# DESCRIPTION

## BACKGROUND OF THE INVENTION

### 1. TECHNICAL FIELD

**[0001]** The invention relates to the use of pimobendan for the preparation of a medication for the reverse remodelling of the heart of a patient with asymptomatic (occult) heart failure and their delayed onset of clinical symptoms.

### 2. BACKGROUND INFORMATION

**[0002]** Heart failure is divided in different stages (ISACHC - Stages - Class I - III). The pathology of the heart begins with ISACHC Class I in which cardiac murmur or cardiac chamber enlargement, but no clinical symptoms are present (Class I or occult stage). It is known that the progress of heart failure is associated with an increase of the size of the heart. In dilated cardiomyopathy (DCM) the ratio of left ventricular wall thickness to chamber diameter is decreased and the circumferences of the annuluses of the mitral and tricuspid valves are increased in proportion to the magnitude of chamber dilation. DCM may either be caused primarily by e.g. genetic abnormalities or secondarily e.g. due to valvular insufficiency both resulting in cardiac volume overload. However, it involves usually cardiac remodeling that may be defined as genome expression, molecular, cellular, and interstitial changes manifested clinically as changes in size, shape, and function of the heart. Cardiac remodelling is generally an adverse sign and linked to heart failure progression. Reverse cardiac remodelling is a goal of the treatment of heart failure therapy.

**[0003]** Heart failure therapy has traditionally focussed largely on symptomatic relief rather than on addressing underlying disease problems. Many dogs with symptomatic DCM have a very guarded prognosis (Monnet et al., 1995), with Dobermanns in particular generally experiencing only short survival times (Calvert et al., 1982; Calvert et al., 1997). There have been few studies examining the influence of treatment on survival in dogs with symptomatic DCM, although a subanalysis of the dogs with DCM in the LIVE study showed an improvement in time to treatment failure in those dogs receiving enalapril compared with placebo (142.8 versus 56.5 days, respectively) (Ettinger et al., 1998). On the whole, oral positive inotropic agents have lost favour in the treatment of chronic heart failure in human patients in recent years, after a number of trials revealed adverse effects on survival despite short-term hemodynamic benefits (Packer et al., 1991; Cowley and Skene, 1994). Recently it has been suggested that calcium sensitising agents may result in positive inotropic effects without producing some of the adverse effects (including calcium overload) associated with more traditional positive inotropes such as dobutamine, amrinone and milrinone.

**[0004]** In ISACHC Class I stage heart failure, in which cardiac murmur or cardiac chamber enlargement, but no clinical symptoms are present, therapy would have two objectives:

- reduce the pathologic changes of the dimensions of the heart (to the normal parameters - "reverse remodelling")
- prolong the time until onset of clinical symptoms

**[0005]** However, there is currently no drug available which has proven to be efficacious in the reduction of the pathologic changes of the dimensions of the heart to the normal parameters "reverse remodelling", at asymptomatic stage (ISACHC Class I). A study has been published with the use of ACE - Inhibitors in the asymptomatic stage, but no therapeutic effect was shown (SVEP - Trial), neither a reverse remodelling nor a prolongation of the time until onset of clinical symptoms.

**[0006]** When the pathology progresses also clinical symptoms are present (Class II or III) and for this stage, several drugs showed a benefit in quality of life and some also in survival time. One of these drugs are phosphodiesterase type III (PDE III) inhibitors or "Ca<sup>2+</sup>-sensitizing agents", for example cilostazol, pimobendan, milrinone, levosimendan, amrinone, enoximone and piroximone TZC-5665, etc. Rather than increasing calcium entry into cardiac myocytes, calcium sensitizers achieve their positive inotropic effect by sensitizing the contractile proteins to existing cytosolic calcium, by altering the binding of calcium with troponin-C. Producing a positive inotropic effect by calcium sensitizing thereby avoids some of the adverse effects of cytosolic calcium overload. Increased cytosolic calcium levels have been associated with an increased tendency for arrhythmias and sudden death. Clinical trials of long-term use of oral pimobendan in human patients with heart failure have demonstrated an improvement in exercise tolerance and quality of life without significantly adverse effects on survival (Kubo et al., 1992; Katz et al., 1992).

**[0007]** Relevant prior art documents that could be identified are (i) EP 1 579 862, which is directed to the use of PDE III inhibitors for the reduction of heart size in mammals suffering from heart failure, (ii) WO 03/012030, which is directed to type 3 phosphodiesterases (PDE3), as well as (iii) Deneke T et al. (Herzschrittmachertherapie und Elektrophysiologie 2004, 15(suppl. 1): I/74 - I/80), which is directed to the medical therapy for chronic heart failure, and O'Grady MR et al. (Journal of Veterinary Internal Medicine 1997, 11: 138), which is directed to ACE inhibitor therapy in occult DCM.

**[0008]** The problem underlying the present invention was to provide a medication, which allows to increase the time without clinical symptoms and to remodel the size of the heart to reduce the risk of death in patients with asymptomatic heart disease (ISACHC Class I).

#### **BRIEF DESCRIPTION OF THE INVENTION**

**[0009]** It has surprisingly been found that pimobendan can be used for the preparation of a medication able to prolong the time until onset of clinical symptoms and for the reduction of the heart size in cases of asymptomatic (occult) heart failure, e.g. asymptomatic DCM.

**[0010]** Furthermore, described herein is an article of manufacture comprising packaging material contained within which is a composition effective to prolong the time until onset of symptoms and to reduce the heart size of a patient having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM, and the packaging material comprises a label which indicates that the composition can be used to prolong the time until onset of symptoms and to reduce the heart size of a patient having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM, wherein said composition comprises pimobendan.

#### **DETAILED DESCRIPTION OF THE INVENTION**

**[0011]** The invention relates to the use of pimobendan for the preparation of a medication for the prolongation of the time until onset of clinical symptoms of the heart disease and the reduction of the heart size of a patient having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM.

**[0012]** The term "PDE III inhibitor" as used hereinabove and hereinbelow relates to phosphodiesterase (PDE) III inhibitors, which prevent breakdown of cAMP to 5'AMP and thus maintain the effect of cAMP on protein kinase and other secondary messenger activation.

**[0013]** The effects of PDE III inhibitors are as a rule positive inotropy and vasodilatation, which reduces the afterload patients with heart failure feel better.

**[0014]** The term  $\text{Ca}^{2+}$ -sensitizing agent relates to a compound which increases the  $\text{Ca}^{2+}$  sensitivity of cardiac contractile proteins, i.e. increase the developed contractile force at a given concentration of  $\text{Ca}^{2+}$ .

**[0015]** Pimobendan, known to the public as 4,5-dihydro-6-[2-(4-methoxyphenyl)-1H-benzimidazol-5-yl]-5-methyl-3(2H)-pyridazone, is for example disclosed in EP 008 391 B1. Levosimendan is a pyridazone-dinitrile derivative. In particular, levosimendan is known to the public as (R)-[[4-(1,4,5,6-Tetrahydro-4-methyl-6-oxo-3-pyridazinyl)phenyl]hydrazono]propanedinitrile and has been described earlier for example in GB 2228004, US 5,151,420 and US 5,569,657.

**[0016]** The term "patient" as used hereinabove and hereinbelow relates to an animal or a person having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM. The term "patient" embraces mammal such as primates including humans.

**[0017]** In addition to primates, a variety of other mammals can be treated according to the use of the present invention. For instance, mammals, including but not limited to, cows, sheep, goats, horses, dogs, cats, guinea pigs, rats or other bovine, ovine, equine, canine, feline, rodent or murine species can be treated. However, the use can also be practiced in other species, such as avian species.

**[0018]** Preferred are human patients, dogs, cats and horses. Human patients are female or male persons, having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM. As a rule such persons are children, young adults, adults or elderly people with an age of between 6 and 80, preferably between 30 and 65 years.

**[0019]** The term "asymptomatic heart disease" as used hereinabove and hereinbelow relates to any contractile disorder or disease of the heart without clinical symptoms of heart failure. In particular, it relates to heart failure of ISACHC - Stages - Class I. More particular, it relates to a DCM of ISACHC - Stages - Class I.

**[0020]** Degree of heart insufficiency was evaluated using a 5-class score adapted from the international Small Animal Cardiac Health Council (ISACHC) System of Heart Failure Classification:

Class 1: The asymptomatic patient

(heart disease associated with no clinical signs)

Heart disease is detectable (e.g. cardiac murmur, arrhythmia, or cardiac chamber enlargement that is detected by radiography or echocardiography); however the patient is not overtly affected and does not demonstrate clinical signs of heart failure. The need for treatment at this stage is arguable but not justifiable with currently available data.

The stage is subdivided as follows:

1. A.: Signs of heart disease are present but no signs of compensation (volume or pressure overload ventricular hypertrophy) are evident (**Class IA**).
2. B.: Signs of heart disease are present and signs of compensation (volume or pressure overload ventricular hypertrophy) are detected radiographically or echocardiographically (**Class IB**).

Class II: Mild-to-moderate heart failure

Clinical signs of heart failure are evident at rest or with mild exercise and adversely affect the quality of life. Typical signs of Heart failure include exercise intolerance, cough, tachypnoea, mild respiratory distress (dyspnoea), and mild to moderate ascites. Hypoperfusion at rest is generally not present (**Class II**). Home treatment is often indicated at this stage.

Class III: Advanced heart failure

1. A.: Clinical signs of advanced congestive heart failure are immediately obvious. These clinical signs could include respiratory distress (Dyspnoea), marked ascites, profound exercise intolerance, or hypoperfusion at rest. In the most severe cases, the patient is moribund and suffers from cardiogenic shock. Death or severe debilitation is likely

without therapy.

2. B.: Patients with advanced heart failure are divided into two

Subcategories:

1. 1. Home care is possible (**Class IIIA**).
2. 2. Hospitalisation is mandatory (cardiogenic shock, life-threatening oedema, or a large pleural effusion is present) (**Class IIIB**).

**[0021]** The term "reduction of the heart size" as used hereinabove and hereinbelow relates to a reduction of the size of the heart of the patient, which is diagnosed using the echocardiography, and having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM.

**[0022]** The term "prolongation until onset of clinical symptoms" as used hereinabove and hereinbelow relates to the time from diagnosing the changes of the heart until the beginning of clinical symptoms of heart failure. In particular, it relates to the prolongation from heart failure of ISACHC Class I to Class II and further to Class III. It more particular relates to the prolongation from heart failure of DCM of ISACHC Class I to Class II and further to Class III.

**[0023]** The term "effective amount" as used herein means an amount sufficient to achieve a prolongation of the time until onset of clinical symptoms and reduction of the heart size when pimobendan is administered in a single dosage form.

**[0024]** According to a further embodiment of the present invention, pimobendan is administered in combination with a second active therapeutic agent. Such a second active therapeutic agent is preferably selected from the group consisting of calcium channel blockers, ACE inhibitors, diuretics, platelet inhibitors, beta blockers and angiotensin II antagonists, aldosterone antagonists, digitalis glycosides, antiarrhythmic agents or diuretics in particular

- wherein the calcium channel blocker inhibitor is selected from the group consisting of diltiazem, verapamil and felodipine or a pharmaceutically acceptable derivative thereof; and/or
- wherein the ACE inhibitor is selected from the group consisting of omapatrilat, MDL100240, alacepril, benazepril, captopril, cilazapril, delapril, enalapril, enalaprilat, fosinopril, fosinoprilat, imidapril, lisinopril, perindopril, quinapril, ramipril, ramiprilat, saralasin acetate, temocapril, trandolapril, trandolaprilat, ▪ ceranapril, moexipril, quinaprilat and spirapril or a pharmaceutically acceptable derivative thereof; and/or
- wherein the beta blocker is selected from the group consisting of bisoprolol, carvediol, metoprolol, propranolol and timolol or a pharmaceutically acceptable derivative thereof; and/or
- wherein the angiotensin II antagonist is selected from the group consisting of saralasin acetate, candesartan, cilxetil, valsartan, candesartan, losartan potassium, eprosartan, irbesartan, tasosartan, pomisartan and telmisartan or a pharmaceutically acceptable derivative thereof and/or

- wherein the aldosterone antagonist is selected from the group consisting of spironolactone, eplerenone, canrenone, potassium canrenone or a pharmaceutically acceptable derivative thereof., and/or
- wherein the antiarrhythmic agents are selected from the group consisting of amiodarone, betrylium, disopyramide, dofetilide, flecainide, ibutilide, mexiletine, tocainide, procainamide, propafenone, quinidine, sotalol or a pharmaceutically acceptable derivative thereof., and/or
- wherein the diuretic is selected from the group consisting of furosemide, torasemide, bumetanide, etacrynic acid, azosemide, muzolimine, piretanide, tripamide, bendroflumethazide, chlorothiazide, hydrochlorothiazide, hydroflumethiazide, methychlothiazide, polythiazide, trichlormethiazide, chlorthalidone, indapamide, metolazone, quinethazone, etozolin, triamteren, amiloride, or a pharmaceutically acceptable derivative thereof., and/or
- wherein the digitalis glycosides is selected from the group consisting of digoxin, digitoxin, g-strophantin,  $\beta$ -methyldigoxin,  $\beta$ -acetyldigoxin or a pharmaceutically acceptable derivative thereof.

**[0025]** Most preferably, pimobendan is administered together with one or more medicaments selected from the group consisting of one or more ACE-inhibitors, one or more diuretics and one or more digitalis glycosides.

**[0026]** The compounds of this invention can be administered in such oral dosage forms as tablets, capsules (each of which includes sustained release or timed release formulations), pills, powders, granules, elixirs, tinctures, suspensions, syrups, and emulsions. They may also be administered in intravenous (bolus or infusion), intraperitoneal, subcutaneous, or intramuscular form, all using dosage forms well known to those of ordinary skill in the pharmaceutical arts. They can be administered alone, but generally will be administered with a pharmaceutical carrier selected on the basis of the chosen route of administration and standard pharmaceutical practice.

**[0027]** The dosage regimen for the compounds of the present invention will, of course, vary depending upon known factors, such as the pharmacodynamic characteristics of the particular agent and its mode and route of administration; the species, age, sex, health, medical condition, and weight of the recipient; the nature and extent of the symptoms; the kind of concurrent treatment; the frequency of treatment; the route of administration, the renal and hepatic function of the patient, and the effect desired. A physician or veterinarian can determine and prescribe the effective amount of the drug required to prevent, counter, or arrest the progress of the disorder.

**[0028]** By way of general guidance, the daily oral dosage of each active ingredient, preferably of pimobendan, when used for the indicated effects, will range between about 10 $\mu$ g/kg to 10

mg/kg, preferably from 0.05 mg/kg to 5 mg/kg, in particular from 0.1 mg/kg to 2 mg/kg. Most preferably from about 0.1 mg/kg to 1.5 mg/kg of pimobendan are administered per day.

**[0029]** Pimobendan may be administered in a single daily dose, or the total daily dosage may be administered in divided doses of two, three, or four times daily.

**[0030]** Pimobendan can be administered in intranasal form via topical use of suitable intranasal vehicles, or via transdermal routes, using transdermal skin patches. When administered in the form of a transdermal delivery system, the dosage administration will, of course, be continuous rather than intermittent throughout the dosage regimen.

**[0031]** Pimobendan is typically administered in admixture with suitable pharmaceutical diluents, excipients, or carriers (collectively referred to herein as pharmaceutical carriers) suitably selected with respect to the intended form of administration, that is, oral tablets, capsules, elixirs, syrups and the like, and consistent with conventional pharmaceutical practices.

**[0032]** For instance, for oral administration in the form of a tablet or capsule, the active drug component can be combined with an oral, non-toxic, pharmaceutically acceptable, inert carrier such as lactose, starch, sucrose, glucose, methyl cellulose, magnesium stearate, dicalcium phosphate, calcium sulfate, mannitol, sorbitol and the like; for oral administration in liquid form, the oral drug components can be combined with any oral, non-toxic, pharmaceutically acceptable inert carrier such as ethanol, glycerol, water, and the like. Moreover, when desired or necessary, suitable binders, lubricants, disintegrating agents, and colouring agents can also be incorporated into the mixture. Suitable binders include starch, gelatine, natural sugars such as glucose or beta-lactose, corn sweeteners, natural and synthetic gums such as acacia, tragacanth, or sodium alginate, carboxymethylcellulose, polyethylene glycol, waxes, and the like. Lubricants used in these dosage forms include sodium oleate, sodium stearate, magnesium stearate, sodium benzoate, sodium acetate, sodium chloride, and the like. Disintegrators include, without limitation, starch, methyl cellulose, agar, bentonite, xanthan gum, and the like.

**[0033]** Pimobendan can also be administered in the form of liposome delivery systems, such as small unilamellar vesicles, large unilamellar vesicles, and multilamellar vesicles. Liposomes can be formed from a variety of phospholipids, such as cholesterol, stearylamine, or phosphatidylcholines.

**[0034]** Pimobendan may also be coupled with soluble polymers as targetable drug carriers. Such polymers can include polyvinylpyrrolidone, pyran copolymer, polyhydroxypropylmethacrylamide-phenol, polyhydroxyethylaspart-amidephenol, or polyethyleneoxidepolylysine substituted with palmitoyl residues.

**[0035]** Furthermore, pimobendan may be coupled to a class of biodegradable polymers useful in achieving controlled release of a drug, for example, polylactic acid, polyglycolic acid,

copolymers of polylactic and polyglycolic acid, polyepsilon caprolactone, polyhydroxy butyric acid, polyorthoesters, polyacetals, polydihydropyrans, polycyanoacylates, and cross linked or amphipathic block copolymers of hydrogels.

**[0036]** Dosage forms (pharmaceutical compositions) suitable for administration may contain from about 1 milligram to about 100 milligrams of active ingredient per dosage unit.

**[0037]** In these pharmaceutical compositions the active ingredient will ordinarily be present in an amount of about 0.5-95% by weight based on the total weight of the composition.

**[0038]** Gelatine capsules may contain the active ingredient and powdered carriers, such as lactose, starch, cellulose derivatives, magnesium stearate, stearic acid, and the like. Similar diluents can be used to make compressed tablets. Both tablets and capsules can be manufactured as sustained release products to provide for continuous release of medication over a period of hours. Compressed tablets can be sugar coated or film coated to mask any unpleasant taste and protect the tablet from the atmosphere, or enteric coated for selective disintegration in the gastrointestinal tract.

**[0039]** Liquid dosage forms for oral administration can contain colouring and flavouring to increase patient acceptance.

**[0040]** In general, water, suitable oil, saline, aqueous dextrose (glucose), and related sugar solutions and glycols such as propylene glycol or polyethylene glycols are suitable carriers for parenteral solutions. Solutions for parenteral administration preferably contain a water soluble salt of the active ingredient, suitable stabilizing agents, and if necessary, buffer substances. Antioxidizing agents such as sodium bisulfite, sodium sulfite, or ascorbic acid, either alone or combined, are suitable stabilizing agents. Also used are citric acid and its salts and sodium EDTA. In addition, parenteral solutions can contain preservatives, such as benzalkonium chloride, methyl-or propyl-paraben, and chlorobutanol.

**[0041]** Suitable pharmaceutical carriers are described in Remington's Pharmaceutical Sciences, Mack Publishing Company, a standard reference text in this field.

Where two or more of the foregoing second therapeutic agents are administered with pimobendan, generally the amount of each component in a typical daily dosage and typical dosage form may be reduced relative to the usual dosage of the agent when administered alone, in view of the additive or synergistic effect of the therapeutic agents when administered in combination.

Particularly when provided as a single dosage unit, the potential exists for a chemical interaction between the combined active ingredients. For this reason, when the active agent and a second therapeutic agent are combined in a single dosage unit, they are formulated such that although the active ingredients are combined in a single dosage unit, the physical contact between the active ingredients is minimized (that is, reduced). For example, one active ingredient may be enteric coated. By enteric coating one of the active ingredients, it is possible not only to minimize the contact between the combined active ingredients, but also, it is

possible to control the release of one of these components in the gastrointestinal tract such that one of these components is not released in the stomach but rather is released in the intestines. One of the active ingredients may also be coated with a material which effects a sustained-release throughout the gastrointestinal tract and also serves to minimize physical contact between the combined active ingredients.

Furthermore, the sustained-released component can be additionally enteric coated such that the release of this component occurs only in the intestine. Still another approach would involve the formulation of a combination product in which the one component is coated with a sustained and/or enteric release polymer, and the other component is also coated with a polymer such as a low viscosity grade of hydroxypropyl methylcellulose (HPMC) or other appropriate materials as known in the art, in order to further separate the active components. The polymer coating serves to form an additional barrier to interaction with the other component.

**[0042]** Procedures by way of example for preparing the compositions according to the invention will be described in more detail hereinafter. The Examples which follow serve solely as a detailed illustration without restricting the subject matter of the invention. The study was done in asymptomatic dogs.

#### **EXAMPLES**

**[0043]** The study which supports the invention is done with pimobendan (Vetmedin®) in dogs suffering of occult dilated cardiomyopathy.

Inclusion criteria were dogs which are diagnosed to have a congestive heart failure of class I according to the ISACHC - score due to dilated cardiomyopathy (DCM). Dogs having an asymptomatic (occult) heart failure, e.g. asymptomatic DCM must have reduced contractility of the heart or other signs of reduced cardiac efficacy such as volume overload or ventricle dilatation as confirmed by echocardiography. The dogs stay under mono-therapy until signs of congestive heart failure are developing, deteriorate to heart insufficiency score (ISACHC) class II or III a or b. After confirmation of the congestion by X-ray - radiography the dogs receive furosemid treatment or if the clinical or echocardiografic results makes the addition of another heart failure treatment necessary (primary endpoint). The dogs will be investigated at day 0 prior to first treatment and then approximately 3 month post initiation of the therapy. In order to get long time survival data the investigators' makes then control visits will be repeated every 3 - 6 months. An Echo is performed prior to initiation of therapy (Day 0) and at the following visits to support the clinical diagnosis and to evaluate the effect of the drugs on the contractility of the heart. The echocardiography is performed according to the cardiologic case report form for Irish Wolfhounds. The primary parameter investigated will be the heart insufficiency score (ISACHC). Other parameters will be exercise tolerance, findings of the respiratory and circulatory system as well as echocardiography data.

#### **Results:**

**[0044]** After 4 years the interim analysis showed that significantly less dogs treated with pimobendan went in the state of clinical symptoms (Class II).

**[0045]** A Left Ventricular Reverse Remodeling (LVRR, = Normalising of the size and function of the left ventricle) has been shown in dogs treated with Pimobendan (ca 80%).

**[0046]** Since other studies in dogs with asymptomatic heart failure with other drugs could not show a prolongation until onset of clinical symptoms these results were unexpected and thus inventive. Furthermore no other study has been shown in dogs with asymptomatic heart disease a reverse remodeling in heart failure and thus the results were unexpected and thus inventive.

**P A T E N T K R A V**

1. Anvendelse af pimobendan til fremstilling af et lægemiddel til reduktion af hjerte-  
størrelsen hos en patient med asymptomatisk (okkult) hjertesvigt og/eller til fremstilling af  
5 et lægemiddel til forlængelse af tidsrummet indtil indtræden af kliniske symptomer hos pa-  
tienter med asymptomatisk (okkult) hjertesvigt.
2. Anvendelse ifølge krav 1, hvor det asymptomatiske (okkulte) hjertesvigt er asymp-  
tomatisk (okkult) dilateret kardiomyopati (DCM).
3. Anvendelse ifølge et hvilket som helst af de foregående krav, hvor pimobendan  
10 anvendes på oral eller parenteral form.
4. Anvendelse ifølge et hvilket som helst af de foregående krav, hvor pimobendan  
indgives i en daglig dosis fra 10 µg/kg til 10 mg/kg.
5. Anvendelse ifølge et hvilket som helst af de foregående krav, hvor patienten er et  
pattedyr udvalgt fra gruppen bestående af primater indbefattende mennesker, hunde, katte  
15 og heste.

Figure 1:

## Heart insufficiency scoring

Degree of heart insufficiency was evaluated using a 5-class score adapted from the International Small Animal Cardiac Health Council (ISACHC) System of Heart Failure Classification.

- Class I:** The asymptomatic patient (heart disease associated with no clinical signs)  
Heart disease is detectable (e.g. cardiac murmur, arrhythmia, or cardiac chamber enlargement that is detected by radiography or echocardiography); however the patient is not overtly affected and does not demonstrate clinical signs of heart failure. The need for treatment at this stage is arguable but not justifiable with currently available data.
- The stage is subdivided as follows:
- A.: Signs of heart disease are present but no signs of compensation (volume or pressure overload ventricular hypertrophy) are evident (**Class IA**).
  - B.: Signs of heart disease are present and signs of compensation (volume or pressure overload ventricular hypertrophy) are detected radiographically or echocardiographically (**Class IB**).
- Class II:** Mild-to-moderate heart failure  
Clinical signs of heart failure are evident at rest or with mild exercise, and adversely affect the quality of life. Typical signs of heart failure include exercise intolerance, cough, tachypnoea, mild respiratory distress (dyspnoea), and mild to moderate ascites. Hypoperfusion at rest is generally not present (**Class II**). Home treatment is often indicated at this stage.
- Class III:** Advanced heart failure
- A.: Clinical signs of advanced congestive heart failure are immediately obvious. These clinical signs could include respiratory distress (Dyspnoea), marked ascites, profound exercise intolerance, or hypoperfusion at rest. In the most severe cases, the patient is moribund and suffers from cardiogenic shock. Death or severe debilitation is likely without therapy.
  - B.: Patients with advanced heart failure are divided into two subcategories:
    1. Home care is possible (**Class IIIA**).
    2. Hospitalisation is mandatory (cardiogenic shock, life-threatening oedema, or a large pleural effusion is present) (**Class IIIB**).
