Title: FUZZY FULL TEXT SEARCH

Abstract: A method and system for fuzzy full text search is disclosed. The system includes an inverted index where tokens are organized in a Next Valid Character (NVC) tree. Each path through the tree defines a token. The document lists for the tokens are stored at leaf nodes. When performing a fuzzy full text search, the system uses an edit distance greater than zero. After receiving search tokens, the system traverses the NVC tree to generate document error lists. The system then compares the error lists to identify relevant document identifiers and provides a result set.

Published: with international search report (Art. 21(3))
FUZZY FULL TEXT SEARCH

FIELD

The present invention relates generally to full text search, and more particularly, relates to fuzzy full text search.

BACKGROUND

Full text search (FTS) systems search for relevant documents based on key words entered by a system user. The user enters a set of terms, referred to as tokens, and the FTS system finds documents containing all of the terms in the set. In order to support queries efficiently, the FTS system typically uses inverted indexes. For example, Lucene (described at http://lucene.apache.org/) and SQLite's FTS module (described at http://www.sqlite.org/cvstrac/wiki?p=FtsUsage) are both FTS systems that use inverted indexes.

An inverted index assigns a set of document identifiers to each token. The document identifiers are associated with documents that include the token at least once. Upon receiving a search request, the FTS system selects the set of document identifiers for each token in the request and then compares the document sets to each other. If a document identifier is contained in all document sets, the FTS system provides the document identifier in a result set of all identifiers contained in all document sets.

From a logical point of view, the inverted index can be regarded as a relation $\text{InvertedIndex}(\text{Term, DocID})$ with a combined index on $\text{Term}$ and $\text{DocID}$. If a user of the FTS system enters the token "Neuschwanstein," the inverted index allows the FTS system to efficiently execute queries such as the following query.

$$\text{SELECT DocID FROM InvertedIndex WHERE Term= 'Neuschwanstein' }$$

However, if the user misspells "Neuschwanstein," SQLite's FTS system will not find any relevant documents. That is because SQLite's FTS system does not support fault-tolerant (or fuzzy) searching.

Lucene's FTS system does support fuzzy search. However, Lucene performs a fuzzy search in two steps. First, Lucene searches for tokens stored in the database that are similar to the query tokens. To determine if tokens are similar, Lucene computes an edit distance (also referred to as a Levenshtein Distance) from the query tokens to the tokens stored in the database. Second, Lucene uses the similar tokens it finds as new query tokens to retrieve relevant documents. This two-step process may result in severe performance problems.

SUMMARY

A method and system for performing a fuzzy full text search is described. The system uses an inverted token Next Valid Character (NVC) tree. Each path through the tree defines a token. Document sets for the tokens are stored in leaf nodes. The system traverses the tree in a single pass to identify relevant document sets. The system intersects the document sets to generate a result set.
The system uses the same index structure, the inverted token NVC tree, for both full text search and fuzzy full text search. For full text search, an error value of zero is used, while for fuzzy full text search an error value greater than zero is used.

These as well as other aspects and advantages will become apparent to those of ordinary skill in the art by reading the following detailed description, with reference to the accompanying drawings. Further, it is understood that this summary is merely an example and is not intended to limit the scope of the invention as claimed.

BRIEF DESCRIPTION OF THE DRAWINGS

Presently preferred embodiments are described below in conjunction with the appended drawing figures, wherein like reference numerals refer to like elements in the various figures, and wherein:

- Figure 1 is a block diagram of a fuzzy full text search system, according to an example;
- Figure 2 is a document list, according to an example;
- Figure 3 is an inverted index where tokens are organized in a Next Valid Character (NVC) tree, according to an example; and
- Figure 4 is a flow diagram of a method of performing a fuzzy full text search using the fuzzy full text search system depicted in Figure 1, according to an example.

DETAILED DESCRIPTION

Figure 1 depicts a block diagram of a computing platform 100. The computing platform 100 may be a mobile telephone, a navigation system, a tablet computer, a personal computer, or any other computer. The computing platform 100 is a combination of hardware and software components.

The computing platform 100 includes a fuzzy Full Text Search (FTS) system 104. The computing platform 100 may also include other sub-systems. For example, if the computing platform 100 is a navigation system, the computing platform 100 may also include a positioning system, a user interface, a geographic database, and software that facilitates destination entry, route calculation, route guidance, map display, and other navigation functions and features.

The fuzzy FTS system 104 may be a combination of hardware and software components. For example, the fuzzy FTS system 104 includes a processor 106 and memory 108 for storing a document list 110, an index 112, query processing 114, and possibly other information. In other examples, the fuzzy FTS system 104 may be a software system and use a processor and memory associated with the computing platform 100.

The computing platform 100 receives search tokens 102 entered by a user of the platform 100 and provides the search tokens 102 to the fuzzy FTS system 104. For example, a user of a navigation system may enter search terms associated with an address to identify a destination. As a result of the query processing 114, the fuzzy FTS system 104 provides a result set 116 as an output. The navigation system may use this result set to provide a list of relevant destinations to the user.
The document list 110 is a list of document identifiers and tokens located within
documents associated with the identifiers. The term "document" in this context means any kind
of electronic data record or file that contains text. In the example of a navigation system,
relevant documents may be a segment record, a node record, a point of interest record, or any
other record stored in a geographic database.

The document list 110 includes a document identifier column and a token column. The
document identifier column includes data representing document identifiers. Document
identifiers may be any combination of letters, numbers, and other characters. The document
identifiers reference documents that may be stored in the memory 108. Alternatively, the
documents may be stored elsewhere on the computing platform 100 or on another system.

The document list 110 may be stored in memory 108 as a sequence of document
identifiers. As another example, the document list 110 may be stored in memory 108 as a bit
vector. The length of the bit vector is equal to the number of documents identified in the
document identifier column. If a term is located in a certain document, the bit vector includes a
1-Bit and if the term is not located in that document, the bit vector includes a 0-Bit (or vice
versa). If the document list 110 is stored as a bit vector, the intersection of document lists may
be performed by intersecting the bit vectors.

Figure 2 depicts an example document list 200. In this example, the document list 200
includes a document identifier column 202 and an address column 204. The document
identifiers in the document identifier column 202 are associated with terms in an address. For
example, document identifier 5 is associated with the terms "Garmin," "Kansas," "City," and
"USA."

The document list 200 may be used by a navigation system or an on-line mapping
application during destination search. Other document lists may include terms relevant for other
types of computing platforms and/or applications. For example, the token column may include
data regarding books, music, web pages, files, and so on.

Returning to Figure 1, the index 112 is an inverted token Next Valid Character (NVC)
tree. Figure 3 depicts an index 300 where tokens are organized in a NVC tree using the
document list 200 depicted in Figure 2.

The node 302 in the tree 300 is the root node, which is also referred to as the starting
node. Branches extend from the root node 302 to additional nodes. The root node 302 is the
parent node to the next layer of nodes (i.e., nodes 1, 39, 4, B, CITY, G, K, N, O, S, USA, VOL),
which are referred to as children nodes. In some cases, the children nodes are parent nodes to
other nodes. For example, the B node is the parent node to the ACH, ERLIN, and OSCH nodes.

After following the paths from the root node through the branches and other nodes, the
paths end at leaf nodes. Leaf nodes are nodes without children and are sometimes referred to as
end nodes. At each leaf node is a set of document identifiers. In this example, the leaf nodes
refer to the document identifiers in Figure 2. A path from the root node 302 to a leaf node
defines a token. In this example, each token is a token from the address column 204 of the document list 200.

For example, assume that a user enters the search terms OTTO, VOLGER, and GERMANY into the computing platform 100. Using the index 300, the path from the root node 302 to a leaf node for the token OTTO results in a leaf node associated with document identifier 1. Similarly, VOLGER results in a leaf node associated with document identifier 1 and GERMANY results in a leaf node associated with document identifiers 1, 2, and 3. The query processing 114 intersects the lists of document identifiers and provides document identifier 1 as the result set 116.

Returning to Figure 1, the index 112 may be stored in memory 108 in a file or as a set of files. Alternatively, the index 112 may be stored in memory 108 as a relation containing a binary large object (BLOB). A BLOB is a collection of binary data stored as a single entity in a database management system. As both files and BLOBs can become large, the index 112 may be split into several smaller files or BLOBs. The files are stored in a file system, while the BLOBs are stored in one or more relational tables.

The index 112 may also be stored in a relation, such as NVC(FatherNode integer, SonNode integer, SonData BLOB). In this example, the father and son node values are integer values describing the NVC tree structure. The SonData values are the prefixes stored in the NVC tree. If a node is a leaf node, the SonNode value is null (or 0 if null values are not allowed in a column belonging to the primary key). If a node is a leaf node, SonData value is the document list. An example NVC relation for the index 300 is shown as follows.

<table>

</tbody>
</table>

If the NVC tree is stored in a relation, the traversal through the tree is performed using SQL statements or other appropriate syntax.

The query processing 114 may be embodied as program instructions stored on a non-transitory computer-readable medium, which when executed by the processor 106 cause the processor 106 to carry out functions as described further herein. The program instructions may be written in a suitable computer programming language, such as C, C++, Java, or any other suitable program language now known or later developed.

The query processing 114 performs a fuzzy search for relevant document identifiers based on the entered search tokens. A fuzzy search is a fault tolerant search that allows
misspelled search tokens to be used to find relevant document identifiers despite the error. Before the query processing 114 can perform a fuzzy search, the query processing 114 needs to know how much error is acceptable to the fuzzy FTS system 104.

The error is the distance between tokens in a document and query tokens entered by a user. The error is determined based on an edit distance, which is also referred to as Levenshtein distance. The Levenshtein distance between two tokens is defined as the minimum number of edit operations needed to transform one token into the other. The allowable edit operations are insertion, deletion, or substitution of a single character.

For example, the Levenshtein distance between "kitten" and "sitting" is three since it takes the following three edits to change "kitten" into "sitting" and there is no way to make the transformation with fewer than three edits.

- kitten → sitten (substitution of 'k' by 's')
- sitten → sittin (substitution of 't' by 'i')
- sittin → sitting (insert 'g' at the end).

The user of the computing platform 100 or other entity (e.g., designer, developer, or owner of the computing platform 100 or the fuzzy FTS system 104) may set a threshold value that determines how much error is acceptable. The edit value may be stored in memory 108, for example, as part of the query processing 114. The query processing 114 operates more efficiently with a lower threshold value than with a larger threshold value. With an error value of zero, the query processing 114 performs a non-fuzzy full text search, such as the full text search performed by SQLite.

Figure 4 is a flow diagram of a method 400 of performing a fuzzy full text search using the fuzzy FTS system 104. In this example, the query processing 114 has received an edit distance of one. Of course, other edit distance values may be used. In this example, only one error is allowed in the entire set of entered search terms. As described later, the error threshold may be applied to search terms individually or to groups of search terms.

At block 402, the fuzzy FTS system 104 receives one or more search terms. For example, a user enters the terms OTTO and VOLKER into the computing platform 100.

At block 404, the query processing 114 explores paths in the index 112. The query processing 114 starts at the root node and follows the branches to the children nodes of the root node. Then the query processing 114 determines whether the children nodes are relevant to the entered search terms. If not, branches from these children do not need to be further explored (referred to as pruning). If the children nodes are relevant to the entered search terms, the query processing 114 continues exploring the index 112 by following the branches to the next layer of nodes. This process continues until all paths are either pruned or end at a leaf node.

At block 406, the query processing 114 computes document error lists. The document error lists include the document identifier and the number of edits needed to reach the leaf node associated with the document identifier. For example, the query processing computes the document error list of [{1}, 0], [{2}, 1] for the search token OTTO and the document error list of [{3}, 0], [{1}, 1] for the search term VOLKER.
The error list for OTTO identifies that zero errors were detected while exploring the path from the root node 302, to the O node, to the TTO node, and to the leaf node associated with document identifier 1. The error list for OTTO also identifies that one error was detected while exploring the path from the root node 302, to the O node, to the TO node, and to the leaf node associated with document identifier 2. The error list for VOLKER identifies that zero errors were detected while exploring the path from the root node 302, to the VOL node, to the KER node, and to the leaf node associated with document identifier 3. The error list for VOLKER also identifies that one error was detected while exploring the path from the root node 302, to the VOL node, to the GER node, and to the leaf node associated with document identifier 1.

At block 408, the query processing 114 compares the error lists. The query processing 114 may compare the first item in the error list associated with the first search token with each item in the error list associated with the next search token. Then, the query processing 114 compares the next item in the error list associated with the first search token with the error list associated with the next search token. This process continues until each item in the error lists have been compared to the other items in the error lists.

Using the error lists described with respect to block 406, the query processing 114 compares the pair (1, 0) for the search term OTTO with the pairs [(3}, 0), (1, 1)] for the search term VOLKER. Document identifier 1 is in both the OTTO pair and one of the VOLKER pairs and the overall error is 1 from the VOLKER pair. Thus, document identifier 1 is added to the result set as described with respect to block 410.

Next, the query processing 114 compares the OTTO pair (2, 1) with the VOLKER pair (3, 0) and no further match is detected. Note that the query processing 114 does not have to compare the OTTO pair (2, 1) to the VOLKER pair (1, 1) as the overall error is two, which exceeds the threshold value used in this example.

At block 410, the query processing 114 adds document identifiers to the result set. The result set includes the document identifiers that are associated with data tokens that are within a pre-defined edit distance with at least one of the search tokens. As described with respect to block 408, document identifier 1 is added to the result set. Document identifier 1 is associated with both the tokens OTTO and VOLGER, which was within an edit distance of one from the entered search terms of OTTO and VOLKER.

At block 412, the fuzzy FTS system 104 provides the result set to another entity to retrieve the documents associated with the document identifiers in the result set. Alternatively, the fuzzy FTS system 104 may also have the programming to retrieve the documents and provide the documents. The documents may be stored on the computing platform 100 or another system.

In a navigation system example, the query processing 114 may provide document identifier 1 to a map display application, which then retrieves data from a geographic database associated with the navigation system. The map display application may then display a map that identifies a location associated with the address "NAVTEQ, OTTO-VOLGER-STRASSE 1, SULZBACH, GERMANY" on the user interface of the navigation system. The geographic database may be located in the navigation system or be part of another system, such as a server.
In the server example, the navigation system includes a communication system that allows it to request and receive documents from the server using document identifiers.

The query processing 114 may be encapsulated in a virtual table in a similar manner as SQLite’s FTS search module. In this example, the query syntax is extended by the allowed error threshold $\epsilon$. To create a virtual table for the addresses depicted in Figure 2, the following command may be used.

```
CREATE VIRTUAL TABLE Addresses USING FuzzyFTS(DocID integer, Address TEXT)
```

To insert the addresses into the virtual table the following command may be used.

```
INSERT INTO Addresses (DocID, Address) VALUES(1, "NAVEQ, OTTO-VOLGER-STRASSE 1, SULZBACH, GERMANY");
INSERT INTO Addresses (DocID, Address) VALUES(2, "NOKIA, OTO-BACH STRASSE 10, BERLIN, GERMANY");
INSERT INTO Addresses (DocID, Address) VALUES(3, "BOSCH, VOLKER 4, KÖLN GERMANY");
INSERT INTO Addresses (DocID, Address) VALUES(4, "VOLVO, KALKA, 39, STOCKHOLM, SWEDEN");
INSERT INTO Addresses (DocID, Address) VALUES(5, "GARMIN, KANSAS CITY, USA")
```

With the virtual table, the query processing 114 may perform a fuzzy full text search query based on the following command.

```
SELECT * FROM Addresses WHERE Address MATCH 'ε:1(OTTO VOLKER)';
```

This query returns all documents that have an overall edit distance within one for the two query tokens entered (OTTO and VOLKER). This example and others that follow use SQLite syntax.

It is understood that other suitable commands and data structures may be used as well.

As described previously, the error threshold may be applied to a single token. For example, the query processing 114 may perform a fuzzy full text search query based on the following command.

```
SELECT * FROM Addresses WHERE Address MATCH 'ε:0(OTTO)
ε:1(VOLKER)'
```

This command requests document identifiers associated with documents that contain the token OTTO without errors and tokens that are within an edit distance of one to the term VOLKER.

For the OTTO token, the query processing 114 prunes all paths in the tree 300 that do not exactly match OTTO. For VOLKER the query processing 114 allows an error of 1. The query processing 114 then generates a result set as described with reference to Figure 4.

As also described previously, the error threshold may be applied to a group of tokens. For example, the query processing 114 may perform a fuzzy full text search query based on the following command.

```
SELECT * FROM Addresses WHERE Address MATCH 'ε:1(OTTO)
ε:1(VOLKER, GERMANY)';
```
For the OTTO token, the query processing 114 allows an error of 1. For the VOLKER,
GERMANY pair, the query processing 114 also allows an error of 1. The query processing 114
then generates a result set as described with reference to Figure 4.

It is also possible to use tokens twice in a query. For example, the following query uses
GERMANY twice, limits the error to two for the token pair OTTO, GERMANY, and limits the
error to one for the token pair VOLKER, GERMANY.

```
SELECT DocID FROM Addresses WHERE Address MATCH 'ε:2(OTTO,
GERMANY) ε:1(VOLKER, GERMANY)';
```

In response to this query, the query processing 114 explores the NVC tree 300 for each entered
query token to find the maximum error allowed for a token. The query processing 114 prunes
the tree 300 for GERMANY and OTTO with an error threshold of 2 and for VOLKER with an
error threshold of 1.

Next, the query processing 114 intersects the document sets with each other for terms that
occur in brackets and, thereafter, the resulting document sets are intersected. Note that the
foregoing query is semantically equivalent to the following query.

```
SELECT DocID FROM Addresses WHERE Address MATCH 'ε:2(OTTO,
GERMANY)';
INTERSECT
SELECT DocID FROM Addresses WHERE Address MATCH 'ε:1(VOLKER,
GERMANY)';
```

Another search variation is using token prefixes. Instead of entering the complete search
terms, the user of the computing platform 100 may enter just the beginning portions of the search
terms. For example, instead of entering OTTO and GERMANY, the user can enter OT and G.
The query processing 114 may perform a fuzzy full text search query based on the following
command.

```
SELECT DocID FROM Addresses WHERE Address MATCH 'ε:0(OT*, G*)';
```

The query processing 114 may explore the tree 300 by pruning all non-relevant paths in the tree.
The query processing 114 compares document identifier 5 (from the "G," "ARMIN," "5" path) to
document identifiers 1 and 2 (from the "O," "TO," "2" and the "O," "TTO," "1" paths); and
compares the document list of identifiers 1, 2, 3 (from the "G," "ERMANY," "1,2,3" path) to
document identifiers 1 and 2 (from the "O," "TO," "2" and the "O," "TTO," "1" paths). Thus,
the query processing adds document identifiers 1 and 2 to the result set. Changing the error
value to one in this query causes the query processing 114 to explore all nodes because one error
from "G*" can be any character.

The fuzzy FTS system 104 and the method 400 allow for a single pass fault-tolerant
search. Moreover, the fuzzy FTS system 104 and the method 400 allows for a single index
structure to be used in both non-fuzzy FTS and fuzzy FTS. The fuzzy FTS system 104 and the
method 400 can be used in many different types of computing platforms for searching many
types of documents.
It is intended that the foregoing detailed description be regarded as illustrative rather than limiting and that it is understood that the following claims including all equivalents are intended to define the scope of the invention. The claims should not be read as limited to the described order or elements unless stated to that effect. Therefore, all embodiments that come within the scope and spirit of the following claims and equivalents thereto are claimed as the invention.
CLAIMS:

1. A computer-implemented method for performing fuzzy full text search, comprising:
   - receiving search terms;
   - exploring paths of an inverted token next valid character tree;
   - computing document error lists for each path that reaches a leaf node in the tree, wherein
     the error list includes a document identifier and an error distance;
   - comparing the document error lists to identify common document identifiers within a
     threshold error distance;
   - adding the common document identifiers to a result set; and
   - providing the result set of document identifiers.

2. The method of claim 1, wherein the search terms include token prefixes.

3. The method of claim 1, wherein exploring paths includes pruning paths that do not
   contribute to the result set.

4. The method of claim 1, wherein the threshold error distance is a limit to an edit distance
   calculated for all entered search terms.

5. The method of claim 1, wherein the threshold error distance is a limit to an edit distance
   calculated for an individual search term.

6. The method of claim 1, wherein the threshold error distance is a limit to an edit distance
   calculated for a group of entered search terms.

7. The method of claim 1, further comprising retrieving documents associated with the
   document identifiers in the result set.

8. A computer-implemented method, comprising:
   - receiving a threshold error distance;
   - receiving search tokens;
   - querying an inverted token next valid character tree with each received search token,
     wherein each branch through the tree defines a token and a document set for the token is stored
     at a leaf node;
   - pruning branches that are irrelevant to the search tokens or exceed the threshold error
     distance;
   - for leaf nodes reached during querying, comparing the document sets stored at the leaf
     nodes; and
   - providing a result set of document identifiers that are found in all document sets.
9. The method of claim 8, wherein the threshold error distance is applied to a single received search term.

10. The method of claim 8, wherein the threshold error distance is applied to a group of the received search terms.

11. The method of claim 8, wherein the threshold error distance is applied to all received search terms.

12. The method of claim 8, wherein the search tokens include at least one token prefix.

13. The method of claim 8, further comprising retrieving documents associated with the document identifiers in the result set.

14. A fuzzy full text search system, comprising:
   a processor; and
   memory storing an index organized as an inverted token next valid character tree and query processing executable by the processor to perform a fuzzy full text search with a single pass through the index.

15. The system of claim 14, wherein the index is stored in the memory as a set of files.

16. The system of claim 14, wherein the index is stored in the memory as a relation containing a binary large object.

17. The system of claim 14, wherein the index is stored in the memory as a relation containing parent-child relationships.

18. The system of claim 14, wherein the query processing is encapsulated in a virtual table.

19. The system of claim 14, further comprising the memory storing a document list as a sequence of document identifiers.

20. The system of claim 14, further comprising the memory storing a document list as a bit vector.
