## SEPIAPTERIN REDUCTASE INHIBITORS FOR THE TREATMENT OF PAIN

### CROSS-REFERENCE TO RELATED APPLICATIONS

- 5 This application claims benefit of U.S. Provisional Application No. 61/252,013, filed October 15, 2009, which is hereby incorporated by reference.

### BACKGROUND OF THE INVENTION

- In general, the present invention relates to small molecule heterocyclic  
10 inhibitors of sepiapterin reductase (SPR), and to the medical use of these compounds.

Tetrahydrobiopterin (BH<sub>4</sub>), which has the following structure,

- is an essential cofactor of hydroxylase enzymes that are involved in the synthesis of neurotransmitters such as serotonin, melatonin, dopamine, norepinephrine  
15 (noradrenaline), epinephrine (adrenaline), and nitric oxide (NO). SPR catalyzes the final step in the BH<sub>4</sub> synthetic pathway, which is the conversion of 6-pyruvoyl tetrahydropterin to BH<sub>4</sub>. SPR is also one of the two enzymes involved in *de novo* BH<sub>4</sub> synthesis that is up-regulated in preclinical pain models, and reducing the activity of these enzymes leads to preclinical pain relief (Tegeder et al., *Nature Medicine* 12:1269-  
20 1277, 2006). Accordingly, the inhibition of SPR can be a useful target for developing new methods for the treatment or prevention of pain.

25 knowledge in the field relevant to the present disclosure as it existed before the priority date of each claim of this application.

Throughout this specification the word "comprise", or variations such as "comprises" or "comprising", will be understood to imply the inclusion of a stated

element, integer or step, or group of elements, integers or steps, but not the exclusion of any other element, integer or step, or group of elements, integers or steps.

For example, in the context of administering an agent that inhibits SPR, an effective amount of an agent is, for example, an amount sufficient to achieve a reduction in SPR activity as compared to the response obtained without administration of the agent  
30 and thereby prevents, reduces, or eliminates the sensation of pain. The effective amount of active compound(s) used to practice the present invention for therapeutic treatment of pain also varies depending upon the manner of administration, the age, and body weight, of the subject as well as the underlying pathology that is causing the

pain. Ultimately, the attending physician or veterinarian will decide the appropriate amount and dosage regimen.

For example, a compound of the invention that contains an OH group may be acylated at this position in its prodrug form. A thorough discussion is provided in T. Higuchi and V. Stella, Pro-drugs as Novel

As used herein, and as well understood in the art, "treatment" is an approach for obtaining beneficial or desired results, such as clinical results. Beneficial or desired results can include, but are not limited to, alleviation or amelioration of one or  
15 more symptoms or conditions; diminishment of extent of disease, disorder, or condition; stabilized (i.e. not worsening) state of disease, disorder, or condition; preventing spread of disease, disorder, or condition; delay or slowing the progress of the disease, disorder, or condition; amelioration or palliation of the disease, disorder, or condition; and remission (whether partial or total), whether detectable or  
20 undetectable. "Palliating" a disease, disorder, or condition means that the extent and/or undesirable clinical manifestations of the disease, disorder, or condition are lessened and/or time course of the progression is slowed or lengthened, as compared to the extent or time course in the absence of treatment. As compared with an equivalent untreated control, such a reduction of pain is at least a 5%, 10%, 20%,  
25 40%, 50%, 60%, 80%, 90%, 95%, or 100% reduction as measured by any standard technique known in the art. To treat pain, according to the methods of this invention, the treatment does not necessarily provide therapy for the underlying pathology that is causing the painful sensation. Treatment of pain can be purely symptomatic.

Any of the groups described herein can be substituted or unsubstituted. Where  
30 a group is substituted, the group may be substituted with 1, 2, 3, 4, 5, or 6 substituents. Optional substituents include, but are not limited to: C<sub>1-6</sub> alkyl, C<sub>2-6</sub> alkenyl, C<sub>2-6</sub> alkynyl, cycloalkyl, cycloalkenyl, heterocyclyl, aryl, heteroaryl, halogen; azido(-N<sub>3</sub>), nitro (-NO<sub>2</sub>), cyano (-CN), acyloxy(-OC(=O)R'), acyl (-C(=O)R'), alkoxy

(-OR'), amido (-NR'C(=O)R'' or -C(=O)NRR'), amino (-NRR'), carboxylic acid (-CO<sub>2</sub>H), carboxylic ester (-CO<sub>2</sub>R'), carbamoyl (-OC(=O)NR'R'' or -NRC(=O)OR'), hydroxy (-OH), isocyano (-NC), sulfonate (-S(=O)<sub>2</sub>OR), sulfonamide (-S(=O)<sub>2</sub>NRR' or -NRS(=O)<sub>2</sub>R'), or sulfonyl (-S(=O)<sub>2</sub>R), where each R or R' is selected,

5 independently, from H, C<sub>1-6</sub> alkyl, C<sub>2-6</sub> alkenyl, C<sub>2-6</sub> alkynyl, cycloalkyl, heterocyclyl, aryl, or heteroaryl. A substituted group may have, for example, 1, 2, 3, 4, 5, 6, 7, 8, or 9 substituents. In some embodiments, each hydrogen in a group may be replaced by a substituent group (e.g., perhaloalkyl groups such as -CF<sub>3</sub> or -CF<sub>2</sub>CF<sub>3</sub> or perhaloaryls such as -C<sub>6</sub>F<sub>5</sub>). In other embodiments, a substituent group may itself be further

10 substituted by replacing a hydrogen of the substituent group with another substituent group such as those described herein. Substituents may be further substituted with, for example, 1, 2, 3, 4, 5, or 6 substituents as defined herein. For example, a lower C<sub>1-6</sub> alkyl or an aryl substituent group (e.g., heteroaryl, phenyl, or naphthyl) may be further substituted with 1, 2, 3, 4, 5, or 6 substituents as described herein.

15 Asymmetric or chiral centers may exist in any of the compounds of the present invention. The present invention contemplates the various stereoisomers and mixtures thereof. Individual stereoisomers of compounds of the present invention are prepared synthetically from commercially available starting materials that contain asymmetric or chiral centers or by preparation of mixtures of enantiomeric

20 compounds followed by resolution well-known to those of ordinary skill in the art. These methods of resolution are exemplified by (1) attachment of a racemic mixture of enantiomers, designated (+/-), to a chiral auxiliary, separation of the resulting diastereomers by recrystallization or chromatography and liberation of the optically pure product from the auxiliary or (2) direct separation of the mixture of optical

25 enantiomers on chiral chromatographic columns. Alternatively, chiral compounds can be prepared by an asymmetric synthesis that favors the preparation of one enantiomer over the other. Alternatively a chiral pool synthesis (starting with an enantiomerically pure building block) can be used wherein the chiral group or center is retained in the intermediate or final product. Enantiomers are designated herein by

30 the symbols "R," or "S," depending on the configuration of substituents around the chiral atom. Alternatively, enantiomers are designated as (+) or (-) depending on whether a solution of the enantiomer rotates the plane of polarized light clockwise or counterclockwise, respectively. In other cases, diastereomeric isomers such as cis and

trans isomers may be separated by column chromatography, chiral chromatography, or recrystallization. In some cases, derivatization can improve the separation of these mixtures.

Geometric isomers may also exist in the compounds of the present invention.

5 The present invention contemplates the various geometric isomers and mixtures thereof resulting from the arrangement of substituents around a carbon-carbon double bond and designates such isomers as of the *Z* or *E* configuration. It is also recognized that for structures in which tautomeric forms are possible, the description of one tautomeric form is equivalent to the description of both, unless otherwise specified.

10 It is understood that substituents and substitution patterns on the compounds of the invention can be selected by one of ordinary skill in the art to provide compounds that are chemically stable and that can be readily synthesized by techniques known in the art, as well as those methods set forth below, from readily available starting materials. If a substituent is itself substituted with more than one  
15 group, it is understood that these multiple groups may be on the same carbon or on different carbons, so long as a stable structure results.

Other features and advantages of the invention will be apparent from the following Detailed Description, the drawings, and the claims.

## 20 BRIEF DESCRIPTION OF THE DRAWING

BH4 is also generated by a separate recycling pathway

### Synthesis

The compounds described herein, e.g., any of Compounds (1)-(39) or a compound according to Formula (I) or (II), can be prepared according to methods known in the art. Exemplary methods include the following.

#### Synthesis of Formula (I) Compounds

Compounds of Formula (I) can be synthesized by treating various 2-(1H-indol-3-yl)ethanamine starting materials with electrophiles as shown in **Scheme 1**.

**Scheme 1**

In this scheme,  $R^2$ -A-LG is an electrophilic reagent, where  $R^2$  and A are as defined for Formula (I) and LG is a leaving group. Suitable  $R^2$ -A-LG reagents include, but are not limited to, alkyl halides, alkyl sulfonates, acyl chlorides, carbonates, acyl anhydrides, and sulfonyl chlorides. Further exemplary reagents are described in the synthetic examples provided herein. In some embodiments, e.g., when  $R^1$  is OH, it may be desirable to selectively deprotect this group (e.g., deacylate any acyl esters that may have formed). Such transformations can be accomplished using methods

known in the art, e.g., deprotection under basic conditions, or those described in Greene, *Protective Groups In Organic Synthesis*, 3<sup>rd</sup> Edition (John Wiley & Sons, New York, 1999), which is incorporated herein by reference.

Compounds of Formula (I) can also be prepared from other indole starting materials, as shown in **Scheme 2**.

Using Route A, an indole compound can be elaborated to the corresponding 3-carboxamido intermediate (see, for example, the synthetic protocols for Compounds (10)-(12)). If desired, the carbonyl can be treated under reducing conditions to afford a saturated linking group.

When  $R^1$  is an electron-withdrawing group, Route B can be used. Accordingly, the indole starting material is olefinated to form the corresponding nitroalkene intermediate. Reduction of the nitro group to an amino group followed by treatment with an electrophile  $R^2$ -A-LG, as described for Scheme 1, can afford still other compounds of Formula (I). If desired, the indole compound can be *N*-alkylated using an electrophilic reagent such as  $R^6$ -LG, where  $R^6$  is as defined for Formula (I) and LG is a leaving group.

Compounds of Formula (I) can also be prepared by the cyclization of arylhydrazine starting materials as shown in Scheme 3 (see, for example, the synthesis of Compound (17)).

### 5 *Synthesis of Formula (II) Compounds*

Compounds of Formula (II) can be prepared by the treatment of phenethylamino starting materials with electrophilic RLG reagents, as shown in **Scheme 4**.

In Scheme 4, R can be any of the  $R^2$  or  $R^3$  groups described for Formula (II), and LG is a leaving group. If a tertiary amine is desired, the number of equivalents of RLG can be adjusted accordingly.

If the required phenethylamino starting material is not commercially available, the required compounds can be prepared from the corresponding phenylcarboxaldehyde via olefination to the corresponding nitroalkene and reduction to form the desired phenethylamino compound (**Scheme 5**).

Compounds of Formula (II) can also be prepared using carboxylic acid starting materials, as shown in **Scheme 6**.

In Scheme 6, Ar represents an aryl group, e.g., phenyl, and Het represents a heteroaryl group, e.g., pyridyl. In this scheme, the carboxylic acid group is transformed to a chloromethyl group. Treatment of this intermediate with cyanide followed by

reduction affords the desired amine compound. If required, the amine compound can be treated with an electrophile RLG to afford still other compounds of Formula (II).

solvate, or prodrug thereof, may be incorporated with an excipient and used in the form of ingestible tablets, buccal tablets, troches, capsules, elixirs, suspensions, syrups, wafers, and the like.

5 A compound of the invention (e.g., any of Compounds (1)-(39) or a compound according to Formula (I) or (II)), or a tautomer, salt, solvate, or prodrug thereof, may also be administered parenterally. Solutions of a compound of the invention can be prepared in water suitably mixed with a surfactant, such as hydroxypropylcellulose. Dispersions can also be prepared in glycerol, liquid polyethylene glycols, DMSO and mixtures thereof with or without alcohol, and in oils. Under ordinary conditions of  
10 storage and use, these preparations may contain a preservative to prevent the growth of microorganisms. Conventional procedures and ingredients for the selection and preparation of suitable formulations are described, for example, in Remington's Pharmaceutical Sciences (2003 - 20th edition) and in The United States Pharmacopeia: The National Formulary (USP 32-NF 27), published in 2008.

15 The pharmaceutical forms suitable for injectable use include sterile aqueous solutions or dispersions and sterile powders for the extemporaneous preparation of sterile injectable solutions or dispersions. In all cases the form must be sterile and must be fluid to the extent that may be easily administered via syringe.

Pharmaceutical compositions for nasal administration may conveniently be  
20 formulated as aerosols, drops, gels, and powders. Aerosol formulations typically include a solution or fine suspension of the active substance in a physiologically acceptable aqueous or non-aqueous solvent and are usually presented in single or multidose quantities in sterile form in a sealed container, which can take the form of a cartridge or refill for use with an atomizing device. Alternatively, the sealed  
25 container may be a unitary dispensing device, such as a single dose nasal inhaler or an aerosol dispenser fitted with a metering valve which is intended for disposal after use. Where the dosage form comprises an aerosol dispenser, it will contain a propellant, which can be a compressed gas, such as compressed air or an organic propellant, such as fluorochlorohydrocarbon. The aerosol dosage forms can also take the form of a  
30 pump-atomizer.

Compositions suitable for buccal or sublingual administration include tablets, lozenges, and pastilles, where the active ingredient is formulated with a carrier, such as sugar, acacia, tragacanth, or gelatin and glycerine. Compositions for rectal

administration are conveniently in the form of suppositories containing a conventional suppository base, such as cocoa butter.

The compounds of the invention may be administered to an animal, e.g., a human, alone or in combination with pharmaceutically acceptable carriers, as noted  
5 above, the proportion of which is determined by the solubility and chemical nature of the compound, chosen route of administration, and standard pharmaceutical practice.

The dosage of the compounds of the invention, and/or compositions comprising a compound of the invention, can vary depending on many factors, such as the pharmacodynamic properties of the compound; the mode of administration; the  
10 age, health, and weight of the recipient; the nature and extent of the symptoms; the frequency of the treatment, and the type of concurrent treatment, if any; and the clearance rate of the compound in the animal to be treated.

One of skill in the art can determine the appropriate dosage based on the above factors. The compounds of the invention may be administered initially in a suitable  
15 dosage that may be adjusted as required, depending on the clinical response. Generally, dosage levels of between 0.1 µg/kg to 100 mg/kg of body weight are administered daily as a single dose or divided into multiple doses. Desirably, the general dosage range is between 250 µg/kg to 5.0 mg/kg of body weight per day. Wide variations in the needed dosage are to be expected in view of the differing  
20 efficiencies of the various routes of administration. For instance, oral administration generally would be expected to require higher dosage levels than administration by intravenous injection. Variations in these dosage levels can be adjusted using standard empirical routines for optimization, which are well known in the art. In general, the precise therapeutically effective dosage will be determined by the  
25 attending physician in consideration of the above identified factors.

### Kits

Any of the compounds or pharmaceutical compositions of the invention (e.g., any of Compounds (1)-(39) or a compound according to Formula (I) or (II)) can be  
30 used together with a set of instructions, i.e., to form a kit. The kit may include instructions for use of the compounds of the invention in a screening method or as a therapy as described herein. For example, the instructions may provide dosing and

therapeutic regimes for use of the compounds of the invention to reduce pain, including any type of pain described herein.

### **Inhibitors of SPR**

5           The compounds and compositions described herein can be used to inhibit SPR, which catalyzes the final step of the transformation of GTP to BH4. BH4 is an essential co-factor required for normal function of several enzyme and neurotransmitter systems: phenylalanine hydroxylase, tyrosine hydroxylase, tryptophan hydroxylase, and the 3 nitric oxide synthases (NOS) subtypes all rely on  
10   BH4 allosteric regulation (Thony et al., *Biochem. J.* 347:1-16, 2000). BH4 is synthesized from guanosine triphosphate (GTP) in three tightly regulated steps by GCH-1, 6-pyruvoyltetrahydriobiopterin synthase (PTPS), and sepiapterin reductase (SPR) (**Figure 1**). The final step in the BH4 synthetic pathway is the conversion of 6-pyruvoyl tetrahydropterin to BH4 by sepiapterin reductase (SPR).

15           Two of the enzymes involved in *de novo* BH4 synthesis, GCH-1 and SPR, are up-regulated in preclinical pain models, and reducing the activity of these enzymes leads to preclinical pain relief (Tegeder et al., *Nature Medicine* 12:1269-1277, 2006). Accordingly, agents that reduce *de novo* BH4 synthesis (e.g., via direct active site inhibition of SPR) can be used in the prevention or treatment of pain.

20           Initial studies demonstrated that SPR is weakly inhibited by catecholamines and indoleamines, suggesting a negative feedback mechanism by downstream biogenic amines (Katoh et al., *Biochem. Biophys. Res. Commun.* 105:75-81, 1982; Smith et al., *J. Biol. Chem.* 267:5509-5607, 1992). Additional structural information can be obtained by analysis of the SPR protein structure. The crystal structures of  
25   human, mouse, and *Chlorobium tepidum* SPR have been solved in complex with a range of active site ligands including N-acetyl serotonin, NADPH, NADPH<sup>+</sup>, oxaloacetate and sepiapterin. The first solved structure of mouse SPR reveals a homodimeric structure of 261 amino acids (Auerbach et al., *EMBO J.* 16:7219-7230, 1997). The liganded protein X-ray crystal structure complexes of SPR reveal an  
30   active site formed by a 15 Å-deep pocket surrounded by the hydrophobic residues Leu105, Leu159, Tyr165, Trp168, Tyr171, Met206 and Cys160. SPR is a homolog of other oxidoreductase drug targets such as the M.tb InhA, the target of anti-tuberculosis drug isoniazid. The inhibition of SPR can be a useful target for developing new methods for the treatment or prevention of pain.

Inhibitors of SPR can be identified according to the methods described herein or known in the art (e.g., Katoh et al., *Biochem. Biophys. Res. Commun.* 105:75-81, 1982; Smith et al., *J. Biol. Chem.* 267:5509-5607, 1992).

Although not necessary, if desired, candidate SPR inhibitors can be tested for efficacy in any standard animal model of pain. Various models test the sensitivity of normal animals to intense or noxious stimuli (physiological or nociceptive pain). These tests include responses to thermal, mechanical, or chemical stimuli. Thermal stimuli usually involve the application of hot stimuli (typically varying between 42-55 °C) including, for example: radiant heat to the tail (the tail flick test), radiant heat to the plantar surface of the hindpaw (the Hargreaves test), the hotplate test, and immersion of the hindpaw or tail into hot water. Immersion in cold water, acetone evaporation, or cold plate tests may also be used to test cold pain responsiveness. Tests involving mechanical stimuli typically measure the threshold for eliciting a withdrawal reflex of the hindpaw to graded strength monofilament von Frey hairs or to a sustained pressure stimulus to a paw (e.g., the Ugo Basile analgesimeter). The duration of a response to a standard pinprick may also be measured. When using a chemical stimulus, the response to the application or injection of a chemical irritant (e.g., capsaicin, mustard oil, bradykinin, ATP, formalin, acetic acid) to the skin, muscle joints or internal organs (e.g., bladder or peritoneum) is measured.

In addition, various tests assess pain sensitization by measuring changes in the excitability of the peripheral or central components of the pain neural pathway. In this regard, peripheral sensitization (i.e., changes in the threshold and responsiveness of high threshold nociceptors) can be induced by repeated heat stimuli as well as the application or injection of sensitizing chemicals (e.g., prostaglandins, bradykinin, histamine, serotonin, capsaicin, or mustard oil). Central sensitization (i.e., changes in the excitability of neurons in the central nervous system induced by activity in peripheral pain fibers) can be induced by noxious stimuli (e.g., heat), chemical stimuli (e.g., injection or application of chemical irritants), or electrical activation of sensory fibers.

Various pain tests developed to measure the effect of peripheral inflammation on pain sensitivity can also be used, if desired, to confirm the efficacy of SPR inhibitors (Stein et al., *Pharmacol. Biochem. Behav.* (1988) 31: 445-451; Woolf et al., *Neurosci.* (1994) 62: 327-331). Additionally, various tests assess peripheral

neuropathic pain using lesions of the peripheral nervous system. One such example is the “axotomy pain model” (Watson, *J. Physiol.* (1973) 231:41). Other similar tests include the SNL test which involves the ligation of a spinal segmental nerve (Kim and Chung *Pain* (1992) 50: 355), the Seltzer model involving partial nerve injury (Seltzer, 5 *Pain* (1990) 43: 205-18), the spared nerve injury (SNI) model (Decosterd and Woolf, *Pain* (2000) 87:149), chronic constriction injury (CCI) model (Bennett (1993) *Muscle Nerve* 16: 1040), tests involving toxic neuropathies such as diabetes (streptozocin model), pyridoxine neuropathy, taxol, vincristine, and other antineoplastic agent-induced neuropathies, tests involving ischaemia to a nerve, peripheral neuritis models 10 (e.g., CFA applied peri-neurally), models of post-herpetic neuralgia using HSV infection, and compression models.

In all of the above tests, outcome measures may be assessed, for example, according to behavior, electrophysiology, neurochemistry, or imaging techniques to detect changes in neural activity. Furthermore, several pain tests that mimic central 15 neuropathic pain involve lesions of the central nervous system including, for example, spinal cord injury (e.g., mechanical, compressive, ischemic, infective, or chemical). In these particular tests, outcome measures are the same as those used for peripheral neuropathic pain.

## 20 **Therapy and Other Uses**

The methods of this invention are useful, for example, for the diagnosis, treatment, reduction, or prevention of various forms of pain.

Pain can take a variety of forms depending on its origin. Pain may be described as being peripheral neuropathic if the initiating injury occurs as a result of a 25 complete or partial transection of a nerve or trauma to a nerve plexus. Alternatively, pain is described as being central neuropathic following a lesion to the central nervous system, such as a spinal cord injury or a cerebrovascular accident. Inflammatory pain is a form of pain that is caused by tissue injury or inflammation (e.g., in postoperative pain or rheumatoid arthritis). Following a peripheral nerve injury, symptoms are 30 typically experienced in a chronic fashion, distal to the site of injury and are characterized by hyperesthesia (enhanced sensitivity to a natural stimulus), hyperalgesia (abnormal sensitivity to a noxious stimulus), allodynia (widespread tenderness associated with hypersensitivity to normally innocuous tactile stimuli),

and/or spontaneous burning or shooting lancinating pain. In inflammatory pain, symptoms are apparent, at least initially, at the site of injury or inflamed tissues and typically accompany arthritis-associated pain, musculo-skeletal pain, and postoperative pain. Nociceptive pain is the pain experienced in response to a noxious  
5 stimulus, such as a needle prick or during trauma or surgery. Functional pain refers to conditions in which there is no obvious peripheral pathology or lesion to the nervous system. This particular form of pain is generated by abnormal function of the nervous system and conditions characterized by such pain include fibromyalgia, tension-type headache, and irritable bowel syndrome. The different types of pain may coexist or  
10 pain may be transformed from inflammatory to neuropathic during the natural course of the disease, as in post-herpetic neuralgia.

The methods of this invention are useful for the diagnosis, treatment, reduction, or prevention of various forms of pain, namely inflammatory pain, nociceptive pain, functional pain, and neuropathic pain, whether acute or chronic.  
15 Exemplary conditions that may be associated with pain include, for example, soft tissue, joint, bone inflammation and/or damage (e.g., acute trauma, osteoarthritis, or rheumatoid arthritis), myofascial pain syndromes (fibromyalgia), headaches (including cluster headache, migraine, and tension type headache), myocardial infarction, angina, ischemic cardiovascular disease, post-stroke pain, sickle cell  
20 anemia, peripheral vascular occlusive disease, cancer, inflammatory conditions of the skin or joints, diabetic neuropathy, and acute tissue damage from surgery or traumatic injury (e.g., burns, lacerations, or fractures). The present invention is also useful for the treatment, reduction, or prevention of musculo-skeletal pain (after trauma, infections, and exercise), neuropathic pain caused by spinal cord injury, tumors,  
25 compression, inflammation, dental pain, episiotomy pain, deep and visceral pain (e.g., heart pain, bladder pain, or pelvic organ pain), muscle pain, eye pain, orofacial pain (e.g., odontalgia, trigeminal neuralgia, glossopharyngeal neuralgia), abdominal pain, gynecological pain (e.g., dysmenorrhea and labor pain), pain associated with nerve and root damage due to trauma, compression, inflammation, toxic chemicals,  
30 metabolic disorders, hereditary conditions, infections, vasculitis and autoimmune diseases, central nervous system pain, such as pain due to spinal cord or brain stem damage, cerebrovascular accidents, tumors, infections, demyelinating diseases including multiple sclerosis, low back pain, sciatica, and post-operative pain.

Conditions that are amenable to treatment according to the present invention are described in detail, for example, in U.S.S.N. 10/987,289 and 11/584,449, as well as U.S. Patent No. 6,593,331, each of which are hereby incorporated by reference.

5           *Combination Therapy*

The compounds of the present invention (e.g., any of Compounds (1)-(39) or a compound according to Formula (I) or (II)), or a tautomer, salt, solvate, prodrug, or pharmaceutical composition thereof, may be administered either alone or in combination with one or more additional therapeutic agents, such as an analgesic agent used in the treatment of nociception, inflammatory, functional, or neuropathic pain. According to this invention, the second therapeutic agent may or may not produce a therapeutic effect when administered on its own, but results in such an effect (e.g., pain reduction) when administered with the composition of the invention.

Exemplary analgesic agents include, without limitation, nonsteroidal anti-inflammatory agents (NSAIDs) (e.g. rofecoxib, celecoxib, valdecoxib, paracoxib, salicylic acid, acetaminophen, diclofenac, piroxicam, indomethacin, ibuprofen, and naproxen), opioid analgesics (e.g., propoxyphene, meperidine, hydromorphone, hydrocodone, oxycodone, morphine, codeine, and tramadol), NMDA antagonist analgesics (e.g., 2-piperidino-1-alkanol derivatives, ketamine, dextromethorphan, eliprodil, or ifenprodil), anesthetic agents (e.g., nitrous oxide, halothane, fluothane), local anesthetics (lidocaine, etidocaine, ropivacaine, chloroprocaine, sarapin, and bupivacaine), benzodiazepines (diazepam, chlordiazepoxide, alprazolam, and lorazepam), capsaicin, tricyclic antidepressants (e.g., amitriptyline, perphenazine, protriptyline, tranlycypromine, imipramine, desimipramine, and clomipramine), skeletal muscle relaxant analgesics (flexeril, carisoprodol, robaxinal, norgesic, and dantrium), migraine therapeutic agents (e.g., eliptriptan, sumatriptan, rizatriptan, zolmitriptan, and naratriptan), anticonvulsants (e.g., phenytoin, lamotrigine, pregabalin, carbamazepine, oxcarbazepine, topiramate, valproic acid, and gabapentin), baclofen, clonidine, mexilitene, diphenyl-hydramine, hydroxysine, caffeine, prednisone, methylprednisone, decadron, paroxetine, sertraline, fluoxetine, tramadol, ziconotide, and levodopa.

Further, if desired, the mammal being treated may be administered more than one agent that inhibits the production of BH4 (e.g., those described in U.S. Serial No.

10/987,289, hereby incorporated by reference). Optionally, the composition of the invention may contain more than one such inhibitor. Alternatively, the mammal may further be administered with specific inhibitors of enzymes that function downstream of BH4, in addition to the composition of the invention.

### Screening Conditions for Identifying SPR Inhibition

The compounds described herein were screened for activity as inhibitors of Sepiapterin Reductase (SPR).

5

#### Protein Production

His-tagged recombinant human SPR (GenBank accession number: NM\_003124) was cloned as synthetic gene and expressed in *E.coli* Rosetta 2 strain. Bacteria were grown at 37 °C, and expression of SPR protein was induced for 4 hours.

After cell lysis, the His-tagged SPR protein was affinity purified with a TALON column (purity of the isolated SPR protein is >95%). In an initial quality control, the enzymatic activity of recombinant SPR was confirmed with a chromogenic assay (read-out OD at 420 nm).

5

#### *Primary Screen*

To screen for SPR inhibition, a biochemical assay based on LC/MS (and chromogenic) read-out has been developed. The LC/MS assay monitors the product formation (L-biopterin) and the chromogenic assay measures OD at 420 nm.

10 N-methoxyacetyl serotonin was used as a reference compound (positive control). The IC<sub>50</sub> measured using the screening conditions was 20-40 nM, which agrees with the literature (Smith et al., *Journal of Biological Chemistry*, 297:5601, 1992).

The exemplary assay protocol uses the following conditions: SPR (6 nM); L-Sepiapterin (50 µM); NADPH (100 µM); Na-Phosphate buffer, pH 6.5 (100 mM); 82 µL assay volume; 60 minutes incubation with compounds (0.5% final concentration in DMSO) at 37°C in Greiner µclear® 384 well plates.

The following experimental procedure was applied:

- 20 (1) Add 2 µL compound (inhibitor) dilutions (20 % DMSO) in Greiner µclear® 384 well plates.
- (2) Add 40 µL enzyme / assay buffer.
- (3) Start: 40 µL substrate solution / assay buffer.
- (4) Final: 82 µL assay solution.
- 25 (5) Incubation: Safire 1 hour at 37 °C and measuring after 1 hour using OD at 420 nm (chromogenic read-out).
- (6) Transfer 50 µL to a 384 Matrix flat bottom (clear) for LC/MS measurement.
- (7) Stop: add 5 µL 1M HCl and 10 µL of 0.1 M I<sub>2</sub>/NaI solution.
- (8) Incubation: 45 minutes at 37 °C.
- 30 (9) Neutralization: 10 µL 0.1 M ascorbic acid and 5 µL 1 N NaOH.
- (10) LC/MS measurement.

If desired, the compounds can be been further screened using an 8 point dilution series to validate the results. For example, the compounds of Table 1 were

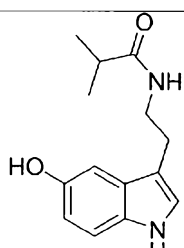

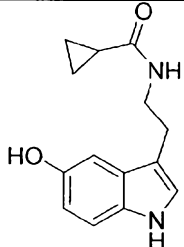

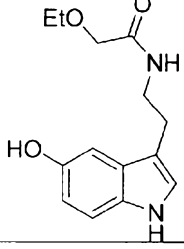

screened using this additional method in triplicate. These tests were performed at the following concentrations:

- Most potent: 0.2 - 0.7 - 2.1 - 6.2 - 18.5 - 55.6 - 166.7 - 500 nM
- Medium potent: 0.002 - 0.007 - 0.02 - 0.06 - 0.02 - 0.7 - 1.7 - 5  $\mu$ M
- 5 ○ Less potent: 0.02 - 0.07 - 0.2 - 0.6 - 1.9 - 5.6 - 16.7 - 50  $\mu$ M

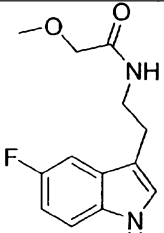

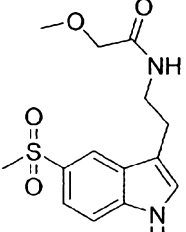

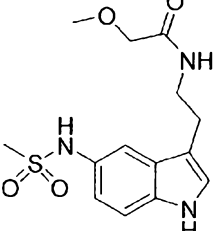

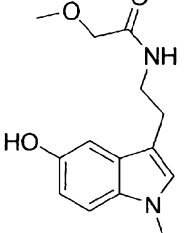

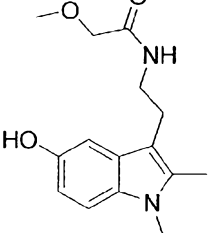

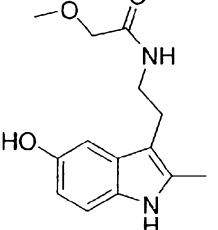

A robust performance of the SPR assay was achieved throughout the screen, resulting in a mean  $Z'$ -value of 0.93 (chromogenic) and 0.82 (LC/MS), and the inhibitors showed the expected response in the LC/MS (chromogenic) assay.

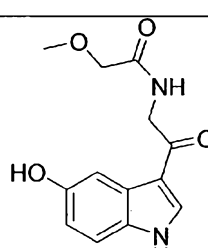

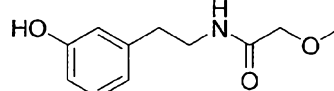

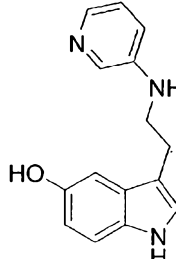

- Screening of the compounds has been performed at three concentrations (20 nM, 200 nM, and 2000 nM) in singletons (0.5 % final concentration in DMSO).  $Z'$  was 0.91 and 0.81 for the chromogenic and the LC/MS measurements, respectively. The screens showed that compounds of Formulas (I) and (II) can inhibit SPR, even at the lower concentrations. For example, at the 20 nM concentration, up to 77% inhibition of enzyme activity was observed. Exemplary  $IC_{50}$  values are presented in
