(54) Title: SYSTEM AND METHOD FOR IMPLEMENTING HYBRID AUTOMATIC REPEAT REQUEST USING PARITY CHECK COMBINING

(57) Abstract: The system has a transmitter (200), having a complete data packet which is divided into a number of data units (Dus) (200). The DUs (220) are encoded for both error detection and error correction. Both the error correction and error detection parity check bits are separately combined into one or more blocks. Thereafter, the DUs (220) and the block(s) containing the combined parity check bits are transmitted to the receiver (250). If the receiver (250) determines that a received DU (220) does not contain any errors, the error correction parity check bits for that DU (220) are generated and their effect on the combined error correction parity check bits removed. Thereafter, the remaining error correction parity check bits, which now only contains information about the Dus (220) actually in error, are used to correct the erroneous Dus (220).

SYSTEM AND METHOD FOR IMPLEMENTING HYBRID AUTOMATIC
REPEAT REQUEST USING PARITY CHECK COMBINING

BACKGROUND OF THE PRESENT INVENTION

This application claims the priority under 35
U.S.C. 119(e)(1) of co-pending U.S. Provisional
Application No. 60/141,159, filed on June 25, 1999.

5 Field of the Invention

The present invention relates generally to
telecommunications systems and methods for reliable
transmission of information, and specifically to error
control coding to ensure the reliability of transmitted
10 information.

Background and Objects of the Present Invention

There are many applications where large volumes of
digital data must be transmitted and received in a
substantially error free manner. In cellular
15 telecommunications and satellite communications
systems, in particular, it is imperative that the
transmission of digital data over the air interface be
completed in as accurate a manner as is possible.
Accurate transmission and reception of digital data
20 has, however, been difficult because the communications
channels utilized for data transmissions over the air
interface are plagued by error introducing factors.
For example, such errors may be attributable to
transient conditions in the channel, such as noise and
25 distortion, or they may be due to recurrent conditions
attributable to defects in the channel. The existence
of transient conditions or defects results in instances

where the digital data is not transmitted properly or cannot be reliably received.

Digital data is often transmitted in packets (or blocks or frames), in which each packet includes a number of information bytes followed by a frame check sequence of parity check bits (PCBs). The errors that typically occur in the transmission and reception of digital data are of two types: "random" channel errors and "burst" channel errors. Random channel errors are errors that occur independent of one another and are uniformly spread in a packet, while burst channel errors are errors that occur in clusters. The PCBs in each data packet are used to detect when and where a channel error has been introduced into the data packet.

Considerable attention has been directed towards discovering methods for addressing the problems concerning errors which typically accompany data transmission activities over the air interface. For example, two common techniques of error correction include Forward Error Correction (FEC) and Automatic Repeat Request (ARQ). The FEC error correction technique adds redundant information in the transmitter, which is used by the receiver to correct transmission errors, whereas in the (ARQ) error correction technique, the data is encoded in such a way that errors in the data packet can be detected, but not corrected. With ARQ, when errors are detected, the receiver requests retransmission of those erroneously received data packets.

One common way of detecting errors is to include error detecting PCBs, such as a Cyclic Redundancy Check (CRC) code, with the data packet. The CRC code is generated from the information included in the data

packet. At the receiver, the receiver uses the information included in the received data packet to generate an additional CRC code. If the CRC code generated by the receiver matches the CRC code included with the received data packet, the data packet is accepted as correctly received. If not, the receiver requests retransmission of that data packet. It should be understood that the error could be with the data packet or with the CRC code itself. However, since the CRC code and data packet are considered one unit, an error to either is considered an error to the whole unit.

If the bit error rate (BER) on the communications channel is relatively small, the ARQ technique will give a high throughput for feasible packet lengths. However, if the BER is increased, the throughput will be heavily reduced due to the increased number of retransmissions needed. Therefore, typically, a combination of FEC and ARQ techniques are applied in order to have a reliable link without sacrificing too much in average through-put. This combination of ARQ and FEC is referred to as Hybrid ARQ.

For example, in order to improve the performance for the ARQ technique when the BER is high, Hybrid ARQ type-I techniques can be used. In a Hybrid ARQ type-I technique, the data is encoded such that in addition to error detection, correction of the most likely errors can be performed at the receiver. Only the most likely errors, e.g., error patterns with only a few bits in error, are corrected at the receiver, which reduces the number of retransmissions. The rare error patterns are detected, and retransmission of those data packets with rare errors is requested. Therefore, the effective

data rate of the packet can be kept relatively high. Hybrid ARQ type-I techniques are best suited for channels where the BER is relatively constant.

However, there are many practical cases where the BER is not constant, but rather varies considerably. The reasons for this variance in BER can include, for instance, an interferer present during a part of the packet, but not during another part of the packet. The effect of this variance can be either a good channel, such that no error correction is needed, or an extremely bad channel, such that a very powerful code (implying low rate) would be needed. Hybrid ARQ type-I techniques do not perform well when the channel is good, because the error correcting capability is not needed. In addition, when the channel is extremely bad, which implies that excessive rare error patterns might be present, the error correcting capability of the Hybrid ARQ type-I technique might not be sufficient.

In these cases of BER variance, a Hybrid ARQ type-II technique can be employed. The Hybrid ARQ type-II technique adapts the ARQ technique to the actual channel conditions. First, a data packet is sent with a block of PCBs for error detection only. If no errors are detected by the receiver, the packet is considered correctly received. If, however, errors are detected, the received packet is buffered, and the receiver requests the transmitter to transmit another block of PCBs, which can be used, together with the previously received block of PCBs, to perform error correction. Thus, error correction is only performed when it is actually needed. However, as with the conventional ARQ

technique, the ARQ type-II technique introduces additional delay due to the retransmission of the PCBs.

It is, therefore, an object of the present invention to provide for both error detection and error correction of data packets without the need for retransmission of the data packet or parity check bits associated with the data packet.

It is a further object of the present invention to provide error correction only for those data packets received incorrectly.

SUMMARY OF THE INVENTION

The present invention is directed to telecommunications systems and methods for performing error detection on data packets at a receiver, and for performing error correction on only those data packets that were received in error, without the need for retransmission of the data packets or parity checking bits. The complete data packet to be transmitted is first divided into a number of blocks denoted data units (DUs). The DUs are encoded for both error detection and error correction. Subsequently, the error correction parity check bits for the DUs of the complete data packet are combined into one or more blocks, and likewise, the error detection parity check bits are preferably combined into one or more separate blocks. Thereafter, a transmitter transmits the DUs and the block(s) containing the combined parity check bits to the receiver. When the receiver decodes the DUs, the receiver checks for errors in each of the DUs. For each DU that does not contain any errors, the parity check bits for error correction for that DU are generated and their effect on the combined parity check

bits for error correction removed. Thereafter, the parity check bits for error correction, which now only contains information about the DUs actually in error, are used in an attempt to correct the erroneous DUs. Thus, the parity check bits for error correction are only used for those DUs determined to have errors, and no error correcting capability is wasted on those DUs that have been correctly received.

BRIEF DESCRIPTION OF THE DRAWINGS

The disclosed invention will be described with reference to the accompanying drawings, which show important sample embodiments of the invention and which are incorporated in the specification hereof by reference, wherein:

FIGURE 1 is a block diagram illustrating the seven layers forming the Open Systems Interconnection model;

FIGURE 2 is a block diagram illustrating the transmission of data packets from a transmitter to a receiver over the air interface using an Automatic Repeat Request (ARQ) error detecting technique;

FIGURE 3 illustrates the transmission of data packets using a Hybrid ARQ technique that utilizes both error detection and error correction in accordance with preferred embodiments of the present invention;

FIGURE 4 illustrates the steps for transmitting data packets utilizing the Hybrid ARQ technique shown in FIGURE 3 of the drawings; and

FIGURE 5 illustrates the generation of combined parity check bits for both error detection and error correction for a plurality of data units.

DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED
EXEMPLARY EMBODIMENTS

5 The numerous innovative teachings of the present application will be described with particular reference to the presently preferred exemplary embodiments. However, it should be understood that this class of embodiments provides only a few examples of the many advantageous uses of the innovative teachings herein. In general, statements made in the specification of the
10 present application do not necessarily delimit any of the various claimed inventions. Moreover, some statements may apply to some inventive features but not to others.

15 The Open Systems Interconnection (OSI) model was developed in the early 1980's by the International Standards Organization (ISO) for use in mainframe environments. This protocol provides the procedures and mechanisms necessary for mainframe computers to communicate with other devices, including terminals and
20 modems. The OSI model divides data transmission into three distinct functions (process, transport and network) to carry out an application, which can be, for example, a file transfer or a voice transmission. The process function uses protocols which are unique to the application that uses them, while the transport
25 function interfaces with the process function to provide reliable data transmission over the network. For example, the transport function provides error detection and correction, as well as other tasks such as sequencing of segments of data. Finally, the
30 network function provides the mechanisms for actually

routing the data over the network to the destination node.

With reference now to FIGURE 1 of the drawings, the Open Systems Interconnection (OSI) model addresses the process function, the transport function and the network function, and divides these functions into seven different layers: application 10, presentation 20, session 30, transport 40, network 50, data link 60 and physical 70. Each layer provides a service to the layer above and below it. For example, the physical layer 70 provides a service to the data link layer 60, which, in turn, provides a service to the network layer 50 and the physical layer 70, and so on. However, each layer is independent, and therefore, should the function change at any one layer, it will not impact the function of the other layers.

The physical layer 70, which is the bottom layer, is the layer responsible for converting the digital data into a bit stream for transmission over the communications channel. The data link layer 60 provides reliable communications between two devices, such as a transmitter and a receiver. For example, with reference now to FIGURE 2 of the drawings, when data 215 is to be transmitted from a transmitter 200 to a receiver 250 over an air interface 240, the network layer 50a in the transmitter 200 passes a block of data 215 known as a service data unit (SDU) 210, which is typically composed of several data packets, to the data link layer 60a in the transmitter 200. The data link layer 60a in the transmitter 200 segments the SDU 210 into multiple data units (DUs) 220, which have a predefined short length, e.g., 40 bytes, as compared to the length of the SDUs 210, e.g., 1500 bytes. These

DUs 220 are stored in a transmit buffer 230 in the data link layer 60a, and passed to the physical layer 70a in the transmitter 200 for conversion of the digital data 215 in the DUs 220 into a bit stream for transmission over the communications channel 240, such as an air interface, to the physical layer 70b in the receiver 250.

When the physical layer 70a of the transmitter 200 transmits the DUs 220 containing the data 215 over the communications channel 240 to the receiver 250, the communications channel 240 between the transmitter 200 and receiver 250 used to transmit the data 215 may introduce a number of errors into the transmitted data 215. Therefore, in addition to transmitting the DU's 220, an error detecting code 225a, such as a Cyclic Redundancy Checking (CRC) code containing parity check bits (PCBs), can be transmitted for each DU 220. This type of error detecting technique is known as the Automatic Repeat Request (ARQ) technique. The CRC code 225a for each DU 220 is generated by the transmitter 200 based upon the data 215 within the respective DU 220. Thus, each CRC code 225a is derived from the data 215 within the DU 220 that it is associated with.

When the data link layer 60b of the receiver 250 receives the DUs 220 from the physical layer 70b of the receiver 250, the data link layer 60 of the receiver 250 generates additional CRC codes 225b for each of the received DUs 220 based upon the data 215 contained in each of the received DUs 220. The CRC codes 225b are used to detect which DUs 220 are in error. The data link layer 60b of the receiver 250 stores those DUs 220 in error and all DUs 220 associated with the SDU 210 having the DUs 220 in error in a receiver buffer 260.

Thereafter, the data link layer 60b of the receiver 250 requests retransmission by the data link layer 60a of the transmitter 200 of those DUs 220 not correctly received by the receiver 250. If, and when, a DU 220 is correctly received, the data link layer 60b of the receiver 250 transmits an acknowledgment message 270 to the data link layer 60a of the transmitter 200, informing the transmitter 200 that the DU 220 was correctly received. In addition, when all of the DUs 220 associated with the SDU 210 are received correctly, the SDU 210 is transmitted to the network layer 50b of the receiver 250.

This type of ARQ technique is simple but inherently inefficient because of the idle time spent waiting for an acknowledgment 270 of each transmitted DU 220. Thus, although the reliability of the ARQ technique is high, in that the probability of the receiver 250 accepting an incorrect DU 220 is low, the throughput efficiency is low due to the number of retransmissions needed.

Therefore, in accordance with embodiments of the present invention, a Hybrid ARQ technique can be employed such that error correction can be performed for only those DUs 220 received in error, without the need for retransmission of the DUs 220 in error. With reference now to FIGURE 3 of the drawings, which will be described in connection with the steps listed in FIGURE 4 of the drawings, once the data 215 to be transmitted to the receiver 250 is divided into a number of DUs 220₁ and 220₂ by the data link layer 60a of the transmitter 200 (step 400), the DUs 220₁ and 220₂ are individually encoded for both error detection and error correction (step 405). Thereafter, error

correction PCBs 228_1 and 228_2 for the DUs 220_1 and 220_2 , respectively, are combined into one or several blocks 229 (step 410). Likewise, in preferred embodiments, error detection PCBs $225a_1$ and $225a_2$, such as CRC bits, are combined into one or several blocks 226 (step 415). Alternatively, instead of combining the error detection PCBs $225a_1$ and $225a_2$, the error detection PCBs $225a_1$ and $225a_2$ can be transmitted with the DUs 220_1 and 220_2 that they appertain to.

Once the transmitter transmits the DUs 220 and the block(s) 229 and 226 containing the combined error correction and error detection PCBs, respectively, over the communications channel 240, such as the air interface, to the data link layer 60b of the receiver 250 (step 420), the received DUs 220_1 and 220_2 are used to generate additional error detection PCBs $225b_1$ and $225b_2$, respectively, for each of the received DUs 220_1 and 220_2 (step 425). Thereafter, the additional error detection PCBs $225b_1$ and $225b_2$ and the received error detection PCB block 226 are used to determine if there are any erroneous DUs 220 (step 435). For example, as shown in FIGURE 3, since DU 220_1 is determined not to be in error (step 435), the error correction PCBs 228_1 for those DUs 220_1 are generated (step 440). Since these error correction PCBs 228_1 are known, their influence on the combined error correction block(s) 229 is known and can be removed (step 445).

However, if any one of the DUs, here DU 220_2 , is found to be in error (step 435), the erroneously received DU 220_2 is buffered in the receiver buffer 260 (shown in FIGURE 2) (step 450), and the erroneously received DU 220_2 , together with the remaining error correction PCBs 228_2 , which are dependent only upon the

erroneous DUs 220, are used to correct the erroneously received DU 220₂ (step 460). If, after error correction, the erroneously received DU 220₂ is still found to be in error (step 465), which would not normally be the case, the receiver 250 requests retransmission of the erroneously received DU 220₂ (step 470). For all DUs 220₁ and 220₂ received correctly (step 435) or corrected by error correction (step 465), the receiver 250 transmits an acknowledgment message 270 to the transmitter 200 (step 475), which in turn, removes each of these DUs 220₁ and 220₂ from the transmit buffer 230 (shown in FIGURE 2) (step 480).

In effect, this Hybrid ARQ technique allows all of the error correcting capability obtained through the combined error correcting PCB block 229 to be used for correcting the DUs 220 found in error, while no error correcting capability is wasted on those DUs 220 that were correctly received. Thus, the overhead decreases without increasing the number of retransmissions.

Embodiments of the present invention will now be more fully described in connection with FIGURE 5 of the drawings. Starting with K bits of data 215, this data 215 is first divided into N blocks, containing n_1, n_2, \dots, n_N bits, respectively. These blocks correspond to the DUs 220 shown in FIGURE 3 and are denoted $DU_1 \dots DU_N$.

Each of these DUs 220 is first encoded for error detection, for instance, by adding CRC bits 225a. The N codes used for generating the error detection PCBs are denoted ED_1, ED_2 , etc. The PCBs 225a used for error detection for each DU 220 are denoted C_1, C_2, \dots, C_N ,

respectively. Next, each one of these DUs 220 is encoded for error correction, such that redundancy PCBs 228 are added for each one of the DUs 220. The N codes used for error correction are denoted EC_1 , EC_2 , etc. The PCBs 228 for error correction for each of the different DUs 220 are denoted P_1 , P_2 , ..., P_N , respectively.

Thereafter, the PCBs 228 for error correction for all of the DUs 220 are encoded into an error correction block 229, hereinafter denoted, P_{comb} , using the code EC_{N+1} . For example, the code EC_{N+1} can add all of the error correction PCBs 228 bitwise modulo-2 (assuming the PCBs 228 to have the same length), to form P_{comb} . As an alternative, the code EC_{N+1} can be a Reed-Solomon code, which facilitates better error correcting capability as compared with the modulo-2 sum method. In addition, a trellis code, block code or convolutional code can be used for the code EC_{N+1} . It should be understood that the code EC_{N+1} can both combine the error correction PCBs 228, and generate additional error detection PCBs (not shown) for the combined error correction PCBs 228. Therefore, the receiver 250 can ensure that the combined PCBs 228 for error correction are received correctly.

In addition, in preferred embodiments, the CRC bits 225a for all of the DUs 220 are encoded (combined) into a block 226, hereinafter denoted C_{comb} , using the code ED_{N+1} , which can be, for example, a Reed-Solomon code. Alternatively, instead of combining the CRC bits 225a, all of the CRC bits 225a can be sent unaffected with the DUs 220 they appertain to, or the CRC bits 225a can be put together into one packet.

Thereafter, the N DUs 220 as well as the C_{comb} bits used for error detection and the P_{comb} bits used for error correction are transmitted to the receiver 250. At the receiver 250, upon reception of the N DUs 220, denoted $DU'_1, DU'_2, \dots, DU'_N$, the C_{comb} bits for error detection are used to determine which ones, if any, of the DUs 220 are in error. This is accomplished by generating, for each of the DUs 220, the corresponding CRC bits 225b, $C'_1 \dots C'_N$. These additional CRC bits 225b, in addition to the C_{comb} bits, are used for error detection.

For example, if DU'_1 is the DU 220 received at the receiver 250 that corresponds to transmitted DU_1 , the receiver 250 computes CRC bits C'_1 based upon DU'_1 . The receiver repeats this process for each DU 220, $DU_1 \dots DU_N$, to produce CRC bits 225b, $C'_1 \dots C'_N$. These CRC bits 225b, $C'_1 \dots C'_N$, together with the received C_{comb} , are used to determine which, if any, DUs 220 were received in error.

For all correctly received DUs 220, the corresponding PCBs 228 for error correction, $P'_1 \dots P'_N$, are generated, and their influence on the P_{comb} bits removed. Therefore, the remaining part of P_{comb} , shown as block P'_{comb} , entirely depends upon the DUs 220 not correctly received. For example, assuming that all DUs 220 except one, such as DU_2 , were correctly received as determined by the error detection step above, and also assuming that P_{comb} was correctly received, if P_{comb} is the modulo-2 sum of all of the PCBs 228 for error correction for the different DUs 220, the PCBs 228 for the erroneous DU 220, here DU_2 , can simply be obtained by adding modulo-2 the sum of P_{comb} with all of the PCBs

228 for error correction generated by the receiver 250
for the correctly received DUs 220. It should be
understood that the method of using modulo-2 sums only
works if at most one DU 220 is in error. More complex
5 methods are needed if it is anticipated that more than
one erroneous DU 220 will occur.

Finally, the generated P'_{comb} for error correction
for the erroneous DUs 220 can be used to correct errors
in those DUs 220. If, after error correction, one or
10 more of the DUs 220 is still not correct, a
retransmission of those DUs 220 is requested. The
process of determining whether or not the DUs 220
subjected to the correction process were actually
corrected is similar to the error detection process
15 described above. For example, if DU_2 was not correctly
received, in an attempt to correct DU_2 , the receiver
250 would apply the error correction PCBs, P_2 , to
produce DU'_2 . Thereafter, the CRC bits 225b, C'_2 , are
generated by the receiver 250 based upon the estimated
20 DU'_2 , and DU'_2 is now checked in the same way as before
the correction took place. If DU_2 is still considered
not correctly received, retransmission would be
requested by the receiver 250. It should be noted that
it is not necessary to retransmit all of the DUs 220
25 that were not received correctly, but only so many of
those DUs 220 that error correction becomes possible at
the receiver 250.

As will be recognized by those skilled in the art,
the innovative concepts described in the present
30 application can be modified and varied over a wide
range of applications. Accordingly, the scope of
patented subject matter should not be limited to any of

the specific exemplary teachings discussed, but is instead defined by the following claims.

WHAT IS CLAIMED IS:

1. A telecommunications system for detecting and correcting errors in transmitted data, comprising:

a transmitter for receiving a block of data, segmenting said block of data into at least two data units, generating error detection codes and error correction codes for each of said at least two data units and combining all of said error correction codes into an error correction block; and

a receiver for receiving said at least two data units, said error detection codes and said error correction block from said transmitter, determining whether any of said at least two received data units is in error using said associated error detection codes, removing said error correction codes associated with each of said at least two data units that are received correctly from said error correction block and correcting each of said at least two data units that are received in error using said associated error correction codes generated from a remainder of said error correction block.

2. The telecommunications system of Claim 1, further comprising:

a channel for transmitting said at least two data units, said error detection codes and said error correction block from said transmitter to said receiver.

3. The telecommunications system of Claim 2, wherein said channel is an air interface.

4. The telecommunications system of Claim 1,
wherein said transmitter further combines said error
detection codes into an error detection block, said
receiver using said error detection block to determine
whether any of said at least two received data units is
in error.

5. The telecommunications system of Claim 4,
wherein said receiver generates additional error
detection codes using said at least two received data
units, said receiver using said additional error
detection codes along with said error detection block
to determine whether any of said at least two received
data units is in error.

6. The telecommunications system of Claim 1,
wherein said transmitter further comprises:

a network layer for generating said block of data;
a data link layer for receiving said block of data
from said network layer, segmenting said block of data
into said at least two data units and generating said
error detection codes and said error correction block;
and

a physical layer for transmitting said at least
two data units, said error detection codes and said
error correction block to said receiver.

7. The telecommunications system of Claim 6, wherein said receiver further comprises:

a physical layer for receiving said at least two data units, said error detection codes and said error correction block from said transmitter; and

a data link layer for determining whether any of said at least two received data units is in error and correcting each of said at least two data units that are received in error using said associated error correction codes generated from said remainder of said error correction block.

8. The telecommunications system of Claim 1, wherein said receiver transmits an acknowledgment message to said transmitter for each of said at least two data units that are received correctly or are corrected using said associated error correction codes generated from said remainder of said error correction block.

9. The telecommunications system of Claim 8, wherein said transmitter further comprises:

a transmit buffer for storing said at least two data units until said acknowledgment message for each of said at least two data units is received.

10. The telecommunications system of Claim 1, wherein said receiver further comprises:

a receiver buffer for storing each of said at least two data units received in error until each of said at least two data units received in error is corrected.

11. The telecommunications system of Claim 10, wherein said receiver requests retransmission from said transmitter of said error correction codes for each of said at least two data units that cannot be corrected.

5 12. The telecommunications system of Claim 1, wherein said error correction block is generated by adding all of said error correction codes together bitwise modulo-2.

10 13. The telecommunications system of Claim 1, wherein said error detection codes comprise Cyclic Redundancy Check bits.

 14. The telecommunications system of Claim 1, wherein said error correction codes comprise parity checking bits.

15 15. The telecommunications system of Claim 1, wherein said error correction block consists of at least two error correction blocks.

16. A method for transmitting data from a transmitter to a receiver without the need for retransmission of said data, comprising the steps of:

receiving, at said transmitter, a block of data;

5 segmenting said block of data into at least two data units;

generating an error detection code for each of said at least two data units;

10 generating an error correction code for each of said at least two data units;

combining all of said error correction codes to form an error correction block; and

transmitting said at least two data units, said error detection codes and said error correction block.

15 17. The method of Claim 16, further comprising the step of:

combining said error detection codes into an error detection block, said error detection block being transmitted.

20 18. The method of Claim 16, wherein said step of transmitting further comprises the steps of:

storing said at least two data units within a transmit buffer within said transmitter;

25 removing said at least two data units from said transmit buffer when an acknowledgment message for each of said at least two data units is received.

19. The method of Claim 16, wherein said step of combining further comprises the step of:

combining said error correction codes into said error correction block by adding all of said error correction codes together bitwise modulo-2.

20. A method for detecting and correcting errors in data transmitted from a transmitter to a receiver, comprising the steps of:

receiving, at the receiver, at least two data units, an error detection code for each of said at least two data units and an error correction block containing a combination of error correction codes for each of said at least two data units;

determining whether any of said at least two received data units is in error using said associated error detection codes;

removing said error correction codes associated with each of said at least two data units that are received correctly from said error correction block; and

correcting each of said at least two data units that are received in error using said associated error correction codes generated from a remainder of said error correction block.

21. The method of Claim 20, wherein said step of receiving further comprises the step of:

receiving an error detection block containing a combination of said error detection codes; and

using said error detection block to determine whether any of said at least two received data units is in error.

22. The method of Claim 21, wherein said step of determining further comprises the step of:

generating second error detection codes for each of said at least two received data units using said at least two received data units; and

using said second error detection codes along with said received error detection block to determine if any of said at least two data units is in error.

23. The method of Claim 20, wherein said step of correcting further comprises the steps of:

generating said error correction codes for said at least two data units received in error using said remainder of said error correction block; and

applying said generated error correction codes to said at least two data units received in error to correct said at least two data units received in error.

24. The method of Claim 20, further comprising the step of:

transmitting an acknowledgment message to said transmitter for each of said at least two data units that are received correctly or are corrected using said associated error correction codes generated from said remainder of said error correction block.

25. The method of Claim 20, further comprising the step of:

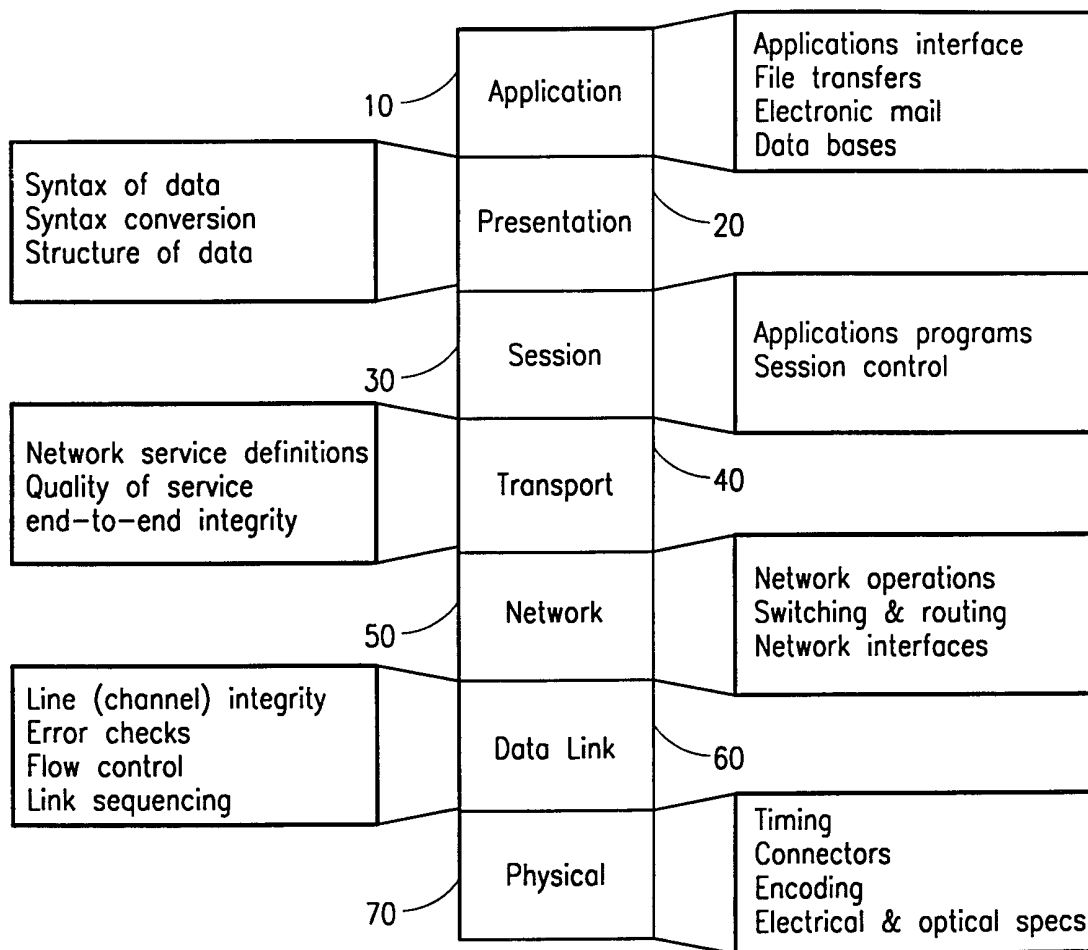

storing each of said at least two data units received in error in a receiver buffer until each of said at least two data units received in error is corrected.

26. The method of Claim 20, further comprising the step of:

requesting retransmission from said transmitter of said error correction codes for each of said at least two data units that cannot be corrected.

27. The method of Claim 20, wherein said step of removing further comprises the step of:

generating said error correction codes for each of said at least two data units that are received correctly.

INTERNATIONAL SEARCH REPORT

International Application No
PCT/EP 00/05315

A. CLASSIFICATION OF SUBJECT MATTER
IPC 7 H04L1/18

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 7 H04L

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

EPO-Internal, WPI Data, PAJ, INSPEC

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	US 5 638 384 A (HAYASHI KATSUHIKO ET AL) 10 June 1997 (1997-06-10) abstract column 3, line 24 -column 4, line 45 figure 7	1,16,20

* Special categories of cited documents :

"A" document defining the general state of the art which is not considered to be of particular relevance

"E" earlier document but published on or after the international filing date

"L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)

"O" document referring to an oral disclosure, use, exhibition or other means

"P" document published prior to the international filing date but later than the priority date claimed

"T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

"X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone

"Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

"&" document member of the same patent family

Date of the actual completion of the international search
