(57) An electron source comprises one or more electron-emitting devices, especially of surface conduction type, and is provided with means for supplying an activating substance to the device(s). The means comprises preferably a substance source and a heater or electron beam generator for gasifying the substance source. The electron source can be combined with an image-forming member (e.g. fluorescent body) to constitute an image-forming apparatus. The means is used for in situ activation or re-activation of the electron-emitting device(s).

ABSTRACT OF THE DISCLOSURE

An electron source comprises one or more electron-
emitting devices, especially of surface conduction
type, and is provided with means for supplying an
5 activating substance to the device(s). The means
comprises preferably a substance source and a heater or
electron beam generator for gasifying the substance
source. The electron source can be combined with an
image-forming member (e.g. fluorescent body) to
10 constitute an image-forming apparatus. The means is
used for in situ activation or re-activation of the
electron-emitting device(s).

ELECTRON SOURCE AND IMAGE FORMING APPARATUS
AS WELL AS METHOD OF PROVIDING THE SAME WITH MEANS
FOR MAINTAINING ACTIVATED STATE THEREOF

5 BACKGROUND OF THE INVENTION

Field of the Invention

This invention relates to an electron source and an
image forming apparatus and, more particularly, it
relates to an electron source provided with means for
10 maintaining it in an activated state by suppressing
degradation of and restoring the performance thereof
and an image forming apparatus comprising such an
electron source as well as a method of providing it
with such means.

15 Related Background Art

There have been known two types of electron-emitting
device; the thermionic cathode type and the cold
cathode type. Of these, the cold cathode refers to
devices including field emission type (hereinafter
20 referred to as the FE type) devices, metal/insulation
layer/metal type (hereinafter referred to as the MIM
type) electron-emitting devices and surface conduction
electron-emitting devices. Examples of FE type device
include those proposed by W. P. Dyke & W. W. Dolan,
25 "Field emission", Advance in Electron Physics, 8, 89
(1956) and C. A. Spindt, "PHYSICAL Properties of
thin-film field emission cathodes with molybdenum

cones", J. Appl. Phys., 47, 5284 (1976).

Examples of MIM device are disclosed in papers including C. A. Mead, "The tunnel-emission amplifier", J. Appl. Phys., 32, 646 (1961).

5 Examples of surface conduction electron-emitting device include one proposed by M. I. Elinson, Radio Eng. Electron Phys., 10, 1290 (1965).

10 A surface conduction electron-emitting device is realized by utilizing the phenomenon that electrons are emitted out of a small thin film formed on a substrate when an electric current is forced to flow in parallel with the film surface. While Elinson proposes the use of SnO_2 thin film for a device of this type, the use of Au thin film is proposed in [G. Dittmer: "Thin Solid
15 Films", 9, 317 (1972)] whereas the use of $\text{In}_2\text{O}_3/\text{SnO}_2$ and that of carbon thin film are discussed respectively in [M. Hartwell and C. G. Fonstad: "IEEE Trans. ED Conf.", 519 (1975)] and [H. Araki et al.: "Vacuum", Vol. 26, No. 1, p.22 (1983)].

20 Fig. 27 of the accompanying drawings schematically illustrates a typical surface conduction electron-emitting device proposed by M. Hartwell. In Fig. 27, reference numeral 1 denotes a substrate. Reference numeral 4 denotes an electroconductive thin
25 film normally prepared by producing an H-shaped thin metal oxide film by means of sputtering, part of which eventually makes an electron-emitting region 5 when it

is subjected to an electrically energizing process referred to as "energization forming" as described hereinafter. In Fig. 27, the thin horizontal area of the metal oxide film separating a pair of device electrodes has a length L of 0.5 to 1mm and a width W' of 0.1mm.

Conventionally, an electron-emitting region 5 is produced in a surface conduction electron-emitting device by subjecting the electroconductive thin film 4 of the device to an electrically energizing preliminary process, which is referred to as "energization forming". In the energization forming process, a constant DC voltage or a slowly rising DC voltage that rises typically at a rate of 1 V/min. is applied to given opposite ends of the electroconductive thin film 4 to partly destroy, deform or transform the film and produce an electron-emitting region 5 which is electrically highly resistive. Thus, the electron-emitting region 5 is part of the electroconductive thin film 4 that typically contains a fissure and fissures therein so that electrons may be emitted from the fissure.

Currently available electron-emitting devices of the type under consideration have room for improvement in terms of performance and efficiency of electron emission in order to realize image forming apparatuses

that provide bright and clear images on a stable basis. The efficiency here refers to the ratio of the electric current flowing through the surface conduction electron-emitting device (hereinafter referred to as "device current" or I_f) to the electric current formed by electrons discharged from the device into vacuum (hereinafter referred to as "emission current" or I_e) when a voltage is applied to the paired device electrodes of the device. An ideal electron-emitting device will show a large emission current relative to a small device current. If an electron-emitting device is rigorously controllable for its electron emitting performance and has an improved efficiency, an image forming apparatus realized by arranging a number of such electron-emitting devices and a fluorescent member for forming images thereon will be able to produce high quality images with a reduced energy consumption rate if the apparatus is made very flat. Then, the drive circuit of such an image forming apparatus can be manufactured at reduced cost because of the low energy consumption rate of the electron-emitting devices of the apparatus.

However, the Hartwell's electron-emitting device does not necessarily perform satisfactorily in terms of stable emission of electrons and efficiency and, therefore, it is thought to be very difficult to realize an image forming apparatus that operates stably

to produce highly bright images with Hartwell's devices.

As a result of intensive research efforts, the inventors of the present invention discovered that, if
5 a certain voltage is applied to a surface conduction electron-emitting device in an atmosphere that contains organic substances after producing an electron-emitting region therein by energization forming as described above, both I_f and I_e of the device remarkably
10 increase. This operation of applying a certain voltage is termed "activation".

The above phenomenon of increased I_f and I_e is attributable to an activated filmy deposit of carbon or a carbon compound produced in the vicinity of the
15 electron-emitting region as a result of the voltage application.

As an electron-emitting device is operated for a long time for electron emission, the deposit in the vicinity of the electron-emitting region may be gradually
20 decomposed and eroded to degrade the electron-emitting performance of the device, although such degradation may be suppressed by selecting appropriate parameters for the activation process. This may be because the crystallinity of the deposit affects the rate of
25 erosion and the crystallinity is by turn affected by the parameters of the activation process. The use of a metal having a high melting point such as tungsten for

the deposit is effective for suppressing the erosion of the deposit.

Nevertheless, the performance of a surface conduction electron-emitting device has to be further improved in order to prevent degradation and prolong its service life if it is to be used in an image forming apparatus or a similar application.

In view of the above identified problems and other problems, it is therefore an object of the present invention to provide an improved surface conduction electron-emitting device.

Additionally, the "activation process" requires the use of a large vacuum apparatus provided with equipment for introducing carbon and/or metal compounds into the apparatus. When a large image forming apparatus having a vacuum container (envelope) is subjected to an activation process with such a vacuum apparatus, the latter has to be provided with an exhaust pipe for evacuating the inside of the vacuum container and introducing carbon and/or metal compounds into the vacuum container to make the overall operation rather complicated and time consuming to push up the manufacturing cost of the image forming apparatus particularly if such compounds have a large molecular weight. Thus, the present invention is also intended to provide a method that allows the use of a down-sized vacuum apparatus and a simplified manufacturing process

to bypass the above problems.

SUMMARY OF THE INVENTION

Therefore, it is an object of the present invention
5 to provide a method of suppressing degradation of and
restoring the electron emitting performance of an
electron source and an image forming apparatus
comprising such an electron source.

According to the invention, there is provided an
10 electron source comprising electron-emitting devices,
characterized in that it is provided with means for
supplying an activating substance to the
electron-emitting devices.

According to the invention, there is also provided an
15 image forming apparatus comprising an electron source
by turn comprising electron-emitting devices and an
image forming member to be irradiated with electron
beams from said electron source to form images thereon,
characterized in that said image forming apparatus is
20 provided with means for supplying an activating
substance to the electron-emitting devices.

According to the invention, there is also provided a
method of activating an electron source comprising
electron-emitting devices and an activating substance
25 source, characterized in that it comprises a step of
gasifying the activating substance from the activating
substance source and applying it to the

electron-emitting devices.

According to the invention, there is also provided a method of activating an image forming apparatus comprising an electron source by turn comprising
5 electron-emitting devices and an image forming member to be irradiated with electron beams from said electron source to form images thereon, characterized in that it comprises a step of gasifying the activating substance from the activating substance source and applying it to
10 the electron-emitting devices.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

The present invention provides a method of suppressing degradation of and restoring the electron emitting performance of an electron source and an image forming apparatus comprising such an electron source. Such a method can be used in the "activation step" in the process of manufacturing an electron source and an image forming apparatus comprising such an electron source to simplify the step. Additionally, such a method can be used for suppressing degradation with time of and temporarily restoring the electron emitting

20

25

performance of an electron source and the electron-emitting devices of an image forming apparatus.

Now, the present invention will be described by referring to the accompanying drawings that illustrate preferred embodiments of the invention.

Figs. 1A through 1C are schematic views of a surface conduction electron-emitting device of an electron source according to the invention, of which Fig. 1A is a plan view and Figs. 1B and 1C are cross sectional views taken along lines 1B-1B and 1C-1C respectively.

Referring to Figs. 1A through 1C, there are shown a substrate 1, a pair of device electrodes 2 and 3, an electroconductive thin film 4, an electron-emitting region on 5, a film resistance heater 7 and an active substance source 8, of which the film resistance heater 7 is arranged between one of the device electrodes, or the electrode 2, and an electrode for supplying an activating substance 6. Note that the device electrodes 2 and 3 and the electroconductive thin film 4 including the electron-emitting region 5 constitute a surface conduction electron-emitting device, while the film resistance heater 7, the activating substance source 8 and the electrodes 2 and 6 constitute an activating substance supply means.

Materials that can be used for the substrate 1 include quartz glass, glass containing impurities such

as Na to a reduced concentration level, soda lime glass, glass substrate realized by forming an SiO_2 layer on soda lime glass by means of sputtering, ceramic substances such as alumina as well as Si.

5 While the oppositely arranged device electrodes 2 and 3 and the electrode for supplying an activating substance 6 may be made of any highly conducting material, preferred candidate materials include metals such as Ni, Cr, Au, Mo, W, Pt, Ti, Al, Cu and Pd and
10 their alloys, printable conducting materials made of a metal or a metal oxide selected from Pd, Ag, RuO_2 , Pd-Ag and glass, transparent conducting materials such as In_2O_3 - SnO_2 and semiconductor materials such as polysilicon.

15 The distance L separating the device electrodes, the lengths W_1 through W_3 of the device electrodes and the electrode for supplying an activating substance, the contour of the electroconductive film 4 and other factors for designing a surface conduction
20 electron-emitting device according to the invention may be determined depending on the application of the device. The distance L separating the device electrodes 2 and 3 is preferably between several hundred nanometers and several hundred micrometers and,
25 still preferably, between several micrometers and tens of several micrometers.

The lengths W_1 and W_2 of the device electrodes 2 and

3 is preferably between several micrometers and
hundreds of several micrometers depending on the
resistance of the electrodes and the electron-emitting
characteristics of the device. The film thickness d of
5 the device electrodes 2 and 3 is between tens of
several nanometers and several micrometers.

A surface conduction electron-emitting device that
can be used for the purpose of the present invention
may have a configuration other than the one illustrated
10 in Figs. 1A through 1C and, alternatively, it may be
prepared by laying a thin film 4 including an
electron-emitting region on a substrate 1 and then a
pair of oppositely disposed device electrodes 2 and 3
on the thin film.

15 The electroconductive thin film 4 is preferably a
fine particle film in order to provide excellent
electron-emitting characteristics. The thickness of
the electroconductive thin film 4 is determined as a
function of the step coverage of the electroconductive
20 thin film on the device electrodes 2 and 3, the
electric resistance between the device electrodes 2 and
3 and the parameters for the forming operation that
will be described later as well as other factors and
preferably between a tenth of a nanometer and hundreds
25 of several nanometers and more preferably between a
nanometer and fifty nanometers. The electroconductive
thin film 4 normally shows a resistance R_s between

10² and 10⁷ Ω/□. Note that R_s is the resistance defined by $R = R_s(l/w)$, where t, w and l are the thickness, the width and the length of the thin film respectively. R is a resistance value measured along the direction of the length l.

The electroconductive thin film 4 is made of fine particles of a material selected from metals such as Pd, Pt, Ru, Ag, Au, Ti, In, Cu, Cr, Fe, Zn, Sn, Ta, W and Pb, oxides such as PdO, SnO₂, In₂O₃, PbO and Sb₂O₃, borides such as HfB₂, ZrB₂, LaB₆, CeB₆, YB₄ and GdB₄, carbides such as TiC, ZrC, HfC, TaC, SiC and WC, nitrides such as TiN, ZrN and HfN, semiconductors such as Si and Ge and carbon.

The term a "fine particle film" as used herein refers to a thin film constituted of a large number of fine particles that may be loosely dispersed, tightly arranged or mutually and randomly overlapping (to form an island structure under certain conditions). The diameter of fine particles to be used for the purpose of the present invention is between a tenth of a nanometer and hundreds of several nanometers and preferably between a nanometer and twenty nanometers.

Since the term "fine particle" is frequently used herein, it will be described in greater depth below.

A small particle is referred to as a "fine particle" and a particle smaller than a fine particle is referred to as an "ultrafine particle". A particle smaller than

an "ultrafine particle" and constituted by several hundred atoms is referred to as a "cluster".

However, these definitions are not rigorous and the scope of each term can vary depending on the particular aspect of the particle to be dealt with. An "ultrafine particle" may be referred to simply as a "fine particle" as in the case of this patent application.

"The Experimental Physics Course No. 14: Surface/Fine Particle" (ed., Koreo Kinoshita; Kyoritu Publication, September 1, 1986) describes as follows.

"A fine particle as used herein referred to a particle having a diameter somewhere between 2 to 3 μ m and 10nm and an ultrafine particle as used herein means a particles having a diameter somewhere between 10nm and 2 to 3nm. However, these definitions are by no means rigorous and an ultrafine particle may also be referred to simply as a fine particle. Therefore, these definitions are a rule of thumb in any means. A particle constituted of two to several hundred atoms is called a cluster." (Ibid., p.195, 11.22-26)

Additionally, "Hayashi's Ultrafine Particle Project" of the New Technology Development Corporation defines an "ultrafine particle" as follows, employing a smaller lower limit for the particle size.

"The Ultrafine Particle Project (1981-1986) under the Creative Science and Technology Promoting Scheme defines an ultrafine particle as a particle having a

diameter between about 1 and 100nm. This means an
ultrafine particle is an agglomerate of about 100 to 10^8
atoms. From the viewpoint of atom, an ultrafine
particle is a huge or ultrahuge particle." (Ultrafine
5 Particle - Creative Science and Technology: ed.,
Chikara Hayashi, Ryoji Ueda, Akira Tazaki; Mita
Publication, 1988, p.2, 11.1-4) A particle smaller
than an ultrafine particle formed by several to several
hundred atoms is generally called a cluster." (Ibid:
10 p.2, 11.12-13)

Taking the above general definitions into
consideration, the term a "fine particle" as used
herein refers to an agglomerate of a large number of
atoms and/or molecules having a diameter with a lower
15 limit between several times of 0.1nm and 1nm and an
upper limit of several micrometers.

The electron-emitting region 5 is part of the
electroconductive thin film 4 and comprises an
electrically highly resistive fissure, although its
20 performance is dependent on the thickness and the
material of the electroconductive thin film 4 and the
energization forming process which will be described
hereinafter. The electron emitting region 5 may
contain in the inside fine particles having a diameter
25 between several times of a tenth of a nanometer and
tens of several nanometers. The material of such fine
particles may be selected from all or part of the

materials that can be used to prepare the thin film 4 including the electron emitting region. The electron emitting region 5 and part of the thin film 4 surrounding the electron emitting region 5 may contain carbon and carbon compounds.

If the activating substance is a carbide, the activating substance source is preferably a thin film of a baked or unbaked polymerized compound or a baked or unbaked porous material that has adsorbed an organic compound such as a hydrocarbon compound.

Polymerized compounds that can be used for the purpose of the present invention include, polyvinyl acetate, polyvinyl butyral, 3,5-dimethylphenol, polyvinyl chloride. Any of these materials is used after baking at temperature between 200 and 300°C so that it may produce little gas of the organic compound if it is held in vacuum at room temperature. Examples of carbon compounds that may be used for adsorption include aromatic hydrocarbon compounds and olefinic compounds.

If the activating substance is a metal compound and the activation process is carried out by depositing a high melting point metal such as W or Nb on the electron-emitting region, materials that may be used for the activating substance source include metal halides such as fluorides, chlorides, bromides and iodides, metal alkylates such as methylates, ethylates

and benzylates, metal β -diketonates such as acetylacetonates, dipivaloylmethanates and hexafluoroacetylacetonates, metal enyl complexes such as allyl complexes and cyclopentadienyl complexes, arene complexes such as benzene complexes, metal carbonyls and metal alkoxides as well as compounds obtained by combining any of such substances. Specific examples include NbF_5 , NbCl_5 , $\text{Nb}(\text{C}_5\text{H}_5)(\text{CO})_4$, $\text{Nb}(\text{C}_5\text{H}_5)_2\text{Cl}_2$, OsF_4 , $\text{Os}(\text{C}_3\text{H}_7\text{O}_2)_3$, $\text{Os}(\text{CO})_5$, $\text{Os}(\text{CO})_{12}$, $\text{Os}(\text{C}_5\text{H}_5)_2$, ReF_5 , ReCl_5 , $\text{Re}(\text{CO})_{10}$, $\text{ReCl}(\text{CO})_5$, $\text{Re}(\text{CH}_3)(\text{CO})_5$, $\text{Re}(\text{C}_5\text{H}_5)(\text{CO})_3$, $\text{Ta}(\text{C}_5\text{H}_5)(\text{CO})_4$, $\text{Ta}(\text{OC}_2\text{H}_5)_5$, $\text{Ta}(\text{C}_5\text{H}_5)_2\text{Cl}_2$, $\text{Ta}(\text{C}_5\text{H}_5)_2\text{H}_3$, WF_6 , $\text{W}(\text{CO})_6$, $\text{W}(\text{C}_5\text{H}_5)_2\text{Cl}_2$, $\text{W}(\text{C}_5\text{H}_5)_2\text{H}_2$ and $\text{W}(\text{CH}_3)_6$. Of these, $\text{W}(\text{CO})_6$ (tungsten hexacarbonyl) is preferable because it can be used to produce tungsten which is a metal having a high melting point and handled relatively easily.

In the above described electron-emitting device, the activating substance source 8 is formed on the film resistance heater 7, which is designed to be heated and to evaporate the activating substance of the activating substance source 8 as a voltage is applied to the device electrode 2 and the electrode for supplying an activating substance 6 to cause an electric current to flow through the heater 7. The evaporated substance is eventually fed to and near the electron-emitting region. The film resistance heater 7 may be made of a metal such as Au, Pt or Ni or an electroconductive oxide such as $\text{SnO}_2\text{-In}_2\text{O}_3$ (ITO). In stead of a thin film,

the heater may be realized in the form of a wire.

In the above described electron-emitting device, one of the device electrodes also operates as an electrode for feeding the film resistance heater with electricity
5 (electrode for supplying an activating substance).

Alternatively, however, a pair of electrodes for supplying an activating substance may be arranged independently of the device electrodes. Still alternatively, activating substance source and film
10 resistance heater may be arranged on both lateral side of the electron-emitting region. The positional arrangement of these components may be appropriately modified so long as the activating substance can be effectively fed to and near the electron-emitting
15 region.

For the purpose of the invention, step type surface conduction electron-emitting devices each having a profile as illustrated in Fig. 2 may be used in place of devices each having a profile of 1B, which is a
20 sectional view taken along line 1B-1B in Fig. 1A. In Fig. 2, reference numeral 10 denotes a step forming member typically made of an electrically insulating material.

The method of supplying an activating substance from
25 the activating substance source according to the invention may be so modified that, in place of passing electric current through and heating the film

resistance heater, electron beams emitted from the electron-emitting device may be used to irradiate the activating substance source in order to supply the activating substance to and near the electron-emitting region. Fig. 3 schematically illustrates the arrangement of the electron source for such a modified method. Then, the electrode for supplying an activating substance 6 is subjected to a voltage higher than that of the anode of the corresponding surface conduction electron-emitting device comprising a pair of device electrodes 2 and 3 and an electroconductive thin film 5 including an electron-emitting region 5 so that it may attract electrons emitted from the electron-emitting region 5 and cause them to collide with the activating substance source 8, which is consequently energized and supplies the activating substance to and near the electron-emitting region.

Now, a method of manufacturing a surface conduction electron-emitting device having a configuration as described above will be described by referring to Figs. 1A through 1C and 4A through 4E.

1) After thoroughly cleansing a substrate 1 with detergent and pure water, a material is deposited on the substrate 1 (as shown in Fig. 4A which is a cross sectional view taken along line 1B-1B in Fig. 1A) by means of vacuum evaporation, sputtering or some other appropriate technique for a pair of device electrodes 2

and 3 and an electrode for supplying an activating substance 6, which are then patterned with photolithography technique or the like (Fig. 4B).

2) An organic metal thin film is formed on the substrate 1 carrying thereon the pair of device electrodes 2 and 3 and an electrode for supplying an activating substance 6 by applying an organic metal solution and leaving the applied solution for a given period of time. The organic metal solution may contain as a principal ingredient any of the metals listed above for the electroconductive thin film 4. Thereafter, the organic metal thin film is heated, baked and subsequently subjected to a patterning operation, using an appropriate technique such as lift-off or etching, to produce an electroconductive thin film 4 (Fig. 4C which is a cross sectional view also taken along line 1B-1B in Fig. 1A). While an organic metal solution is applied to produce a thin film in the above description, an electroconductive thin film 4 may alternatively be formed by vacuum evaporation, sputtering, chemical vapor deposition, dispersed application, dipping, spinner or some other technique.

3) Then, a film resistance heater 7 and an activating substance source 8 are formed. Any method that may be used for forming an electroconductive thin film 4 may also be used for the film resistance heater 7.

Subsequently, the activating substance source 8 is formed thereon and, if necessary, subjected to other processing operations such as baking (Fig. 4D which is a cross sectional view also taken along line 1C-1C in Fig. 1A).

4) Thereafter, the device electrodes 2 and 3 are subjected to a process referred to as "forming". Here, an energization forming process will be described as a choice for forming. More specifically, voltage is applied between the device electrodes 2 and 3 by means of a power source (not shown) until an electron emitting region (fissures) 5 is produced in a given area of the electroconductive thin film 4 to show a modified structure that is different from that of the electroconductive thin film 4 (Fig. 4E which is a cross sectional view also taken along line 1B-1B in Fig. 1A). Figs. 5A through 5D show different pulse voltages that can be used for energization forming.

The voltage to be used for energization forming preferably has a pulse waveform. A pulse voltage having a constant height or a constant peak voltage may be applied continuously as shown in Fig. 5A or, alternatively, a pulse voltage having an increasing height or an increasing peak voltage may be applied as shown in Fig. 5B.

In Fig. 5A, the pulse voltage has a pulse width T_1 and a pulse interval T_2 , which are typically between

1μsec. and 10msec. and between 10μsec. and 100msec.
respectively. The height of the triangular wave (the
peak voltage for the energization forming operation)
may be appropriately selected depending on the profile
5 of the surface conduction electron-emitting device.
The voltage is typically applied for a period between
several seconds and tens of several minutes in vacuum.
Note, however, that the pulse waveform is not limited
to triangular and a rectangular or some other waveform
10 may alternatively be used.

Fig. 5B shows a pulse voltage whose pulse height
increases with time. In Fig. 5B, the pulse voltage has
an width T_1 and a pulse interval T_2 that are
substantially similar to those of Fig. 5A. The height
15 of the triangular wave (the peak voltage for the
energization forming operation) is, however, increased
at a rate of, for instance, 0.1V per step.

The energization forming operation will be terminated
by measuring the current running through the device
20 electrodes when a pulse voltage that is sufficiently
low and does not locally destroy or deform the
electroconductive thin film 2, or about 0.1V, is
applied to the device between the pulses for the
energization forming. Typically the energization
25 forming operation is terminated when a resistance
greater than $1M\Omega$ is observed for the device current
running through the electroconductive thin film 4 while

applying a pulse voltage of approximately 0.1V to the device electrodes.

5 5) After the energization forming operation, the electron-emitting device is subjected to an activation process.

 In an activation process, a pulse voltage is repeatedly applied to the device in a vacuum chamber, in which a carbon compound or a metal compound (activating substance) exists at a very small
10 concentration. As a result of this process, carbon, a carbon compound or a metal compound is deposited on the electron-emitting region so that device current I_f and the emission current I_e change remarkably. The
15 activation step is conducted, observing the device current I_f and the emission current I_e , and terminated when the emission current I_e gets to a saturated level, for instance.

 The activating substance may be supplied by passing electric current through the film resistance heater 7
20 formed in the preceding step and evaporating the activating substance in the activating substance source 8 or by introducing an appropriate substance from a substance feeding device fitted to the vacuum apparatus.

25 If a carbon compound is used as an activating substance, a component of oil diffusing within the vacuum chamber from an exhaust system equipped with a

diffusion pump or a rotary pump involving the use of oil may be utilized. Alternatively, a carbon compound may be introduced into the vacuum chamber after evacuating the inside of the apparatus by means of a
5 ultrahigh vacuum system equipped with an ion pump. Substances that can be suitably used for the purpose of the activation process include aliphatic hydrocarbons such as alkanes, alkenes and alkynes, aromatic hydrocarbons, alcohols, aldehydes, ketones, amines,
10 organic acids such as phenol, carbonic acids and sulfonic acids. Specific examples include saturated hydrocarbons expressed by general formula C_nH_{2n+2} such as methane, ethane and propane, unsaturated hydrocarbons expressed by general formula C_nH_{2n} such as ethylene and
15 propylene, benzene, toluene, methanol, ethanol, formaldehyde, acetaldehyde, acetone, methylethylketone, methylamine, ethylamine, phenol, formic acid, acetic acid and propionic acid.

If a metal compound is used as an activating
20 substance, any of the metal compounds listed above by referring to the activating substance source may be used.

The pulse waveform of the voltage applied to the electron-emitting device in this activation step may be
25 rectangular as shown in Fig. 5C. Alternatively, an alternating rectangular pulse waveform that alternately changes the polarity as shown in Fig. 5D may be used.

6) An electron-emitting device that has been treated in an energization forming process and an activation process is then preferably subjected to a stabilization process. This is a process for removing any activating substance remaining in the vacuum chamber typically through adsorption except the substance existing in the activating substance source 8 arranged on the electron source. The vacuuming and exhausting equipment to be used for this process preferably does not involve the use of oil so that it may not produce any evaporated oil that can adversely affect the performance of the treated device during the process. Thus, the use of a sorption pump and an ion pump may be a preferable choice.

The partial pressure of the activating substance in the vacuum chamber is preferably lower than 1×10^{-6} Pa and more preferably lower than 1×10^{-8} Pa, in which no carbon or carbon compound is additionally deposited. The vacuum chamber is preferably heated during evacuating so that organic molecules adsorbed by the inner walls of the vacuum chamber and the electron-emitting device(s) in the chamber may also be easily eliminated. While the vacuum chamber is preferably heated to 80 to 250°C for more than 5 hours in most cases, other heating conditions may alternatively be selected depending on the size and the profile of the vacuum

chamber and the configuration of the electron-emitting device(s) in the chamber as well as other considerations. The pressure in the vacuum chamber needs to be made as low as possible and it is preferably lower than 1×10^{-5} Pa and more preferably lower than 1×10^{-6} Pa.

After the stabilization process, the atmosphere for driving the electron-emitting device or the electron source is preferably same as the one when the stabilization process is completed, although a lower pressure may alternatively be used without damaging the stability of operation of the electron-emitting device or the electron source if the activating substance in the chamber is sufficiently removed.

By using such a vacuum like atmosphere, the formation of any additional deposit of carbon or a carbon compound can be effectively suppressed and the H_2O , O_2 and other substances adsorbed to the inner wall surface of the envelope (vacuum chamber) and the outer surface of the substrate can be removed to consequently stabilize the device current I_f and the emission current I_e .

As described earlier, the carbon, carbon compound or metal deposited on the electron-emitting region can erode to degrade the electron emitting performance of the device but such degradation in the performance of the device can be prevented by passing electric current through the film resistance heater and supplying the

activating substance from the activating substance source at a reduced rate in a controlled manner so that the activating substance may not be supplied excessively. Alternatively, the performance of the device may be checked periodically and, if the detected degradation is not negligible, the activating substance may be supplied to the electron-emitting region to recover the performance so that the device may get rid of any practical degradation of performance.

10 While an electron-emitting device of Fig. 3 is prepared substantially in a manner as described above, the activation step is limited to the technique of introducing an activating substance. With such an electron-emitting device, degradation in the performance of the device may be prevented and a degraded performance of the device may be recovered by feeding part of the electrons emitted from it toward the activating substance source and cause them to collide with the activating substance so that the activating substance may be additionally supplied to the electron-emitting region.

25 The performance of an electron-emitting device prepared by way of the above processes, to which the present invention is applicable, will be described by referring to Figs. 6 and 7.

Fig. 6 is a schematic block diagram of an arrangement of a vacuum treatment equipment that can be used for

the above processes. It can also be used as a measuring system for determining the performance of an electron emitting device of the type under consideration. Referring to Fig. 6, reference numeral 16 denotes a vacuum chamber and reference numeral 17 denotes a vacuum pump. An electron-emitting device is placed in the vacuum chamber 16. The device comprises a substrate 1, a pair of device electrodes 2 and 3, a thin film 4 and an electron-emitting region 5.

Otherwise, the measuring system has a power source 11 for applying a device voltage V_f to the device, an ammeter 12 for metering the device current I_f running through the thin film 4 between the device electrodes 2 and 3, an anode 15 for capturing the emission current I_e produced by electrons emitted from the electron-emitting region of the device, a high voltage source 14 for applying a voltage to the anode 15 of the measuring system and another ammeter 13 for metering the emission current I_e produced by electrons emitted from the electron-emitting region 5 of the device. For determining the performance of the electron-emitting device, a voltage between 1 and 10kV may be applied to the anode, which is spaced apart from the electron emitting device by distance H which is between 2 and 8mm.

Instruments including a pressure gauge and other pieces of equipment necessary for measuring an

atmosphere in the vacuum chamber 16 so that the performance of the electron-emitting device or the electron source may be properly tested under desired atmosphere. The vacuum pump 17 may be provided with an ordinary high vacuum system comprising a turbo pump and a rotary pump or the like, and an ultra-high vacuum system comprising an ion pump or the like. The entire vacuum chamber containing an electron source substrate therein can be heated by means of a heater (not shown). While not shown in Figs. 6 and 7, the measuring system is also provided with a power source for applying a voltage to the electrode for supplying an activating substance so that, whenever necessary, a selected voltage may be applied to the electrode for supplying an activating substance in a coordinated manner as another voltage is applied to the device electrodes from the power source 11. In short the steps from the energization forming step on can be carried out with the above described vacuum arrangement.

Fig. 7 shows a graph schematically illustrating the relationship between the device voltage V_f and the emission current I_e and the device current I_f typically observed by the measuring system of Fig. 6. Note that different units are arbitrarily selected for I_e and I_f in Fig. 7 in view of the fact that I_e has a magnitude by far smaller than that of I_f . Note that both the vertical and horizontal axes of the graph represent a

linear scale.

As seen in Fig. 7, an electron-emitting device that can be used for the purpose of the invention has three remarkable features in terms of emission current I_e ,
5 which will be described below.

(i) Firstly, an electron-emitting device according to the invention shows a sudden and sharp increase in the emission current I_e when the voltage applied thereto exceeds a certain level (which is referred to as a
10 threshold voltage hereinafter and indicated by V_{th} in Fig. 7), whereas the emission current I_e is practically undetectable when the applied voltage is found lower than the threshold value V_{th} . Differently stated, an electron-emitting device according to the invention is
15 a non-linear device having a clear threshold voltage V_{th} to the emission current I_e .

(ii) Secondly, since the emission current I_e is highly dependent on the device voltage V_f , the former can be effectively controlled by way of the latter.

20 (iii) Thirdly, the emitted electric charge captured by the anode 15 is a function of the duration of time of application of the device voltage V_f . In other words, the amount of electric charge captured by the anode 15 can be effectively controlled by way of the
25 time during which the device voltage V_f is applied.

Because of the above remarkable features, it will be understood that the electron-emitting behavior of a

surface conduction electron-emitting device that can be used for the purpose of the invention can be controlled as a function of the input signal. Thus, an electron source may be realized by arranging a number of such electron-emitting devices, taking advantage of this controllability, and then such an electron source may be used for an image forming apparatus or some other possible application.

Referring to Fig. 7, the device current I_f monotonically increases relative to the device voltage V_f (referred to as "MI characteristic" hereinafter). However, it may so change as to show a curve (not shown) specific to a voltage-controlled-negative-resistance characteristic (a characteristic referred to as "VCNR characteristic" hereinafter). These characteristics of the device current can be controlled by conducting the above steps in a controlled manner. The VCNR characteristic may become apparent when the activating substance is supplied excessively to the electron-emitting region by the means for supplying the activating substance.

A linear or a planar electron source may be realized by arranging a number of surface conduction electron-emitting devices on an insulating substrate and wiring them appropriately. Then, an image forming apparatus may be produced by using such an electron source.

Electron-emitting devices may be arranged on a substrate in a number of different modes.

For instance, a number of electron-emitting devices may be arranged in parallel rows along a direction (hereinafter referred to row-direction), each device being connected by wires at opposite ends thereof, and driven to operate by control electrodes (hereinafter referred to as grids) arranged in a space above the electron-emitting devices along a direction perpendicular to the row direction (hereinafter referred to as column-direction) to realize a ladder-like arrangement. Alternatively, a plurality of electron-emitting devices may be arranged in rows along an X-direction and columns along a Y-direction to form a matrix, the X- and Y-directions being perpendicular to each other, and the electron-emitting devices on the same row are connected to a common X-directional wire by way of one of the electrodes of each device while the electron-emitting devices on a same column are connected to a common Y-directional wire by way of the other electrode of each device. The latter arrangement is referred to as a simple matrix arrangement. Now, the simple matrix arrangement will be described in detail.

In view of the above described three basic characteristic features (i) through (iii) of a surface conduction electron-emitting device, to which the

invention is applicable, it can be controlled for electron emission by controlling the wave height and the wave width of the pulse voltage applied to the opposite electrodes of the device above the threshold
5 voltage level. On the other hand, the device does not practically emit any electron below the threshold voltage level. Therefore, regardless of the number of electron-emitting devices arranged in an apparatus, desired surface conduction electron-emitting devices
10 can be selected and controlled for electron emission in response to an input signal by applying a pulse voltage to each of the selected devices.

Fig. 8 is a schematic plan view of the substrate of an electron source realized by arranging a plurality of
15 electron-emitting devices, to which the present invention is applicable, in order to exploit the above characteristic features. In Fig. 8, the electron source comprises a substrate 21, X-directional wires 22, Y-directional wires 23, wires for supplying an
20 activating substance 26, surface conduction electron-emitting devices 24, connecting wires 25 and means for supplying an activating substance 27 consisting of a film resistance heater and an activating substance source. The surface conduction
25 electron-emitting devices 24 may be either of the flat type or of the step type described earlier.

There are provided a total of m X-directional

wires 22, which are denoted by $Dx_1, Dx_2, \dots, Dx_m$ respectively and made of an electroconductive metal produced by vacuum evaporation, printing or sputtering. These wires are appropriately designed in terms of material, thickness and width. A total of n Y-directional wires 23 are arranged and denoted by $Dy_1, Dy_2, \dots, Dy_n$ respectively, which are similar to the X-directional wires in terms of material, thickness and width. There are also provides a total of m wires for supplying an activating substance 26, which are denoted by $Ax_1, Ax_2, \dots, Ax_m$ respectively and arranged like the X- and Y-directional wires. An interlayer insulation layer (not shown) is disposed between the m X-directional wires 22 and the m wires for supplying an activating substance 26 and the n Y-directional wires to electrically isolate them. (Both m and n are integers.)

The interlayer insulation layer (not shown) is typically made of SiO_2 and formed on the entire surface or part of the surface of the insulating substrate 21 carrying the X-directional wires 22 and the wires for supplying an substrate 26 to show a desired contour by means of vacuum evaporation, printing or sputtering. The thickness, material and manufacturing method of the interlayer insulation layer are so selected as to make it withstand the potential difference between any of the X-directional wires 22 and the wires for supplying

an activating substance 26 and any of the Y-directional wire 23 observable at the crossing thereof. Each of the X-directional wires 22, the wires for supplying an activating substance 26 and the Y-directional wires 23
5 is drawn out to form an external terminal.

The oppositely arranged electrodes (not shown) of each of the surface conduction electron-emitting devices 24 are connected to related one of the m X-directional wires 22 and related one of the
10 n Y-directional wires 23 by respective connecting wires 25 which are made of an electroconductive metal.

The electroconductive metal material of the device electrodes and that of the wires 22 and 23 and the connecting wires 25 may be same or contain a common
15 element as an ingredient. Alternatively, they may be different from each other. These materials may be appropriately selected typically from the candidate materials listed above for the device electrodes. If the device electrodes and the connecting wires are made
20 of a same material, they may be collectively called device electrodes without discriminating the connecting wires.

The X-directional wires 22 are electrically connected to a scan signal application means (not shown) for
25 applying a scan signal to a selected row of surface conduction electron-emitting devices 24. On the other hand, the Y-directional wires 23 are electrically

connected to a modulation signal generation means (not shown) for applying a modulation signal to a selected column of surface conduction electron-emitting devices 24 and modulating the selected column according to an
5 input signal. Note that the drive signal to be applied to each surface conduction electron-emitting device is expressed as the voltage difference of the scan signal and the modulation signal applied to the device.

With the above arrangement, each of the devices can
10 be selected and driven to operate independently by means of a simple matrix wire arrangement.

On the other hand, the means for supplying an activating substance can be driven to supply an activating substance on a line by line basis as an
15 appropriate voltage is applied between a selected X-directional wire 26 and a corresponding wire for supplying an activating substance 26.

Now, an image-forming apparatus comprising an electron source having a simple matrix arrangement as
20 described above will be described by referring to Figs. 9A, 10A, 10B and 11. Fig. 9A is a partially cut away schematic perspective view of the image forming apparatus and Figs. 10A and 10B are schematic views, illustrating two possible configurations of a
25 fluorescent film that can be used for the image forming apparatus of Fig. 9A, whereas Fig. 11 is a block diagram of a drive circuit for the image forming

apparatus that operates with NTSC television signals.

Referring firstly to Fig. 9A illustrating the basic configuration of the display panel of the image-forming apparatus, it comprises an electron source substrate 21
5 of the above described type carrying thereon a plurality of electron-emitting devices, a rear plate 31 rigidly holding the electron source substrate 21, a face plate 36 prepared by laying a fluorescent film 34 and a metal back 35 on the inner surface of a glass
10 substrate 33 and a support frame 32, to which the rear plate 31 and the face plate 36 are bonded by means of frit glass. Reference numeral 37 denote an envelope, which is baked to 400 to 500°C for more than 10 minutes in the atmosphere or in nitrogen and hermetically and
15 airtightly sealed.

In Fig. 9A, reference numeral 24 denotes each of the electron-emitting devices and reference numerals 22 and 23 respectively denotes the X-directional wire and the Y-directional wires connected to the respective device
20 electrodes of each of the electron-emitting devices.

While the envelope 37 is formed of the face plate 36, the support frame 32 and the rear plate 31 in the above described embodiment, the rear plate 31 may be omitted if the substrate 21 is strong enough by itself because
25 the rear plate 31 is provided mainly for reinforcing the substrate 21. If such is the case, an independent rear plate 31 may not be required and the substrate 21

may be directly bonded to the support frame 32 so that the envelope 37 is constituted of a face plate 36, a support frame 32 and a substrate 21. The overall strength of the envelope 37 may be increased by
5 arranging a number of support members called spacers (not shown) between the face plate 36 and the rear plate 31.

Figs. 10A and 10B schematically illustrate two possible arrangements of fluorescent film. While the
10 fluorescent film 34 comprises only a single fluorescent body if the display panel is used for showing black and white pictures, it needs to comprise for displaying color pictures black conductive members 38 and fluorescent bodies 39, of which the former are referred
15 to as black stripes or members of a black matrix depending on the arrangement of the fluorescent bodies. Black stripes or members of a black matrix are arranged for a color display panel so that the fluorescent bodies 39 of three different primary colors are made
20 less discriminable and the adverse effect of reducing the contrast of displayed images of external light is weakened by blackening the surrounding areas. While graphite is normally used as a principal ingredient of the black stripes, other conductive material having low
25 light transmissivity and reflectivity may alternatively be used.

A precipitation or printing technique is suitably be

used for applying a fluorescent material on the glass substrate regardless of black and white or color display. An ordinary metal back 35 is arranged on the inner surface of the fluorescent film 34. The metal
5 back 35 is provided in order to enhance the luminance of the display panel by causing the rays of light emitted from the fluorescent bodies and directed to the inside of the envelope to turn back toward the face plate 36, to use it as an electrode for applying an
10 accelerating voltage to electron beams and to protect the fluorescent bodies against damages that may be caused when negative ions generated inside the envelope collide with them. It is prepared by smoothing the inner surface of the fluorescent film (in an operation
15 normally called "filming") and forming an Al film thereon by vacuum evaporation after forming the fluorescent film.

A transparent electrode (not shown) may be formed on the face plate 36 facing the outer surface of the
20 fluorescent film 34 in order to raise the conductivity of the fluorescent film 34.

Care should be taken to accurately align each set of color fluorescent bodies and an electron-emitting device, if a color display is involved, before the
25 above listed components of the envelope are bonded together.

An image forming apparatus as illustrated in Fig. 9A

is typically prepared in a manner as described below.

The envelope 37 is evacuated by means of an appropriate vacuum pump such as an ion pump or a sorption pump that does not involve the use of oil, while it is being heated as in the case of the abovedescribed stabilization process, until the atmosphere in the inside is reduced to a degree of vacuum of 10^{-5} Pa containing an organic substance to a sufficiently low level and then it is hermetically and airtightly sealed. A getter process may be conducted in order to maintain the achieved degree of vacuum in the inside of the envelope 37 after it is sealed. In a getter process, a getter arranged at a predetermined position in the envelope 37 is heated by means of a resistance heater or a high frequency heater to form a film by vapor deposition immediately before or after the envelope 37 is sealed. A getter typically contains Ba as a principal ingredient and can maintain pressure between 1.3×10^{-4} and 1.3×10^{-5} Pa by the adsorption effect of the vapor deposition film. The steps from the energization forming step on to be conducted on the surface conduction electron-emitting devices may be carried out appropriately as described earlier.

If a getter process is repeated for a number of times as will be described hereinafter, an amount of getter that exceeds the amount to be consumed in this step should be arranged inside the envelope 37. For

instance, a getter 28 may be arranged between the envelope 37 and the electron source substrate 21 as schematically illustrated in Fig. 9B. Protecting wall 29 may be arranged to prevent an evaporated getter material from depositing on the electron source substrate to form a getter film there.

Now, a drive circuits for driving a display panel comprising an electron source with a simple matrix arrangement for displaying television images according to NTSC television signals will be described by referring to Fig. 11. In Fig. 11, reference numeral 41 denotes a display panel. Otherwise, the circuit comprises a scan circuit 42, a control circuit 43, a shift register 44, a line memory 45, a synchronizing signal separation circuit 46 and a modulation signal generator 47. V_x and V_a in Fig. 11 denote DC voltage sources.

The display panel 41 is connected to external circuits via terminals $Dox1$ through $Doxm$, $Do1$ through $Doyn$ and high voltage terminal Hv , of which terminals $Dox1$ through $Doxm$ are designed to receive scan signals for sequentially driving on a one-by-one basis the rows (of N devices) of an electron source in the apparatus comprising a number of surface-conduction type electron-emitting devices arranged in the form of a matrix having M rows and N columns.

On the other hand, terminals $Do1$ through $Doyn$ are designed to receive a modulation signal for controlling

the output electron beam of each of the surface-conduction type electron-emitting devices of a row selected by a scan signal. High voltage terminal Hv is fed by the DC voltage source Va with a DC voltage of a level typically around 10kV, which is sufficiently high to energize the fluorescent bodies of the selected surface-conduction type electron-emitting devices.

The scan circuit 42 operates in a manner as follows. The circuit comprises M switching devices (of which only devices S1 and Sm are specifically indicated in Fig. 13), each of which takes either the output voltage of the DC voltage source Vx or 0[V] (the ground potential level) and comes to be connected with one of the terminals Dox1 through Doxm of the display panel 41. Each of the switching devices S1 through Sm operates in accordance with control signal Tscan fed from the control circuit 43 and can be prepared by combining transistors such as FETs.

The DC voltage source Vx of this circuit is designed to output a constant voltage such that any drive voltage applied to devices that are not being scanned due to the performance of the surface conduction electron-emitting devices (or the threshold voltage for electron emission) is reduced to less than threshold voltage.

The control circuit 43 coordinates the operations of related components so that images may be appropriately

displayed in accordance with externally fed video signals. It generates control signals Tscan, Tsft and Tmry in response to synchronizing signal Tsync fed from the synchronizing signal separation circuit 46, which
5 will be described below.

The synchronizing signal separation circuit 46 separates the synchronizing signal component and the luminance signal component from an externally fed NTSC television signal and can be easily realized using a
10 popularly known frequency separation (filter) circuit. Although a synchronizing signal extracted from a television signal by the synchronizing signal separation circuit 46 is constituted, as well known, of a vertical synchronizing signal and a horizontal
15 synchronizing signal, it is simply designated as Tsync signal here for convenience sake, disregarding its component signals. On the other hand, a luminance signal drawn from a television signal, which is fed to the shift register 44, is designed as DATA signal.

20 The shift register 44 carries out for each line a serial/parallel conversion on DATA signals that are serially fed on a time series basis in accordance with control signal Tsft fed from the control circuit 43. (In other words, a control signal Tsft operates as a
25 shift clock for the shift register 44.) A set of data for a line that have undergone a serial/parallel conversion (and correspond to a set of drive data for N

electron-emitting devices) are sent out of the shift register 44 as N parallel signals Id1 through Idn.

5 The line memory 45 is a memory for storing a set of data for a line, which are signals Id1 through Idn, for a required period of time according to control signal Tmry coming from the control circuit 43. The stored data are sent out as signals I'd1 through I'dn to a modulation signal generator 47.

10 Said modulation signal generator 47 is in fact a signal source that appropriately drives and modulates the operation of each of the surface-conduction type electron-emitting devices according to each of the image data I'd1 through I'dn and output signals of this device are fed to the surface-conduction type
15 electron-emitting devices in the display panel 41 via terminals Doy1 through Doyn.

As described above, an electron-emitting device, to which the present invention is applicable, is characterized by the following features in terms of
20 emission current I_e . Firstly, there exists a clear threshold voltage V_{th} and the device emit electrons only a voltage exceeding V_{th} is applied thereto. Secondly, the level of emission current I_e changes as a function of the change in the applied voltage above the
25 threshold level V_{th} . More specifically, when a pulse-shaped voltage is applied to an electron-emitting device according to the invention, practically no

emission current is generated so far as the applied voltage remains under the threshold level, whereas an electron beam is emitted once the applied voltage rises above the threshold level. It should be noted here
5 that the intensity of an output electron beam can be controlled by changing the peak level V_m of the pulse-shaped voltage. Additionally, the total amount of electric charge of an electron beam can be controlled by varying the pulse width P_w .

10 Thus, either a voltage modulation method or a pulse width modulation method may be used for modulating an electron-emitting device in response to an input signal. With voltage modulation, a voltage modulation type circuit is used for the modulation signal
15 generator 47 so that the peak level of the pulse shaped voltage is modulated according to input data, while the pulse width is held constant.

With pulse width modulation, on the other hand, a pulse width modulation type circuit is used for the
20 modulation signal generator 47 so that the pulse width of the applied voltage may be modulated according to input data, while the peak level of the applied voltage is held constant.

Although it is not particularly mentioned above, the
25 shift register 44 and the line memory 45 may be either of digital or of analog signal type so long as serial/parallel conversions and storage of video

signals are conducted at a given rate.

If digital signal type devices are used, output signal DATA of the synchronizing signal separation circuit 46 needs to be digitized. However, such
5 conversion can be easily carried out by arranging an A/D converter at the output of the synchronizing signal separation circuit 46. It may be needless to say that different circuits may be used for the modulation signal generator 47 depending on if output signals of
10 the line memory 45 are digital signals or analog signals. If digital signals are used, a D/A converter circuit of a known type may be used for the modulation signal generator 47 and an amplifier circuit may additionally be used, if necessary. As for pulse width
15 modulation, the modulation signal generator 47 can be realized by using a circuit that combines a high speed oscillator, a counter for counting the number of waves generated by said oscillator and a comparator for comparing the output of the counter and that of the
20 memory. If necessary, an amplifier may be added to amplify the voltage of the output signal of the comparator having a modulated pulse width to the level of the drive voltage of a surface-conduction type electron-emitting device according to the invention.

25 If, on the other hand, analog signals are used with voltage modulation, an amplifier circuit comprising a known operational amplifier may suitably be used for

the modulation signal generator 47 and a level shift circuit may be added thereto if necessary. As for pulse width modulation, a known voltage control type oscillation circuit (VCO) may be used with, if
5 necessary, an additional amplifier to be used for voltage amplification up to the drive voltage of surface-conduction type electron-emitting device.

With an image forming apparatus having a configuration as described above, to which the present
10 invention is applicable, the electron-emitting devices emit electrons as a voltage is applied thereto by way of the external terminals Dox1 through Doxm and Doy1 through Doyn. Then, the generated electron beams are accelerated by applying a high voltage to the metal
15 back 35 or a transparent electrode (not shown) by way of the high voltage terminal Hv. The accelerated electrons eventually collide with the fluorescent film 34, which by turn glows to produce images.

The above described configuration of image forming
20 apparatus is only an example to which the present invention is applicable and may be subjected to various modifications. The TV signal system to be used with such an apparatus is not limited to a particular one and any system such as NTSC, PAL or SECAM may feasibly
25 be used with it. It is particularly suited for TV signals involving a larger number of scanning lines (typically of a high definition TV system such as the

MUSE system) because it can be used for a large display panel comprising a large number of pixels.

Now, an electron source comprising a plurality of surface conduction electron-emitting devices arranged in a ladder-like manner on a substrate and an
5 image-forming apparatus comprising such an electron source will be described by referring to Figs. 12 and 13.

Firstly referring to Fig. 12, reference numeral 51
10 denotes an electron source substrate and reference numeral 52 denotes an surface conduction electron-emitting device arranged on the substrate, whereas reference numeral 53 denotes common wires Dx1 through Dx10 for connecting the surface conduction
15 electron-emitting devices 52. The electron-emitting devices 52 are arranged in rows along the X-direction (to be referred to as device rows hereinafter) on the substrate 51 to form an electron source comprising a plurality of device rows, each row having a plurality
20 of devices. The surface conduction electron-emitting devices of each device row are electrically connected in parallel with each other by a pair of common wires so that they can be driven independently by applying an appropriate drive voltage to the pair of common wires.
25 More specifically, a voltage exceeding the electron emission threshold level is applied to the device rows to be driven to emit electrons, whereas a voltage below

the electron emission threshold level is applied to the remaining device rows. Alternatively, any two external terminals arranged between two adjacent device rows can share a single common wire. Thus, of the common wires
5 Dx2 through Dx9, Dx2 and Dx3 can share a single common wire instead of two wires.

Reference numeral 54 denotes means for supplying an activating substance typically consisting of a film resistance heater and an activating substance source,
10 each of said means being arranged close to a corresponding electron-emitting device 52. Each of said means for supplying an activating substance 54 is connected to one of the related common wires (Dx1, Dx3, ..., Dx_m) and a related one of the wires for supplying
15 an activating substance 55 (Ax1, Ax2, ..., Ax_m) so that the activating substance may be applied to the electron-emitting device as a voltage is applied thereto.

Fig. 13 is a schematic perspective view of the
20 display panel of an image-forming apparatus incorporating an electron source having a ladder-like arrangement of electron-emitting devices. In Fig. 13, the display panel comprises grid electrodes 61, each provided with a number of bores 62 for allowing
25 electrons to pass therethrough, a set of external terminals 63 denoted by Dox1, Dox2, ..., Dox_m along with another set of external terminals 64 denoted by

G1, G2, ..., Gn and connected to the respective grid electrodes 61, and external terminals 65 denoted by Aox1, Aox2, ..., Aox(m/2) for supplying an activating substance. Note that, in Fig. 13, the components same as those of Figs. 9A and 12 are denoted respectively by the same reference symbols. The image forming apparatus shown there differs from the image forming apparatus with a simple matrix arrangement of Fig. 9A mainly in that the apparatus of Fig. 13 has grid electrodes 61 arranged between the electron source substrate 51 and the face plate 36.

In Fig. 13, the stripe-shaped grid electrodes 61 are arranged between the substrate 51 and the face plate 36 perpendicularly relative to the ladder-like device rows for modulating electron beams emitted from the surface conduction electron-emitting devices, each provided with through bores 62 in correspondence to respective electron-emitting devices for allowing electron beams to pass therethrough. Note that, however, while stripe-shaped grid electrodes are shown in Fig. 13, the profile and the locations of the electrodes are not limited thereto. For example, they may alternatively be provided with mesh-like openings and arranged around or close to the surface conduction electron-emitting devices.

The external terminals 63 and the external terminals 64 for the grids are electrically connected to a

control circuit (not shown).

An image-forming apparatus having a configuration as described above can be operated for electron beam irradiation by simultaneously applying modulation
5 signals to the rows of grid electrodes for a single line of an image in synchronism with the operation of driving (scanning) the electron-emitting devices on a row by row basis so that the image can be displayed on a line by line basis.

10 While each of the electron-emitting devices of the above described image forming apparatus is provided with means for supplying an activating substance arranged on the insulating substrate and located close to the corresponding electron-emitting device, said
15 means may be replaced or used in combination with other means for supplying an activating substance provided independently from the electron-emitting devices and arranged within the vacuum envelope of the image forming apparatus or outside the envelope and connected
20 thereto.

Regardless of matrix or ladder-like arrangement, the image forming apparatus can be made to operate stably without losing the quality of performance after the end of the stabilization step by repeatedly carrying out a
25 getter process after hermetically sealing the envelope and supplying an activating substance by any of the above described methods.

Thus, a display apparatus according to the invention and having a configuration as described above can have a wide variety of industrial and commercial applications because it can operate as a display apparatus for television broadcasting, as a terminal apparatus for video teleconferencing, as an editing apparatus for still and movie pictures, as a terminal apparatus for a computer system, as an optical printer comprising a photosensitive drum and in many other ways.

[Examples]

Now, the present invention will be described by way of examples.

[Example 1]

Figs. 14A through 14D schematically illustrate an electron source in this example. As shown in Figs. 14A through 14D, a surface conduction electron-emitting devices of the electron source of the example is constituted by a pair of device electrodes 2 and 3 and an electroconductive thin film 4 including an electron-emitting region 5, while means for supplying an activating substance is constituted by a pair of electrodes 2 and 6, a film resistance heater 7 and an activating substance source 8. While the arrangement of this example is similar to that of Figs. 1A through 1C, the former differs from the latter in that a pair of means for supplying an activating substance are

arranged along the respective lateral sides of the electron-emitting region.

Fig. 14A is a schematic plan view of the arrangement of this example, whereas Figs. 14B, 14C and 14D are schematic sectional views respectively taken along lines 14B-14B, 14C-14C and 14D-14D. The device electrode 3 and the electrode for supplying an activating substance 6 are electrically isolated from each other by means of an insulation layer 9.

The process employed for manufacturing the electron source of this example will be described by referring to Figs. 15A through 15J and Fig. 15L.

(a) After thoroughly cleansing a quartz substrate 1 and drying it, photoresist (RD-2000N-41: available from Hitachi Chemical Co., Ltd.) was applied thereto by means of a spinner and then subjected to a pre-baking operation at 80°C for 25 minutes to produce a photoresist layer 71. (Fig. 15A)

(b) The substrate was exposed to light, using a photomask, to form the pattern of the pair of device electrode and the exposed photoresist was photochemically developed. Thereafter, openings 72 having profiles corresponding to those of the device electrodes were formed and the photoresist was subjected to a post-baking operation at 120°C for 20 minutes. (Fig. 15B or cross section along line 14B-14B in Fig. 14A)

(c) An Ni film 73 was formed by vacuum evaporation to a film thickness of 100nm. (Fig. 15C or cross section along line 14B-14B in Fig. 14A)

5 (d) The resist was dissolved into acetone and the device electrodes 2 and 3 were formed by lift-off and cleansed with acetone, isopropylalcohol (IPA) and then butyl acetate. Thereafter, the substrate carrying the formed device electrodes were dried. (Fig. 15D or cross section along line 14B-14B in Fig. 14A)

10 (e) An SiO_2 film was formed to a thickness of 600nm by sputtering and the pattern of the insulating layer 9 was formed with photoresist, which was then etched with CF_4 and H_2 to produce the insulation layer 9. (Fig. 15E or the plan view)

15 (f) An electrode for supplying an activating substance 6 was formed, following the steps (a) through (d) above. (Fig. 15F or the plan view)

(g) An $\text{ITO}(\text{In}_2\text{O}_3\text{-SnO}_2)$ film was formed by sputtering. Photoresist (AZ-1370: available from Hoechst Corporation) was applied thereon by means of a spinner and subjected to a pre-baking operation at 90°C for 30 minutes. Thereafter, a photomask was used to expose the photoresist to light, which was then photochemically developed and subjected to a post-baking operation at 120°C for 20 minutes. Then, the photoresist was dry-etched, using the photomask to produce a film resistance heater 7 of ITO. The film

20

25

showed an electric resistance of $R_s \approx 100 \Omega/\square$. (Fig. 15G or the plan view).

(h) A Cr film 74 having a film thickness of 50nm was formed by vacuum evaporation. Subsequently,
5 photoresist (AZ-1370) was applied thereto by means of a spinner and subjected to a pre-baking operation as described above to produce a photoresist layer 75, which was then exposed to light, photochemically developed and subjected to a post-baking operation to
10 produce an opening 76 having a profile corresponding to that of the activating substance source to be formed. (Fig. 15H or a cross section along line 14C-14C in Fig. 14A)

(i) The device was then immersed into an etchant for
15 30 seconds to remove the Cr film under the above opening. The etchant has a composition of $(\text{NH}_4)\text{Ce}(\text{NO}_3)_6/\text{HClO}_4/\text{H}_2\text{O}=17\text{g}/5\text{cc}/100\text{cc}$. The resist was then dissolved into acetone to form an Cr mask. (Fig. 15I or a cross section along line 14C-14C in Fig. 14A)

20 (j) A methylethylketone solution containing 3% polyvinylacetate was applied to the device by means of a spinner and heated to dry at 60°C for 10 minutes. Thereafter, the Cr mask was removed with the above etchant and a polyvinylacetate film was formed for an
25 activating substance source 8 by lift-off. (Fig. 15J or a cross section along line 14C-14C in Fig. 14A)

(k) A Cr mask having an opening with a profile

corresponding to that of the electroconductive thin film to be formed there was produced by following the steps (h) through (i) above.

(1) A butylacetate solution of Pd amine complex
5 (ccp4230: available from Okuno Pharmaceutical Co.,
Ltd.) was applied to the Cr film by means of a spinner
and baked at 300°C for 10 minutes. Then, the Cr film
was removed to produce an electroconductive thin film 4
principally made of fine particles containing palladium
10 oxide (PdO) as a principal ingredient and had a film
thickness of about 10nm. The electroconductive thin
film showed an electric resistance of $R_s=5 \times 10^4 \Omega/\square$.
(Fig. 15L or a cross section along line 14B-14B in Fig.
14A)

15 In the above example, the distance separating the
device electrodes was $L=2\mu\text{m}$, which had a width of
 $W_1=500\mu\text{m}$.

(m) The prepared device was then placed in the vacuum
chamber of a vacuum system of Fig. 6, which was then
20 evacuated to a pressure level of $2.7 \times 10^{-5} \text{Pa}$. Then, a
pulse voltage was applied to the device electrodes 2
and 3 from a power source 11 to carry out an
energization forming operation. In this operation, the
electric potential of the electrode for supplying an
25 activating substance 6 as shown in Fig. 14A was made
equal to that of the device electrode 2 and no voltage
was applied to the film resistance heater 7.

The waveform of the applied pulse voltage was a triangular pulse with an gradually increasing wave height. The pulse width of $T_1=1\text{msec.}$ and the pulse interval of $T_2=10\text{msec.}$ were used. During the energization forming process, an extra pulse voltage of 0.1V was inserted into intervals of the forming pulse voltage in order to determine the resistance of the electroconductive film and the forming process was terminated when the resistance exceeded $1\text{M}\Omega$. The peak value of the pulse voltage was 5.0V when the forming process was terminated. An electron-emitting region 5 was produced in the electroconductive thin film 4 as a result of this energization forming operation.

(n) Subsequently, the electron source was subjected to an activation process in the vacuum chamber, introducing acetone into the chamber and maintaining the partial pressure of acetone in the vacuum chamber to about $1.3 \times 10^{-2}\text{Pa}$. A pulse voltage was then applied to the device electrodes 2 and 3 in the vacuum chamber. No voltage was applied to the film resistance heater 7 shown in Fig. 14A during this operation as in the case of Step-m above. A rectangular pulse voltage having a pulse width of $T_1=100\mu\text{sec.}$ and a pulse interval of $T_2=10\text{msec.}$ was used. The wave height of the pulse voltage was gradually raised from 10V to 14V at a rate of 3.3 mV/sec.

Thereafter, the application of pulse voltage was

stopped and the acetone remaining in the inside of the vacuum chamber was removed. As a result of this operation, carbon or a carbon compound was deposited near the electron-emitting region 5.

5 The performance of the prepared electron source was then tested with the same system. The internal pressure in the vacuum chamber 16 was held below 1.3×10^{-6} Pa and the anode was separated from the device by a distance of $H=4$ mm. A rectangular pulse voltage
10 having a wave height of 14V, a pulse width of $T_1=100 \mu\text{sec}$. and a pulse interval of 10 msec. was applied between the device electrodes 2 and 3. Similarly, a rectangular pulse voltage having a wave height of 5V, a pulse width of $T_1=50 \mu\text{sec}$. and a pulse interval of
15 10 msec. was applied between the device electrode 2 and the electrode for supplying an activating substance 6. The application of the two pulse voltages was so controlled for timing that they might not be turned on simultaneously.

20 The time of the start of the measuring operation is defined as $\tau=0$ and the device current $I_f(\tau)$ and the emission current $I_e(\tau)$ were measured. The reduction ratio of I_f and that of I_e are defined as follow to evaluate them.

25

$$\delta I_f(\tau) = \frac{I_f(\tau) - I_f(0)}{I_f(0)}$$

$$\delta I_e(\tau) = \frac{I_e(\tau) - I_e(0)}{I_e(0)}$$

In this example, $I_f(0)=1.8\text{mA}$ and $I_e(0)=0.9\mu\text{A}$. Thus,
 5 if $\eta(\tau)=I_e(\tau)/I_f(\tau)$, $\eta(0)=0.05\%$. So, the reduction
 ratios after an hour were $\delta I_f(1\text{hour})=5\%$ and
 $\delta I_e(1\text{hour})=5\%$.

[Example 2]

An electron source having a configuration as shown in
 10 Figs. 14A through 14D was prepared as in the case of
 Example 1 and was then tested for performance. The
 electron source was driven to operate without applying
 any voltage between the device electrode 2 and the
 electrode for supplying an activating substance 6. The
 15 performance at the start of the operation was equal to
 that of the electron source of Example 1, although the
 reduction ratios of I_f and I_e were respectively
 $\delta I_f(1\text{hour})=20\%$ and $\delta I_e(1\text{hour})=25\%$.

Thereafter, while heating the film resistance heater
 20 7 by applying a pulse voltage between the device
 electrode 2 and the electrode for supplying an
 activating substance 6 and electrically energizing the
 film resistance heater 7, another pulse voltage was
 applied between the device electrodes 2 and 3 to drive
 25 the electron source for operation. The pulse voltage
 applied between the device electrode 2 and the
 electrode for supplying an activating substance 6 was a

rectangular pulse voltage having a wave height of 5V
and a pulse width of 200μsec. The application of the
two pulse voltages was so controlled for timing that
they might not be turned on simultaneously. After
5 continuing the operation for 3 minutes, the application
of the voltages was stopped.

Then, after waiting for 5 minutes in order to cool
the activating substance source, the operation of
driving the electron source was resumed to obtain
10 values of $I_f=1.5\text{mA}$ and $I_e=0.8\mu\text{A}$, which proved that the
electron emitting performance of the electron source
was recovered.

[Example 3]

The electron source prepared in this example had a
15 configuration substantially same as that of the
electron source of Example 1. Therefore, only the
manufacturing steps that are different from their
counterparts of Example 1 will be described below by
referring to Figs. 16H, 16J and 16K.

20 Steps-(a) through (g) of Example 1 were followed.
Thereafter, the following steps were carried out.

(h) Photoresist (AZ-1370) was applied thereto by
means of a spinner and subjected to a pre-baking
operation at 90°C for 30 minutes to produce a
25 photoresist layer 74, which was then exposed to light,
photochemically developed and subjected to a
post-baking operation to produce an opening 76 having a

profile corresponding to that of the activating substance source to be formed. (Fig. 16H or a cross section along line 14C-14C in Fig. 14A)

(i) A aqueous solution containing 2% polyvinylalcohol (PVA) was applied thereto by means of a spinner and heated to dry at 60°C for 10 minutes to produce a PVA layer 77. (Fig. 16J or a cross section along line 14C-14C in Fig. 14A)

(j) The photoresist was then dissolved into acetone and the PVA layer was subjected to a patterning operation to produce a desired pattern by means of lift-off, which was then heated and baked at 300°C to produce an activating substance source 8. (Fig. 16K or a cross section along line 14C-14C in Fig. 14A)

Then, Steps-(k) through (n) of Example 1 were followed to produce an electroconductive thin film 4 of fine PdO particles, which was then subjected to energization forming and activation processes.

When tested for performance as in the case of Example 1, $I_f(0)=1.7\text{mA}$ and $I_e(0)=1.4\mu\text{A}$ were observed at the onset to provide an electron emission efficiency of $\eta(0)=0.085\%$. The reduction ratios after an hour were $\delta I_f(1\text{hour})=7\%$ and $\delta I_e(1\text{hour})=8\%$.

[Example 4]

Fig. 17A schematically shows a plan view of the electron source prepared in this example. It comprised a substrate 1, a pair of device electrodes 2 and 3, an

electroconductive thin film 4 of fine PdO particles including an electron-emitting region 5, an electrode for supplying an activating substance 6 and an activating substance source 8 made of polyvinylacetate.

5 In the electron source of this example, a surface conduction electron-emitting device was constituted by the device electrodes 2 and 3 and the electroconductive thin film 4 including the electron-emitting region 5, whereas the means for supplying an activating substance
10 is constituted by the electrode 6 and the activating substance source 8.

In the example, a distance separating the device electrodes of $L=10\mu\text{m}$, a width of the device electrodes of $W_1=300\mu\text{m}$ were selected.

15 The electron source of this example was prepared in a manner as described below.

(a) Steps-(a) through (d) of Example 1 were followed to produce a pair of device electrode 2 and 3 and an electrode for supplying an activating substance 6 on a
20 substrate 1.

(b) Steps-(h) through (j) of Example 1 were also followed to produce an activating substance source 8 made of polyvinylacetate on the electrode for supplying an activating substance 6.

25 (c) Steps-(k) through (n) of Example 1 were also followed to produce an electroconductive thin film 4 of fine PdO particles and then an electron-emitting region

2160656

5 was produced by an energization forming process. The prepared electron source was subsequently subjected to an activation process.

5 The prepared electron source was tested for its electron emitting performance by applying a rectangular pulse voltage as shown in Fig. 5C. The pulse wave height was 16V and the pulse width and the pulse interval were respectively $T_1=100\mu\text{sec.}$ and $T_2=10\text{msec.}$ The device was separated from the anode by a distance
10 of $H=4\text{mm}$ and the potential difference between them was equal to $V_a=1\text{kV.}$

When tested for performance, $I_f(0)=1.3\text{mA}$ and $I_e(0)=1.1\mu\text{A}$ were observed at the onset to provide an electron emission efficiency of $\eta(0)=0.085\%$. The
15 reduction ratios after an hour were $\delta I_f(1\text{hour})=20\%$ and $\delta I_e(1\text{hour})=25\%$.

Thereafter, the application of the voltage V_a to the anode was stopped and, while a voltage of 100V were being applied to the electrode for supplying an
20 activating substance 6, a pulse voltage as described above was applied between the device electrodes 2 and 3 for 3 minutes. Thereafter, the application of the voltage to the electrode for supplying an activating substance 6 was stopped and the application of the
25 voltage $V_a=1\text{kV}$ to the anode was resumed to test the performance of the electron source once again and obtain $I_f=1.1\text{mA}$ and $I_e=1.0\mu\text{A}$. Thus, it was proved that

2160656

the electron emitting performance of the electron source was recoverable.

5 This remarkable feature of a recoverable electron emitting performance on the part of the electron source may be because electrons emitted from the electron-emitting region 5 are partly attracted by the electrode for supplying an activating substance 6 and collide with the activating substance source 8 to impart energy to the latter, molecules of
10 polyvinylacetate are decompositted, resulted materials are released and carbon or a carbon compound is deposited near the electron-emitting region as in the case of an activation process to offset the eroded portion of the deposit of carbon or a carbon compound.

15 [Example 5]

In this example, an image forming apparatus comprising an electron source and an image displaying member of a fluorescent material was prepared. The electron source was formed by arranging a plurality of
20 surface conduction electron-emitting devices on a substrate and wiring them in a ladder-like manner. Figs. 12 and 13 schematically show the electron source and the image forming apparatus of this example respectively.

25 Now, the steps used for manufacturing the image forming apparatus of the example will be described below by referring to Figs. 18A through 18F.

2160656

(A) After thoroughly cleansing a soda lime glass plate, a silicon oxide film was formed thereon to a thickness of $0.5\mu\text{m}$ by sputtering to produce a substrate 51, on which a pattern of photoresist (RD-2000N-41: available from Hitachi Chemical Co., Ltd.) was formed, said pattern having openings for common wires 53 that also operated as device electrodes and wires for supplying and activating substance 55 that also operated as electrodes for supplying an activating substance. Then Ti and Ni were sequentially deposited thereon respectively to thicknesses of 5nm and 100nm by vacuum evaporation. The photoresist pattern was dissolved by an organic solvent and the Ni/Ti deposit film was treated by using a lift-off technique to produce common wires 53 operating as device electrodes 2 and 3 and wires for supplying an substrate 55 operating as electrodes for supplying an activating substance. The distance separating the device electrodes of each electrode pair was $L=3\mu\text{m}$. (Fig. 18A)

(B) An SiO_2 film was formed to a thickness of 600nm by sputtering and then a pattern was formed on the insulation film by means of photoresist, which was then dry-etched by means of CF_4 and H_2 to produce an insulation layer 9 for each device. (Fig. 18B)

(C) An film resistance heater 7 of ITO was formed for each device as in the case of Step-(g) of Example 1.

(Fig. 18C)

(D) An activating substance source 8 of a film of polyvinylacetate was formed on the film resistance heater 7, following Steps-(h) through (j) of Example 1.

5 (Fig. 18D)

(E) A Cr film was formed to a thickness of 300nm by vacuum evaporation and then an opening 56 corresponding to the pattern of a electroconductive thin film was formed by ordinary photolithography to produce a Cr mask 57. (Fig. 18E)

(F) A solution of Pd amine complex (ccp4230: available from Okuno Pharmaceutical Co., Ltd.) was applied to the Cr film by means of a spinner, and baked at 300°C for 12 minutes in the air. As a result, an electroconductive film of fine particles containing PdO as a principal ingredient was produced and had a film thickness of 7nm (Fig. 18F).

The Cr mask was then wet-etched to be removed and the PdO film was lifted-off to produce an electroconductive thin film 4 having a desired pattern. The electric resistance of the electroconductive thin film was $R_s=2 \times 10^4 \Omega/\square$.

By using an electron source manufactured in a manner as described above, an image forming apparatus was prepared. This will be described by referring to Fig. 13.

After securing the electron source substrate 51 onto

a rear plate 31, a face plate 36 (carrying a fluorescent film 34 and a metal back 35 on the inner surface of a glass substrate 33) was arranged above the substrate 51 with a support frame 32 disposed therebetween to form an envelope and, subsequently, frit glass was applied to the contact areas of the face plate 36, the support frame 32 and rear plate 31 and baked at 400°C for 10 minutes in a nitrogen atmosphere to hermetically seal the envelope. The substrate 51 was also secured to the rear plate 31 by means of frit glass.

While the fluorescent film 34 is consisted only of a fluorescent material if the apparatus is for black and white images, the fluorescent film 34 of this example was prepared by forming black stripes and filling the gaps with stripe-shaped fluorescent members of red, green and blue. The black stripes were made of a popular material containing graphite as a principal ingredient. A slurry technique was used for applying fluorescent materials onto the glass substrate 33.

An ordinary metal back 35 was arranged on the inner surface of the fluorescent film 34. After preparing the fluorescent film, the metal back was prepared by carrying out a smoothing operation (normally referred to as "filming") on the inner surface of the fluorescent film and thereafter forming thereon an aluminum layer by vacuum evaporation.

While a transparent electrode (not shown) might be arranged on the outer surface of the fluorescent film 84 in order to enhance its electroconductivity, it was not used in this example because the fluorescent film
5 showed a sufficient degree of electroconductivity by using only a metal back.

For the above bonding operation, the fluorescent members of the primary colors and the corresponding electron-emitting device were accurately aligned. As
10 shown in Fig. 13, the electron source substrate 51, the rear plate 31, the face plate 36 and the grid electrodes 61 were carefully combined and the external terminals 63, the external grid electrode terminals 64 and the terminals for the electrodes for supplying an
15 activating substance 65 were electrically connected. Reference numeral 62 denotes a hole for allowing electrons to pass therethrough.

The subsequent manufacturing steps and a measuring operation were carried out in a vacuum system as
20 illustrated in Fig. 19.

The vacuum container (envelope) 82 of the image forming apparatus 81 was connected to the vacuum chamber 85 of the vacuum system by way of an exhaust pipe 84. The vacuum chamber 85 was evacuated by means
25 of a vacuum pump unit 89 by way of a gate valve 88 and the atmosphere in the inside of the vacuum container 82 was monitored by a pressure gauge 86 arranged in the

vacuum chamber 85. A quadrupole mass (Q-mass) spectrometer 87 was also arranged within the vacuum chamber 85 to measure the partial pressures of the gases within the chamber.

5 After evacuating the inside of the vacuum container 82 to a reading of the pressure gauge 86 less than 1.3×10^{-4} Pa, an energization forming operation was carried out on the electron-emitting devices of the electron source by applying a pulse voltage to each
10 device by way of an electric circuit (not shown) as in the case of Example 1. The pulse voltage was applied by connecting the anode and the cathode of each device to a power source by way of the external terminals 63. No voltage was applied to the film resistance heater 7
15 of the device.

Subsequently, the image forming apparatus was subjected to an activation process. The vacuum chamber 85 was also connected to an ampule containing an activating substrate by way of a valve 90 for
20 introducing gas of the activating substance. In this example, acetone was used for the activating substance. Acetone was introduced into the vacuum chamber 85 by controlling the valve 90 and the gate valve 88 until the reading of the pressure gauge became equal to
25 1.3×10^{-2} Pa. Thereafter, a pulse voltage was applied to the image forming apparatus on a row by row basis to carry out an energization forming process. The pulse

had a waveform as that of the pulse used in Example 1.

After the completion of the activation process, the supply of acetone was stopped and the gate valve 88 was made full open to evacuate the inside the vacuum container 82, maintaining the temperature of the vacuum
5 container 82 to about 200°C. After 5 hours, the internal pressure reached to 1.3×10^{-4} Pa and it was confirmed by Q-mass 87 that no acetone was remaining inside the chamber.

10 Then, the heater was turned off to cool the image forming apparatus. Thereafter, the electron source 83 was made to emit electrons until the entire surface of the image displaying member (fluorescent film) glowed to prove that the image forming apparatus was operating
15 normally before the exhaust pipe 84 was sealed off by means of a burner. Finally, the getter arranged within the image forming apparatus 81 was heated by means of high frequency heating to produce a vapor deposition film. The getter contained Ba as a principal
20 ingredient and was designed to maintain the vacuum inside the vacuum container 82 by the adsorption effect of the vapor deposition film of getter material.

For displaying an image on the image forming apparatus of this example, a voltage was applied from a
25 power source to the device rows on a row by row basis to "select a row" and causes all the devices of the row to emit electron beams. The emission of electron beam

of each device was made on and off by controlling the potentials of the grid electrodes running perpendicularly relative to the device rows so that desired pixels may be irradiated by electron beams to
5 emit light.

In a measuring operation for determining the performance of the image forming apparatus, no voltage was applied to the grid electrodes because electron beams did not have to be made on and off and,
10 therefore, a voltage was applied only to the device rows on a row by row basis. The voltage applied to each device was a rectangular pulse voltage as shown in Fig. 5C, having a wave height of 14V, a pulse width of 100μsec. and a pulse interval of 10msec. The timing of
15 the pulse voltage applied to each device row was so controlled that the on period of the pulse voltage being applied to a device row did not coincide with the on period of the pulse voltage being applied to any other row.

20 A rectangular pulse voltage was also applied to each means for supplying an activating substrate comprising a film resistance heater and an activating substance source of the image forming apparatus. The voltage applied to each means for supplying an activating
25 substrate was also a rectangular pulse voltage, having a wave height of 5V, a pulse width of 50μsec. and a pulse interval of 10msec. The two pulses were so

arranged for timing that they were displaced from each other by a half period. The electron emitting performance of the devices would be modified undesirably if a too large pulse width is used mainly because the activating substrate is supplied excessively. Therefore, the pulse width and other critical factors have to be rigorously selected in order to supply the activating substrate at an appropriate rate if the design of the image forming apparatus is modified.

When tested for performance, as average values per one device, $I_f(0)=1.8\text{mA}$ and $I_e(0)=2.4\mu\text{A}$ were observed at the onset to provide an electron emission efficiency of $\eta(0)=0.013\%$. The reduction ratios after an hour of operation were $\delta I_f(1\text{hour})=5\%$ and $\delta I_e(1\text{hour})=7\%$.

[Example 6]

An image forming apparatus was prepared as in the case of Example 5 and driven to operate without applying a voltage to the means for supplying an activating substrate and the performance of the apparatus was evaluated. Otherwise, the operating conditions were same as those of Example 5. An excessive amount of getter was arranged and not used at the time of sealing the exhaust pipe.

When tested for performance, both $I_f(0)$ and $I_e(0)$ were observed at the onset were substantially same as their counterparts of Example 5. The reduction ratios

after an hour of operation were $\delta I_f(1\text{hour})=22\%$ and $\delta I_e(1\text{hour})=24\%$.

Thereafter, the voltage H_v applied to the face plate was removed and the devices were driven to operate, applying a pulse voltage to the means for supplying an activating substrate. The voltage applied to the devices was same as that of the performance test and a rectangular pulse voltage having a wave height of 5V, a pulse width of 200 μ sec. and a pulse interval of 10msec. was applied to the means for supplying an activating substrate. The two pulses were so arranged for timing that they were displaced from each other by a half period. This operation of voltage application was conducted for 3 minutes and then the remaining getter was partly heated by high frequency heating for another getter operation before the image forming apparatus was tested once again for performance. The, $I_f=1.6\text{mA}$ and $I_e=2.2\mu\text{sec.}$ were obtained to prove a recovery of the performance of the devices.

[Example 7]

In this example, an image forming apparatus comprising an electron source realized by arranging a plurality of surface conduction electron-emitting device on a substrate and wiring them to form a matrix wiring arrangement and an image forming member of a fluorescent body housed in a glass vacuum container. The electron source had 100 devices in each row and

each column along the X- and Y-directions respectively.

The image forming apparatus of the examples was prepared in a manner as described below by referring to Figs. 20 through 22G.

5 Fig. 20 is an enlarged schematic plan view of part of the electron source of this example. Fig. 21 is a schematic sectional view of the electron source taken along line 21-21 in Fig. 20. In these figures, reference numeral 24 denotes a surface conduction
10 electron-emitting device comprising a pair of device electrodes and an electroconductive thin film including an electron-emitting region. Reference numerals 22 and 23 respectively denote a lower wire (X-directional wire) and an upper wire (Y-directional wire).

15 (A) After thoroughly cleansing a soda lime glass plate a silicon oxide film was formed thereon to a thickness of 0.5 μ m by sputtering to produce a substrate 21, on which Cr and Au were sequentially laid to thicknesses of 5nm and 600nm respectively and then a
20 photoresist (AZ1370: available from Hoechst Corporation) was formed thereon by means of a spinner, while rotating the film, and baked. Thereafter, a photo-mask image was exposed to light and
photochemically developed to produce a resist pattern
25 for a lower wire 22 and then the deposited Au/Cr film was wet-etched to produce a lower wire 22. (Fig. 22A).

(B) A silicon oxide film was formed as an interlayer

insulation layer 93 to a thickness of 1.0 μ m by RF sputtering. (Fig. 22B).

(C) A photoresist pattern was prepared for producing a contact hole 94 in the silicon oxide film deposited in Step-B, which contact hole 94 was then actually formed by etching the interlayer insulation layer 93, using the photoresist pattern for a mask. A technique of RIE (Reactive Ion Etching) using CF₄ and H₂ gas was employed for the etching operation. (Fig. 22C)

(D) Thereafter, a pattern of photoresist (RD-2000N-41: available from Hitachi Chemical Co., Ltd.) was formed for a pair of device electrodes 2 and 3 and a gap G separating the electrodes and then Ti and Ni were sequentially deposited thereon respectively to thicknesses of 5nm and 100nm by vacuum evaporation. The photoresist pattern was dissolved into an organic solvent and the Ni/Ti deposit film was treated by using a lift-off technique to produce a pair of device electrodes 2 and 3 having a width of 300 μ m and separated from each other by a distance G of 3 μ m. (Fig. 22D).

(E) After forming a photoresist pattern on the device electrodes 2, 3 for an upper wire 23, Ti and Au were sequentially deposited by vacuum evaporation to respective thicknesses of 5nm and 500nm and then unnecessary areas were removed by means of a lift-off technique to produce an upper wire 23 having a desired

profile. (Fig. 22E).

(F) Then, an electroconductive thin film 4 was formed as in the case of (k) of Example 1. (Fig. 22F)

5 (G) Then, a pattern for applying photoresist to the entire surface area except the contact hole 94 was prepared and Ti and Au were sequentially deposited by vacuum evaporation to respective thicknesses of 5nm and 500nm. Any unnecessary areas were removed by means of a lift-off technique to consequently bury the contact
10 hole 94.

By using an electron source prepared in a manner as described above, an image forming apparatus was prepared. This will be described by referring to Figs. 23A and 23B.

15 (H) After securing an electron source substrate 21 onto a rear plate 31, a face plate 36 (carrying a fluorescent film 34 and a metal back 35 on the inner surface of a glass substrate 33) was arranged 5mm above the substrate 21 with a support frame disposed
20 therebetween and, subsequently, frit glass was applied to the contact areas of the face plate 36, the support frame 32 and rear plate 31 and baked at 400°C in a nitrogen atmosphere for more than 10 minutes to hermetically seal the container. The substrate 21 was
25 also secured to the rear plate 31 by means of frit glass.

While the fluorescent film is consisted only of a

fluorescent body if the apparatus is for black and white images, the fluorescent film of this example was prepared by forming black stripes and filling the gaps with stripe-shaped fluorescent members of primary
5 colors. The black stripes were made of a popular material containing graphite as a principal ingredient. A slurry technique was used for applying fluorescent materials onto the glass substrate 33.

10 A metal back 35 is arranged on the inner surface of the fluorescent film 34. After preparing the fluorescent film, the metal back was prepared by carrying out a smoothing operation (normally referred to as "filming") on the inner surface of the fluorescent film and thereafter forming thereon an
15 aluminum layer by vacuum evaporation.

While a transparent electrode (not shown) might be arranged on the outer surface of the fluorescent film 34 of the face plate 36 in order to enhance its electroconductivity, it was not used in this example
20 because the fluorescent film showed a sufficient degree of electroconductivity by using only a metal back.

For the above bonding operation, the components were carefully aligned in order to ensure an accurate positional correspondence between the color fluorescent
25 members and the electron-emitting devices.

As shown in Fig. 25, the envelope (vacuum container) 37 was provided with a glass container 105 by way of a

connector pipe 106 and an activating substance source 8 was arranged within the glass container 105. In this example, the activating substance source 8 was made of a molecular sieve of the type popularly used for an adsorption agent of a sorption pump, to which n-dodecane was adsorbed. The connecting pipe 106 is provided with a valve 40 that be opened and closed appropriately.

(I) The image forming apparatus was then evacuated by means of a vacuum system shown in Fig. 19 as in the case of Example 5. As illustrated in Fig. 24, the Y-directional wires 23 were connected to a common wire so that an energization forming operation was carried out on a row by row basis. In Fig. 24, reference numeral 101 denotes a common electrode for commonly connecting the Y-directional wires 23 and reference numeral 102 denote a power source, while reference numeral 103 denotes a resistor for determining the electric current and reference numeral 104 denotes an oscilloscope for monitoring the electric current.

A pulse voltage having a wave form same as that of the pulse voltage of Example 1 was used for the energization forming operation. During the energization forming process, an extra pulse voltage of 0.1V was inserted into intervals of the forming pulse voltage in order to determined the resistance of the electron-emitting region and the energization forming

process was terminated when the resistance exceeded 10k Ω .

(J) Subsequently, an activation process was carried out. The activating substance was supplied by opening the valve 40 and heating the glass container 105 through irradiation of He-Ne laser in order to cause the activating substance source to release n-dodecane into the vacuum container 37. The voltage was applied to the devices on a row by row basis as in the case of Step-(I) above. The remaining conditions for the operation were same as those of Example 5.

(K) After the end of the activation process, the valve 40 was closed and the inside of the vacuum container was evacuated as in the case of Example 5. Then, the operation of the image forming apparatus was checked again and the exhaust pipe was sealed. At the very end, a getter operation was conducted for the image forming apparatus.

The image forming apparatus of this examples was then tested for performance. In a measuring operation for determining the performance of the image forming apparatus, a voltage was applied only to the device rows on a row by row basis by so connecting the wires as in the case of the energization forming and activation processes, although the simple matrix arrangement was to be utilized to drive each electron-emitting device independently for electron

emission if images were to be displayed on the screen.

A rectangular pulse voltage as shown in Fig. 5C was applied to the X-directional wires. The pulse voltage had a wave height of 14V, a pulse width of 100μsec. and
5 a pulse interval of 10msec. The phases of the pulse voltages applied to any adjacently located X-directional wires were shifted by 100μsec. or a value equal to the pulse width.

A voltage of 4kV was applied between the electron
10 source and the metal back of the face plate in order to accelerate electron beams.

With the image forming apparatus of this example, no large and bulky arrangement is required for introducing an activating substance into the vacuum system so that
15 a simple manufacturing apparatus and a simplified manufacturing method could be used.

[Example 8]

The steps up to the activation step of Example 7 were followed. The pipe 106 connecting the vacuum container
20 37 and the glass container 105 was provided with a valve 40 in order to open and close the pipe. After evacuating the inside of the vacuum container 37, closing the valve 40, the exhaust pipe (84 in Fig. 19) was sealed off by means of a burner. Subsequently, a
25 getter operation was carried out by means of high frequency heating, although an excessive amount of getter was left inside and was not used in the getter

operation.

The image forming apparatus was driven to operate and a degradation in the electron emitting performance was confirmed as in the case of Example 6. Then, the
5 performance of the apparatus was recovered by opening the valve 40 on the connecting pipe 106, irradiating the glass container with laser to heat it as in the case of an activation process, supplying n-dodecane into the vacuum container again and applying a voltage
10 to the electron-emitting devices also as in the case of an activation process, the remaining getter was partly heated by high frequency heating for another getter operation before the image forming apparatus was tested once again for performance. When tested again for
15 performance, it was found that the image forming apparatus recovered its original performance.

[Example 9]

An image forming apparatus was prepared as in the case of Example 8 except that the glass container 105
20 was made to contain $W(CO)_6$. After carrying out an activation process as in the case of the above examples, the valve 40 was closed and the inside of the vacuum container 37 was evacuated, heating the container to 200°C. Under this condition, the vacuum
25 container 106 was evacuated, blowing nitrogen gas onto the glass container 105 in order to prevent it from being heated.

When the evacuation was over, the exhaust pipe was sealed off by means of a burner and then a getter operation was carried out.

5 The prepared image forming apparatus was tested for performance as in the case of Example 7. At the onset of the measuring operation, $I_f(0)=1.8\text{mA}$ and $I_e(0)=2.0\mu\text{A}$ were observed to prove $\eta(0)=0.11\%$.

10 Thereafter, however, the performance of the image forming apparatus showed a change that was different from that of its counterpart that had a deposit of a carbon compound. While both I_f and I_e were observed to be decreasing in the first 30 minutes after the onset of the operation, the rate of decrease was reduced remarkably thereafter if compared that of the apparatus
15 of Example 8.

This may be because, while a device comprising a deposit of carbon or a carbon compound loses the deposit quickly as it is heated and evaporates as a result of electron emission to eventually deform the
20 electroconductive thin film such that it can no longer emit electrons, each of the devices of this example comprised a deposit of tungsten (W) that had a high melting point and hence would not be lost nor deformed easily. The degradation of performance observed in the
25 initial stages may prove that H_2 and CO existing within the vacuum container of the image forming apparatus were adsorbed by the surface of the film of the W

deposit to deter electron emission.

When the initial decreasing in the electron emitting performance came to an end, the high voltage source for applying a voltage between the face plate and the metal back was turned off. Then, the valve 40 was opened and the glass container 105 was heated before a pulse voltage was applied to the devices for 30 seconds as in the case of an activation process. Subsequently, the valve was closed again and a getter operation was repeated.

Thereafter, the performance of the apparatus was tested again to prove that it had been considerably recovered and that the initial decreasing in the electron emitting performance was almost half of one in the first measurement. This may be because that, the clean surface of the W deposit was formed again. While the cause of the reduction of decreasing in the performance is not clear, it may be because only a very small amount of gas was remaining in the container of the image forming apparatus thanks to the adsorption.

This example proved that the present invention is effective if a metal compound is used as an activating substance. With the image forming apparatus of this example again, no large and bulky arrangement is required for introducing an activating substance into the vacuum system so that a simple manufacturing apparatus and a simplified manufacturing method could

be used.

Fig. 26 is a block diagram of a display apparatus realized by using the image forming apparatus of Example 9 and designed to display a variety of visual data as well as pictures of television transmission in accordance with input signals coming from different signal sources. Referring to Fig. 26, it comprises the image forming apparatus or the display panel 111, a display panel drive circuit 112, a display controller 113, a multiplexer 114, a decoder 115, an input/output interface circuit 116, a CPU 117, an image generation circuit 118, image memory interface circuits 119, 120 and 121, an image input interface circuit 122, TV signal receiving circuits 123 and 124 and an input section 125. (If the display apparatus is used for receiving television signals that are constituted by video and audio signals, circuits, speakers and other devices are required for receiving, separating, reproducing, processing and storing audio signals along with the circuits shown in the drawing. However, such circuits and devices are omitted here in view of the scope of the present invention.)

Now, the components of the apparatus will be described, following the flow of image signals therethrough.

Firstly, the TV signal reception circuit 124 is a circuit for receiving TV image signals transmitted via

a wireless transmission system using electromagnetic waves and/or spatial optical telecommunication networks. The TV signal system to be used is not limited to a particular one and any system such as NTSC, PAL or SECAM may feasibly be used with it. It is particularly suited for TV signals involving a larger number of scanning lines (typically of a high definition TV system such as the MUSE system) because it can be used for a large display panel comprising a large number of pixels. The TV signals received by the TV signal reception circuit 124 are forwarded to the decoder 115.

Secondly, the TV signal reception circuit 123 is a circuit for receiving TV image signals transmitted via a wired transmission system using coaxial cables and/or optical fibers. Like the TV signal reception circuit 124, the TV signal system to be used is not limited to a particular one and the TV signals received by the circuit are forwarded to the decoder 115.

The image input interface circuit 122 is a circuit for receiving image signals forwarded from an image input device such as a TV camera or an image pick-up scanner. It also forwards the received image signals to the decoder 115.

The image memory interface circuit 121 is a circuit for retrieving image signals stored in a video tape recorder (hereinafter referred to as VTR) and the

retrieved image signals are also forwarded to the decoder 115.

5 The image memory interface circuit 120 is a circuit for retrieving image signals stored in a video disc and the retrieved image signals are also forwarded to the decoder 115.

10 The image memory interface circuit 119 is a circuit for retrieving image signals stored in a device for storing still image data such as so-called still disc and the retrieved image signals are also forwarded to the decoder 115.

15 The input/output interface circuit 116 is a circuit for connecting the display apparatus and an external output signal source such as a computer, a computer network or a printer. It carries out input/output operations for image data and data on characters and graphics and, if appropriate, for control signals and numerical data between the CPU 117 of the display apparatus and an external output signal source.

20 The image generation circuit 118 is a circuit for generating image data to be displayed on the display screen on the basis of the image data and the data on characters and graphics input from an external output signal source via the input/output interface circuit 116 or those coming from the CPU 117. The circuit 25 comprises relatable memories for storing image data and data on characters and graphics, read-only memories for

storing image patterns corresponding given character codes, a processor for processing image data and other circuit components necessary for the generation of screen images.

5 Image data generated by the image generation circuit 118 for display are sent to the decoder 115 and, if appropriate, they may also be sent to an external circuit such as a computer network or a printer via the input/output interface circuit 116.

10 The CPU 117 controls the display apparatus and carries out the operation of generating, selecting and editing images to be displayed on the display screen.

For example, the CPU 117 sends control signals to the multiplexer 114 and appropriately selects or combines
15 signals for images to be displayed on the display screen. At the same time it generates control signals for the display panel controller 113 and controls the operation of the display apparatus in terms of image display frequency, scanning method (e.g., interlaced
20 scanning or non-interlaced scanning), the number of scanning lines per frame and so on.

The CPU 117 also sends out image data and data on characters and graphic directly to the image generation circuit 118 and accesses external computers and
25 memories via the input/output interface circuit 116 to obtain external image data and data on characters and graphics. The CPU 117 may additionally be so designed

as to participate other operations of the display
apparatus including the operation of generating and
processing data like the CPU of a personal computer or
a word processor. The CPU 117 may also be connected to
5 an external computer network via the input/output
interface circuit 116 to carry out computations and
other operations, cooperating therewith.

The input section 125 is used for forwarding the
instructions, programs and data given to it by the
10 operator to the CPU 117. As a matter of fact, it may
be selected from a variety of input devices such as
keyboards, mice, joysticks, bar code readers and voice
recognition devices as well as any combinations
thereof.

15 The decoder 115 is a circuit for converting various
image signals input via said circuits 118 through 124
back into signals for three primary colors, luminance
signals and I and Q signals. Preferably, the decoder
115 comprises image memories as indicated by a dotted
20 line in Fig. 26 for dealing with television signals
such as those of the MUSE system that require image
memories for signal conversion. The provision of image
memories additionally facilitates the display of still
images as well as such operations as thinning out,
25 interpolating, enlarging, reducing, synthesizing and
editing frames to be optionally carried out by the
decoder 115 in cooperation with the image generation

circuit 118 and the CPU 117.

The multiplexer 114 is used to appropriately select images to be displayed on the display screen according to control signals given by the CPU 117. In other
5 words, the multiplexer 114 selects certain converted image signals coming from the decoder 115 and sends them to the drive circuit 112. It can also divide the display screen in a plurality of frames to display different images simultaneously by switching from a set
10 of image signals to a different set of image signals within the time period for displaying a single frame.

The display panel controller 113 is a circuit for controlling the operation of the drive circuit 112 according to control signals transmitted from the CPU
15 117.

Among others, it operates to transmit signals to the drive circuit 112 for controlling the sequence of operations of the power source (not shown) for driving the display panel in order to define the basic
20 operation of the display panel. It also transmits signals to the drive circuit 112 for controlling the image display frequency and the scanning method (e.g., interlaced scanning or non-interlaced scanning) in order to define the mode of driving the display panel.

25 If appropriate, it also transmits signals to the drive circuit 112 for controlling the quality of the images to be displayed on the display screen in terms

of luminance, contrast, color tone and sharpness.

The drive circuit 112 is a circuit for generating drive signals to be applied to the display panel. It operates according to image signals coming from said
5 multiplexer 114 and control signals coming from the display panel controller 113.

A display apparatus according to the invention and having a configuration as described above and illustrated in Fig. 26 can display on the display panel
10 various images given from a variety of image data sources. More specifically, image signals such as television image signals are converted back by the decoder 115 and then selected by the multiplexer 114 before sent to the drive circuit 112. On the other
15 hand, the display controller 113 generates control signals for controlling the operation of the drive circuit 112 according to the image signals for the images to be displayed on the display panel. The drive circuit 112 then applies drive signals to the display
20 panel according to the image signals and the control signals. Thus, images are displayed on the display panel. All the above described operations are controlled by the CPU 117 in a coordinated manner.

The above described display apparatus can not only
25 select and display particular images out of a number of images given to it but also carry out various image processing operations including those for enlarging,

reducing, rotating, emphasizing edges of, thinning out,
interpolating, changing colors of and modifying the
aspect ratio of images and editing operations including
those for synthesizing, erasing, connecting, replacing
5 and inserting images as the image memories incorporated
in the decoder 115, the image generation circuit 118
and the CPU 117 participate such operations. Although
not described with respect to the above embodiment, it
is possible to provide it with additional circuits
10 exclusively dedicated to audio signal processing and
editing operations.

The above described display apparatus can not only
select and display particular pictures out of a number
of images given to it but also carry out various image
15 processing operations including those for enlarging,
reducing, rotating, emphasizing edges of, thinning out,
interpolating, changing colors of and modifying the
aspect ratio of images and editing operations including
those for synthesizing, erasing, connecting, replacing
20 and inserting images as the image memories incorporated
in the decoder 115, the image generation circuit 118
and the CPU 117 participate such operations. Although
not described with respect to the above embodiment, it
is possible to provide it with additional circuits
25 exclusively dedicated to audio signal processing and
editing operations.

Thus, a display apparatus according to the invention

and having a configuration as described above can have a wide variety of industrial and commercial applications because it can operate as a display apparatus for television broadcasting, as a terminal apparatus for video teleconferencing, as an editing apparatus for still and movie pictures, as a terminal apparatus for a computer system, as an OA apparatus such as a word processor, as a game machine and in many other ways.

10 It may be needless to say that Fig. 26 shows only an example of possible configuration of a display apparatus comprising a display panel provided with an electron source prepared by arranging a number of surface conduction electron-emitting devices and the
15 present invention is not limited thereto. For example, some of the circuit components of Fig. 26 may be omitted or additional components may be arranged there depending on the application. For instance, if a display apparatus according to the invention is used
20 for visual telephone, it may be appropriately made to comprise additional components such as a television camera, a microphone, lighting equipment and transmission/reception circuits including a modem.

[Advantage of the Invention]

25 With the present invention, the degradation of performance of an electron-emitting device can be effectively suppressed or the original performance of

an electron-emitting device can be recovered to prolong the service life of an image forming apparatus comprising such electron-emitting devices.

5 Additionally, no large and bulky arrangement is required for introducing an activating substance into the vacuum system used for manufacturing an image forming apparatus so that a simple manufacturing apparatus and a simplified manufacturing method could be used.

THE EMBODIMENTS OF THE INVENTION IN WHICH AN EXCLUSIVE PROPERTY OR PRIVILEGE IS CLAIMED ARE DEFINED AS FOLLOW:

- 5 1. An electron source comprising one or more than one
electron-emitting devices comprising an electro-
conductive thin film including an electron-emitting
region between a pair of electrodes, wherein said
electron source is provided with means for supplying an
10 activating substance to the electron-emitting device or
devices, said means for supplying an activating
substance comprising an activating substance source
holding the activating substance, wherein said
activating substance is a substance capable of changing
15 to a second substance which includes a carbon or a
metal having a melting point higher than constituent
material of the electro-conductive thin film.
- 20 2. An electron source according to claim 1, wherein
said activating substance is a substance that increases
the rate of electron emission of said electron-emitting
device or each of the devices as it is applied to said
electron-emitting device.
- 25 3. An electron source according to claim 1, wherein
said means for supplying an activating substance is
arranged on a substrate where said electron-emitting
device or each of said devices is disposed.
- 30 4. An electron source according to claim 1, wherein
said means for supplying an activating substance
comprises an activating substance source and means for
gasifying the activating substance from the activating
substance source.
- 35 5. An electron source according to claim 4, wherein

said means for gasifying the activating substance
comprises means for heating said activating substance
source.

5 6. An electron source according to claim 5, wherein
said means for heating said activating substance source
comprises a resistor disposed close to said activating
substance source and means for passing electric current
through the resistor.

10 7. An electron source according to claim 4, wherein
said means for gasifying the activating substance
comprises means for causing electrons collide with said
activating substance source.

15 8. An electron source according to claim 1, wherein
it comprises a plurality of electron-emitting devices.

20 9. An electron source according to claim 1, wherein
said electron-emitting device or each of said electron-
emitting devices is a surface conduction electron-
emitting device.

25 10. An image-forming apparatus comprising an electron
source by turn comprising one or more than one electron
emitting devices comprising an electro-conductive thin
film including an electron-emitting region between a
pair of electrodes, an image-forming member to be
irradiated with electron beams from said electron
30 source to form images thereon, and means for supplying
an activating substance to the electron-emitting device
or devices, said means for supplying the activating
substance comprising an activating substance source
holding the activating substance, and wherein the
35 activating substance is a substance capable of changing

to a second substance which includes a carbon or a metal having a melting point higher than constituent material of the electro-conductive thin film.

5 11. An image forming apparatus according to claim 10, wherein said activating substance is a substance that increases the rate of electron emission of said electron-emitting device or each of the devices as it is applied to said electron-emitting device.

10 12. An image forming apparatus according to claim 10, wherein said means for supplying an activating substance is arranged on a substrate where said electron-emitting device or each of said devices is
15 disposed.

13. An image forming apparatus according to claim 10, wherein said means for supplying an activating substance is fitted to an envelope containing electron
20 source and said image-forming member.

14. An image forming apparatus according to claim 10, wherein said means for supplying an activating substance comprises an activating substance source and
25 means for gasifying the activating substance from the activating substance source.

15. An image forming apparatus according to claim 14, wherein said means for gasifying the activating substance comprises means for heating said activating
30 substance source.

16. An image forming apparatus according to claim 15, wherein said means for heating the activating substance source comprises a resistor disposed close to said
35

activating substance source and means for electrically energizing the resistor.

5 17. An image forming apparatus according to claim 14, wherein said means for gasifying the activating substance comprises means for causing electrons collide with said activating substance source.

10 18. An image forming apparatus according to claim 10, wherein it further comprises a getter.

15 19. An image forming apparatus according to claim 10, wherein it comprises a plurality of electron-emitting devices.

20 20. An image forming apparatus according to claim 10, wherein said electron-emitting device or each of said electron-emitting devices is a surface conduction electron-emitting device.

21. An image forming apparatus according to claim 10, wherein said image forming member is a fluorescent body.

25 22. A method of activating an electron source comprising one or more than one electron-emitting devices comprising an electro-conductive thin film including an electron-emitting region between a pair of electrodes and an activating substance source, wherein
30 the electron source is provided with means for supplying an activating substance to the electron-emitting device or devices, the means for supplying an activating substance comprising an activating substance source holding the activating substance, wherein the
35 activating substance is a substance capable of changing

to a second substance which includes a carbon or a metal having a melting point higher than constituent material of the electro-conductive thin film, and wherein said method comprises the step of gasifying the activating substance from the activating substance source and applying it to the electron-emitting device or devices.

23. A method of activating an electron source according to claim 22, wherein said activating substance is a substance that increases the rate of electron emission of said electron-emitting device or each of the devices as it is applied to said electron-emitting device.

24. A method of activating an electron source according to claim 22, wherein said step of gasifying an activating substance is a step of heating the activating substance source.

25. A method of activating an electron source according to claim 24, wherein said step of heating the activating substance source is a step of passing electric current through a resistor arranged close to said activating substance source.

26. A method of activating an electron source according to claim 24, wherein said step of heating the activating substance source is a step of irradiating said activating substance source with light.

27. A method of activating an electron source according to claim 22, wherein said step of gasifying an activating substance is a step of causing electrons to collide with said activating substance source.

28. A method of activating an electron source according to claim 22, wherein said electron source comprises a plurality of electron-emitting devices.

5 29. A method of activating an electron source according to claim 22, wherein said electron-emitting device or each of said electron-emitting devices is a surface conduction electron-emitting device.

10 30. A method of activating an electron source according to any of claims 22 through 29, wherein said step of applying an activating substance to said electron-emitting device or devices is conducted, while driving said electron source.

15 31. A method of activating an electron source according to any of claims 22 through 29, wherein said step of applying an activating substance to said electron-emitting device or devices is conducted
20 whenever the performance of the device or devices is degraded.

25 32. A method of activating an image forming an apparatus comprising an electron source by turn comprising one or more than one electron-emitting devices comprising an electro-conductive thin film including an electron-emitting region between a pair of electrodes, an image forming member to be irradiated with electron beams from the electron source to form
30 images thereon, and means for supplying an activating substance to the electron-emitting device or devices, the means for supplying the activating substance comprising an activating substance source holding the activating substance, and wherein the activating
35 substance is a substance capable of changing to a

second substance which includes a carbon or a metal having a melting point higher than constituent material of the electro-conductive thin film, and said method comprising the step of gasifying the activating substance from the activating substance source and applying the activating substance to the electron-emitting device or devices.

33. A method of activating an image forming apparatus according to claim 32, wherein said activating substance is a substance that increases the rate of electron emission of said electron-emitting device or each of the devices as it is applied to said electron-emitting device.

34. A method of activating an image forming apparatus according to claim 32, wherein said step of gasifying an activating substance is a step of heating the activating substance source.

35. A method of activating an image forming apparatus according to claim 34, wherein said step of heating the activating substance source is a step of passing electric current through a resistor arranged close to said activating substance source.

36. A method of activating an image forming apparatus according to claim 34, wherein said step of heating the activating substance source is a step of irradiating said activating substance source with light.

37. A method of activating an image forming apparatus according to claim 32, wherein said step of gasifying an activating substance is a step of causing electrons to collide with said activating substance source.

38. A method of activating an image forming apparatus according to claim 32, it comprises a step of activating a getter to be carried out after the step of applying an activating substance to said electron-emitting device or devices.

39. A method of activating an image forming apparatus according to claim 32, wherein said image forming apparatus comprises a plurality of electron-emitting devices.

40. A method of activating an image forming apparatus according to claim 32, wherein said electron-emitting device is or each of said electron-emitting devices is a surface conduction electron-emitting device.

41. A method of activating an image forming apparatus according to any of claims 32 through 40, wherein said step of applying an activating substance to said electron-emitting device or devices is conducted, while driving said electron source.

42. A method of activating an image forming apparatus according to any of claims 32 through 40, wherein said step of applying an activating substance to said electron-emitting device or devices is conducted whenever the performance of the device or devices is degraded.
