5 PRIORITY CLAIM TO RELATED PATENT APPLICATION
[1] This patent claims priority to U.S. Provisional Patent Application Serial
No. 60/494,917 (filed August 13, 2003). The entire text of U.S. Provisional Patent
Application Serial No. 60/494,917 is incorporated by reference into this patent.

10 FIELD OF THE INVENTION
[2] This invention is directed generally to a combination therapy (particularly
for the treatment of cancer, and more particularly for the treatment of human cancer)
comprising administration of a carbamoylating chemotherapeutic agent in conjunction
with administration of a selective iNOS inhibiting compound. This invention also is
generally directed to a medicament comprising a carbamoylating chemotherapeutic agent
and a selective iNOS inhibiting compound together with a pharmaceutically acceptable
carrier. This invention is further generally directed to a kit comprising a carbamoylating
chemotherapeutic agent and a selective iNOS inhibiting compound.

20 BACKGROUND OF THE INVENTION
[3] Cancer is one of the leading causes of death in industrialized nations, and
represents a staggering cost in terms of medical treatment and lost work.
[4] There are currently four principal therapeutic modalities for the treatment
of cancer: surgery, radiation therapy, chemotherapy and biologic therapy. Frequently,
several different therapeutic treatment modalities are combined to enhance the benefits of
each individual therapy, and to decrease the deleterious side effects of an individual
therapeutic modality.
[5] Surgery is used to physically remove a neoplasia, and thereby eliminate the
tumor cells. Surgery is also beneficial in the diagnosis of cancer, as well as the evaluation
of the tumor cell type and characterization of the cancer. The risks associated with surgery
are well known, and include adverse reactions with anesthesia, and risk of infection.

Page 1 of 200
Surgery alone may not be effective in terminating cancer if the entire neoplasm is not removed, or if the tumor has metastasized. Further, many areas of the body are not accessible to, or are inappropriate for, surgical procedures.

Radiation interacts with molecular oxygen present in tissues and induces the formation of oxygen radical compounds, such as superoxide, hydrogen peroxide, or hydroxyl radicals that damage or break cellular DNA, and thereby kill cells. High linear energy transfer (LET) radiation can induce direct damage to the molecular structure of DNA. Both tumor cells and non-cancerous cells may be affected. The basic unit of ionizing radiation is the gray (Gy), which is equivalent to one hundred rads. Irradiation is commonly fractionated in doses of about 2.0 Gy to the whole organ being treated, with the total dose being dependent on the type of tumor being treated and the sensitivity of the normal organs and tissues within the radiation field. Some body tissues are more susceptible to radiation than others. For example, in bone marrow, the acceptable limiting dose of radiation is about 2.5 Gy, while in the brain, the generally accepted limiting dose of radiation is relatively high, e.g., about 50.0 Gy ionizing radiation. Some tumors, particularly larger tumors, are less affected by irradiation because of the presence of poorly perfused, hypoxic zones that limit the available molecular oxygen required to produce cytotoxic radicals. Radiation therapy may result in a variety of adverse effects such as aplasia of the bone marrow, nephro sclerosis, hepatitis, tissue fibrosis, acute encephalopathy, transient diffuse encephalopathy, early delayed myelopathy, late delayed myelopathy, headache, dementia, cerebral atrophy, radionecrosis, and even radiation-induced tumors.

Chemotherapy may be broadly categorized into two primary types: Cell cycle-specific (CCS) agents (such as antimetabolites, anthracyclines, bleomycin, camptothecins, and plant alkyloids) and cell-cycle non-specific (CCNS) agents (such as alkylating agents, antibiotics, platinum compounds, nitrosoureas, dacarbazine, and L-asparaginase). CCS agents only exert their effects on cycling cells, while CCNS agents have activity against both cycling and, to a lesser extent, non-cycling cells. It is widely accepted that tumor cells grow in accordance with Gompertzian kinetics, with rapid initial cell growth and traversal of complete cell cycle, followed by slowing cell doubling time as the tumor burden increases and more cells remain in a G0 phase, with cell growth
approaching a Malthusian asymptotic limit. Also, in high tumor burden metastatic solid
tumors, a significant amount of heterogeneity exists with respect to biologic, kinetic,
antigenic, and drug-sensitive cell types present. Therefore, in an individual subject, some
tumor cell subpopulations may be more responsive to CCS agent, such as rapidly growing
tumor cells, while other tumor cell subpopulations may be more or less unresponsive to
the same agent.

[8] Biologic therapy is a relatively recent therapeutic modality. Biological
agents (such as cytokines, antibodies, stem cells, and vaccine growth factors) are
employed as biologic response modifiers. Here, cellular and humoral immunity is
enhanced to recognize and attack cancer cells.

[9] Glioblastoma multiforme (GBM) is among the most frequent and
aggressive neoplasias of the central nervous system in adults. Even after the
administration of standard therapies, median survival is 9-15 months. The current World
Health Organization (WHO) classification of primary brain tumors lists GBM as a Grade
IV astrocytoma. GBM is characterized by cellular pleomorphism, numerous mitotic
figures, and often multinucleated giant cells. Proliferation of the vascular endothelium is
seen, as well as areas of necrosis with circumjacent pseudopalisading of the neoplastic
cells. GBM can appear as either a well- circumscribed globular mass or a more diffuse
mass lesion. The cut surface reveals necrosis, fatty degeneration, and hemorrhage.

Hemorrhages have been found in 40%, with necrosis in up to 52% of the cases. The tumor
is usually solid, although cysts may be present. Rarely the tumor consists of a solitary cyst
and mural nodule. Variants of the tumor include gliosarcoma, multifocal GBM, or
gliomatosis cerebri (in which the entire brain may be infiltrated with tumor cells).

[10] The nitrosoureas carmustine (BCNU) and lomustine (CCNU) are
liposoluble alkylating drugs that have constituted the gold standard of first-line
chemotherapy for recurrent GBM after resection and radiotherapy, with a response rate of
about 30%. Because of their high lipophilicity, BCNU and CCNU are able to cross the
blood-brain barrier, and thus reach brain tumors that are inaccessible to other
chemotherapeutic agents. BCNU is capable of inhibiting the synthesis of DNA, RNA,
and protein, and kills cells in all phases of the cell cycle.
[11] Chemically, BCNU spontaneously degrades to form a carbenium ion and an organic isocyanate group. The organic isocyanate group formed by the decomposition of BCNU attaches a carbamoyl group to a lysine residue of a protein, such as a DNA repair protein, thus deactivating the protein. The carbenium ion formed by the decomposition of BCNU forms a chloroethyl adduct on the O⁶ position of guanine.

[12] In about 10 to 24 hours, the ethyl chloride group loses the chloride and converts spontaneously into a cyclic N¹-O⁶ ethanol-guanine intermediate that is able to form a covalent bond with the adjacent cytosine. These intrastrand cross-links, 1(N₃-cytosine)-2(N¹-guanine), are almost exclusive to BCNU and are the main determinants of
BCNU cytotoxicity, because only 10 are needed to provoke cell death by interfering with
the processes of DNA duplication and transcription.

[13] Resistance to BCNU is essentially pharmacodynamic and is accomplished
by the DNA repair systems through O6-alkylguanine-DNA alkyltransferase (AGT), whose
mechanism of action is "suicidal": it binds to DNA, recognizes the alkyl group bound to
oxygen at position 6 of guanine, and catalyzes its transfer to a sulfhydryl (–SH) group of a
cysteine near its carboxy terminal end (catalytic site); guanine remains intact, while the
alkylated protein is no longer active, loses affinity for DNA, and is rapidly degraded. Thus,
there is a stoichiometric correspondence between the number of removed alkyl groups and
the number of enzyme molecules: at any given moment, a cell may repair only a number
of adducts equal to the number of enzyme molecules it possesses, after which it must await
the synthesis of new enzyme molecules, which takes over 24 hours.

[14] Another recognized event that leads to the resistance of tumor cells to
alkylating agents is the overproduction by the tumor cells of nucleophilic substances, such
as glutathione, that can compete with DNA for alkylation.

[15] Several attempts have been made to overcome the acquired resistance to
alkylating agents. For example, in WO 02/072008, Welt et al. disclose and claim a
combination of immunotherapy and chemotherapy to promote tumor regression by
treating a patient in need thereof with a combination of an antibody that binds to A33
antigen and one or more chemotherapeutic agents.

[16] Another approach has been to pre-expose the tumor to other alkylating
agents prior to administration of BCNU to saturate the endogenous AGT present in the
tumor cells and thereby diminish DNA repair. See Brandes et al., “A multidrug
combination designed for reversing resistance to BCNU in glioblastoma multiforme”,

[17] In WO 02/056823, Hoffman discloses and claims oxidation of glutathione,
and thus altering the redox state of tumor cells. Nitrogen monoxide (also called “nitric
oxide” or “NO”) is an uncharged free radical that serves as a key messenger in immune,
cardiovascular, and nervous systems. The physiological activity of what was later
identified as NO was initially discovered in the early 1980’s when it was found that
vascular relaxation caused by acetylcholine is dependent on the presence of the vascular
endothelium. The factor derived from the endothelium, then called endothelium-derived relaxing factor (EDRF), that mediates such vascular relaxation is now known to be NO that is generated in the vascular endothelium by one isoform of nitric oxide synthase (NOS). In addition, NO is the active species derived from known nitrovasodilators including amyl nitrite, and glyceryl trinitrate. Nitric oxide is also an endogenous stimulator of soluble guanylate cyclase (cGMP), and thus stimulates cGMP production. When NOS is inhibited by N-monomethylarginine (L-NMMA), cGMP formation is completely prevented. In addition to endothelium-dependent relaxation, NO is known to be involved in a number of biological actions, including cytotoxicity of phagocytic cells and cell-to-cell communication in the central nervous system.

[18] The identification of EDRF as NO coincided with the discovery of a biochemical pathway by which NO is synthesized from the amino acid L-arginine by the enzyme NO synthase. There are at least three types of NO synthase:

(i) a constitutive, Ca++/calmodulin dependent enzyme, located in the brain, that releases NO in response to receptor or physical stimulation;

(ii) a Ca++ independent enzyme (a 130 kD protein) which is induced after activation of vascular smooth muscle, macrophages, endothelial cells, and a number of other cells by endotoxin and cytokines; and

(iii) a constitutive, Ca++/calmodulin dependent enzyme, located in the endothelium, that releases NO in response to receptor or physical stimulation.

[19] Once expressed, inducible nitric oxide synthase (hereinafter “iNOS”) generates NO continuously for long periods.

[20] In U.S. Patent Appl. Publ. No. 20010038832, Bonavida et al. disclose and claim the use of NO, iNOS, NO donors, and NO mimics in combination with chemotherapeutic agents, to sensitize cells to chemotherapeutic agents. Among the combination of chemotherapeutic agents claimed in that published application is BCNU.

[21] In Int’l Patent Appl. Publ. No. WO 02/056823, Hoffman dislocates that glutathione (GSH) detoxifies standard chemotherapeutic agents, such as alkylating agents, and indicates that GSH depleting agents, such as oxidizing agents, will convert GSH to
glutathione disulfide (GSSG), thereby enhancing the effectiveness of chemotherapeutic agents.

[22] Yin et al., in “Inducible Nitric Oxide Synthase Neutralizes Carbamoylating Potential of 1,3-Bis(2-chloroethyl)-1-nitrosourea in C6 Glioma Cells”, *J. Pharmacol. Exp. Therap.*, Vol. 297, Issue 1, 308-315, (April 2001), note that iNOS-derived NO confers chemoresistance against the carbamoylating potential of chloroethylnitrosoureas *in vitro*. Inhibition of NO formation by iNOS was achieved by treating C6 cells overexpressing iNOS with L-NAME, a broad-spectrum NOS inhibitor. L-NAME reduced the nitrite levels with corresponding restoration of BCNU toxicity in a concentration-dependent manner.

[23] There is a need in the art for a treatment of cancer (e.g., neoplasia, and in particular glioblastoma multiforme) that is robust and relatively safe, as well as effective for protracted periods of time (e.g., generally not subject to significant resistance by the neoplasias).

**SUMMARY OF THE INVENTION**

[24] The present invention is directed, in part, to a combination therapy comprising administration of a selective iNOS inhibitor in combination with a cytotoxic chemotherapeutic agent capable of carbamoylation (e.g., BCNU [1,3-bis(2-chloroethyl)-1-nitrosourea] and CCNU [1-(2-chloroethyl)-3-cyclohexyl-1-nitrosourea]) to treat neoplastic disorders, such as glioblastoma multiforme. It is believed that such a combination therapy will tend to result in an increase in the anti-tumor effects of the carbamoylating chemotherapeutic agent in brain cancer and other human cancers in which carbamoylating cytotoxics (e.g., BCNU) are used as standard of care. Without wishing to be bound by theory, a postulated mechanism of action is the reduction of intracellular levels of nitrosoglutathione, a cytoprotectant generated by the overproduction of nitric oxide and found in many brain tumors; nitric oxide is thus believed to react with intracellular glutathione to produce GSNO (nitrosoglutathione). Again, without wishing to be bound by theory, it is believed that HIF (hypoxia inducible factor) could be important in the mechanism of iNOS induction and tumor neovascularization.
[25] This combination treatment is counterintuitive to the use of NO donors and/or endogenously produced nitric oxide as anti-tumor agents, a concept embodied in the Bonavida et al., U.S. Patent Appl. Publ. No. 20010038832.

[26] Further, this combination tends to be safer and more effective than the broad-spectrum iNOS inhibitor disclosed by Yin et al. in “Inducible Nitric Oxide Synthase Neutralizes Carbamoylating Potential of 1,3-Bis(2-chloroethyl)-1-nitrosourea in C6 Glioma Cells”, J. Pharmacol. Exp. Therap., Vol. 297, Issue 1, 308-315, (April 2001). More specifically, non-specific or slightly specific inhibitors of iNOS are known to cause serious side effects in subjects, including hypertension and gastrointestinal distress.

[27] Other agents that have carbamoylating activity and are useful in the present methods and combinations include: methyl-CCNU; CCNU; cyclodisone; PCNU; clomesone; chlorozotocin; CBDCA (carboplatin); mitozolamide; triazinate; and L-cysteine analogue.

[28] In some embodiments, the present invention is directed to, for example, a treatment method comprising the administration of the selective iNOS inhibitor and chemotherapeutic agent in conjunction with radiation therapy. In this regard, no order of therapeutic steps are implied. Thus, for example, the radiation therapy may be administered after the chemotherapeutic agent and iNOS inhibitor. Or, for example, the iNOS inhibitor may be administered before radiation therapy, followed by administration of a chemotherapeutic agent.

[29] In some embodiments, the present invention is directed to, for example, a treatment method comprising administration of the selective iNOS inhibitor and chemotherapeutic agent in conjunction with resection of a tumor. For example, the selective iNOS inhibitor may be administered following surgery, and subsequently a chemotherapeutic agent may be administered, or surgery may be performed, followed by administration of a selective iNOS inhibitor and a chemotherapeutic agent, for example.

[30] This invention also is directed, in part, to a treatment method comprising resection of a tumor, radiation therapy, administration of a selective iNOS inhibitor, and administration of a cytotoxic agent for therapeutic intervention in a subject with a neoplastic disorder.
This invention also is directed, in part, to a kit comprising a carboxamoylating chemotherapeutic agent and a selective iNOS inhibitor in amounts that, when combined, are therapeutically effective.

This invention also is directed, in part, to a medicament comprising a carboxamoylating chemotherapeutic agent and a selective iNOS inhibitor in amounts that, when combined, are therapeutically effective.

The foregoing examples are illustrative only, and not limitative. Further benefits of Applicants’ invention will be apparent to one skilled in the art from reading this patent.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

This detailed description of preferred embodiments is intended only to acquaint others skilled in the art with Applicants’ invention, its principles, and its practical application so that others skilled in the art may adapt and apply the invention in its numerous forms, as they may be best suited to the requirements of a particular use. This detailed description and its specific examples, while indicating preferred embodiments of this invention, are intended for purposes of illustration only. This invention, therefore, is not limited to the preferred embodiments described in this patent, and may be variously modified.

In a broad sense, the present invention is directed to agents and methods for the treatment of cancer. Cancers treatable with the present methods include, without limitation: adrenocortical carcinoma, cerebellar astrocytoma, brain stem glioma, ependymoma, medulloblastoma, supratentorial primitive neuroectodermal and pineal tumors, visual pathway and hypothalamic gliomas, astrocytomas including glioblastoma multiforme, primary central nervous system lymphoma, eye cancers including intraocular melanoma and retinoblastoma, head and neck cancer, neuroblastoma, pituitary tumor, meningioma, primitive neuroectodermal tumor and secondary brain tumor.

The combination therapy of the present invention will result in an increase in the anti-tumor effects of BCNU in brain cancer and other human cancers in which
BCNU or other carbamoylating cytotoxics are used as standard of care, or may be therapeutically effective.

[37] Thus, in one embodiment of the present invention, an effective amount of a carbamoylating chemotherapeutic agent is administered in combination with an effective amount of a selective iNOS inhibitor to a subject in need of treatment. In this regard, the carbamoylating chemotherapeutic agent may be administered substantially together with the selective iNOS inhibitor, or may, on the other hand, be administered within a therapeutically effective time of administration of the selective iNOS inhibitor.

[38] Optionally, another treatment modality may be applied in conjunction with the therapeutic combination of carbamoylating chemotherapeutic agent and selective iNOS inhibitor. Therefore, in another embodiment of the present invention, surgery, such as resection of a tumor, may be performed prior to administration of the carbamoylating chemotherapeutic agent and the selective iNOS inhibitor. In addition, in another embodiment of the present invention, surgery, such as resection of a tumor, may be performed subsequent to administration of the carbamoylating chemotherapeutic agent and the selective iNOS inhibitor. Of course, surgery, such as resection of a tumor, may be performed prior to administration of the carbamoylating chemotherapeutic agent and subsequent to administration of the selective iNOS inhibitor, and surgery, such as resection of a tumor, may be performed prior to administration of the selective iNOS inhibitor and subsequent to administration of the carbamoylating chemotherapeutic agent as well.

[39] In still another embodiment of the present invention, radiation therapy may be administered to a subject in conjunction with administration of the selective iNOS inhibitor and the carbamoylating chemotherapeutic agent.

[40] In yet another embodiment of the present invention, radiation therapy may be administered to a subject in conjunction with surgery, such as resection of a tumor, in addition to administration of the selective iNOS inhibitor and the carbamoylating chemotherapeutic agent. No specific order in the administration of the above therapies is implied. Therefore, surgery, radiation therapy, chemotherapy and administration of a selective iNOS inhibitor may be performed in any order.
In another embodiment of the present invention, a medicament comprising a carbamoylating chemotherapeutic agent and a selective iNOS inhibitor is prepared for the treatment of cancer.

[76] In another exemplary compound, the inducible nitric oxide synthase selective inhibitor is the compound having the formula XI, or a pharmaceutically acceptable thereof. [77] The invention also contemplates use of other selective iNOS inhibitors. By way of example, iNOS selective inhibitors also useful in the present invention are described in U.S. Patent No. 6,355,689, Beswick et al., filed November 29, 2000 and issued March 12, 2002, which describes and claims a selective iNOS inhibitor with the formula XII:

\[
\text{XII}
\]

[78] wherein \( R^{79} \) is selected from C\(_{1-4}\) alkyl, C\(_{3-4}\) cycloalkyl, C\(_{1-4}\) hydroxyalkyl, and C\(_{1-4}\) haloalkyl. The description of U.S. Patent 6,355,689 states that \( R^{79} \) is preferably C\(_{1-4}\) alkyl, and most preferably, methyl. Specific embodiments disclosed in US Patent 6,355,689 and suitable for use in the present methods and compositions include:

- S-((R)-2-(1-iminoethylamino)propyl)-L-cysteine;
- S-((S)-2-(1-iminoethylamino)propyl)-L-cysteine;
- S-((R/S)-2-(1-iminoethylamino)propyl)-L-cysteine;
- S-((R)-2-(1-iminoethylamino)propyl)-D-cysteine;
- S-((S)-2-(1-iminoethylamino)propyl)-D-cysteine;
- S-((R/S)-2-(1-iminoethylamino)propyl)-D-cysteine;
S-((R/S)-2-(1-iminoethylamino)butyl)-L-cysteine;
S-((R/S)-2-(1-iminoethylamino,2-cyclopropyl)ethyl)-L-cysteine; and
S-((R/S)-2-(1-iminoethylamino,3-hydroxy)propyl)-L-cysteine,
or a pharmaceutically acceptable salt, solvate, or physiologically functional
derivative thereof.

[79] The above selective iNOS inhibitors are believed to work by competing
with arginine as a substrate for the iNOS enzyme. Another strategy for inhibition of iNOS
has been described by Arnaiz et al. in international patent application number
PCT/US98/03176, publication number WO 98/37079 (Berlex Laboratories, Inc.
Richmond, CA 94804-0099 and Pharmacopeia, Inc. Princeton, NJ 08540), published
August 27, 1998 (Arnaiz). The Arnaiz application describes inhibitors of iNOS monomer
dimerization. The iNOS enzyme is a homodimer; each monomer has a reductase domain,
incorporating binding sites for flavin cofactors (FAD and FMN) and for NADPH. The
reductase domain supplies electrons to the oxidase domain of the other monomer, where
L-arginine is oxidized at the active site, which incorporates a heme group (Fe) cytochrome
P-450 domain. Tetrahydrobiopterin (BH4) is required for homodimerization and
modulates the heme redox state during electron transfer. iNOS monomers are inactive,
and dimerization is required for activity.

[80] Thus, in another embodiment of the present invention, the selective iNOS
inhibitor is a dimerization inhibitor represented by a compound of Formula XIII, Formula

and halogen; for example \( R^{11} \) can be methyl. Alternatively, \( R^{11} \) can be fluoromethyl. In another alternative, \( R^{11} \) can be hydroxymethyl.

[148] In another compound \( R^{18} \) can be \(-OR^{24}\). \( R^{24} \) can be as defined above. Preferably \( R^{24} \) is \( C_1-C_6 \) alkyl optionally substituted by one or more moieties selected from the group consisting of cycloalkyl, heterocyclyl, aryl, and heteroaryl; more preferably \( R^{24} \) is \( C_1-C_3 \) alkyl; and more preferably still \( R^{24} \) is methyl. In yet another example of compound II, \( R^{18} \) can be \(-N(R^{25})(R^{26})\), wherein \( R^{25} \) and \( R^{26} \) are as defined above. In still another compound, \( R^{18} \) can be \(-N(R^{30})\), and \( R^{13} \) can be \(-C(O)\), wherein \( R^{18} \) and \( R^{13} \) together with the atoms to which they are attached form a ring. In another example still, \( R^{18} \) can be \(-O-\), and \( R^{13} \) can be \(-C(R^{31})(R^{32})\), wherein \( R^{18} \) and \( R^{13} \) together with the atoms to which they are attached form a ring.

[149] In a compound of Formula II, \( R^{21} \) can be selected from the group consisting of \(-OH, -C(O)-O-R^{34}, \) and \(-C(O)-S-R^{35}\). Preferably \( R^{21} \) is \(-OH\). In a further example, \( R^{22} \) is \(-H\) when \( R^{21} \) is \(-OH\).

In another useful compound, \( R^{21} \) is \(-C(O)\), and \( R^{22} \) is \(-O-\), wherein \( R^{21} \) and \( R^{22} \) together with the atoms to which they are attached form a ring. Alternatively, \( R^{22} \) can be selected from the group consisting of \(-OH, -C(O)-O-R^{36}, \) and \(-C(O)-S-R^{37}\). In this alternative, \( R^{21} \) is preferably \(-H\).

Definitions

5 [291] The term “compound” means a molecule or salt thereof consisting of a physiologically active ingredient. When a compound may take different or alternative forms in nature, such as a keto-enol tautomer, for example, the alternative forms are intended to be encompassed in the definition of the compound.

10 [292] The term “composition” means a compound and at least one other ingredient. Examples of such other ingredients are excipients, carriers, adjuvants, surfactants, diluents, fillers and the like. Compositions may be mixtures, solutions, emulsions, suspensions, colloidal dispersions and the like. Compositions may be in the solid phase, liquid phase, gas phase, or combinations thereof.

15 [293] The term “therapeutic agent” means a compound or a composition that promotes therapy, and acts to modulate a physiological function other than excretion or enzymatic decomposition into inactive components.

20 [294] The term “chemotherapeutic agent” means a therapeutic agent that acts to modulate a physiological function related to tumor cell growth, maintenance, transformation, metastasis or neovascularization. A chemotherapeutic agent may act either exclusively on tumor cells, or preferentially on tumor cells, or non-preferentially on tumor cells with respect to non-tumor cells.

25 [295] The term “carbamoylating chemotherapeutic agent” means a compound or composition that acts at least in part by transferring a carbamoyl group to an amino acid residue of a protein, particularly a lysine residue, and thereby modulating the physiological activity of the protein.

The term “combination therapy” means the administration of two or more therapeutic agents to treat a therapeutic condition or disorder described in the present disclosure. Such administration encompasses co-administration of these therapeutic agents in a substantially simultaneous manner, such as in a single capsule having a fixed ratio of active ingredients or in multiple, separate capsules for each active ingredient. In addition, such administration also encompasses use of each type of therapeutic agent in a sequential manner. In either case, the treatment regimen will provide beneficial effects of the drug combination in treating the conditions or disorders described herein.

The phrase “in conjunction with” means that one first treatment modality is used with at least one, second treatment modality at a period of time conducive to treatment. When a first treatment modality is used in conjunction with a second treatment modality, the treatment modalities may be applied in a substantially simultaneous manner, or the treatment modalities may be applied in a sequential manner. Although the treatment modalities may be referred to as a “first” or “second” treatment modality, the order of application or administration is not necessarily sequential, and the terms “first,” “second” and “third,” when used in the context of the phrase “in conjunction with” are intended only to differentiate the treatment modalities, and do not infer chronological order, unless such treatment modalities are specifically designated as ordered chronologically.

The terms “nitric oxide synthase inhibitor” and “NOS inhibitor” mean a compound that reduces the physiological effect of a nitric oxide synthase enzyme. Such an inhibitor may be selective for a particular isoform of nitric oxide synthase, or may be substantially non-selective, that is, effective to a large extent on two or more isoforms of nitric oxide synthase.

The terms “selective inducible nitric oxide synthase inhibitor”, “selective NOS-2 inhibitor”, and “selective iNOS inhibitor” denote a compound capable of reducing the physiological effect of the calcium ion independent isoform of nitric oxide synthase.
preferentially over other isoforms of nitric oxide synthase. For purposes of this invention, a selective inducible nitric oxide synthase inhibitor, or selective iNOS inhibitor, acts, at least in part, as either a competitive substrate for the iNOS enzyme (competing with L-arginine at the active site of the iNOS enzyme), or as an inhibitor of dimerization of iNOS monomers.

[340] Example A. Preparation of (2S,5S)-2-amino-6-fluoro-7-[(1-iminoethyl)amino]-5-heptenoic acid, dihydrochloride, monohydrate

[341] EX-A-1. Preparation of:

Trimethylsilyl chloride (107.8 g, 1.00 mol) was added dropwise to a cooled solution of L-glutamic acid (30.00 g, 0.20 mol) in 300 mL of methanol at 0°C. The resulting clear,
colorless solution was allowed to stir at room temperature. After 18 hr, analysis by thin layer chromatography (30% ethyl acetate in hexane) showed that no starting material remained. The reaction was then cooled to 0°C, triethylamine (134 g, 1.33 mol) was added, and a white precipitate formed. Di-tert-butyldicarbonate (49 g, 0.23 mol) was added, and the mixture was allowed to warm to room temperature. After 3 hr the solvent was removed, and 700 mL of diethyl ether was added. The solution was filtered, and the filter cake was rinsed with an additional 500 mL of diethyl ether. The filtrate was concentrated to 60.8 g (>95%) of a tan oil which was carried onto the next step without further purification. LCMS: m/z = 298.1 [M+Na]+. HRMS calcd. for C_{12}H_{21}NO_6: 276.1447 [M+H]^+, found: 276.1462. ¹H NMR (CDCl₃) δ 1.45 (s, 9H), 1.95 (m, 1H), 2.50 (m, 1H), 2.40 (m, 2H), 3.69 (s, 3H), 3.75 (s, 3H), 4.32 (m, 1H), 5.15 (m, 1H).

Ex-V-1. Preparation of:
A 3-neck 3 L flask was purged with N₂ before it was charged with cyclohexanone (1.27 mol, 132 mL) and 500 mL of toluene. This stirred mixture was cooled to 0°C and 157.2 g (1.1 eq) of potassium t-butoxide was added. After stirring this mix for 1 hr, a color and texture change was noted before a solution of 5-pentenyl bromide (1.27 mol, 136 mL) in 100 mL toluene was added dropwise over 1 hr to the mechanically stirred reaction mixture. The reaction mixture was allowed to warm to 25°C and stir overnight. It was then diluted with 800 mL of 1 N KHSO₄ and the organic phase was dried (MgSO₄), filtered and evaporated to dryness to yield 208.5 g of crude product. This material was then purified by vacuum distillation (under water aspirator pressure) to give the title product in 47% yield. ^1H NMR (CDCl₃, 6 ppm): 1.0-2.4 (m, 13H), 4.9-5.1 (m, 2H), 5.7-5.9 (m, 1H).

[484] Example X. Preparation of (αS,2S)-α-aminohexahydro-7-imino-1H-azepine-2-hexanoic acid, trihydrate hydrochloride

[485] Ex-X-1. Preparation of:

To a 22L round bottom flask equipped with overhead stirrer, half moon shape paddle, heating mantle, thermocouple, and a silver vacuum jacketed distillation column (5 plates) was charged cyclohexanone (4500.0 g, 45.85 mol), acetone dimethyl acetal (5252.6 g, 50.43 mol), allyl alcohol (6390.87 g, 110.04 mol) and p-toluene sulfonic acid (PTSA) (0.256 g, 0.001 mol). After the stirring was started (137 rpm) the pot was heated slowly with the initial set point being 70°C. Heating was increased step wise to a final pot temperature of 150°C. The decision to increase the reactor set point was made based on distillation rate. If the rate of distillate slowed or stopped, additional heat was applied.

The additional heating to 150°C allowed the Claisen rearrangement to occur. After the pot temperature was raised to 150°C and no distillate was observed, the heating mantle was
lowered and the reaction mixture allowed to cool to 130°C. The PTSA was then neutralized with 3 drops of 2.5 N NaOH. The vacuum stripping was then started with the heating mantle lowered away from the flask. Evaporative cooling was used to lower the pot temperature, and the pressure was gradually lowered to 40 mm Hg. When the pot temperature had decreased to ~100°C, the heating mantle was raised back into the proper position for heating. Unreacted cyclohexanone and low boiling impurities were distilled off. The pot temperature was slowly raised (the maximum temperature differential between the pot and vapor was ~12°C). The product was isolated at 109-112°C @ 40 mm Hg. Typical yields were 40-45%. Fractions which were <95% by area (GC) were combined and redistilled to afford the title product in a total yield of 55%. ^1H NMR (CDCl₃, 8 ppm): 5.8-5.6 (m, 1H), 4.8-5.0 (m, 2H), 2.5-2.4 (m, 1H), 2.3-2.1 (m, 3H), 2.1-1.2 (m, 7H). ^13C NMR (CDCl₃, 8 ppm): 212.53, 136.62, 116.32, 50.39, 42.18, 33.91, 33.52, 28.09, 25.10. Hydroxyl amine-O-sulfonic acid (91.8 g) dissolved in acetic acid (470 g) was added to a 1 L Bayer flask equipped with a mechanical stirrer, thermocouple, condenser chilled to 0°C, and an addition funnel and heated to 70°C. The allyl cyclohexone (100 g) was added dropwise in approximately 40 min to the above solution while maintaining the temperature between 70 and 78°C. During the addition, the reaction appearance changed from a white slurry to a clear orange solution. After the addition, the reaction was heated and stirred for an additional 5 hr at 75°C. An IPC sample was taken each hour. After the reaction was complete, the acetic acid was stripped at 50°C under reduced pressure on a rotary evaporator. Water (200 mL) was then added to the residue and the solution extracted with toluene (2x300 mL). The organic layers were combined, treated with water (150 ml) and stirred for 10 min. A sodium hydroxide solution (79.4 g of 50 solution) was added until the aqueous layer turned basic (pH 12). The neutralization was carried out in the reactor by controlling the temperature below 40°C. The layers were then separated and the
toluene layer was passed through a filter to remove any solids or tarry material. The organic solution was then stripped at 50°C under reduced pressure on a rotary evaporator. The residue was taken up in a mixture of toluene (510 mL) and heptanes (2040 mL) and heated to 60°C in a 3 L reactor. A clear yellow-orange solution was obtained. The title product began to crystallize at 53 °C as the solution was slowly cooled to 5°C while being stirred. The solid was filtered, washed with heptanes (50 mL) and dried overnight at 40°C under house vacuum to produce 66.3 g (60%) of title product as off-white crystals obtained. A portion of this material was recrystallized from toluene and heptane to generate the title product as a white crystalline solid. \(^1\)H NMR (CDCl\(_3\), δ ppm): 5.8-5.6 (m, 1H), 5.5 (bs, 1H), 4.8-5.0 (m, 2H), 3.4-3.3 (m, 1H), 2.5-2.3 (m, 2H), 2.3-2.1 (m, 2H) 2.0-1.2 (m, 6H). \(^1\)C NMR (CDCl\(_3\), δ ppm): 117.73, 133.83, 119.31, 52.88, 40.95, 37.20, 35.75, 29.96, 23.33. After 1.5 hr another 86.25 g of Di-tert-butyl-dicarbonate (0.395 mol) dissolved in toluene (50 mL) were added. Heating was continued for 17 hr and IPC by HPLC showed 75% conversion. Another 42.78 g of di-tert-butyl dicarbonate (0.196 mol) in toluene (30 mL) were added and the brown mixture was heated 5.5 hr. After cooling to ambient temperature, the mixture was treated with 4M HCl (215 mL), and the aqueous layer was extracted with toluene (2x80 mL). To a cold (-78°C) solution of triethyl 2-fluorophosphonoacetate (25.4 g, 105 mmol) in 100 mL of THF was added n-butyl lithium (63 mL of 1.6 M in hexane, 101 mmol). This mixture was stirred at -78°C for 20 min producing a bright yellow solution. A solution of crude 3-[[(tert-butyl(dimethyl)silyl)oxy]propanal (J. Org. Chem., 59, 1139-1148 (1994)) (20.0 g, 105 mmol) in 120 mL of THF was then added dropwise over 10 min, and the resulting mixture was stirred for 1.5 hr at -78°C, at which time analysis by thin layer chromatography (5% ethyl acetate in hexane) showed that no starting material remained. The reaction was quenched at -78°C with sat. aqueous NH₄Cl (150 mL). The organic layer was collected, and the aqueous layer was extracted with diethyl ether (300 mL). The combined organics were washed with brine (200 mL), dried over MgSO₄, filtered and concentrated. The crude material was filtered through a plug of silica gel (150 g) eluting with hexane (2 L) to give 14.38 g (52%) of the desired (2E)-5-[[[1,1-dimethylethyl]di-
methylsilyl[oxy]-2-fluoro-2-pentenoic acid ethyl ester product as a clear oil. $^1$H NMR and $^{19}$F NMR indicated that the isolated product had an approximate E:Z ratio of 95:5. HRMS calcd. for C$_{13}$H$_{26}$FO$_3$Si: m/z = 277.1635 [M+H]$^+$, found: 277.1645. $^1$H NMR (CDCl$_3$) $\delta$ 0.06 (s, 6H), 0.94 (s, 9H), 1.38 (t, 3H), 2.74 (m, 2H), 3.70 (m, 2H), 4.31 (q, 2H), 6.0 (dt, vinyl, 1H). $^{19}$F NMR (CDCl$_3$) $\delta$ -129.78 (d, 0.05 F, $J = 35$ Hz, 5% Z-isomer), -121.65 (d, 0.95 F, $J = 23$ Hz, 95% E-isomer).

[555] Ex-HH-2. Preparation of:

To a solution of Ex-HH-1 (6.76 g, 24.5 mmol) in 100 mL of methanol at room temperature was added solid NaBH$_4$ (4.2 g, 220 mmol) in 1.4 g portions over 3 hr. After 3.5 hr water was added (10 mL). Additional solid NaBH$_4$ (4.2 g, 220 mmol) was added in 1.4 g portions over 3 hr. The reaction was quenched with 150 mL of sat. aqueous NH$_4$Cl and extracted with diethyl ether (2x250 mL). The organic layers were combined, dried over MgSO$_4$, filtered and concentrated. The crude material, 4.81 g of clear oil, was purified by flash column chromatography on silica gel eluting with 10% ethyl acetate in hexane to give 2.39 g (42%) of the desired (2E)-5-[[1,1-dimethylethyl]dimethylsilyl[oxy]-2-fluoro-2-penten-1-ol product as a clear oil, that contained an approximate E:Z ratio of 93:7 by $^{19}$F NMR. A solution of the product from Ex-HH-7 (0.58 g, 1.54 mmol) in 1.5 N HCl (25 mL) was washed with diethyl ether (2x20 mL) and refluxed for 1 hr. The solvent was stripped and the crude amino acid ester was dissolved in 6 N HCl (15 mL) and heated to reflux. After 6 hr, the solvent was removed in vacuo, and the resulting foam was purified by reverse-phase HPLC eluting with a 30 min gradient of 0-40% CH₃CN/H₂O (0.25% acetic acid).

Fractions containing product were combined and concentrated to a foam. The product was dissolved in 1 N HCl and the solvent removed in vacuo (2x) to give 0.15 g (29%) of the desired (2S,5E)-2-amino-2-methyl-6-fluoro-7-[(1-iminoethyl)amino]-5-heptenoic acid, dihydrochloride product. Example II. Preparation of (2S,5E)-2-amino-2-methyl-6-fluoro-7-[(1-iminoethyl)amino]-5-heptenoic acid, dihydrochloride

Ex-II-1. Preparation of:

To a 1-methyl-2-pyrrolidinone (7500 mL) solution of methyl N-[(3,4-dichlorophenyl)methylene]-alaninate (748.5 g, 2.88 mol) under N₂ was added LiI (385.5 g, 2.88 mol) and the resulting slurry stirred approximately 20 min to give a clear solution. The solid from Ex-HH-5 (750 g, 2.40 mol) was then added and the resulting solution cooled in an ice bath to ~0°C. Neat BTPP (900 g, 2.88 mol) was added dropwise over 25 min maintaining the internal temperature below 5°C. After stirring for an additional 1.5 hr at 5°C, the reaction was determined to be complete by HPLC. At this time, 7500 mL of methyl t-butyl ether (MTBE) was added followed by addition of 9750 mL of a water/crushed ice mixture. The temperature rose to 20°C during this operation. After stirring vigorously for 5-10 min, the layers were separated and the aqueous layer washed with twice with 6000 mL of MTBE. The MTBE layers were combined and washed 2 times with 7500 mL of water. The resulting MTBE solution was then concentrated to ~5000 mL, treated with 11625 mL of 1.0 N HCl, and stirred vigorously at room temperature for 1 hr. The layers were separated and the aqueous layer washed with 7500 ml of MTBE. About 1 kg of sodium chloride was added to the aqueous layer and the resulting mixture stirred until all the salt had dissolved. At this point, 7500 mL of ethyl acetate was added, the resulting mixture cooled to 10°C, and 2025 mL of 6.0 N sodium hydroxide added with good agitation. The resulting pH should be about 9. The layers were separated and the aqueous layer was saturated with sodium chloride and extracted again with 7500 mL of ethyl acetate. The combined ethyl acetate extracts were dried (MgSO₄) and concentrated to a light oil. It should be noted that the ethyl acetate was not complete removed. With
agitation, 3000 ml of hexane then is added to generate a slurry that was cooled to 10°C. The granular solid was collected by filtration and washed with 1500 ml of hexane. About
564 g (82% yield) of the desired pure aminoester (>95% pure by HPLC) was obtained as a white solid, m.p. 82.9-83.0°C. LCMS: m/z = 288.2 [M+H]^+. Chiral HPLC (Chiralpak-AD normal phase column, 100% acetonitrile, 210 nm, 1 mL/min): Two major peaks at 4.71 and 5.36 min (1:1). ^1H NMR (CDCl₃): δ 1.40 (s, 3H), 1.7-1.8 (m, 2H), 2.0 (br s, 2H), 2.2 (m, 2H), 2.29 (s, 3H), 3.73 (s, 3H), 4.34 (dd, 2H), 5.33 (dt, 1H).

Ex-II-2. Preparation of:

Separation of the individual enantiomers of the product from Ex-II-1 was accomplished on preparative scale using chiral HPLC chromatography (ChiralPak-AD, normal phase column, 100% acetonitrile) to give the desired pure (2S)-2-methyl amino ester product title product. ChiralPak-AD, normal phase column, 100% acetonitrile, 210 nm, 1 mL/min): 5.14 min (99%).

Ex-II-3. Preparation of:

A slurry of the product of Ex-II-2 (2.30 g, 8.01 mmol) in 0.993 M NaOH (30.0 ml, 29.79 mmol) was stirred 2 hr at room temperature. To the resulting clear colorless solution was added 1.023 M HCl (29.10 mL, 29.76 mmol). The resulting clear solution was concentrated until a precipitate began to form (approx. 30 mL). The slurry was warmed to give a clear solution that was allowed to stand at room temperature overnight. The precipitate was isolated by filtration. The solid was washed with cold water (2x10 mL), cold methanol (2x10 mL) and Et₂O (2x20 mL). The white solid was dried in vacuo at 40°C 4 hr to give 1.04 g (53 %) of the desired N-hydroxy illustrated product. mp = 247.2°C. Anal. calcd. for C₁₅H₁₈FN₅O₅: C, 48.57; H, 7.34; N, 16.99; Cl, 0.0. ![Chemical Structure](image)

Method A. A solution of 73.5 g (0.3 mol) of the product from Ex-II-2 was dissolved in 300 mL of methanol and added dropwise to a preformed mixture of 13.7 g of Lindlar catalyst and 73.5 g of formic acid (1.53 mol) in 312 mL of methanol while maintaining the reaction temperature between 22°C and 26°C. After stirring at room temperature for an additional ~15 hr, the reaction was determined to be complete by F\textsuperscript{19} NMR. The resulting reaction mixture was filtered through celite and the celite washed 3 times with 125 mL of methanol. The methanol filtrates were combined and concentrated to generate 115 g of the desired amidine title product as a viscous oil. MS: m/z = 246 (M+H)^+. \textsuperscript{1}H NMR (CD_{3}OD) \delta ppm, 4H) 2.3 (s, 3H), 3.9 (s, 3H), 4.2 (d, 2H), 5.4 (dt, vinyl), 8.4 (s, 3H). \textsuperscript{19}F NMR (CD_{3}OD) \delta ppm, J= 21 Hz) -111.7 (q, J=21 Hz). To remove trace levels of lead, the crude product was dissolved in 750 mL of methanol and 150 g of a thiol-based resin (Deloxan THP 11) was added. After stirring 3 hrs at room temperature, the resin was filtered off and washed 2 times with 500 mL methanol. The filtrates were collected and concentrated to 99 g of the desired amidine title product as a viscous oil.

Method B. A total of 5.0 g of the product from Ex-II-2 (0.0174 mole, 1.0 equiv) was mixed with 5.0 g of zinc dust (0.0765 moles, 4.39 equiv) in 40 mL of 1-butanol.
and 10 mL of acetic acid. After stirring for 5 hrs at 50 °C, LC analyses indicated the reaction to be complete. The solids were readily filtered off. The filtrate, after cooling in ice water to 7 °C, was treated with 30 mL of 6 N NaOH (0.180 moles) in 1 portion with vigorous stirring. After cooling the reaction mixture from 33 °C to 20 °C, the clear butanol layer was separated off and the aqueous layer extracted again with 40 mL of 1-butanol. The butanol extracts were combined, and washed with 30 mL of brine, followed by approx 10 mL of 6N HCl. After concentration at 70°C, a clear glass resulted which was identified as the desired amidine title product.

To a CH₂Cl₂ (15 mL) solution of Ex-KK-1 (1.36 g, 4.98 mmol) was added 4-chlorobenzaldehyde (0.70 g, 5.0 mmol) and MgSO₄ (~5 g). The slurry was stirred at room
temperature for 18 hr. The slurry was filtered, and the filtrate stripped to give 1.98 g (100 %) of the desired title imine product as a pale yellow oil. This product was used in the next step without further purification. $^1$H NMR (CD$_2$D$_2$) δ 1.34 (s, 3H), 2.0 (br m, 4H), 3.32 (s, 3H), 3.42 (m, 2H), 3.83 (t, 1H), 4.98 (dt, vinyl, 1H).

[578] Ex-KK-3. Preparation of:

To a CH$_2$Cl$_2$ (2 mL) solution of the product of Ex-KK-2 (0.25 g, 0.63 mmol) was added methyl iodide (0.200 mL, 3.23 mmol) and O(9)-allyl-N-(9-anthracenylmethyl)-cinchonidinium bromide (40 mg, 0.066 mmol). The solution was cooled to -78°C and neat BTPP (0.289 mL, 0.95 mmol) was added. The resulting orange solution was stirred at -78°C for 2 hr and allowed to reach -50°C. After 2 hr at -50°C, the solution was diluted with CH$_2$Cl$_2$ (10 mL), washed with water (10 mL), dried (MgSO$_4$), filtered, and evaporated to give the crude desired racemic alkylated imine as a yellow oil. The crude material was dissolved in ethyl acetate (10 mL) and 1N HCl (10 mL) was added. The mixture was stirred for 1 hr at room temperature, and the organic layer was separated. The aqueous layer was neutralized with solid NaHCO$_3$ and extracted with ethyl acetate (2x30 mL). The organic layer was dried (MgSO$_4$), filtered and evaporated to give 0.16 g of the desired racemic 2-methylamino ester product as a yellow oil. The product was used in the next step without further purification. LCMS: m/$z = 288.2$ [M+H]$^+$.  

[579] Ex-KK-4. Preparation of:

The racemic product from Ex-KK-3 is dissolved in water and acetic acid. Zinc dust is added, and the mixture is heated at 60 °C until HPLC analysis shows that little of the starting material remains. The Zn dust is filtered through celite from the reaction mixture, and the filtrate is concentrated. The crude material is purified by reverse-phase HPLC
column chromatography. Fractions containing product are combined and concentrated
affording the desired acetamidine product.

After 1 hr of controlling the temperature between 45-55°C, the mixture turned clear. At this point, the mixture was heated up to 66°C and stirred for 2.5 hr. Mixture was cooled to room temperature and saturated ammonium chloride (125 mL) was added slowly over 30 min (strong exotherm was observed) keeping the temperature below 40°C. The liquid phase was separated by decantation; ethyl acetate (250 mL) and brine (50 mL) were added. The organic phase was separated and washed with brine (2x50 mL) and water (1x50 mL). The organic layer was dried over sodium sulfate and concentrated under reduced pressure to afford 51 g of a lightly yellow colored oil (85% crude yield); GC area% = 88% title product, 6% starting material.

The mixture was cooled to -5°C and methanesulfonyl chloride (7.3 g, 0.63 mol) was added via syringe at such rate as to keep the pot temperature below 10 °C. The mixture was allowed to warm to room temperature and stirred for 2 hr. The mixture was filtered by suction and rinsed on the filter with toluene (2x20 mL). The filtrate and washes were added to a mixture of the sodium salt of 3-methyl-1,2,4-oxadiazolin-5-one (8.6 g, 0.063 mol) in DMF (10 mL). The mixture was stirred with a mechanical stirrer and heated at 45°C for 5 hr. Water (40 mL) was added and the mixture was stirred for 5 min and then the layers were separated. The solution of starting material was then added at ambient temperature to the light grey catalyst slurry followed by a methanol rinse (200 mL). The heterogeneous reaction mixture was heated at 45°C for 1 ½ hr. Steady gas evolution was observed starting at about 40°C, which indicated the ongoing reaction. The mixture was cooled in an ice/water bath and then filtered through a plug of Supercell HyFlo. The yellow solution was concentrated in vacuo to give a viscous oil, which was dissolved and partitioned between 2 N aqueous HCl (2 L) and ethyl acetate (0.8 L). Layers were separated and the aqueous layer was washed once with ethyl acetate (0.8 L). Solvent and volatiles were removed in vacuo at elevated temperatures (= 70°C). Ex-LL-13. Preparation of:

The crude product of Ex-LL-12 (170 g) was dissolved in 2 N aqueous HCl (1 L). The resulting orange solution was refluxed overnight before it was allowed to cool back to ambient temperature. The reaction mixture was concentrated to about 1/3 of its volume, and the acidic solution was passed through a solid phase extraction cartridge (25 g of C18 silica) to remove color and other impurities. Solvent was removed in vacuo (= 70°C) to give 208 g of crude product as yellowish gum. The crude gum (31.3 g) was taken up in water (250 mL) and the material was loaded onto a pretreated ion exchange column packed with the acidic resin Dowex 50WX4-400 (about 600 g). The resin was first washed with water (1 L), then with dilute aqueous HCl (1 L of 10/90 v/v conc. HCl/water). The product was eluted off the resin with higher ion strength aqueous HCl (1.5 L of 20/90 v/v to 25/75 v/v conc. HCl/water). The aqueous solvent was removed in vacuo (= 70°C), and the gummy residue was taken up in 4 vol% aqueous trifluoroacetic acid (100 mL). The aqueous solvent was removed in vacuo (= 70°C), and the procedure was repeated once more. The residue was then dried under high vacuum to give 32.2 g of gum as the trifluoroacetic acid salt. Crude (2S,5Z)-7-aceitimido-2-amino-2-methyl-hept-5-enoic acid, ditrifluoroacetate acid salt hydrate (32.2 g) was purified by reverse-phase preparative chromatography. The crude was dissolved in 0.1% aqueous TFA (50 ml) and loaded onto a 2-inch ID x 1 meter stainless steel column packed with adsorbent (BHK polar W/S, 50 □, 1.16 kg). The product was eluted at a flow rate of 120 mL/min with a step gradient from 0.1% aqueous TFA to 25/75/0.1 acetonitrile/water/TFA. The loading ratio was 36:1 w/w silica to sample. Solvent was removed in vacuo, and the material was converted into the HCl salt by repeated rinses with dilute aqueous HCl and solvent removals in vacuo. Drying under high vacuum gave 27.4 g of the title dihydrochloride hydrate as yellowish gum. After being stirred for 1 hr, the reaction mixture was concentrated under vacuum. The residue was distributed between 60 mL of ethyl acetate (EtOAc) and 50 mL of water. The layers were separated. The organic layer was washed with 50 mL of 1M KHSO_{4} solution and 2
times with 50 mL of water. The product started to precipitate and the suspension was concentrated in vacuum giving 9 g of crude compound. After drying, the product was purified by boiling in methylene chloride followed by filtration, giving 3.7 g of 1A (62.7%). The compound was characterized by $^1$H NMR.

[601] Ex-NN-2. (2 g, 4.5 mmol) was reduced under catalytic hydrogenation conditions using Pd black at 5 psi in 50% EtOH/AcOH solution for 12 hr, giving 1.55 g (100%) of NN-2. The compound was characterized by $^1$H NMR.

[602] Ex-NN-3. To a stirring solution of NN-2 (1.55 g, 4.15 mmol) and methyl acetimidate hydrochloride (0.91 g, 8.31 mmol) in 25 mL of DMF was added triethylamine (TEA) (1.26 g, 1.74 mL, 12.45 mmol). After being stirred 16 hr at ambient temperature, the reaction mixture was filtered from triethylamine hydrochloride and the filtrate was concentrated in vacuum. The residue was dissolved in 50% AcOH and lyophilized. The crude product (2 g) was purified using reverse-phase chromatography on a C-18 column giving 0.9 g (52.3%) of 1C. The product was characterized by $^1$H NMR.

[603] Ex-NN-4. (0.9 g, 2.17 mmol) was dissolved in 30 mL of acetic acid and 3 mL of 4 N HCl/dioxane were added. The reaction was stirred for 20 min. at ambient temperature then 150 mL of ethyl ether were added. After 2 hr, the precipitate was filtered, washed with ethyl ether, and dried giving 0.78 g of 1 (96%). Anal. Calcd. for C$_9$H$_{18}$N$_8$O$_2$HCl, 1.25H$_2$O: C, 30.91; H, 6.48; N, 32.04; Cl, 20.27. Found: C, 31.64; H, 6.43; N, 32.19; Cl, 20.19. DSC mp 144.9°C.

[604] Example NN is a desirable crystalline product, as are all its intermediates. In contrast, NIL is a glass, which makes it difficult to handle.

**Biological Data**

[605] Some (or all) of the following assays may be used to demonstrate the nitric oxide synthase inhibitory activity of the invention’s compounds, as well as demonstrate the useful pharmacological properties.
A. Citrulline Assay for Nitric Oxide Synthase

Nitric oxide synthase (NOS) activity can be measured by monitoring the conversion of L-[2,3-\(^3\)H]-arginine to L-[2,3-\(^3\)H]-citrulline (Bredt and Snyder, Proc. Natl. Acad. Sci. U.S.A., 87, 682-685, 1990 and Moore et al, J. Med. Chem., 39, 669-672, 1996). Human inducible NOS (hiNOS), human endothelial constitutive NOS (hecNOS) and human neuronal constitutive NOS (hncNOS) are each cloned from RNA extracted from human tissue. The cDNA for human inducible NOS (hiNOS) is isolated from a \(\lambda\)cDNA library made from RNA extracted from a colon sample from a patient with ulcerative colitis. The cDNA for human endothelial constitutive NOS (hecNOS) is isolated from a \(\lambda\)cDNA library made from RNA extracted from human umbilical vein endothelial cells (HUVEC) and the cDNA for human neuronal constitutive NOS (hncNOS) is isolated from a \(\lambda\)cDNA library made from RNA extracted from human cerebellum obtained from a cadaver. The recombinant enzymes are expressed in \(Sf9\) insect cells using a baculovirus vector (Rodi et al, in The Biology of Nitric Oxide, Pt. 4: Enzymology, Biochemistry and Immunology; Moncada, S., Feelisch, M., Busse, R., Higgs, E., Eds.; Portland Press Ltd.: London, 1995; pp 447-450). Enzyme activity is isolated from soluble cell extracts and partially purified by DEAE-Sepharose chromatography. To measure NOS activity, 10 \(\mu\)L of enzyme is added to 40 \(\mu\)L of 50 mM Tris (pH 7.6) in the presence or absence of test compounds and the reaction initiated by the addition of 50 \(\mu\)L of a reaction mixture containing 50mM Tris (pH 7.6), 2.0 mg/mL bovine serum albumin, 2.0 mM DTT, 4.0 mM CaCl\(_2\), 20 \(\mu\)M FAD, 100 \(\mu\)M tetrahydrobiopterin, 0.4 mM NADPH and 60 \(\mu\)M L-arginine containing 0.9 \(\mu\)Ci of L-[2,3-\(^3\)H]-arginine. The final concentration of L-arginine in the assay is 30 \(\mu\)M. For hncNOS or hncNOS, calmodulin is included at a final concentration of 40-100 nM. Following incubation at 37°C for 15 min, the reaction is terminated by addition of 400 \(\mu\)L of a suspension (1 part resin, 3 parts buffer) of Dowex 50W X-8 cation exchange resin in a stop buffer containing 10 mM EGTA, 100 mM HEPES, pH 5.5 and 1 mM L-citrulline. After mixing the resin is allowed to settle and L-[2,3-\(^3\)H]-Citrulline formation is determined by counting aliquots of the supernatant with a liquid scintillation counter.

Results are reported in Table I as the IC\(_{50}\) values of compounds for hiNOS, hecNOS and hncNOS.
B. Raw Cell Nitrite Assay

RAW 264.7 cells can be plated to confluence on a 96-well tissue culture plate grown overnight (17h) in the presence of LPS to induce NOS. A row of 3-6 wells can be left untreated and served as controls for subtraction of nonspecific background. The media can be removed from each well and the cells washed twice with Kreb-Ringers-Hepes (25 mM, pH 7.4) with 2 mg/ml glucose. The cells are then placed on ice and incubated with 50 μL of buffer containing L-arginine (30 μM) +/- inhibitors for 1h. The assay can be initiated by warming the plate to 37°C in a water bath for 1h. Production of nitrite by intracellular iNOS will be linear with time. To terminate the cellular assay, the plate of cells can be placed on ice and the nitrite-containing buffer removed and analyzed for nitrite using a previously published fluorescent determination for nitrite. T. P. Misko et al, *Analytical Biochemistry*, 214, 11-16 (1993).

C. Human cartilage explant assay

Bone pieces are rinsed twice with Dulbecco's Phosphate Buffered Saline (GibcoBRL) and once with Dulbecco's Modified Eagles Medium (GibcoBRL) and placed into a petri dish with phenol red free Minimum Essential Medium (MEM) (GibcoBRL). Cartilage was cut into small explants of approximately 15-45 mg in weight and 1 or 2 explants per well are placed into either 96 or 48 well culture plates with 200-500 μL of culture media per well. The culture media was either a custom modification of Minimum Essential Medium(Eagle) with Earle's salts (GibcoBRL) prepared without L-Arginine, without L-Glutamine and without phenol red or a custom modification of serumless Neuman and Tytell (GibcoBRL) medium prepared without L-arginine, without insulin, without ascorbic acid, without L-glutamine and without phenol red. Both are supplemented before use with 100 μM L-Arginine (Sigma), 2 mM L-glutamine, 1X HL-1 supplement (BioWhittaker), 50 mg/ml ascorbic acid (Sigma) and 150 pg/ml recombinant human IL-1β (RD Systems) to induce nitric oxide synthase. Compounds are then added in 10 μL aliquots and the explants incubated at 37°C with 5% CO₂ for 18-24 hr. The day old supernatant is then discarded and replaced with fresh culture media containing recombinant human IL-1β and compound and incubated for another 20-24 hr. This supernatant is analyzed for nitrite with a fluorometric assay (Misko et al, Anal. Biochem.,
214, 11-16 (1993)). All samples are done in quadruplicate. Unstimulated controls are
cultured in media in the absence of recombinant human IL-1\( \tilde{ } \) IC\(_{50}\) values (Table I) are
determined from plotting the percent inhibition of nitrite production at 6 different
concentrations of inhibitor.

Table I shows examples of biological activity for some compounds of the
present invention.

**D. In Vivo Assay**

Rats can be treated with an intraperitoneal injection of 1-12.5 mg/kg of endotoxin (LPS) with or without oral administration of the nitric oxide synthase inhibitors. Plasma nitrite/nitrate levels can be determined 5 hr post-treatment. The results can be used to show that the administration of the nitric oxide synthase inhibitors decreases the rise in plasma nitrite/nitrate levels, a reliable indicator of the production of nitric oxide induced by endotoxin. As shown in **Table II**, Example A ((2S,5E)-2-amino-6-fluoro-7-[(1-iminoethyl)amino]-5-heptenoic acid, dihydrochloride) inhibited the LPS-induced
increase in plasma nitrite/nitrate levels with an observed ED$_{50}$ value of <0.1 mg/kg, demonstrating the ability to inhibit inducible nitric oxide synthase activity \textit{in vivo}.

\textbf{E. Assay for Time Dependent Inhibition}

[611] Compounds are evaluated for time dependent inhibition of human NOS isoforms by preincubation of the compound with the enzyme at 37°C in the presence of the citrulline enzyme assay components, minus L-arginine, for times ranging from 0-60 min. Aliquots (10 μL) are removed at 0, 10, 21, and 60 min and immediately added to a citrulline assay enzyme reaction mixture containing L-[2,3-$^3$H]-arginine and a final L-arginine concentration of 30 μM in a final volume of 100 μL. The reaction is allowed to proceed for 15 min at 37°C and terminated by addition of stop buffer and chromatography.
with Dowex 50W X-8 cation exchange ion exchange resin as described for the citrulline NOS assay. The % inhibition of NOS activity by an inhibitor was taken as the per cent inhibition in activity compared to control enzyme preincubated for the same time in the absence of inhibitor. Data shown in Table III is the % inhibition after 21 and 60 min preincubation of inhibitor with enzyme.

**Dosages, Formulations and Routes of Administration**

Many of the iNOS selective inhibitor compounds useful in the methods of the present invention can have at least 2 asymmetric carbon atoms, and therefore include racemates and stereoisomers, such as diastereomers and enantiomers, in both pure form and in admixture. Such stereoisomers can be prepared using conventional techniques, either by reacting enantiomeric starting materials, or by separating isomers of compounds of the present invention. Isomers may include geometric isomers, for example cis-isomers or trans-isomers across a double bond. All such isomers are contemplated among the
compounds useful in the methods of the present invention. The methods also contemplate use of tautomers, salts, solvates and prodrugs of iNOS selective inhibitor compounds.

[613] For the methods of the present invention, suitable routes of administration of the selective iNOS inhibitors include any means that produce contact of these compounds with their site of action in the subject's body, for example especially in the brain. More specifically, suitable routes of administration include inhalation, including oral inhalation or nasal inhalation, intranasal mucosal administration, oral, intravenous, subcutaneous, rectal, topical, buccal (i.e. sublingual), intramuscular, and intradermal.

[614] For the treatment of cancer, the methods include use of an iNOS selective inhibitor as the compound per se, or as pharmaceutically acceptable salts thereof. The term "pharmaceutically-acceptable salt" embraces, for example, any salts commonly used to form alkali metal salts and to form addition salts of free acids or free bases. The nature of the salt is not critical, provided that it is pharmaceutically acceptable. Pharmaceutically acceptable salts are particularly useful as products of the methods of the present invention because of their greater aqueous solubility relative to a corresponding parent or neutral compound. Such salts must have a pharmaceutically acceptable anion or cation. Suitable pharmaceutically acceptable acid addition salts of compounds of the present invention may be prepared from inorganic acid or from an organic acid. Examples of such inorganic acids are hydrochloric, hydrobromic, hydroiodic, nitric, carbonic, sulfuric and phosphoric acid. Appropriate organic acids include from aliphatic, cycloaliphatic, aromatic, araliphatic, heterocyclic, carboxylic and sulfonic classes of organic acids, examples of which are formic, acetic, propionic, succinic, glycolic, gluconic, lactic, malic, tartaric, citric, ascorbic, glucoronic, maleic, fumaric, pyruvic, aspartic, glutamic, benzoic, anthranilic, mesylic, salicylic, p-hydroxybenzoic, phenylacetic, mandelic, embonic (pamoic), methanesulfonic, ethylsulfonic, benzenesulfonic, sulfanilic, stearic, cyclohexylaminosulfonic, algenic, galacturonic acid. Suitable pharmaceutically-acceptable base addition salts of compounds of the present invention include metallic salts made from aluminum, calcium, lithium, magnesium, potassium, sodium and zinc or organic salts made from N,N'-dibenzylethlenediamine, choline, chlorprocaine, diethanolamine, ethylenediamine, meglumine (N-methylglucamine) and procain. Suitable pharmaceutically acceptable acid addition salts of the compounds of the present invention
when possible include those derived from inorganic acids, such as hydrochloric, hydrobromic, hydrofluoric, boric, fluoroboric, phosphoric, metaphosphoric, nitric, carbonic (including carbonate and hydrogen carbonate anions), sulfonic, and sulfuric acids, and organic acids such as acetic, benzenesulfonic, benzoic, citric, ethanesulfonic, fumaric, gluconic, glycolic, isothionic, lactic, lactobionic, maleic, malic, methanesulfonic, trifluoromethanesulfonic, succinic, toluenesulfonic, tartaric, and trifluoroacetic acids. The chloride salt is particularly preferred for medical purposes. Suitable pharmaceutically acceptable base salts include ammonium salts, alkali metal salts such as sodium and potassium salts, and alkaline earth salts such as magnesium and calcium salts. All of these salts may be prepared by conventional means from the corresponding conjugate base or conjugate acid of the compounds of the present invention by reacting, respectively, the appropriate acid or base with the conjugate base or conjugate acid of the compound.

[615] In one embodiment, the iNOS selective inhibitors useful in the methods of the present invention are presented with an acceptable carrier in the form of a pharmaceutical combination or medicament. The carrier must be acceptable in the sense of being compatible with the other ingredients of the pharmaceutical combination and must not be deleterious to the subject. Suitable forms for the carrier include solid or liquid or both, and in an exemplary embodiment the carrier is formulated with the therapeutic compound as a unit-dose combination, for example as a tablet that contains from about 0.05% to about 95% by weight of the active compound. In alternative embodiments, other pharmacologically active substances are also present, including other compounds of the present invention. The pharmaceutical compounds of the present invention are prepared by any of the well-known techniques of pharmacy, consisting essentially of admixing the ingredients.

[616] Preferred unit dosage formulations are those containing an effective dose, as herein below described, or an appropriate fraction thereof, of one or more of the therapeutic compounds of the combinations.

[617] In general, a total daily dose of an iNOS selective inhibitor is in the range of about 0.001 mg/kg body weight/day to about 2500 mg/kg body weight/day. The dose range for adult humans is generally from about 0.005 mg to about 10 g per day. Tablets or other forms of presentation provided in discrete units may conveniently contain an amount
of a therapeutic compound that is effective at such dosage, or at a multiple of the same. For instance, selective iNOS inhibitory compounds used in the present invention can be presented in units containing 5 mg to 500 mg, and typically around 10 mg to about 200 mg.

[618] In the case of pharmaceutically acceptable salts of the therapeutic compounds, the weights indicated above refer to the weight of the acid equivalent or the base equivalent of the therapeutic compound derived from the salt.

[619] For the methods herein described, it should be understood that the amount of a selective iNOS inhibitory compound that is required to achieve the desired biological effect depends on a number of factors, including the specific individual compound or compounds chosen, the specific use, the route of administration, the clinical condition of the subject, and the age, weight, gender, and diet of the subject.

[620] The daily doses described in the preceding paragraphs for the various therapeutic compounds are administered in a single dose, or in proportionate multiple subdoses. Subdoses are administered from 2 to 6 times per day. In one embodiment, doses are administered in sustained release form effective to obtain the desired biological effect.

[621] Delivery by inhalation, whether oral or nasal inhalation, according to the methods of the present invention can include formulations as are well known in the art, that are capable of being aerosolized for delivery by inhalation. A metered dose inhaler or a nebulizer provides aerosol delivery. Both devices are capable of providing delivery of a range of particle sizes including particles in the preferred range of about 1 micron to about 5 microns. Particles larger than about 10 microns are deposited primarily in the mouth and oropharynx, while particles smaller than about 0.5 microns are inhaled to the alveolae and then exhaled without significant deposition in the lungs. An alternative device for inhalant therapy is a dry powder inhaler using, for example, lactose or glucose powder to carry the therapeutic compound. For all forms of inhalant therapy, factors other than particle size and type of device also influence the amount of deposition in the lungs, including tidal volume, rate of breathing and breath holding. Therefore, an individual being instructed in inhalation therapy according to the methods of current invention should also be instructed to take slow deep breaths and hold each breath for several seconds, and
preferably for about 5-10 seconds. Typically, the total daily dose of the therapeutic compounds according to the methods of the present invention will be administered as 1-4 puffs on a b.i.d-q.i.d. basis (i.e. twice-a-day, 3 times per day or 4 times a day), and as needed, or solely on an as-needed basis.

Oral delivery according to the methods of the present invention can include formulations, as are well known in the art, to provide prolonged or sustained delivery of the drug by any number of mechanisms. These include, but are not limited to, pH sensitive release from the dosage form based on the changing pH of the small intestine, slow erosion of a tablet or capsule, retention in the stomach based on physical properties of the formulation, bioadhesion of the dosage form to the mucosal lining of the intestinal tract, or enzymatic release of the active drug from the dosage form.

Oral delivery according to the methods of the present invention can be achieved using a solid, semi-solid or liquid dosage form. Suitable semi-solid and liquid forms include, for example, a syrup or liquid contained in a gel capsule.

To practice the methods of the present invention, pharmaceutical compositions suitable for oral administration can be presented in discrete units, such as capsules, cachets, lozenges, or tablets, each containing a predetermined amount of at least one of the therapeutic compounds useful in the methods of the present invention; as a powder or in granules; as a solution or a suspension in an aqueous or non-aqueous liquid; or as an oil-in-water or water-in-oil emulsion.
