 protein, a chimeric protein, and the like).

[00288] Examples of suitable Cas9 proteins include, but are not limited to, those set forth in SEQ ID NOs: 5-816. Naturally occurring Cas9 proteins bind a Cas9 guide RNA, are thereby directed to a specific sequence within a target nucleic acid (a target site), and cleave the target nucleic acid (e.g., cleave dsDNA to generate a double strand break, cleave ssDNA, cleave ssRNA, etc.). A chimeric Cas9 protein is a fusion protein comprising a Cas9 polypeptide that is fused to a heterologous protein (referred to as a fusion partner), where the heterologous protein provides an activity (e.g., one that is not provided by the Cas9 protein). The fusion partner can provide an activity, e.g., enzymatic activity (e.g., nuclease activity, activity for DNA and/or RNA methylation, activity for DNA and/or RNA cleavage, activity for histone acetylation, activity for histone methylation, activity for RNA modification, activity for RNA-binding, activity for RNA splicing etc.). In some cases, a portion of the Cas9 protein (e.g., the RuvC domain and/or the HNH domain) exhibits reduced nuclease activity relative to the corresponding portion of a wild

type Cas9 protein (e.g., in some cases the Cas9 protein is a nickase). In some cases, the Cas9 protein is enzymatically inactive, or has reduced enzymatic activity relative to a wild-type Cas9 protein (e.g., relative to *Streptococcus pyogenes* Cas9).

[00289] In some cases, a fusion protein comprises: a) a catalytically inactive Cas9 protein (or other catalytically inactive CRISPR effector polypeptide); and b) a catalytically active endonuclease. For example, in some cases, the catalytically active endonuclease is a FokI polypeptide. As one non-limiting example, in some cases, a fusion protein comprises: a) a catalytically inactive Cas9 protein (or other catalytically inactive CRISPR effector polypeptide); and b) is a FokI nuclease comprising an amino acid sequence having at least at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the FokI amino acid sequence provided below; where the FokI nuclease has a length of from about 195 amino acids to about 200 amino acids.

[00291] Assays to determine whether given protein interacts with a Cas9 guide RNA can be any convenient binding assay that tests for binding between a protein and a nucleic acid. Suitable binding assays (e.g., gel shift assays) will be known to one of ordinary skill in the art (e.g., assays that include adding a Cas9 guide RNA and a protein to a target nucleic acid).

[00292] Assays to determine whether a protein has an activity (e.g., to determine if the protein has nuclease activity that cleaves a target nucleic acid and/or some heterologous activity) can be any convenient assay (e.g., any convenient nucleic acid cleavage assay that tests for nucleic acid cleavage). Suitable assays (e.g., cleavage assays) will be known to one of ordinary skill in the art and can include adding a Cas9 guide RNA and a protein to a target nucleic acid.

[00293] In some cases, a suitable Cas9 protein comprises an amino acid sequence having 60% or more, 70% or more, 75% or more, 80% or more, 85% or more, 90% or more, 95% or more, 99% or more or 100% amino acid sequence identity to amino acids 7-166 or 731-1003 of the Cas9 amino acid sequence set forth in SEQ ID NO: 5, or to the corresponding portions in any of the amino acid sequences set forth as SEQ ID NOs: 6-816.

[00294] Examples of various Cas9 proteins (and Cas9 domain structure) and Cas9 guide RNAs (as well as information regarding requirements related to protospacer adjacent motif (PAM) sequences present in targeted nucleic acids) can be found in the art, for example, see Jinek et al., Science.

Variant Cas9 proteins – nickases and dCas9

[00295] In some cases, a Cas9 protein is a variant Cas9 protein. A variant Cas9 protein has an amino acid sequence that is different by at least one amino acid (e.g., has a deletion, insertion, substitution, fusion) when compared to the amino acid sequence of a corresponding wild type Cas9 protein. In some instances, the variant Cas9 protein has an amino acid change (e.g., deletion, insertion, or substitution) that reduces the nuclease activity of the Cas9 protein. For example, in some instances, the variant Cas9 protein has 50% or less, 40% or less, 30% or less, 20% or less, 10% or less, 5% or less, or 1% or less of the nuclease activity of the corresponding

wild-type Cas9 protein. In some cases, the variant Cas9 protein has no substantial nuclease activity. When a Cas9 protein is a variant Cas9 protein that has no substantial nuclease activity, it can be referred to as a nuclease defective Cas9 protein or "dCas9" for "dead" Cas9. A protein (e.g., a class 2 CRISPR/Cas protein, e.g., a Cas9 protein) that cleaves one strand but not the other of a double stranded target nucleic acid is referred to herein as a "nickase" (e.g., a "nickase Cas9").

[00296] In some cases, a variant Cas9 protein can cleave the complementary strand (sometimes referred to in the art as the target strand) of a target nucleic acid but has reduced ability to cleave the non-complementary strand (sometimes referred to in the art as the non-target strand) of a target nucleic acid. For example, the variant Cas9 protein can have a mutation (amino acid substitution) that reduces the function of the RuvC domain. Thus, the Cas9 protein can be a nickase that cleaves the complementary strand, but does not cleave the non-complementary strand. As a non-limiting example, in some embodiments, a variant Cas9 protein has a mutation at an amino acid position corresponding to residue D10 (e.g., D10A, aspartate to alanine) of SEQ ID NO: 5 (or the corresponding position of any of the proteins set forth in SEQ ID NOs: 6-261 and 264-816) and can therefore cleave the complementary strand of a double stranded target nucleic acid but has reduced ability to cleave the non-complementary strand of a double stranded target nucleic acid (thus resulting in a single strand break (SSB) instead of a double strand break (DSB) when the variant Cas9 protein cleaves a double stranded target nucleic acid) (see, for example, Jinek et al., Science. 2012 Aug 17;337(6096):816-21). See, e.g., SEQ ID NO: 262.

[00297] In some cases, a variant Cas9 protein can cleave the non-complementary strand of a target nucleic acid but has reduced ability to cleave the complementary strand of the target nucleic acid. For example, the variant Cas9 protein can have a mutation (amino acid substitution) that reduces the function of the HNH domain. Thus, the Cas9 protein can be a nickase that cleaves the non-complementary strand, but does not cleave the complementary strand. As a non-limiting example, in some embodiments, the variant Cas9 protein has a mutation at an amino acid position corresponding to residue H840 (e.g., an H840A mutation, histidine to alanine) of SEQ ID NO: 5 (or the corresponding position of any of the proteins set forth as SEQ ID NOs: 6-261 and 264-816) and can therefore cleave the non-complementary strand of the target nucleic acid but has reduced ability to cleave (e.g., does not cleave) the complementary strand of the target nucleic acid. Such a Cas9 protein has a reduced ability to cleave a target nucleic acid (e.g., a single stranded target nucleic acid) but retains the ability to bind a target nucleic acid (e.g., a single stranded target nucleic acid). See, e.g., SEQ ID NO: 263.

[00298] In some cases, a variant Cas9 protein has a reduced ability to cleave both the complementary and the non-complementary strands of a double stranded target nucleic acid. As a non-limiting

example, in some cases, the variant Cas9 protein harbors mutations at amino acid positions corresponding to residues D10 and H840 (e.g., D10A and H840A) of SEQ ID NO: 5 (or the corresponding residues of any of the proteins set forth as SEQ ID NOs: 6-261 and 264-816) such that the polypeptide has a reduced ability to cleave (e.g., does not cleave) both the complementary and the non-complementary strands of a target nucleic acid. Such a Cas9 protein has a reduced ability to cleave a target nucleic acid (e.g., a single stranded or double stranded target nucleic acid) but retains the ability to bind a target nucleic acid. A Cas9 protein that cannot cleave target nucleic acid (e.g., due to one or more mutations, e.g., in the catalytic domains of the RuvC and HNH domains) is referred to as a "dead" Cas9 or simply "dCas9." See, e.g., SEQ ID NO: 264.

Type V and Type VI CRISPR/Cas Endonucleases

[00299] In some cases, a suitable CRISPR/Cas effector polypeptide is a type V or type VI CRISPR/Cas endonuclease (i.e., the CRISPR/Cas effector polypeptide is a type V or type VI CRISPR/Cas endonuclease) (e.g., Cpf1, C2c1, C2c2, C2c3). Type V and type VI CRISPR/Cas endonucleases are a type of class 2 CRISPR/Cas endonuclease. Examples of type V CRISPR/Cas endonucleases include but are not limited to: Cpf1, C2c1, and C2c3. An example of a type VI CRISPR/Cas effector polypeptide is C2c2. In some cases, a suitable CRISPR/Cas effector polypeptide is a type V CRISPR/Cas endonuclease (e.g., Cpf1, C2c1, C2c3). In some cases, a Type V CRISPR/Cas effector polypeptide is a Cpf1 protein. In some cases, a suitable CRISPR/Cas effector polypeptide is a type VI CRISPR/Cas endonuclease (e.g., Cas13a).

[00300] Like type II CRISPR/Cas endonucleases, type V and VI CRISPR/Cas endonucleases form a complex with a corresponding guide RNA. The guide RNA provides target specificity to an endonuclease-guide RNA RNP complex by having a nucleotide sequence (a guide sequence) that is complementary to a sequence (the target site) of a target nucleic acid (as described elsewhere herein). The endonuclease of the complex provides the site-specific activity. In other words, the endonuclease is guided to a target site (e.g., stabilized at a target site) within a target nucleic acid sequence (e.g. a chromosomal sequence or an extrachromosomal sequence, e.g., an episomal sequence, a minicircle sequence, a mitochondrial sequence, a chloroplast sequence, etc.) by virtue of its association with the protein-binding segment of the guide RNA.

[00324] In some cases, the fusion partner has enzymatic activity that modifies a protein associated with a target nucleic acid (e.g., ssRNA, dsRNA, ssDNA, dsDNA) (e.g., a histone, an RNA binding protein, a DNA binding protein, and the like). Examples of enzymatic activity (that modifies a protein associated with a target nucleic acid) that can be provided by the fusion partner include but are not limited to: methyltransferase activity such as that provided by a histone methyltransferase (HMT) (e.g., suppressor of variegation 3-9 homolog 1 (SUV39H1, also known as KMT1A), euchromatic histone lysine methyltransferase 2 (G9A, also known as KMT1C and EHMT2), SUV39H2, ESET/SETDB1, and the like, SET1A, SET1B, MLL1 to 5, ASH1, SYMD2, NSD1, DOT1L, Pr-SET7/8, SUV4-20H1, EZH2, RIZ1), demethylase activity such as that provided by a histone demethylase (e.g., Lysine Demethylase 1A (KDM1A also known as LSD1), JHDM2a/b, JMJD2A/JHDM3A, JMJD2B, JMJD2C/GASC1, JMJD2D, JARID1A/RBP2, JARID1B/PLU-1, JARID1C/SMCX, JARID1D/SMCY, UTX, JMJD3, and the like), acetyltransferase activity such as that provided by a histone acetyl transferase (e.g., catalytic core/fragment of the human acetyltransferase p300, GCN5, PCAF, CBP, TAF1, TIP60/PLIP, MOZ/MYST3, MORF/MYST4, HBO1/MYST2, HMOF/MYST1, SRC1, ACTR, P160, CLOCK, and the like), deacetylase activity such as that provided by a histone deacetylase (e.g., HDAC1, HDAC2, HDAC3, HDAC8, HDAC4, HDAC5, HDAC7, HDAC9, SIRT1, SIRT2, HDAC11, and the like), kinase activity, phosphatase activity, ubiquitin ligase activity, deubiquitinating activity, adenylation activity, deadenylation activity, SUMOylating activity, deSUMOylating activity, ribosylation activity, deribosylation activity, myristoylation activity, and demyristoylation activity.

[00325] In some cases, a fusion protein comprises: a) a catalytically inactive CRISPR/Cas effector polypeptide (e.g., a catalytically inactive Cas9 polypeptide); and b) a catalytically active endonuclease. For example, in some cases, the catalytically active endonuclease is a FokI polypeptide. As one non-limiting example, in some cases, a fusion protein comprises: a) a

catalytically inactive Cas9 protein (or other catalytically inactive CRISPR effector polypeptide); and b) is a FokI nuclease comprising an amino acid sequence having at least at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the FokI amino acid sequence provided below; where the FokI nuclease has a length of from about 195 amino acids to about 200 amino acids.

[00338] Cytidine deaminases suitable for inclusion in a CRISPR/Cas effector polypeptide fusion polypeptide include any enzyme that is capable of deaminating cytidine in DNA.

[00339] In some cases, the cytidine deaminase is a deaminase from the apolipoprotein B mRNA-editing complex (APOBEC) family of deaminases. In some cases, the APOBEC family deaminase is selected from the group consisting of APOBEC1 deaminase, APOBEC2 deaminase, APOBEC3A deaminase, APOBEC3B deaminase, APOBEC3C deaminase, APOBEC3D deaminase, APOBEC3F deaminase, APOBEC3G deaminase, and APOBEC3H deaminase. [00340] In some cases, a suitable cytidine deaminase comprises an amino acid sequence having at least 80%, at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the following amino acid sequence:

[00344] In some cases, a CRISPR/Cas effector polypeptide fusion polypeptide comprises a CRISPR/Cas effector polypeptide that exhibits nickase activity. Suitable nickases are described elsewhere herein.

[00345] In some cases, a fusion CRISPR/Cas effector polypeptide comprises one or more localization signal peptides. Suitable localization signals ("subcellular localization signals") include, e.g., a nuclear localization signal (NLS) for targeting to the nucleus; a sequence to keep the fusion protein out of the nucleus, e.g., a nuclear export sequence (NES); a sequence to keep the fusion protein retained in the cytoplasm; a mitochondrial localization signal for targeting to the mitochondria; a chloroplast localization signal for targeting to a chloroplast; an endoplasmic reticulum (ER) retention signal; and ER export signal; and the like. In some cases, a fusion polypeptide does not include an NLS so that the protein is not targeted to the nucleus (which can be advantageous, e.g., when the target nucleic acid is an RNA that is present in the cytosol).

[00346] In some cases, a fusion polypeptide includes (is fused to) a nuclear localization signal (NLS) (e.g., in some cases 2 or more, 3 or more, 4 or more, or 5 or more NLSs). Thus, in some cases, a fusion polypeptide includes one or more NLSs (e.g., 2 or more, 3 or more, 4 or more, or 5 or more NLSs). In some cases, one or more NLSs (2 or more, 3 or more, 4 or more, or 5 or more NLSs) are positioned at or near (e.g., within 50 amino acids of) the N-terminus and/or the C-terminus. In some cases, one or more NLSs (2 or more, 3 or more, 4 or more, or 5 or more NLSs) are positioned at or near (e.g., within 50 amino acids of) the N-terminus. In some cases, one or more NLSs (2 or more, 3 or more, 4 or more, or 5 or more NLSs) are positioned at or near (e.g., within 50 amino acids of) the C-terminus. In some cases, one or more NLSs (3 or more, 4 or more, or 5 or more NLSs) are positioned at or near (e.g., within 50 amino acids of) both the N-terminus and the C-terminus. In some cases, an NLS is positioned at the N-terminus and an NLS is positioned at the C-terminus.

[00347] In some cases, a fusion polypeptide includes (is fused to) between 1 and 10 NLSs (e.g., 1-9, 1-8, 1-7, 1-6, 1-5, 2-10, 2-9, 2-8, 2-7, 2-6, or 2-5 NLSs). In some cases, a fusion polypeptide includes (is fused to) between 2 and 5 NLSs (e.g., 2-4, or 2-3 NLSs).

[00348] Non-limiting examples of NLSs include an NLS sequence derived from: the NLS of the SV40 virus large T-antigen, having the amino acid sequence PKKKRKV (SEQ ID NO:914); the NLS from nucleoplasmin (e.g., the nucleoplasmin bipartite NLS with the sequence

KRPAATKKAGQAKKKK (SEQ ID NO:915)); the c-myc NLS having the amino acid sequence PAAKRVKLD (SEQ ID NO:916) or RQRRNELKRSP (SEQ ID NO:917); the hRNPA1 M9 NLS having the sequence NQSSNFGPMKGGNFGGRSSGPYGGGGQYFAKPRNQGGY (SEQ ID NO:918); the sequence RMRIZFKNKGKDTAELRRRRVEVSVELRKAKKDEQILKRRNV (SEQ ID NO:919) of the IBB domain from importin-alpha; the sequences VSRKRPRP (SEQ ID NO:920) and PPKKARED (SEQ ID NO:921) of the myoma T protein; the sequence PQPKKKPL (SEQ ID NO:922) of human p53; the sequence SALIKKKKKMAP (SEQ ID NO:923) of mouse c-abl IV; the sequences DRLRR (SEQ ID NO:924) and PKQKKRK (SEQ ID NO:925) of the influenza virus NS1; the sequence RKLKKKIKKL (SEQ ID NO:926) of the Hepatitis virus delta antigen; the sequence REKKKFLKRR (SEQ ID NO:927) of the mouse Mx1 protein; the sequence KRKGDEVDGVDEVAKKKSKK (SEQ ID NO:928) of the human poly(ADP-ribose) polymerase; and the sequence RKCLQAGMNLEARKTKK (SEQ ID NO:929) of the steroid hormone receptors (human) glucocorticoid. In some cases, an NLS comprises the amino acid sequence MDSLLMNRRKFLYQFKNVRWAKGRRETYLC (SEQ ID NO:930). In general, NLS (or multiple NLSs) are of sufficient strength to drive accumulation of the fusion polypeptide in a detectable amount in the nucleus of a eukaryotic cell. Detection of accumulation in the nucleus may be performed by any suitable technique. For example, a detectable marker may be fused to the fusion polypeptide such that location within a cell may be visualized. Cell nuclei may also be isolated from cells, the contents of which may then be analyzed by any suitable process for detecting protein, such as immunohistochemistry, Western blot, or enzyme activity assay. Accumulation in the nucleus may also be determined indirectly.

[00349] In some cases, a CRISPR/Cas effector polypeptide fusion polypeptide includes a "Protein Transduction Domain" or PTD (also known as a CPP – cell penetrating peptide), which refers to a polypeptide, polynucleotide, carbohydrate, or organic or inorganic compound that facilitates traversing a lipid bilayer, micelle, cell membrane, organelle membrane, or vesicle membrane. A PTD attached to another molecule, which can range from a small polar molecule to a large macromolecule and/or a nanoparticle, facilitates the molecule traversing a membrane, for example going from extracellular space to intracellular space, or cytosol to within an organelle. In some embodiments, a PTD is covalently linked to the amino terminus of a polypeptide. In some embodiments, a PTD is covalently linked to the carboxyl terminus of a polypeptide. In some cases, the PTD is inserted internally in the fusion polypeptide (i.e., is not at the N- or C-terminus of the fusion polypeptide) at a suitable insertion site. In some cases, a subject fusion polypeptide includes (is conjugated to, is fused to) one or more PTDs (e.g., two or more, three or more, four or more PTDs). In some cases, a PTD includes a nuclear localization signal (NLS) (e.g., in some cases 2 or more, 3 or more, 4 or more, or 5 or more NLSs). Thus, in

some cases, a fusion polypeptide includes one or more NLSs (e.g., 2 or more, 3 or more, 4 or more, or 5 or more NLSs). In some embodiments, a PTD is covalently linked to a nucleic acid (e.g., a guide nucleic acid, a polynucleotide encoding a guide nucleic acid, a polynucleotide encoding a fusion polypeptide, a donor polynucleotide, etc.). Examples of PTDs include but are not limited to a minimal undecapeptide protein transduction domain (corresponding to residues 47-57 of HIV-1 TAT comprising YGRKKRRQRRR; SEQ ID NO:931); a polyarginine sequence comprising a number of arginines sufficient to direct entry into a cell (e.g., 3, 4, 5, 6, 7, 8, 9, 10, or 10-50 arginines); a VP22 domain (Zender et al. (2002) *Cancer Gene Ther.* 9(6):489-96); an Drosophila Antennapedia protein transduction domain (Noguchi et al. (2003) *Diabetes* 52(7):1732-1737); a truncated human calcitonin peptide (Trehin et al. (2004) *Pharm. Research* 21:1248-1256); polylysine (Wender et al. (2000) *Proc. Natl. Acad. Sci. USA* 97:13003-13008); RRQRRTSKLMKR (SEQ ID NO:932); Transportan GWTLNSAGYLLGKINLKALAALAKKIL (SEQ ID NO:933); KALAWEAKLAKALAKALAKHLAKALAKALKCEA (SEQ ID NO:934); and RQIKIWFQNRRMKWKK (SEQ ID NO:935). Exemplary PTDs include but are not limited to, YGRKKRRQRRR (SEQ ID NO:936), RKKRRQRRR (SEQ ID NO:937); an arginine homopolymer of from 3 arginine residues to 50 arginine residues; Exemplary PTD domain amino acid sequences include, but are not limited to, any of the following: YGRKKRRQRRR (SEQ ID NO:938); RKKRRQRR (SEQ ID NO:939); YARAAARQARA (SEQ ID NO:940); THRLPRRRRRR (SEQ ID NO:941); and GGRRARRRRRR (SEQ ID NO:942). In some embodiments, the PTD is an activatable CPP (ACPP) (Aguilera et al. (2009) *Integr Biol (Camb)* June; 1(5-6): 371-381). ACPPs comprise a polycationic CPP (e.g., Arg9 or "R9") connected via a cleavable linker to a matching polyanion (e.g., Glu9 or "E9"), which reduces the net charge to nearly zero and thereby inhibits adhesion and uptake into cells. Upon cleavage of the linker, the polyanion is released, locally unmasking the polyarginine and its inherent adhesiveness, thus "activating" the ACPP to traverse the membrane.

Guide RNA

[00350] Where a target polypeptide is a CRISPR/Cas effector polypeptide, in some cases, the CRISPR/Cas effector polypeptide is complexed with a CRISPR/Cas effector polypeptide guide RNA (also referred to as a "CRISPR-Cas guide RNA").

[00351] A nucleic acid molecule that binds to a CRISPR/Cas effector polypeptide protein and targets the complex to a specific location within a target nucleic acid is referred to herein as a "CRISPR/Cas effector polypeptide guide RNA" or simply a "guide RNA."

[00352] A guide RNA (can be said to include two segments, a first segment (referred to herein as a "targeting segment"); and a second segment (referred to herein as a "protein-binding segment").

By "segment" it is meant a segment/section/region of a molecule, e.g., a contiguous stretch of nucleotides in a nucleic acid molecule. A segment can also mean a region/section of a complex such that a segment may comprise regions of more than one molecule. The "targeting segment" is also referred to herein as a "variable region" of a guide RNA. The "protein-binding segment" is also referred to herein as a "constant region" of a guide RNA. In some cases, the guide RNA is a Cas9 guide RNA.

[00353] The first segment (targeting segment) of a guide RNA includes a nucleotide sequence (a guide sequence) that is complementary to (and therefore hybridizes with) a specific sequence (a target site) within a target nucleic acid (e.g., a target ssRNA, a target ssDNA, the complementary strand of a double stranded target DNA, etc.). The protein-binding segment (or "protein-binding sequence") interacts with (binds to) a CRISPR/Cas effector polypeptide. The protein-binding segment of a guide RNA includes two complementary stretches of nucleotides that hybridize to one another to form a double stranded RNA duplex (dsRNA duplex). Site-specific binding and/or cleavage of a target nucleic acid (e.g., genomic DNA) can occur at locations (e.g., target sequence of a target locus) determined by base-pairing complementarity between the guide RNA (the guide sequence of the guide RNA) and the target nucleic acid.

[00354] A guide RNA and a CRISPR/Cas effector polypeptide form a complex (e.g., bind via non-covalent interactions). The guide RNA provides target specificity to the complex by including a targeting segment, which includes a guide sequence (a nucleotide sequence that is complementary to a sequence of a target nucleic acid). The CRISPR/Cas effector polypeptide of the complex provides the site-specific activity (e.g., cleavage activity or an activity provided by the CRISPR/Cas effector polypeptide when the CRISPR/Cas effector polypeptide is a CRISPR/Cas effector polypeptide fusion polypeptide, i.e., has a fusion partner). In other words, the CRISPR/Cas effector polypeptide is guided to a target nucleic acid sequence (e.g. a target sequence in a chromosomal nucleic acid, e.g., a chromosome; a target sequence in an extrachromosomal nucleic acid, e.g. an episomal nucleic acid, a minicircle, an ssRNA, an ssDNA, etc.; a target sequence in a mitochondrial nucleic acid; a target sequence in a chloroplast nucleic acid; a target sequence in a plasmid; a target sequence in a viral nucleic acid; etc.) by virtue of its association with the guide RNA.

[00355] The "guide sequence" also referred to as the "targeting sequence" of a guide RNA can be modified so that the guide RNA can target a CRISPR/Cas effector polypeptide to any desired sequence of any desired target nucleic acid, with the exception that the protospacer adjacent motif (PAM) sequence can be taken into account. Thus, for example, a guide RNA can have a targeting segment with a sequence (a guide sequence) that has complementarity with (e.g., can hybridize to) a sequence in a nucleic acid in a eukaryotic cell, e.g., a viral nucleic acid, a

eukaryotic nucleic acid (e.g., a eukaryotic chromosome, chromosomal sequence, a eukaryotic RNA, etc.), and the like.

[00356] In some embodiments, a guide RNA includes two separate nucleic acid molecules: an "activator" and a "targeter" and is referred to herein as a "dual guide RNA", a "double-molecule guide RNA", or a "two-molecule guide RNA" a "dual guide RNA", or a "dgRNA." In some embodiments, the activator and targeter are covalently linked to one another (e.g., via intervening nucleotides) and the guide RNA is referred to as a "single guide RNA", a "Cas9 single guide RNA", a "single-molecule Cas9 guide RNA," or a "one-molecule Cas9 guide RNA", or simply "sgRNA."

[00357] A guide RNA comprises a crRNA-like ("CRISPR RNA" / "targeter" / "crRNA" / "crRNA repeat") molecule and a corresponding tracrRNA-like ("trans-acting CRISPR RNA" / "activator" / "tracrRNA") molecule. A crRNA-like molecule (targeter) comprises both the targeting segment (single stranded) of the guide RNA and a stretch ("duplex-forming segment") of nucleotides that forms one half of the dsRNA duplex of the protein-binding segment of the guide RNA. A corresponding tracrRNA-like molecule (activator / tracrRNA) comprises a stretch of nucleotides (duplex-forming segment) that forms the other half of the dsRNA duplex of the protein-binding segment of the guide nucleic acid. In other words, a stretch of nucleotides of a crRNA-like molecule are complementary to and hybridize with a stretch of nucleotides of a tracrRNA-like molecule to form the dsRNA duplex of the protein-binding domain of the guide RNA. As such, each targeter molecule can be said to have a corresponding activator molecule (which has a region that hybridizes with the targeter). The targeter molecule additionally provides the targeting segment. Thus, a targeter and an activator molecule (as a corresponding pair) hybridize to form a guide RNA. The exact sequence of a given crRNA or tracrRNA molecule is characteristic of the species in which the RNA molecules are found. A dual guide RNA can include any corresponding activator and targeter pair.

[00358] The term "activator" or "activator RNA" is used herein to mean a tracrRNA-like molecule (tracrRNA : "trans-acting CRISPR RNA") of a dual guide RNA (and therefore of a single guide RNA when the "activator" and the "targeter" are linked together by, e.g., intervening nucleotides). Thus, for example, a guide RNA (dgRNA or sgRNA) comprises an activator sequence (e.g., a tracrRNA sequence). A tracr molecule (a tracrRNA) is a naturally existing molecule that hybridizes with a CRISPR RNA molecule (a crRNA) to form a dual guide RNA. The term "activator" is used herein to encompass naturally existing tracrRNAs, but also to encompass tracrRNAs with modifications (e.g., truncations, sequence variations, base modifications, backbone modifications, linkage modifications, etc.) where the activator retains at least one function of a tracrRNA (e.g., contributes to the dsRNA duplex to which Cas9 protein

binds). In some cases, the activator provides one or more stem loops that can interact with Cas9 protein. An activator can be referred to as having a tracr sequence (tracrRNA sequence) and in some cases is a tracrRNA, but the term "activator" is not limited to naturally existing tracrRNAs.

[00359] The term "targeter" or "targeter RNA" is used herein to refer to a crRNA-like molecule (crRNA: "CRISPR RNA") of a dual guide RNA (and therefore of a single guide RNA when the "activator" and the "targeter" are linked together, e.g., by intervening nucleotides). Thus, for example, a guide RNA (dgRNA or sgRNA) comprises a targeting segment (which includes nucleotides that hybridize with (are complementary to) a target nucleic acid, and a duplex-forming segment (e.g., a duplex forming segment of a crRNA, which can also be referred to as a crRNA repeat). Because the sequence of a targeting segment (the segment that hybridizes with a target sequence of a target nucleic acid) of a targeter is modified by a user to hybridize with a desired target nucleic acid, the sequence of a targeter will often be a non-naturally occurring sequence. However, the duplex-forming segment of a targeter (described in more detail below), which hybridizes with the duplex-forming segment of an activator, can include a naturally existing sequence (e.g., can include the sequence of a duplex-forming segment of a naturally existing crRNA, which can also be referred to as a crRNA repeat). Thus, the term targeter is used herein to distinguish from naturally occurring crRNAs, despite the fact that part of a targeter (e.g., the duplex-forming segment) often includes a naturally occurring sequence from a crRNA. However, the term "targeter" encompasses naturally occurring crRNAs.

[00360] A guide RNA can also be said to include 3 parts: (i) a targeting sequence (a nucleotide sequence that hybridizes with a sequence of the target nucleic acid); (ii) an activator sequence (as described above)(in some cases, referred to as a tracr sequence); and (iii) a sequence that hybridizes to at least a portion of the activator sequence to form a double stranded duplex. A targeter has (i) and (iii); while an activator has (ii).

[00361] A guide RNA (e.g. a dual guide RNA or a single guide RNA) can be comprised of any corresponding activator and targeter pair. In some cases, the duplex forming segments can be swapped between the activator and the targeter. In other words, in some cases, the targeter includes a sequence of nucleotides from a duplex forming segment of a tracrRNA (which sequence would normally be part of an activator) while the activator includes a sequence of nucleotides from a duplex forming segment of a crRNA (which sequence would normally be part of a targeter).

[00362] As noted above, a targeter comprises both the targeting segment (single stranded) of the guide RNA and a stretch ("duplex-forming segment") of nucleotides that forms one half of the dsRNA duplex of the protein-binding segment of the guide RNA. A corresponding tracrRNA-like molecule (activator) comprises a stretch of nucleotides (a duplex-forming segment) that forms

the other half of the dsRNA duplex of the protein-binding segment of the guide RNA. In other words, a stretch of nucleotides of the targeter is complementary to and hybridizes with a stretch of nucleotides of the activator to form the dsRNA duplex of the protein-binding segment of a guide RNA. As such, each targeter can be said to have a corresponding activator (which has a region that hybridizes with the targeter). The targeter molecule additionally provides the targeting segment. Thus, a targeter and an activator (as a corresponding pair) hybridize to form a guide RNA. The particular sequence of a given naturally existing crRNA or tracrRNA molecule is characteristic of the species in which the RNA molecules are found. Examples of suitable activator and targeter are well known in the art.

Nucleic acid modifications

[00363] In some cases, a CRISPR-Cas guide RNA has one or more modifications, e.g., a base modification, a backbone modification, a sugar modification, etc., to provide the nucleic acid with a new or enhanced feature (e.g., improved stability).

[00364] Suitable nucleic acid modifications include, but are not limited to: 2'O-methyl modified nucleotides, 2' fluoro modified nucleotides, locked nucleic acid (LNA) modified nucleotides, peptide nucleic acid (PNA) modified nucleotides, nucleotides with phosphorothioate linkages, and a 5' cap (e.g., a 7-methylguanylate cap (m7G)).

[00365] Suitable modified nucleic acid backbones containing a phosphorus atom therein include, for example, phosphorothioates, chiral phosphorothioates, phosphorodithioates, phosphotriesters, aminoalkylphosphotriesters, methyl and other alkyl phosphonates including 3'-alkylene phosphonates, 5'-alkylene phosphonates and chiral phosphonates, phosphinates, phosphoramidates including 3'-amino phosphoramidate and aminoalkylphosphoramidates, phosphorodiamidates, thionophosphoramidates, thionoalkylphosphonates, thionoalkylphosphotriesters, selenophosphates and boranophosphates having normal 3'-5' linkages, 2'-5' linked analogs of these, and those having inverted polarity wherein one or more internucleotide linkages is a 3' to 3', 5' to 5' or 2' to 2' linkage. Suitable oligonucleotides having inverted polarity comprise a single 3' to 3' linkage at the 3'-most internucleotide linkage i.e. a single inverted nucleoside residue which may be a basic (the nucleobase is missing or has a hydroxyl group in place thereof). Various salts (such as, for example, potassium or sodium), mixed salts and free acid forms are also included.

[00366] In some cases, a CRISPR-Cas guide RNA has one or more nucleotides that are linked by a phosphorothioate bond (i.e., the subject nucleic acid has one or more phosphorothioate linkages). The phosphorothioate (PS) bond (i.e., a phosphorothioate linkage) substitutes a sulfur atom for a non-bridging oxygen in the phosphate backbone of a nucleic acid (e.g., an oligo). This modification renders the internucleotide linkage resistant to nuclease degradation.

Phosphorothioate bonds can be introduced between the last 3-5 nucleotides at the 5'- or 3'-end of the oligo to inhibit exonuclease degradation. Including phosphorothioate bonds within the oligo (e.g., throughout the entire oligo) can help reduce attack by endonucleases as well.

[00367] Also suitable are CRISPR-Cas guide RNAs having morpholino backbone structures as described in, e.g., U.S. Pat. No. 5,034,506. For example, in some embodiments, a CRISPR-Cas guide RNA comprises a 6-membered morpholino ring in place of a ribose ring. In some of these embodiments, a phosphorodiamidate or other non-phosphodiester internucleoside linkage replaces a phosphodiester linkage.

[00368] A CRISPR-Cas guide RNA can also include one or more substituted sugar moieties. Suitable polynucleotides comprise a sugar substituent group selected from: OH; F; O-, S-, or N-alkyl; O-, S-, or N-alkenyl; O-, S- or N-alkynyl; or O-alkyl-O-alkyl, wherein the alkyl, alkenyl and alkynyl may be substituted or unsubstituted C_1 to C_{10} alkyl or C_2 to C_{10} alkenyl and alkynyl. Particularly suitable are $O((CH_2)_nO)_mCH_3$, $O(CH_2)_nOCH_3$, $O(CH_2)_nNH_2$, $O(CH_2)_nCH_3$, $O(CH_2)_nONH_2$, and $O(CH_2)_nON((CH_2)_nCH_3)_2$, where n and m are from 1 to about 10. Other suitable polynucleotides comprise a sugar substituent group selected from: C_1 to C_{10} lower alkyl, substituted lower alkyl, alkenyl, alkynyl, alkaryl, aralkyl, O-alkaryl or O-aralkyl, SH, SCH_3, OCN, Cl, Br, CN, CF_3, OCF_3, $SOCH_3$, SO_2CH_3, ONO_2, NO_2, N_3, NH_2, heterocycloalkyl, heterocycloalkaryl, aminoalkylamino, polyalkylamino, substituted silyl, an RNA cleaving group, a reporter group, an intercalator, a group for improving the pharmacokinetic properties of an oligonucleotide, or a group for improving the pharmacodynamic properties of an oligonucleotide, and other substituents having similar properties. A suitable modification includes 2'-methoxyethoxy (2'-O-CH_2 CH_2OCH_3, also known as 2'-O-(2-methoxyethyl) or 2'-MOE) (Martin et al., Helv. Chim. Acta, 1995, 78, 486-504) i.e., an alkoxyalkoxy group. A further suitable modification includes 2'-dimethylaminooxyethoxy, i.e., a $O(CH_2)_2ON(CH_3)_2$ group, also known as 2'-DMAOE, as described in examples herein below, and 2'-dimethylaminoethoxyethoxy (also known in the art as 2'-O-dimethyl-amino-ethoxy-ethyl or 2'-DMAEOE), i.e., 2'-O-CH_2-O-CH_2-$N(CH_3)_2$.

METHODS OF COUPLING TWO PROTEINS VIA A COUPLING PROTEIN

[00369] The present disclosure provides methods for chemoselective coupling of a first polypeptide and a second polypeptide via a coupling polypeptide. The product of the chemoselective coupling can comprise, in order from N-terminus to C-terminus: i) the first polypeptide; ii) the coupling polypeptide; and iii) the second polypeptide. The method takes advantage of the substrate preferences of tyrosinase polypeptides, as described above.

[00370] For example, in some cases, the present disclosure provides a method for chemoselective coupling of a first polypeptide and a second polypeptide to a coupling polypeptide, the method

comprising: a) contacting the first polypeptide with the coupling polypeptide, to generate a first polypeptide-coupling polypeptide conjugate, where the first polypeptide comprises a thiol moiety (e.g., a Cys, where the Cys can be at any solvent-accessible position within the first polypeptide), where the coupling polypeptide comprises an N-terminal reactive moiety that forms a covalent bond with the thiol moiety present in the first polypeptide, where the coupling polypeptide comprising the N-terminal reactive moiety is generated by reaction of a polypeptide ("coupling precursor polypeptide") comprising an N-terminal phenol or catechol moiety and a C-terminal phenol or catechol moiety with a first enzyme capable of oxidizing the N-terminal phenol or catechol moiety, but not the C-terminal phenol or catechol moiety, to generate the N-terminal reactive moiety; and where the coupling polypeptide comprises two or more positively charged or neutral amino acids within ten amino acids of the N-terminal phenol or catechol moiety and two or more negatively charged amino acids within ten amino acids of the C-terminal phenol or catechol moiety; and b) contacting the second polypeptide with the first polypeptide-coupling polypeptide conjugate, where the second polypeptide comprises a thiol moiety (e.g. a Cys, where the Cys can be at any solvent-accessible position within the second polypeptide), where the first polypeptide-coupling polypeptide conjugate comprises a C-terminal reactive moiety that forms a covalent bond with the thiol moiety present in the second polypeptide, where the first polypeptide-coupling polypeptide conjugate comprising the C-terminal reactive moiety is generated by reaction of the first polypeptide-coupling polypeptide conjugate with a second enzyme capable of oxidizing the C-terminal phenol or catechol moiety to generate a C-terminal reactive moiety; and where said contacting generates a first polypeptide-coupling polypeptide-second polypeptide conjugate. In some cases, the first enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to the abTYR amino acid sequence depicted in FIG. 8 or FIG. 9; and the second enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to any one of the amino acid sequences depicted in any one of FIG. 10A-10Z and 10AA-10VV.

[00371] As another example, in some cases, the present disclosure provides a method for chemoselective coupling of a first polypeptide and a second polypeptide to a coupling polypeptide, the method comprising: a) contacting the first polypeptide with the coupling polypeptide, to generate a first polypeptide-coupling polypeptide conjugate, where the first polypeptide comprises a thiol moiety, where the coupling polypeptide comprises an N-terminal reactive moiety that forms a covalent bond with the thiol moiety present in the first polypeptide, where the coupling polypeptide comprising the N-terminal reactive moiety is generated by reaction of a polypeptide comprising an N-terminal phenol or catechol moiety and a C-terminal

phenol or catechol moiety with a first enzyme capable of oxidizing the N-terminal phenol or catechol moiety, but not the C-terminal phenol or catechol moiety, to generate the N-terminal reactive moiety; where the coupling polypeptide comprises two or more negatively charged amino acids within ten amino acids of the N-terminal phenol or catechol moiety and two or more positively charged or neutral amino acids within ten amino acids of the C-terminal phenol or catechol moiety; and b) contacting the second polypeptide with the first polypeptide-coupling polypeptide conjugate, where the second polypeptide comprises a thiol moiety, where the first polypeptide-coupling polypeptide conjugate comprises a C-terminal reactive moiety that forms a covalent bond with the thiol moiety present in the second polypeptide, where the first polypeptide-coupling polypeptide conjugate comprising the C-terminal reactive moiety is generated by reaction of the first polypeptide-coupling polypeptide conjugate with a second enzyme capable of oxidizing the C-terminal phenol or catechol moiety to generate a C-terminal reactive moiety; and where said contacting generates a first polypeptide-coupling polypeptide-second polypeptide conjugate. In some cases, the first enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to any one of the amino acid sequences depicted in any one of FIG. 10A-10Z and 10AA-10VV; and b) the second enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to the abTYR amino acid sequence depicted in FIG. 8 or FIG. 9.

[00372] The coupling polypeptide can have a length of from 10 amino acids to 100 amino acids, or more than 100 amino acids. In some cases, the coupling polypeptide has a length of from 10 amino acids to 25 amino acids. In some cases, the coupling polypeptide has a length of from 25 amino acids to 50 amino acids. In some cases, the coupling polypeptide has a length of from 50 amino acids to 100 amino acids. In some cases, the coupling polypeptide has a length of more than 100 amino acids; e.g., in some cases, the coupling polypeptide has a length of from 100 amino acids to 200 amino acids, from 200 amino acids to 500 amino acids, or more than 500 amino acids (e.g., 500 to 1000, 1000 to 2000, or more than 2000, amino acids). In some cases, the N-terminal phenol moiety and the C-terminal phenol moiety are both tyrosines, and the enzymes that generate the reactive moieties are tyrosinases.

[00373] As noted above, in some cases, the coupling polypeptide comprises: a) two or more negatively charged amino acids within ten amino acids of the N-terminal phenol or catechol moiety; or b) two or more negatively charged amino acids within ten amino acids of the C-terminal phenol or catechol moiety. In such cases, the coupling polypeptide can comprise: a) 2, 3, 4, 5, 6, 7, 8, 9, or 10 negatively charged amino acids within ten amino acids of the N-terminal phenol or catechol moiety; or b) 2, 3, 4, 5, 6, 7, 8, 9, or 10 negatively charged amino acids within

ten amino acids of the C-terminal phenol or catechol moiety. As one non-limiting example, the coupling polypeptide comprises the amino acid sequence: YEEEE$(X)_n$RRRRY (SEQ ID NO: 961), where X is any amino acid, and where n is an integer from 0 to 40 (e.g., where n is an integer from 0 to 5, from 5 to 10, from 10 to 15, from 15 to 20, from 20 to 25, from 25 to 30, from 30 to 35, or from 35 to 40). As another non-limiting example, the coupling polypeptide comprises the amino acid sequence: YDDDD$(X)_n$KKKKY (SEQ ID NO: 962), where X is any amino acid, and where n is an integer from 0 to 40 (e.g., where n is an integer from 0 to 5, from 5 to 10, from 10 to 15, from 15 to 20, from 20 to 25, from 25 to 30, from 30 to 35, or from 35 to 40).

[00374] As noted above, in some cases, the coupling polypeptide comprises: a) two or more positively charged amino acids within ten amino acids of the N-terminal phenol or catechol moiety; or b) two or more positively charged amino acids within ten amino acids of the C-terminal phenol or catechol moiety. In such cases, the coupling polypeptide can comprise: a) 2, 3, 4, 5, 6, 7, 8, 9, or 10 positively charged amino acids within ten amino acids of the N-terminal phenol or catechol moiety; or b) 2, 3, 4, 5, 6, 7, 8, 9, or 10 positively charged amino acids within ten amino acids of the C-terminal phenol or catechol moiety. As one non-limiting example, the coupling polypeptide comprises the amino acid sequence: YKKKK$(X)_n$DDDDY (SEQ ID NO: 963), where X is any amino acid, and where n is an integer from 0 to 40 (e.g., where n is an integer from 0 to 5, from 5 to 10, from 10 to 15, from 15 to 20, from 20 to 25, from 25 to 30, from 30 to 35, or from 35 to 40). As another non-limiting example, the coupling polypeptide comprises the amino acid sequence: YRRRR$(X)_n$EEEEY (SEQ ID NO: 964), where X is any amino acid, and where n is an integer from 0 to 40 (e.g., where n is an integer from 0 to 5, from 5 to 10, from 10 to 15, from 15 to 20, from 20 to 25, from 25 to 30, from 30 to 35, or from 35 to 40).

[00375] The present disclosure provides a coupling polypeptide, as described above. The present disclosure provides a composition comprising a coupling polypeptide of the present disclosure. The present disclosure provides a composition comprising: a) a coupling polypeptide of the present disclosure; and b) a buffer.

[00376] Suitable first and second polypeptides include any of the above-mentioned polypeptides. For example, in some cases, the first and/or the second polypeptide is an antibody (e.g., a single-chain antibody). As another example, in some cases, the first and/or the second polypeptide is a CRISPR/Cas effector polypeptide. As an example, in some cases, the first polypeptide is a CRISPR/Cas effector polypeptide; and the second polypeptide is an Ig Fc polypeptide. As another example, in some cases, the first polypeptide is a CRISPR/Cas effector polypeptide; and

the second polypeptide is a nanobody. As another example, in some cases, the first polypeptide is a CRISPR/Cas effector polypeptide; and the second polypeptide is a scFv polypeptide.

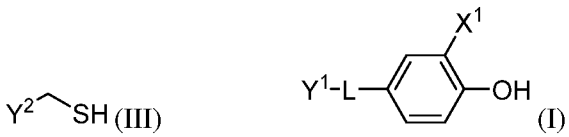
METHODS OF COUPLING TWO OR MORE POLYPEPTIDES

[00377] The present disclosure provides a method of coupling two or more polypeptides to one another in a sequential manner. The method takes advantage of the substrate preferences of tyrosinase polypeptides, as described above. The method can be carried out on an insoluble substrate, i.e., an immobilized surface, such as a bead. Methods of the present disclosure for coupling two or more polypeptides to one another in a sequential manner are depicted schematically in FIG. 39A-39G.

[00378] Thus, the present disclosure provides method of covalently linking a first polypeptide to a second polypeptide, the method comprising: a) contacting the first polypeptide with an immobilized reactive moiety, where the immobilized reactive moiety is generated by reaction of an immobilized phenol moiety or catechol moiety with a first enzyme, wherein the first enzyme is capable of oxidizing the immobilized phenol moiety or catechol moiety, thereby generating the immobilized reactive moiety, where the first polypeptide comprises: i) a thiol moiety; and ii) a phenol moiety or a catechol moiety, wherein the first polypeptide comprises two or more negatively charged amino acids within ten amino acids of the phenol moiety or the catechol moiety, and where the immobilized reactive moiety forms a covalent bond with the thiol moiety present in the first polypeptide, thereby generating an immobilized first polypeptide; b) contacting the immobilized first polypeptide with second enzyme, where the second enzyme is capable of oxidizing the phenol moiety or the catechol moiety present in the first polypeptide to generate an immobilized first polypeptide comprising a reactive moiety; and c) contacting the immobilized first polypeptide comprising a reactive moiety with a second polypeptide, where the second polypeptide comprises: i) a thiol moiety; and ii) a phenol moiety or a catechol moiety, where the second polypeptide comprises two or more neutral or positively charged within ten amino acids of the phenol moiety or the catechol moiety, where the reactive moiety present in the immobilized first polypeptide forms a covalent bond with the thiol moiety present in the second polypeptide, thereby generating an immobilized conjugate comprising the first polypeptide covalently linked to the second polypeptide. In some cases, the first enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to any one of the amino acid sequences depicted in any one of FIG. 8, FIG. 9, FIG. 10A-10Z, and 10AA-10VV. In some cases, the thiol moiety present in the first polypeptide is present in a Cys (e.g., a solvent-accessible Cys; e.g., an N-terminal Cys), and wherein the phenol moiety present in the first polypeptide is present in a Tyr residue. In some cases, the Tyr residue is present in a stretch of amino acids comprising EEEY (SEQ ID NO: 953), EEEEY

(SEQ ID NO: 955), DDDDY (SEQ ID NO: 965), or DDDDY (SEQ ID NO: 965). In some cases, the second enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to any one of the amino acid sequences depicted in any one of FIG. 10A-10Z and 10AA-10VV. In some cases, the second enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, at least 98%, at least 99%, or 100%, amino acid sequence identity to the amino acid sequence depicted in FIG. 10M, where the tyrosinase polypeptide comprises a substitution of D55 (e.g., comprises a D55K substitution).

[00379] The method can be used to link any number of polypeptides, in a sequential manner. For example, in some cases, the method further comprises c) contacting the immobilized conjugate with a third enzyme, wherein the third enzyme is capable of oxidizing the phenol moiety or the catechol moiety present in the second polypeptide to generate an immobilized conjugate comprising a reactive moiety; and d) contacting the immobilized conjugate comprising a reactive moiety with a third polypeptide, where the third polypeptide comprises: i) a thiol moiety; and ii) a phenol moiety or a catechol moiety, wherein the third polypeptide comprises two or more negatively charged within ten amino acids of the phenol moiety or the catechol moiety, and where the reactive moiety present in the immobilized conjugate forms a covalent bond with the thiol moiety present in the second polypeptide, thereby generating an immobilized conjugate comprising the third polypeptide covalently linked to the second polypeptide. In some cases, the third enzyme is a tyrosinase polypeptide comprising an amino acid sequence having at least 75% amino acid sequence identity to the amino acid sequence depicted in FIG. 8 or FIG. 9.



[00380] By alternating use of: a) a tyrosinase enzyme that preferentially modifies a Tyr residue that is present in a negatively charged environment (e.g., where the polypeptide comprises two or more negatively charged within ten amino acids of the Tyr residue); and b) a tyrosinase enzyme that preferentially modifies a Tyr residue that is present in a neutral or positively charged environment ((e.g., where the polypeptide comprises two or more neutral or positively charged within ten amino acids of the Tyr residue), a polypeptide substrate can be sequentially added to an immobilized conjugate comprising one, two, three, or more polypeptides. The method described above can be modified, e.g., such that the first polypeptide comprises: i) a thiol moiety; and ii) a phenol moiety or a catechol moiety, where the first polypeptide comprises two or more neutral or positively charged amino acids within ten amino acids of the phenol moiety or the catechol moiety; in such cases, the second polypeptide would then comprise: i) a thiol moiety; and ii) a phenol moiety or a catechol moiety, where the first polypeptide comprises two or more negatively charged amino acids within ten amino acids of the phenol moiety or the catechol moiety.

[00381] In some cases, the tyrosinase enzyme is inactivated or removed between any two steps of the method and before adding a further tyrosinase enzyme. For example, in some cases, between step (b) and step (c) of the method described above, the second enzyme is inactivated or removed. In some cases, the thiol moiety present in the second polypeptide is present in a Cys, and the phenol moiety present in the second polypeptide is present in a Tyr residue. In some cases, the Tyr residue is present in a stretch of amino acids comprising RRRY (SEQ ID NO: 949), RRRRY (SEQ ID NO: 951), KKKY (SEQ ID NO: 966), or KKKKY (SEQ ID NO: 967).

[00382] As depicted schematically in FIG. 39A, abTYR is used to link biotin-phenol and a first polypeptide ("Protein A") comprising a thiol group and an EEEEY (SEQ ID NO:955) sequence, to generate a biotin-first polypeptide conjugate. The biotin-first polypeptide conjugate can be contacted with streptavidin beads, to immobilize the biotin-first polypeptide conjugate. A second polypeptide ("Protein B") comprising a thiol group and an RRRRY (SEQ ID NO:951) sequence can be conjugated to the first polypeptide of the immobilized biotin-first polypeptide conjugate by action of bmTYR (D55K) (e.g., bmTYR (D55K) depicted in FIG. 10M), to generate an immobilized first polypeptide-second polypeptide conjugate. In some cases, two different polypeptides (e.g., "Protein A" and "Protein B") are alternately added to the concatemer, as depicted in FIG. 39A, FIG. 39B, and FIG. 39C. Alternatively, multiple copies of a single polypeptide are concatenated, as depicted in FIG. 39D and FIG. 39E. As yet another possibility, in some cases, each of the polypeptides that is concatenated is different from the other polypeptides, as depicted in FIG. 39F and FIG. 39G (e.g., "Protein A"; "Protein B"; and "Protein C").

METHODS OF SCREENING TYROSINASE VARIANTS

[00400] The present disclosure provides a method of identifying a tyrosinase variant that has a preference for a particular substrate. The method can provide for identification of a tyrosinase variant that has a preference for a phenol or a catechol that is present in a particular sequence, in a negatively-charged environment, or in a positively-charged environment. The method generally involves: a) contacting a peptide with a test tyrosinase and thiol-modified biotin (biotin-thiol), wherein the peptide has a length of from about 4 amino acids to about 25 amino acids (e.g., about 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15 to 20, or 20 to 25, amino acids) and where the peptide has a C-terminal Tyr residue, to generate a biotin-peptide conjugate; b) contacting the biotin-peptide conjugate with a streptavidin-conjugated bead (e.g., streptavidin conjugated to a magnetic bead), generating a streptavidin-biotin-peptide complex; and c) determine the amino acid sequence of the peptide in the streptavidin-biotin-peptide complex. In some cases, the method further comprises the step of washing the streptavidin-biotin-peptide complex to remove unbound peptides (peptides not conjugated to the biotin. In some cases, the method further comprises the step of releasing the peptide from the streptavidin-biotin-peptide complex before determining the amino acid sequence of the peptide. The peptide can be released (eluted) from streptavidin-biotin-peptide complex by incubating the streptavidin-biotin-peptide complex in a mixture comprising excess free biotin, acetonitrile, and formic acid (e.g., 80% acetonitrile, 5% formic acid, and 2 mM biotin). The amino acid sequence of the peptide present in the streptavidin-biotin-peptide complex (e.g., the eluted peptide) can be determined using any of a variety of well-known methods including, e.g., mass spectrometry (MS) (e.g., tandem MS). A library of peptides can be used to determine whether a test tyrosinase has a preference for a particular amino acid sequence, for a negatively charged environment, or for a positively charged environment.

Tyrosinase Coupling Reactions

[00656] MS2 conjugation was carried out on a cysteine mutant of the capsid which replaces the asparagine residue at position 87 with a cysteine (N87C). Coupling conditions were 20 mM pH 6.5 Phosphate, 10 uM N87C MS2, Tyrosinase purchased from Sigma-Aldrich (CAS number 9002-10-2), was diluted in 50 mM phosphate pH 6.5 was added at a 1:10 ratio to a final concentration of 0.16 μM. The coupling reagent unless otherwise noted was added to a final

concentration of 50 μM or 5x MS2 monomer concentration. Ultra Pure water (Milipore Sigma, 18 uohm resistance) was added to a final volume of 20 μL. Reactions were carried out for 30 minutes at room temperature before quenching with 2 uL 20 mM Tropolone and 20 mM TCEP, yielding a final concentration of 2mM for each.

[00657] For stability studies, loose tyrosinase was replaced with enzyme coupled to resin. Reactions were carried out as above with the addition of a filtration step through 0.2 um filters to remove excess tyrosinase as well as quenching with 1mM Tropolone and TCEP.

[00658] Cas9 coupling occurred under the following conditions: 20 mM Tris HCl, 300 mM KCl, 50 mM Trehalose pH 7.0 (Buffer A), 4°C 1 hr. 10 uM Cas9. All samples were quenched with using the quenching solution as above, then solvent exchanged into Buffer A three times using a 100,000 kDa MWCO spin concentrator. For peptide coupling, peptides were added at a 5x ratio, yielding 50 uM peptide concentration. In protein-protein coupling it was found that a 1:1 ratio of Cas9: target protein yielded near-quantitative conversion to the singly modified Cas9 after filtration, while a 1:5 ratio of Cas9: target yielded full conversion to the doubly modified product.

Example 2

[00670] A system that takes advantage of the charge limitations of abTYR, while employing a semi-orthogonal tyrosinase from the bacteria Bacillus *megaterium* (bmTYR) (Goldfeder et al. (2013) *Biochim. Biophys. Acta - Proteins Proteomics* 1834:629; Kanteev et al. (2013) *J. Biol. Inorg. Chem.* 18:895; Kanteev et al. (2015) *Protein Sci* 24:1360; Sendovski et al. (2010) *Acta Crystallogr. Sect. F Struct. Biol. Cryst. Commun.* 66:1101; Shuster Ben-Yosef et al. (2010) *Enzyme Microb. Technol.* 47:372; Shuster et al. (2009) *J. Mol. Microbiol. Biotechnol.* 17:188) was developed.

[00671] To explore the effects of substrate charge on abTYR, a library of fifteen 5-mer peptides was obtained, and a charge screen of abTYR was conducted by comparing the yields of the coupling reaction between the peptide library and both Y182C GFP and pAF MS2. These substrates were chosen as they represent a single thiol in the case of Y182C GFP and a single aniline in the case of pAF MS2, as well as both a positive and negatively charged protein substrate. Based on the data, it appears that abTYR is sensitive to both charge and steric hinderance around the tyrosine residue, with negative charge being a much more detrimental factor than steric bulk. In both cases, a -4 charge was enough to completely inhibit tyrosinase activity on peptide (FIG. 11).

[00672] In order to explore the potential reasons behind abTYR's charge preferences, the protein's crystal structure was examined and it was noted that abTYR has a large overall negative charge around its active site, due to the abundance of glutamate and aspartate residues. It was hypothesized that these "gatekeeper" residues are what is causing the charge preferences of abTYR (FIG. 12 A).

[00673] Expressing eukaryotic enzymes in bacteria is nontrivial; in addition, abTYR is hetero-tetrameric which adds further complexity to its expression. A monomeric bacterial tyrosinase with a published crystal structure was identified. The tyrosinase from *Bacillus megaterium* (bmTYR) (Goldfeder et al. (2013) *supra*; Kanteev et al. (2013) *supra*; Kanteev et al. (2015) *supra*; Sendovski et al. (2010) *supra*; Shuster Ben-Yosef et al. (2010) *supra*; Shuster et al. (2009) *supra*) was studied. bmTYR has a positively charged active site, which confirmed by the crystal structure (FIG. 12B). bmTYR was expressed in *E. coli* and initial trials of the peptide charge screen were carried out. The data indicated that bmTYR can accept negatively charged substrates (FIG. 13, 14). Additionally, bmTYR is inhibited by tropolone similarly to abTYR. Expressing bmTYR mutants in order to increase catalytic activity can be carried out. Based on

the literature the mutations: F197A, R209H, V218G, and V218F (Kanteev et al. (2015) *supra*; Sendovski et al. (2010) *supra*; Shuster Ben Yosef et al. (2010) *supra*; Shuster Ben-Yosef (2010) *supra*) give rise to some varied and beneficial properties including better retention of copper molecules, greater selectivity for phenolic targets, and both increased and decreased sensitivity to steric bulk. Additionally, bmTYR with the mutations D55K and E141K can be used, which should give rise to a tyrosinase which acts only on negatively charged substrates. These residues, D55 and E141 are located adjacent to the active site and are highlighted in red (FIG. 12 B).

Example 3

Results

[00674] In the course of initial studies on abTYR-mediated oxidative coupling of phenol-functionalized cargo, it was asked whether the N-terminal tyrosine residue on the α-endorphin peptide (FIG. 16 a) would be sterically accessible enough to reach into the abTYR active site. This reaction with p-Aminophenylalanine (pAF) MS2 viral capsid coupling partner was tested. Clean, near-quantitative conversion to the functionalized viral capsid was observed (FIG. 16 b). Acetylation of the α-endorphin N-terminus was essential to the success of the reaction, since the free N-terminus would readily attack the proximal *o*-quinone, as it does upon the oxidation of the free L-Tyrosine amino acid during melanin biosynthesis (Ramsden et al. (2014) *Bioorganic Med. Chem.* 22:2388).

[00675] To test the reaction on a challenging protein substrate, a GGY tag was chosen to be appended to the single chain variable fragment (scFv) of the Trastuzumab antibody. Trastuzumab is an FDA approved monoclonal antibody for the treatment of $HER2^+$ breast cancer (Plosker et al. (2006) *Drugs* 66:449) and is widely used as a model construct for testing bioconjugation reactions (Chen et al. (2016) *Sci. rep.* 6:1; Zhang et al. (2015) *Nat. Chem.* 8:120; Ban et al. (2013) *Bioconjug. Chem.* 24:520; Bruins et al. (2017) *Bioconjug. Chem.* 28:1189). Trastuzumab is also commonly used in single chain variable fragment (scFv) format, which is of interest because of its improved tissue and tumor penetration relative to full length antibodies (Yokota et al. (1992) *Cancer Res.* 52:3402; Batra et al. (2002) 13:603) as well as its potential to be used for constructing bispecific antibodies(Brinkmann et al. (2017) *MAbs* 9:182). An established *E. coli* periplasmic expression protocol was chosen to produce the Trastuzumab scFv with a C-terminal -GGY tag (Rouet et al. (2012) *Nat. Protoc.* 7:364). One potential challenge presented by this substrate is that, of its 15 tyrosine residues, 8 are located on the antigen binding site with their phenol side chains oriented toward the bulk solution. Despite the potential for off target oxidation of the internal tyrosine residues, it was observed that the C-terminally -GGY tagged version of the scFv was near-quantitatively coupled to a model Aniline nucleophile (FIG. 16) while a non-tagged version is virtually untouched under the reaction conditions (FIG. 23).

[00676] The exceptionally clean conversion of this substrate led to the use of it as a model for testing several parameters of the reaction. While conducting these investigations, abTYR concentrations were measured in units of U/mL, as equal masses of different batches of abTYR were found vary somewhat in their enzymatic activity (e.g. 1 mg/mL tyrosinase stock solutions typically had activities of between 900 and 1200 U/mL, corresponding to 150 to 200 nM of enzyme in a typical 12 U/mL reaction).Varying the concentration of Aniline from 25 μM to 750 μM showed that maximum conversion was achieved at a concentration of 150 μM (FIG. 16 b) with at least 8 U/mL abTYR. However, at lower abTYR concentrations, higher concentrations of Aniline appeared to inhibit tyrosinase, as evidenced by residual un-oxidized starting material in these reactions (FIG. 24). To reduce inhibition of abTYR by the nucleophilic coupling partner, the concentration screen was repeated with o-Toluidine and 2,6-Dimethylaniline (FIG. 26, FIG. 17), which was hypothesized to not occlude the tyrosinase active site as readily. However, these nucleophiles provided lower conversion than Aniline at every concentration tested.

[00677] The fact that residual un-coupled protein was fully oxidized by TOF-LCMS in reactions with at least 8 U/mL tyrosinase suggests that the coupling partner has a limited time to intercept the *o*-quinone intermediate before it is quenched by a competing process. A late nucleophile addition experiment, in which Aniline was added to the a series of scFv-GGY OC reactions 5, 10, 20, 40, or 60 min after Tyrosinase, showed that while the starting protein is completely oxidized in every case, the amount of product formed depends upon how soon after the start of the reaction the coupling partner is added (FIG. 25).

[00678] Given the importance of the rate at which the nucleophile reacts with the *o*-quinone intermediate, what the optimal coupling partner might be between the 4-aminophenyl group and its cargo was investigated. 4-Aminophenyl-*N*-methylamide, *p*-Anisidine, and *p*-Toluidine were used as model compounds to probe the best means of attaching 4-Aminophenols to other substrates. 4-Aminophenyl-*N*-methylamide provided the cleanest reactions while *p*-Anisidine and *p*-Toluidine provided poor results. **p*-Anisidine reaction turned orange, indicating oxidation of the nucleophile and secondary modification of the protein. Finally, the coupling efficiencies of various piperazines and a racemic N-methyl pyrrolidine were assessed. These proved to be inferior nucleophiles as much higher micromolar and millimolar concentrations were required to achieve good conversions (FIG. 16 c; FIG. 27). N-methyl-pyrrolidine – a model for a proline N-terminus – provided the best conversion in this category of nucleophiles.

[00679] To demonstrate that the abTYR-mediated modification of the -GGY tagged Trastuzumab scFv did not perturb the binding activity of this construct, the fluorescent dye Oregon Green (O.G.) 488 was derivatized with an Aniline nucleophile and oxidatively coupled onto the scFv. The reaction proceeded optimally with 25 μM Aniline-O.G. 488 with 12 U/mL

abTYR to give the scFv-GGY-An-O.G. 488 construct with 85% conversion. Flow cytometry showed that this construct could recognize the HER2+ SK-BR-3 breast cancer cell line selectively over HER2- MDA-MB-468 breast cancer cells (FIG. 22 d).

[00680] The product structure of the oxidative coupling reaction between p-aminophenylalanine and *o*-methoxyphenols and *o*-aminophenols mediated by sodium periodate and potassium ferricyanide (Obermeyer et al. (2014) *Angew. Chemie – Int. Ed.* 53:1057; Elsohly et al. (2017) *J. Am. Chem. Soc.* 139:3767) has been characterized previously and the product masses observed in the tyrosinase-mediated coupling are consistent with the expected structure. Nonetheless,the coupling product by NMR was characterized to confirm the equivalence of the reactions. A small-molecule model reaction was performed between *N*-Acetyl-L-Tyrosine and *p*-Toluidine in D_2O with abTYR. The reaction required more tyrosinase and an extended reaction time to proceed in D_2O and turned dark purple. Direct NMR observation of the reaction mixture revealed a single primary product consistent with that shown in the figures.

[00681] The stability of the aniline conjugate to the Tyr-tagged scFv was monitored at 4 °C over the course of 7 days in a standard phosphate and NaCl protein storage buffer with 15% glycerol (pH 7.4) and the linkage was found to be intact (FIG. 30). Addition of 10 mM dithiothreitol (FIG. 29) or glutathione (FIG. 31) resulted in the formation of thiol adducts. In the case of glutathione, this further modification occurred quantitatively within 24 hours. FIG. 32 shows sequential treatment of the aniline-coupled scFv with Glutathione then DTT. Despite this additional modification, in both cases the aniline linkage remained intact.

[00682] The methodology was also tested on diverse protein substrates by expressing several full-length proteins with tyrosine tags at the N or C termini.

[00683] Protein-L is an IgG binding protein that recognizes variable regions of human kappa light chains. Discovered in pathogenic *Peptostreptococcus magnus*, it consists of five binding domains (Donaldson et al. (2013) *Proc. Natl. Acad. Sci. U.S.A.* 110:17456) connected in tandem by short 9-10 amino acid linkers (Kastern et al. (1992) *J. Biol. Chem.* 267:12820) (FIG. 20 a). The avidity of the combined interactions of these five domains allows the protein to achieve a K_d of 130 nM at pH 8 (Beckingham et al. (1999) *Biochem. J.* 340:193). When expressed recombinantly, cell-wall anchoring domains of the wild type protein are typically omitted, and some truncated versions have only 3 or 4 light chain binding domains. Protein-L is routinely used for the purification of scFv's (Song et al. (2015) *Protein Expr. Purif.* 116:98) and has been employed as a universal flow cytometry marker for cells expressing Chimeric Antigen Receptors (CARs) (Zheng et al. (2012) *J. Transl. Med.* 10:1) which typically utilize scFv's to recognize their targets. Because Protein-L binds to variable light chains without interfering with the antigen

recognition loops, it can be used as a "secondary" detection reagent for bound scFv's as well as IgG's.

[00684] Protein-L was expressed in *E. coli* with pendent -GGY and -GGGGSGGY (SEQ ID NO: 968) tags for abTYR-mediated modification with aniline-functionalized O.G. 488 to create a secondary scFv detection reagent. However, these constructs were resistant to oxidation by abTYR, most likely because the terminal tyrosine residue does not extend far enough away from the bulk of the protein structure to reach into the sterically occluded abTYR active site. The same problem was encountered when short, -GGY and -SSGGGGY (SEQ ID NO: 948) tags were appended to the C-terminus of Maltose Binding Protein (MBP). In order to circumvent this problem, a collection of Protein-L variants with C-terminal linkers of various types and lengths preceding the tyrosine tag was generated (FIG. 20 b, FIG. 28). In addition to the flexible $(G_4S)_{1-3}$ linkers, Protein-L was extended with an alpha-helical $(EAAAK)_2$ (SEQ ID NO: 969) repeat sequence (Arai et al. (2001) *Protein Eng.* 14:529), a non-hydrogen bonding, rigid $(AP)_3$ repeat (Chen et al. (2013) *Adv. Drug Deliv. Rev.* 65:1357), a poly asparagine (N_{20}) sequence, and the C-terminal sequence of the easily-modified Trastuzumab scFv (EIKRTGGY) (SEQ ID NO: 970). Additionally, the C-terminal 5th light chain binding domain was deleted and the native linker between the 4th and 5th light chain binding domains was extended with -GGY and -G_4SGGY (SEQ ID NO: 968) tags. Disappointingly, none of these variants could be oxidized by abTYR.

[00685] It was recognized that the steric bulk of the 120 kDa tyrosinase protein will likely make access to the active site difficult on many protein substrates. While in principle, it should be possible to generate an abTYR-oxidizable variant by continuing to extend the C-terminal linker, longer linkers increase the risk of the tag interfering with protein function, and are more difficult to install by PCR, reducing the convenience of the tyrosine tagging approach. Therefore, there was motivation to express and test the much smaller *Bacillus megaterium* Tyrosinase (bmTYR). This 35.5 kDa protein is robustly expressed in BL21 (DE3) *E. coli* with a yield of up to 200 mg/L and has a much more sterically exposed active site in comparison to abTYR. Gratifyingly, all tyrosine-tagged Protein-L variants exposed to bmTYR were quantitatively oxidized and reacted with 150 μM aniline with over 90% conversion while the non-tagged variant was untouched (FIG. 20 b, FIG. 28). Tyrosine-tagged MBP variants were successfully oxidized by bmTYR as well, though in this case, the reaction took more than 1 hour to reach high conversion.

[00686] With a solution to Protein-L modification in hand, the bmTYR mediated OC was performed with 25 μM of the Aniline-O.G. 488 nucleophile on the -AN_{20}GGY tagged Protein-L variant. The desired conjugate was obtained with 87% conversion (FIG. 22 c). This construct was then applied to HER2+ (SK-BR-3) or HER2- (MDA-MB-468) breast cancer cells which had

been pre-treated with the non-tyrosine tagged Trastuzumab scFv. Only the Protein-L construct that had been modified with Aniline-O.G. 488 under the bmTYR-mediated OC conditions was able to label HER2+ cells after exposure to the scFv (FIG. 22 d). Cells without HER2 or samples with a component omitted from the coupling and labeling workflow were untagged.

Materials and Methods

Reagents

[00687] All chemicals were ordered from Sigma Aldrich or ThermoFisher Scientific and used as received unless noted otherwise. Milli-Q H_2O was used.

[00688] *Agaricus bisporus* Tyrosinase ("Tyrosinase from Mushroom") was obtained from Sigma Aldrich as a lyophilized powder and stored at -20 °C when received. 1 mg/mL stock solutions were prepared in 50 mM phosphate buffer, in 15% glycerol in water, pH 6.5, stored at -80 °C. Aliquots were thawed on ice shortly before use and the activity of each new stock was assayed. A stability study has indicated that the activity of abTYR aliquots stored in this manner changes very little over months of storage at -80 °C.

Protein Constructs

[00689] Protein gene blocks were ordered from Integrated DNA Technologies, codon-optimized for *E. coli* expression. Bsa1 cut sites were present at either end of the gene sequence for cloning into the pET28b golden gate entry vector. This vector enabled green / white screening for colonies successfully transformed with plasmids bearing the inserted gene.

Representative Tyrosinase-mediated oxidative coupling reaction for subsequent TOF-LCMS analysis

[00690] Volumes of each stock solution were added to an Eppendorf tube with the tyrosinase enzyme added last. The resulting solution was allowed to stand at room temperature for 60 minutes before adding 5.0 µL of a 21 mM aqueous solution of tropolone. The quenched reaction was subject to four cycles of spin desalting in a 10 kDa MWCO 500 µL amicon ultra centrifugal filter, diluting with 400 µL of Milli-Q H_2O before each cycle to remove aniline, and phosphate buffer. The resulting 35-50 µL droplet was passed through a 0.22 µm cellulose acetate centrifugal filter and submitted to TOF-LCMS analysis.

Cytosolic expression of recombinant proteins – Liter Scale

[00691] A 10 mL overnight culture of BL21 (DE3) Star *E. coli* in TB medium with 50 µg/mL kanamycin was inoculated into a 2.8 L trident Erlenmeyer flask with 1 L of sterile Terrific Broth medium and kanamycin. The cultures were grown at 37 °C with 220 rpm shaking until O.D. at 600 nm reached 0.6 – 0.8. To induce expression, IPTG was added from a 1.0 M stock to a final concentration of 1.0 mM. The cultures were incubated at the temperature, time, and shaking

speed given in the table above. The culture was pelleted via centrifugation (3,200 g, 15 min, 4 °C) and the supernatant was discarded. All steps from this point were performed with cold (4 °C) buffers and on ice. Each pellet was re-suspended in 45 mL of D.I. H_2O then pelleted in 50 mL falcon tubes (3,200 g, 15 min, 4 °C). The supernatant was poured off and the pellets were either stored at -80 °C or lysed immediately.

[00692] Each cell pellet (from 0.5 L culture) was re-suspended in 25 mL of lysis buffer (PBS, 20 mM imidazole, pH 7.4 with 0.1 mM Phenylmethylsulfonyl fluoride, 0.05 U/mL benzynase, and 0.5 mg/mL chicken egg white lysozyme). The cells were incubated on ice for at least 30 minutes then lysed by 10 min of sonication (2 sec on, 3 sec off pulses at 60% amplitude). The resulting suspension was centrifuged (14,000 g, 30 min, 4 °C) and the supernatant was passed through a 0.2 μm syringe filter. The crude lysate was subject to NiNTA purification using a G.E. Healthcare HisTrap HP 5mL affinity column equilibrated with Buffer A (PBS with 20 mM imidazole, pH 7.4). The protein was eluted using a gradient of 0-100% Buffer B (PBS with 400 mM imidazole, pH 7.4) over 20 column volumes. Product containing fractions were identified using SDS-PAGE and submitted to further purification as needed. Purified protein was exchanged into protein storage buffer (PBS with 15% glycerol) via 4 rounds of spin concentration in 10 kDa MWCO, 15 mL amicon ultra centrifugal filters, diluting with storage buffer before each spin.

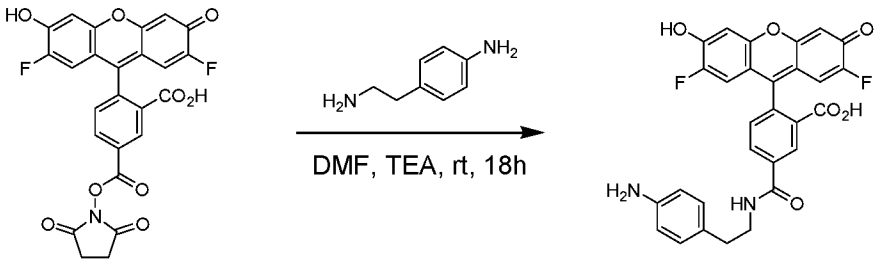
Cytosolic Expression of Recombinant Proteins – 10-50 mL Scale

[00693] Expression and cell pellet processing were carried out as above.

[00694] Pellets were re-suspended in 1.0 mL of lysis buffer and sonicated for 45 sec (5 sec on, 5 sec off pulses at 50% amplitude). Lysates were centrifuged for 10 min at 16,100 g. Supernatant was retained and solids were discarded. For each lysate, 10 μL of HisPur NiNTA resin (Thermo Scientific Products #88221; capacity of 60 mg His_6-protein per mL suspended resin) per mL of cell culture was equilibrated with binding buffer (PBS, 20 mM Imidazole, pH 7.4). The resin was then suspended in the cell lysate and incubated at 4 °C for 1 hour. After binding, resin aliquots were washed 2x with binding buffer, then bound proteins were released with elution buffer (PBS, 80 mM Imidazole, pH 7.4). The purity of eluted proteins was assessed with SDS-PAGE and TOF-LCMS. Proteins were exchanged into protein storage buffer (20 mM Na_2HPO_4, 150 mM NaCl, in 15% glycerol, pH 7.4) via 4 cycles of centrifugation (14,000 g, 20 min, 4 °C) in 10 kDa MWCO 500 μL amicon ultra spin desalting filters, diluting to 500 μL with protein storage buffer before each cycle.

Maltose Binding Protein (MBP)

[00695] After NiNTA purification, MBP-containing fractions were combined, concentrated to 20 mL in 10 kDa MWCO, 15 mL amicon ultra centrifugal filters then dialyzed into anion exchange Buffer A (25 mM TRIS-HCl, 20 mM NaCl, pH 7.9), then loaded onto a G.E. Healthcare HiTrap Q HP 5 mL column and eluted with a gradient of 0-100% Buffer B (25 mM TRIS-HCl, 500 mM NaCl, pH 7.9) over 20 column volumes.



Periplasmic expression and purification of Trastuzumab scFv

[00696] The following procedure was adapted from a protocol by Rouet et al. (2012), *supra*. Two finless 4 L Erlenmeyer flasks containing 1 L of sterile Terrific Broth medium with 50 μg/mL kanamycin each, were inoculated with 10 mL overnight TB medium cultures of BL21 (DE3) Star *E. coli* cells bearing the PelB – Trastuzumab scFv – GGY or wild type C-terminus gene construct in pET28b. The cultures were grown at 37 °C with 220 rpm shaking until O.D. at 600 nm reached 0.6 – 0.8. To induce expression, IPTG was added from a 1.0 M stock to a final concentration of 0.4 mM. The cultures were then incubated at 28 °C with 200 rpm shaking. After 4 hours, each 1 L culture was divided into two centrifuge bottles and pelleted by centrifugation (3,200 g, 15 min, 4 °C) and the supernatant was discarded. All steps from this point were performed with cold (4 °C) buffers and on ice. Each pellet (from 0.5 L culture) was re-suspended in 25 mL of periplasmic extraction buffer 1 (20% w/v sucrose, 100 mM TRIS-HCl, 1.0 mM EDTA, pH 8.0) and incubated for 30 min. The cells were pelleted by centrifugation (10,000 g, 10 min, 4 °C) using a fixed-angle rotor, and the supernatant was poured off and saved as "periplasmic extract 1". The pellets were each re-suspended in 25 mL of periplasmic extraction buffer 2 (5.0 mM $MgCl_2$) and incubated on ice for 30 min. The cells were again pelleted by centrifugation (10,000 g, 10 min, 4 °C) and the supernatant was poured off and saved as "periplasmic extract 2". The periplasmic extracts were both found to contain scFv by SDS-PAGE. The extracts were combined, concentrated to 50 mL via multiple rounds of centrifugation in 10 kDa MWCO amicon ultra centrifugal filters (4000 g, 20 min, 4 °C), then passed through 0.22 μm PES syringe filters. The periplasmic extracts were transferred to 3500 Da MWCO dialysis cassettes and incubated in 4 L of PBS overnight with gentle stirring.

[00697] A 5 mL G.E. Healthcare Capto L (resin-bound Protein L) affinity column was equilibrated with Buffer A (50 mM citrate, 400 mM NaCl, pH 6.0). The dialyzed periplasmic extracts were again passed through a 0.22 μm PES syringe filter, loaded onto the Capto L column, and eluted with a gradient of 0-100% Buffer B (50 mM citrate, pH 2.5) over 22 column volumes. Fraction collection tubes were pre-filled with 1.0 mL of 1.0 M TRIS HCl buffer at pH

8.0 to neutralize elution buffer. scFv typically eluted at 100% buffer B and was pure by TOF-LCMS. 0.8 mg to 1.2 mg per liter of expression media was obtained.

Synthesis

Oregon Green 488 carboxylic acid, Succinimidyl ester, 5-isomer

X

[00698] 5.0 mg (9.8 µmole) of Oregon Green™ 488 carboxylic acid, succinimidyl ester, 5-isomer from ThermoFisher Scientific was dissolved in 200 µL of DMF. 29.1 µL of a solution of 45 µg/µL 4-(2-aminoethyl)aniline (1.34 mg, 9.8 µmol) in DMF and 52.8 µL of a solution of 60 µg/µL TEA (3.17 mg, 31.3 µmol) in DMF were added. The resulting bright red-orange solution was shielded from light, and allowed to stir at room temp for 18 hours. The reaction mixture was purified via semipreparatory HPLC using a gradient of 50-60% solvent B (ACN) in solvent A (Milli-Q H_2O) over 8 minutes. Product-containing fractions (green) were combined, partially concentrated via rotary evaporation to remove ACN, frozen at -80 °C, and lyophilized while shielded from light. 2.418 mg (46%) of an orange powder was obtained. The product was dissolved to a stock concentration of 750 µM in 20% ACN in H_2O and used in coupling reactions without further characterization.

Cell Preparation for scFv binding:

[00699] T-25 flasks with MDA-MB-468 ($Her2^-$) cells or SK-BR-3 ($Her2^+$) cells were obtained from the Berkeley Cell Culture Facility and grown to 90-100% confluency in a 37 °C incubator with 5% CO_2. In preparation for analysis, growth medium was removed and adherent cells were rinsed with D-PBS. Cells were detached by treatment with 0.25% Trypsin for 10-15 min at 37 °C. Trypsin digestions were halted by the addition of Cell Binding Buffer (DPBS supplemented with 10% Fetal Bovine Serum (FBS) and 1.0% w/v NaN_3 to prevent the internalization of cell surface markers) to a total volume of 13-15 mL. Cells were added to 15 mL falcon tubes and subject to two cycles of centrifugation (300 g, 5 min, room temp.), removing the supernatant after each cycle and diluting with 14 mL of Binding Buffer before the second cycle. Cells were re-suspended in 1.0 mL of Cell Binding Buffer, and counted with a BioRad TC20 automated cell counter. Live cell counts were > 95% as indicated by trypan blue staining. The cell

concentrations were adjusted to 2.0 x 10^6 cells/mL with additional Binding Buffer. 100 µL aliquots of the cell suspensions were transferred to Eppendorf tubes and placed on ice.

Binding of scFv-O.G. 488 Conjugate and negative controls

[00700] To each 100µL cell aliquot was added 31.3 µL of 0.048 µg/µL Trastuzumab scFv construct (either -GGY tagged or un-tagged and subject to abTYR-mediated O.C. conditions with or without O.G.-488 or abTYR) so that 1.5 µg of scFv was added to each sample. Samples were incubated on ice for 1 hour in the dark. Samples were then subject to 3 cycles of centrifugation (300 g, 3 min), re-suspending cells in 1000 µL of Cell Binding Buffer before each cycle and discarding supernatant after each cycle. After centrifugation, cell pellets were re-suspended in 1000 µL of DPBS with 0.5% paraformaldehyde and kept on ice for 1-3 hours until ready for flow cytometry analysis.

Binding of Protein-L-AN_{20}GGY-O.G. 488 conjugate to Trastuzumab scFv-treated cells

To each 100µL cell aliquot was added 2.0 µL of 1.5 µg/µL un-tagged Trastuzumab scFv. Samples were incubated on ice for 1 hour, protected from light. Samples were then subject to 2 cycles of centrifugation (300 g, 3 min), re-suspending cells in 1000 µL of Cell Binding Buffer before each cycle and discarding supernatant after each cycle. Cell pellets were re-suspended in 100 µL of Cell Binding Buffer and 60 µL of 0.045 µg/µL Protein-L-AN_{20}GGY-O.G. 488 conjugate or negative control construct was added for a total of 2.7 µg of Protein L construct per sample. Samples were incubated on ice in the dark for 1 hour. Samples were then subject to 3 cycles of centrifugation (300 g, 3 min), re-suspending cells in 1000 µL of Cell Binding Buffer before each cycle and discarding supernatant after each cycle. After centrifugation, cell pellets were re-suspended in 1000 µL of DPBS with 0.5% paraformaldehyde and kept on ice for 1-3 hours until ready for flow cytometry analysis.

Example 4

[00701] Here it is shown that the D55K mutant of bmTYR (amino acid sequence set forth in FIG. 10M) is able to efficiently couple DNA labeled with a phenol to cysteine-containing proteins. In this experiment, oligonucleotides bearing a C6-Amine linker (purchased from Integrated DNA Technologies) were modified with a phenol by incubating with a 10x molar excess of NHS-Phenol at pH 8.0 for 2 hours at RT and purified by ion exchange. The reaction conditions were as follows: i) 50 µM GFP; 157 nM abTYR (or equivalent activity of bmTYR or D55K bmTYR); ii) 250 µM DNA-phenol; iii) 10 mM phosphate, pH 6.5. The reaction was allowed to proceed for 30 minutes at room temperature (RT). GFP: 27.550 kDa; DNA: ~ 8 kDa.

[00702] The data are depicted in **FIG. 35**. The appearance of the large dark band above the GFP indicates that DNA coupling was successful using either bmTYR or D55K bmTYR, but not abTYR.

[00703] This reaction can be carried out in the opposite orientation, i.e., by combining a protein with an N-terminal or C-terminal tyrosine tag and an oligonucleotide with a thiol modification, still yielding the protein-nucleotide conjugate.

Example 5

[00704] **FIG. 36A-36C** depict coupling of nucleic acids to polypeptides using methods of the present disclosure.

[00705] As depicted in FIG. 36A, NHS phenol is coupled to an amine terminal nucleotide of a nucleic acid, to generate a phenol-containing nucleic acid (nucleic acid-phenol). As depicted in FIG. 36C, the nucleic acid-phenol is then coupled to a thiol containing protein (e.g., using a tyrosinase with a D55K substitution (e.g., a TYR polypeptide as depicted in FIG. 10M)), generating a nucleic acid-protein conjugate. As depicted in FIG. 36B, the abTYR (FIG. 8; FIG. 9) does not catalyze the reaction.

[00706] A restriction endonuclease can be included in the nucleotide sequence of the nucleic acid, providing for the ability to selectively cleave the nucleic acid from the protein of the nucleic acid-protein conjugate.

Example 6: Charge preference of TYR mutants

[00707] In these experiments 50 μM Y182C GFP was combined with 200 μM of EEEEY (SEQ ID NO: 955), RRRRY (SEQ ID NO: 951), or both with an equivalent activity to 200 nm abTYR of the relevant tyrosinase. Reactions proceeded for 30 min at RT before quenching with tropolone and analysis by ESI-TOF MS. The data are shown in **FIG. 37A-37C**.

[00708] FIG. 37A-37C show the impact of various mutations to bmTYR on its preference for charged substrates. As shown in FIG. 37C, wild type bmTYR (amino acid sequence provided in FIG. 10A) has a slight preference for the negatively charged substrate EEEEY (SEQ ID NO: 955) (product mass 28260). As shown in FIG. 37B, the R209H mutant (amino acid sequence provided in FIG. 10C) shows more activity for the cationic RRRRY (SEQ ID NO: 951) substrate (product mass 28369). As shown in FIG. 37A, the D55K mutant (amino acid sequence provided in FIG. 10M) shows virtually no activity towards the cationic RRRRY (SEQ ID NO: 951) substrate.

[00709] As shown in FIG. 38, the abTYR shows no ability to activate the negatively charged EEEEY (SEQ ID NO: 955) substrate (expected mass for the product= 28260), leaving only the starting material at mass = 27548.

Example 7: Biotin as a linker/ marker

[00710] To analyze the stability of the tyrosine-thiol bond, 200 μM Biotin-PEG_4-Phenol was combined with 50 μM Y182C GFP and 200 nM abTYR for 1 hour at RT. In a comparative reaction, 500 μM Biotin-Maleimide was separately incubated with 50 μM Y182C GFP for 2 hrs at RT before buffer exchange to remove excess maleimide. This produced Tyrosine-GFP-biotin and Maleimide-GFP-biotin, which were then incubated in human serum (from Sigma Aldrich) or buffer. After incubation, samples were combined with 25 μL streptavidin magnetic beads (from New England Biolabs) for 1 hour at RT. After 3 rounds of washing samples were eluted from the beads by incubating with a mixture of 80% acetonitrile, 5% formic acid, and 2 mM biotin for 10 min at RT. Samples were then analyzed on an Agilent 6224 ESI-TOF mass spectrometer and the relative masses were quantified.

[00711] The data are shown in **FIG. 40A-40C**. Tyrosine-GFP-biotin (BT) and Maleimide-GFP-biotin (BM) were incubated in human serum for 1 day (FIG. 40A), 2 days (FIG. 40B), or 7 days (FIG. 40C), at either room temperature (RT) or at 37°C ("37"). As shown in FIG. 40A and FIG. 40B, both Tyrosine-GFP-biotin and Maleimide-GFP-biotin were still present. However, as shown in FIG. 40C, after 7 days, Maleimide-GFP-biotin (BM) conjugates were no longer detected, while Tyrosine-GFP-biotin levels remained high, even with incubation at 37°C. These results indicate that the thiol-phenol coupling generated using tyrosinase is stable in human serum and is more stable than the maleimide coupling.

Example 8: Coupling Ig Fc proteins or a nanobody to a CRISPR/Cas effector polypeptide

[00712] An immunoglobulin (Ig) Fc and a nanobody were separately conjugated to a Cas9 protein using a method of the present disclosure. 10 μM Cas9 and 20 μM Fc domain were combined with 200 nM abTYR for 1 hour, on ice, in 20 mM Phosphate, 200 mM Trehalose, and 300 mM NaCl at pH 6.5. 10 μM Cas9 was combined with 20 μM nanobody in the trehalose buffer for 1 hour. Conjugates were analyzed on a gel, either alone or complexed with a guide RNA. The data are shown in **FIG. 41**.

[00713] Lanes 2, 3, 4, and 6 are unconjugated Ig Fc (comprising an NNNY (SEQ ID NO: 1059) sequence), unconjugated Ig Fc (comprising a GGYNNN (SEQ ID NO: 1060) sequence), nanobody, and Cas9, respectively. Lanes 8 and 9 are Cas9-Ig Fc conjugate without (Lane 8) or with (Lane 9) guide RNA. Lanes 10 and 11 are Cas9-Ig Fc conjugate without (Lane 10) or with (Lane 11) guide RNA. Lanes 12 and 13 are Nanobody-Cas9 conjugate without (Lane 12) or with (Lane 13) guide RNA.

[00714] The nanobody-Cas9 conjugate was analyzed using TOF-MS. The data are shown in **FIG. 42**.

Example 9: Modifying the surface of live mammalian cells

[00715] The methods described herein can be used for the direct labeling of live mammalian cell surfaces, e.g., using the tyrosinase and a tyrosine-tagged antigen-binding proteins. As a model substrate, GFP-binding nanobodies were attached to Jurkat cells; after attachment to the cell surface, the nanobodies retain the ability to bind antigen. The method is depicted schematically in **FIG. 43A**.

[00716] In brief, Jurkat cells were suspended in solution with 400 nM abTYR and 10 to 200 μM of a GFP binding nanobody. After the reaction, cells were rinsed with 25 μM GFP before final rinsing and analysis via flow cytometry. The data are shown in **FIG. 43B**. The increasing levels of green fluorescence based on nanobody concentration show that there was a dose-dependent binding of GFP to the nanobody-conjugated cells.
