(54) Title: ELLIPTIC CURVE ISOGENY BASED KEY AGREEMENT PROTOCOL

(57) Abstract: An electronic key pre-distribution device (110) for configuring multiple network nodes (210, 211) with local key information is provided. The key pre-distribution device comprises applies at least a first hash function (147) and a second hash function (148) to a digital identifier of a network node. The first and second hash functions map the digital identifier to a first public point (141; $H_1(ID)$) and a second public point (142; $H_2(ID)$) on a first elliptic curve (131) and second elliptic curve (132). A first and second secret isogeny (135) is applied to the first and second public elliptic curve point (141, 142), to obtain a first private elliptic curve point (151) and second private elliptic curve point (152) being part of private key material (155) for the network node (210).

Elliptic curve isogeny based key agreement protocol

FIELD OF THE INVENTION

The invention relates to an electronic key pre-distribution device for configuring multiple network nodes with local key information, a first electronic network node arranged for a key agreement protocol with a second network node, an electronic method for key pre-distribution configuring multiple network nodes with local key information, an electronic method for establishing a shared key between a first network node and a second network node, and a computer readable medium.

BACKGROUND OF THE INVENTION

Key agreement, e.g., in wireless sensor networks, is an important cryptographic primitive. Once two parties have agreed on a common shared key, they can use said key to protect communication between them using, e.g., encryption and authentication. So-called identity-based key pre-distribution schemes provide a possible way to simplify the key agreement. An identity-based key pre-distribution scheme has two phases: key pre-distribution and key derivation. Associated with the two phases of the identity-based key pre-distribution scheme are two algorithms: a local key material generation algorithm and a key establishment algorithm, respectively.

Using an identity-based key pre-distribution schemes, two network nodes can agree on a shared key which is based on their identities. A traditional approach in which a key is determined for each pair of network nodes would grow quadratically. However, an identity-based key pre-distribution scheme needs only distribute one set of local key material for each node, and thus grows linearly.

The identity-based key pre-distribution scheme is set up by providing a trusted third party with root key material. The trusted third party may be the manufacturer of the device, and may, e.g., provision devices during their manufacturing or in some other trusted environment. Alternatively, the trusted third party may be a certificate authority device, e.g., a device that provisions devices, e.g., using some online protocol.

During key pre-distribution, local key material is generated for each network node and stored on the network node, by applying the local key material generation algorithm

on the root key material and an identifier of each network node. During the key derivation phase, two network nodes can derive a shared key by applying the key establishment algorithm on their local key material and the identifier of the other network node. For example, a first node may apply the key establishment algorithm on the second identifier of 5 the second network node and its own first local key material, while the second node may apply the key establishment algorithm on the first identifier of the first network node and its second local key material. The result of the key establishment algorithm is an identity-based key shared between two network nodes.

There exist a number of identity-based key pre-distribution schemes. For 10 example, an identity-based key pre-distribution scheme is described in “HIMMO - A lightweight collusion-resistant key pre-distribution scheme”, by Oscar Garcia-Morchon, Domingo Gomez-Perez, Jaime Gutierrez, Ronald Rietman, Berry Schoenmakers and Ludo Tolhuizen. Published in Cryptology ePrint Archive, Report 2014/698. An improved version of HIMMO is described in European patent application “Improved system for key sharing” 15 filed with the EPO, with attorney docket 2015PF001725, of the same applicant, and incorporated by reference. HIMMO, like some other identity-based key-distribution schemes, has the disadvantage that the unprocessed keys may be slightly off. This may be acceptable, or additional key-reconciliation data (also referred to as helper data) is used to arrive at a shared key. The key-reconciliation data is usually generated by the first network node that 20 has access to both identities, e.g., the second network node, if the first network node initiated the key agreement.

In an embodiment, the root key material comprises a bivariate polynomial and the local key material comprises a univariate polynomial. For example, in the Blundo 25 identity-based key pre-distribution scheme the root key material is formed by a bivariate polynomial $f(x, y)$. Local key material g for a first node with identifier ID_1 , is formed by collapsing the bivariate to a univariate polynomial $g(y) = f(ID_1, y)$. A node with local key material g and the identifier of a second node ID_2 obtains a shared key by computing $g(ID_2)$. All polynomial computations may be done modulo a modulus m .

Recently investigations have started if a bilinear mapping defined on an 30 elliptic curve could be used to create an identity-based key redistribution system. Concerns have arisen though if such approaches allow for sufficient variety in their underlying cryptographic objects and are thus sufficiently hardened against cryptographic analysis. Furthermore, there is a desire that cryptographic protocols resist the new threat of quantum computers.

SUMMARY OF THE INVENTION

An electronic key pre-distribution device is provided for configuring multiple network nodes with local key information. The key pre-distribution device comprises

- a storage comprising information representing a first secret isogeny for a first elliptic curve and a second secret isogeny for a second elliptic curve, an isogeny being arranged to receive a point on an elliptic curve and to produce a point on an elliptic curve as output,

- a processor circuit configured to

- obtain a digital identifier for a network node,

- apply at least a first hash function and a second hash function to the digital identifier, the first and second hash functions mapping the digital identifier to a first public point and a second public point on a first elliptic curve and second elliptic curve, the first elliptic curve being different from the second elliptic curve, the first and second public point being part of public key material for the network node,

- apply the first and second secret isogeny to the first and second public elliptic curve point, thus obtaining a first private elliptic curve point and second private elliptic curve point being part of private key material for the network node, and

- a communication interface arranged to configure the network node with the private elliptic curve point.

Furthermore, an electronic network node is provided arranged for a key agreement protocol with a second network node. For ease of reference the network node will be identified as the first network node, distinguishing it from a second network node with which it communicates. The adjective 'first' and 'second' have no further meaning. The first network node may be the initiating network node, which initiates the protocol with the second network node, and the second network node may be the responding network node; However, it may also be the other way around.

The network node comprises

- a storage comprising

- a digital identifier for the first network node and/or a first and second public elliptic curve point, the first and second public elliptic curve point lying on a first and second elliptic curve, and

- a first private elliptic curve point and second private elliptic curve point corresponding to the first public elliptic curve point and the second public elliptic curve point through a first and second secret isogeny, the first public elliptic curve point and the

second public elliptic curve point corresponding to the digital identifier of the network node through a first and second hash function , the first and second private elliptic curve points being computed by a key pre-distribution device ,

- the processor circuit is configured to

5 - obtain a public elliptic curve point for the second network node, the public elliptic curve point lying on a first one of the first and second elliptic curves,

- selecting a private elliptic curve point from the first and second private elliptic curve points lying on a second one of the first and second elliptic curves, the first one and the second one being different,

10 - apply a bilinear map to the selected private point of the first network node, and the obtained public elliptic curve point of the second network node or the public elliptic curve point of the second network node to which a public isogeny has been applied by the first node,

- deriving a cryptographic key from the result of the bilinear map.

15 Including isogenies on elliptic curves into the cryptographic protocol is advantageous as they are assumed to have an increased quantum-resistance. In particular, there is no efficient known quantum algorithm to reconstruct an isogeny between two super singular elliptic curves. Furthermore, the isogenies increase the choices that are made in the algorithms, and thus make attacking the system harder. An advantage of the protocol

20 implemented in the network node is that shared keys can be computed while exchanging only few and simple messages. In fact, if the digital identifier of the other node can be obtained without a message, then no messages need to be exchanged at all to obtain the shared key.

The derived key can then be used to derive a key for symmetric encryption, etc. Elliptic curve points also cover compressed points, e.g., only the x-coordinate, or the x-coordinate with an additional bit to determine the sign of the y-coordinate.

25 A network node is an electronic device. For example, it may be a mobile electronic device, such as a mobile phone. The network node may be a set-top box, smart-card, a computer, etc. The key pre-distribution device may be a computer, a server, etc. The key pre-distribution device may also be a communication device, such as a phone, e.g., arranged to set-up a so-called ad-hoc wireless communication network, e.g., a mesh network.

30 The methods of described herein may be applied in a wide range of practical applications. Such practical applications include financial applications, e.g., to share credit card information, privacy enhancing applications, e.g., messaging applications, medial applications, etc.

A method according to the invention may be implemented on a computer as a computer implemented method, or in dedicated hardware, or in a combination of both. Executable code for a method according to the invention may be stored on a computer program product. Examples of computer program products include memory devices, optical storage devices, integrated circuits, servers, online software, etc. Preferably, the computer program product comprises non-transitory program code stored on a computer readable medium for performing a method according to the invention when said program product is executed on a computer.

In a preferred embodiment, the computer program comprises computer program code adapted to perform all the steps of a method according to the invention when the computer program is run on a computer. Preferably, the computer program is embodied on a computer readable medium.

Another aspect of the invention provides a method of making the computer program available for downloading. This aspect is used when the computer program is uploaded into, e.g., Apple's App Store, Google's Play Store, or Microsoft's Windows Store, and when the computer program is available for downloading from such a store.

BRIEF DESCRIPTION OF THE DRAWINGS

Further details, aspects, and embodiments of the invention will be described, 20 by way of example only, with reference to the drawings. Elements in the figures are illustrated for simplicity and clarity and have not necessarily been drawn to scale. In the Figures, elements which correspond to elements already described may have the same reference numerals. In the drawings,

- 251 a first private elliptic curve point
- 252 a second private elliptic curve point
- 260 a shared key unit
- 270 an isogeny unit
- 15 280 a key confirmation unit

DETAILED DESCRIPTION OF THE EMBODIMENTS

While this invention is susceptible of embodiment in many different forms, there are shown in the drawings and will herein be described in detail one or more specific embodiments, with the understanding that the present disclosure is to be considered as exemplary of the principles of the invention and not intended to limit the invention to the specific embodiments shown and described.

In the following, for the sake of understanding, elements of embodiments are described in operation. However, it will be apparent that the respective elements are arranged 25 to perform the functions being described as performed by them.

Further, the invention is not limited to the embodiments, and the invention lies in each and every novel feature or combination of features described herein or recited in mutually different dependent claims.

The growth of the Internet of Things (IoT) and the approach of a quantum age 30 has resulted in a need for lightweight, fast, (quantum) secure protocols for IoT networks, even in the case of multiple IoT device compromises. Embodiments described below provide Non-interactive Key Distribution (NIKD) schemes based on public and/or secret isogenies respectively. Including isogenies on elliptic curves into a cryptographic protocol is advantageous as they are presumed quantum-resistant especially when used with super

singular elliptic curves. Especially embodiments in which secret isogenies are provided increased resistance to attack even when attacked using a quantum computer. In addition, embodiments are lightweight and classically-secure against collusion/compromise of any number of devices. The lightweight and fast performance of both schemes makes them
5 suitable for IoT use-cases.

Below some mathematical background is summarized.

For current cryptographic purposes, an elliptic curve may be given by the canonical equation $y^2 = x^3 + ax + b$, where a, b are elements from a finite field with characteristic larger than three. Elliptic curves over finite fields with characteristic two or
10 three may be described by a similar but different type of equation. Points on the curve may be identified by a pair of coordinates, e.g., an x and y coordinate, that satisfies the defining formula of the elliptic curve. Commonly, a point on the curve is represented in a compressed format. For example, a point on the curve may be uniquely identified by only its x- coordinate, a single bit to determine the sign of the accompanying y-coordinate. In fact, often
15 one leaves out the y-coordinate altogether. Although this introduces a small ambiguity in the point, for most applications, this is not relevant. For the purpose of this document we will consider such representations as points on the curve as well.

Pairings (also known as bilinear forms): A pairing is a map from the direct product of two cyclic (additive) groups G_1 and G_2 to a group G_T such that for all $P \in G_1, Q \in G_2$ and all positive integers a, b we have that $e(aP, bQ) = [e(P, Q)]^{ab}$, and $e(P, Q) \neq 1$ for some
20 $(P, Q) \in G_1 \times G_2$. An important pairing in cryptography is the so-called Weil pairing. In that case, a curve $E(K)$ is chosen over a finite field K that contains an m -th root of unity. The Weil pairing e takes as inputs points $P, Q \in E(K)(m) = \{T \in E(K) \mid mT = O\}$ and produces an m -th root of unity in K , that is, $e(P, Q) \in \{x \in K \mid x^m = 1\}$. If points P and Q are given in compressed
25 form, with a bit to indicate signs, one can compute the corresponding y coordinates and subsequently compute the pairings. Alternatively, it is possible to compute, at least for certain pairings like the Weil pairing and the Tate pairing, the value z such that for all points P and Q , $z = (e(P, Q))^{a(P, Q)}$ where the exponent $a(P, Q)$ equals 1 or -1. This is explained in
“Computing pairings using x-coordinates only” by S. Galbraith and X. Lin, Designs, Codes
30 and Cryptography, Vol. 50, Issue 3, pp. 305-324, March 2009. In the same reference, it is explained that from the values of the x-coordinates only, it is possible to compute the trace of $e(P, Q)$, that is, the value $T(P, Q) = e(P, Q) + (e(P, Q))^{-1}$.

Isogenies: Informally, isogenies are maps between elliptic curves. An isogeny can be defined as a non-constant function, defined on a first elliptic curve, that takes values

on a second elliptic curve, and preserves point addition, i.e., it preserves the elliptic curve structure. See the thesis by D. Shumow, “Isogenies of Elliptic Curves: A Computational Approach.” More formally, let E_1/K and E_2/K be two elliptic curves, an isogeny may be defined as a rational map of elliptic curves $\phi: E_1(\bar{K}) \rightarrow E_2(\bar{K})$, with coordinates from \bar{K} that preserves the point at infinity, i.e., $\phi(\infty) = \infty$. It follows that such a mapping preserves the group structure. See the thesis by A. Sankar, “Classical and Quantum Algorithms for Isogeny-based Cryptography.”

Typically, an isogeny is defined as a mapping between two different curves, however we will also consider isogenies between a curve and itself. In the latter case, 10 isogenies can be defined, e.g., as elliptic curve multiplications with a fixed integer, e.g., mapping an elliptic curve point P to the elliptic curve points sP . Note that this mapping preserves addition. Isogenies between different curves have a much richer structure than can be defined by a single integer.

A standard way to represent an isogeny φ is to give 3 homogeneous 15 polynomials $f_1, f_2, f_3 \in \bar{K}[X, Y, Z]$ satisfying $\varphi(x; y; z) = (f_1(x, y, z); f_2(x, y, z); f_3(x, y, z)) \in P^2(\bar{K})$ for a field K . If l denotes the degree of φ , then usually one of these polynomials will have degree roughly l . Reference is made to the paper “Evaluating large degree isogenies and applications to pairing based cryptography” by Reinier Bröker, Denis Charles, and Kristin Lauter. In 20 section 2 of that paper alternative representation of isogenies between elliptic curves over finite fields are given whose length is polynomial in $\log l$. The paper furthermore presents an algorithm that evaluates isogenies between elliptic curves over finite fields.

In this patent application, various embodiment of network nodes and key pre-distributions devices are proposed. These embodiments include isogeny based NIKD 25 schemes. First an introduction is given, and additional embodiments and details are described with reference to the figures.

Nodes in a network register themselves with a trusted third party (TTP) in order to receive secret key-material(s) and optionally public identifier(s) (e.g. a public 30 identifier). Using these, any two nodes can establish a secret key that is unique to them and known only by that pair of nodes, that can then be used by this pair to communicate securely with each other.

Embodiments use two elliptic curves E_1, E_2 . The TTP hashes an identifier (ID) of a network node to points on these two elliptic curves $H_1(ID)$ and $H_2(ID)$. The latter are public points, and may be stored on a network node, or may be computed by a network node from an identifier directly. The TTP maps the two public points to two private points by

mapping the public points on their respective elliptic curves to two private points also on two different elliptic curves. The embodiments can be divided into two main types.

In a first type, the TTP maintains a secret isogeny and its so-called dual isogeny related to the above two curves. The isogeny maps from the first elliptic curve to the second elliptic curve, whereas the dual isogeny maps from the second elliptic curve to the first elliptic curve. During node registration, these are used by the TTP to calculate two unique secret key-materials for a node, after calculating two public points for it. Key-establishment between two nodes may be accomplished using one of the peer node's (public) points and one of the node's two own secret key-materials, which are images of the node's own identifiers in the secret isogeny and the secret dual isogeny respectively, in the Weil pairing. Note that the Weil pairing is an example of a bilinear map. In case of the Weil paring, it is required that all points have a specified order, say m . Note that in the first type a public point and its corresponding private point lie on different elliptic curves.

In a second type, the TTP maintains an isogeny for each elliptic curve, but these isogenies map from the elliptic curve to itself. For example, the TTP may have a single integer s and perform a point multiplication with the integer s for each curve. The TTP may also have two integers s_1 and s_2 , using the first integer for point multiplication on the first curve and the second integer for point multiplication on the second curve. Again, during node registration, the two isogenies are used by the TTP to calculate two unique secret key-materials for a node, after calculating two public points for it. Key-establishment between two nodes may be accomplished using one of the peer node's (public) points and one of the node's two own secret key-materials. Finally, a bilinear map, e.g., the Weil paring is applied to the two points. Here a public isogeny between the two elliptic curves is used as a system parameter.

Mathematically, an embodiment of the first type may work as follows. The first and second network node are referred as initiator and responder depending on who initiated the key agreement protocol.

- TTP has:
 - Two ordinary elliptic curves E_1 and E_2 over a field F_p with isomorphic endomorphism rings of discriminant $\Delta < -4$,
 - a secret key, which is an isogeny $\varphi : E_1 \rightarrow E_2$ specified by an ideal L .

- Public pairings $e': G_1 \times G_2 \rightarrow GT$ and $e: G'_1 \times G'_2 \rightarrow GT$ where G_1 and G_2 are subgroups of the points on E_1 , and G'_1, G'_2 are subgroups of the points of E_1 and E_2 , respectively

5 • φ' is the dual isogeny, also secret, that is, for all $P \in G'_1, Q \in G_2$, It holds that $e(\varphi(P), Q) = e'(P, \varphi'(Q))$. Furthermore, it is assumed that φ maps G_2 to G'_2 , and φ' maps G'_1 to G_1 .

- During key material extraction, each entity with identity ID gets $H_1(ID)$ a point

10 in G_2 and $H_2(ID)$ a point in G'_1 , which serve as its two public identifiers. It further obtains from the TTP two secret key-materials:

- Secret key-material $S_1 = \varphi(H_1(ID))$
- Secret key-material $S_2 = \varphi'(H_2(ID))$

- During key generation, two parties (I)nitiator and (R)esponder that want to generate a common key do the following:

- 15 • Initiator computes: $K_{IR} = e(H_2(R), \varphi(H_1(I)))$

- Initiator uses K_{IR} to encrypt message and sends it to R.
- Responder computes $K_{RI} = e'(\varphi'(H_2(R)), H_1(I))$, and decrypts using key K_{RI} .

20 Operational correctness for the first type is demonstrated by noting that, due to the adjoint property of the isogeny φ and its dual φ' with respect to the Weil pairings: $K_{IR} = e(H_2(R), \varphi(H_1(I))) = e'(\varphi'(H_2(R)), H_1(I)) = K_{RI}$.

25 In an embodiment, $G_1 = G_2 = E_1[m]$, $G'_1 = G'_2 = E_2[m]$, and e, e' are the Weil pairings on E_1 and E_2 . In an alternative embodiment, public key material and secret key material are compressed. The hash functions H_1 and H_2 may only provide the x-coordinate of a point in E_1 and E_2 respectively. From $H_1(ID)$ and $H_2(ID)$ the TTP can compute y-coordinates $y_1(ID), y_2(ID)$ such that $U_1(D) = (H_1(ID), y_1(ID))$ is on E_1 and $U_2(D) = (H_2(ID), y_2(ID))$ is on E_2 . The secret keying material $S_1(ID)$ may equal the x-coordinate of $\varphi(U_1(D))$ and $\varphi'(U_2(D))$ respectively. During key generation, two parties (I)nitiator and (R)esponder that want to generate a common key do the following:

- From its own secret key $S2(I)$ and the public key $H2(R)$, the initiator computes a value T_{IR} satisfying $T_{IR} = e(U2(R), \varphi(U1(I))) + e(U2(R), \varphi(U1(I)))^{-1}$, e.g., as explained by Galbraith and Lin.
- The initiator uses T_{IR} as key to encrypt a message M and sends it to R .
- 5 • The responder R uses its own secret key $S1(R)$ and the public key $H1(I)$ to compute a value T_{RI} satisfying $T_{RI} = e'(U2(R), H1(I)) + e'(U2(R), H1(I))^{-1}$ and decrypts the message using T_{RI} as key.

10 Operational correctness follows from the adjoint property of φ' . It is clear that variations on these embodiments are possible, e.g. with compressed public key and uncompressed secret key, or vice versa., with compressed keys with additional bits to determine signs, etc.

15 More general, one may have: $G1, G2$ subgroups of $E1$, $e': G1 \times G2 \rightarrow GT$; and $G1', G2'$ subgroups of $E2$, $e: G1' \times G2' \rightarrow GT$; and $\varphi(G1) = G1'$, $\varphi'(G2') = G2$. For the Weil pairings: one may require mappings into points on $E1, E2$ for which the order divides m , and GT consist of m -th root of unity in a finite field. The paring need not necessarily be defined for all points in $E1$.

Mathematically, an embodiment in the second type may work as follows

- TTP has secret s .
- During key extraction, each entity with identity ID gets $H_1(ID) \in E_1, H_2(ID) \in E_2$, and $sH_1(ID) \in E_1, sH_2(ID)$ where H_1 is a hash function to E_1 , and H_2 is a hash function to E_2 . $H_1(ID)$ and $H_2(ID)$ serves as the public identifiers of the entity, whereas $sH_1(ID), sH_2(ID)$ serves as its secret key-material.
- During operation, entity (I)nitiator wishing to talk to (R)esponder computes $K_{IR} = e(\varphi(H_1(R)), sH_2(I))$, where e is a pairing on E_2 . Then identity I sends message M encrypted with K_{IR} to R ,
- R computes $K_{RI} = e(\varphi(sH_1(R)), H_2(I))$

20 Operational correctness for the second type is demonstrated by noting that: $K_{IR} e(\varphi(H(R)), sH(I)) = e(\varphi(H(R)), H(I))^s = e(\varphi(sH(R)), H(I)) = K_{RI}$ An embodiment of the second type may optionally have compressed points and use computation of the trace of the pairing operation by using x-coordinates only, and use the trace as key, or as input to key derivation function.

For embodiments using the first type, using secret isogenies: The analyses of possible attacks against this scheme that are detailed below are applicable irrespective of whether the elliptic curves used are ordinary or super singular. In order to recover the TTP's master secret, i.e., the secret isogeny $\varphi : E_1 \rightarrow E_2$ and its dual φ' , an attacker who has

5 compromised multiple nodes (and has thus gained access to their secret key-materials of the form $\varphi(H_1(ID))$ and $\varphi'(H_2(ID))$, where ID is the identifier of the compromised node) must attempt to reconstruct the two secret isogenies mentioned above, using the evaluations of these isogenies, which are precisely the secret key-materials of the compromised nodes.

Recovering the secret key K_{IR} calculated by an initiator node I for a responder node R from 10 the public parameters $H_1(I), H_2(I), H_1(R)$ and $H_2(R)$ is considered a hard problem.

For super singular elliptic curves, the security of this variant is related to the Super singular Isogeny Diffie-Hellman (SIDH) problem. The security of SIDH is based only on the assumption that given a pair of super singular curves E_1 and E_2 , finding an isogeny ϕ such that $\phi: E_1 \rightarrow E_2$ is both a classical and quantum-hard problem. This is a variation of the 15 classical Abelian Hidden Shift problem, however the class group of the common endomorphism ring of super singular curves is not abelian, due to which the only known efficient quantum algorithm for finding secret isogenies does not work in the super singular case. One may use elliptic curves over a field with characteristic p for which the group of geometric points of order p is trivial as super singular.

Indeed, it may not even be enough for an attacker to solve an instance of the discrete logarithm problem, since it is unclear whether there exists a point Q on E_2 such that for any initiator I, the initiator node I's secret key-material $\varphi(H_1(I))$ can be represented as a multiple of Q . In case the initiator node I's secret key-material $\varphi(H_1(I))$ *cannot* be represented as a point on an elliptic curve, then the type 1 embodiments have increased 25 quantum-resistance. Indeed, the question is if $\varphi(H_1(I))$ can be written as scalar multiple of a known point on E_2 . If so, the discrete log problem is relevant. $E_2(m)$ need not have a single generator.

If the discrete logarithm problem is assumed to be hard (i.e., it is assumed that no attacker possessing quantum-computing capabilities exists), then it is assumed that the 30 attacker fails to recover the secret key K_{IR} .

For embodiments using the second type, using a public isogeny: In this scheme, in order to recover the secret key K_{IR} calculated by an initiator node I with a responder node R, an attacker must solve the discrete logarithm problem to obtain s , from the public key $H(I)$ of the initiator with identity I and $sH(I)$ is the secret key of the initiator node

with identity I. If she is successful, the attacker also recovers the TTP's master secret s and can then recover keys belonging to any node that is registered with the TTP. Even if the attacker is able to compromise multiple nodes and gain access to their secret key-material $sH(ID)$, where ID is the identifier of the compromised node, it is assumed that the attacker is 5 still unable to recover the TTP's master secret s , as long as a *single* instance of the discrete logarithm problem remains hard to solve.

In the absence of quantum computers, if it is assumed that an attacker capable of efficiently solving the discrete logarithm problem does not exist, then both the proposed types are secure and operationally correct. If such an attacker does exist however, the second 10 type may be compromised. Embodiments according to the first type are not directly impacted though in the sense that the TTP's secret (the isogeny) cannot be recovered.

The cryptographic operations on the node-side in embodiment using the first type only comprise the evaluation of Weil pairings over elliptic curves, which are operationally relatively efficient. This has desirable implications for nodes, which are 15 typically IoT devices with limited computational and memory capabilities. The calculation of an isogeny between two elliptic curves and the evaluation of an isogeny for an elliptic curve point are comparatively more intensive, but in this variant such isogeny is only computed at the TTP.

Fig. 1 schematically shows an example of an embodiment of a key pre-distribution system 100. System 100 comprises an electronic key pre-distribution device 110 and multiple network nodes. Shown in Fig. 1 are network nodes 210 and 211. The number of network nodes is typically much larger, e.g., larger than 1000, 10000, etc. Key pre-distribution device 110 configures the multiple network nodes for a key agreement protocol; In particular, key pre-distribution device 110 may perform the key pre-distribution phase of 20 an identity-based key pre-distribution scheme, and configures the network nodes 210, 211 with local key material so that later any two of the multiple network nodes can securely agree on shared key between them. The local key material includes at least two private points on two elliptic curves. These private points are private to the network node, and/or to any trusted devices such as device 110. The local key material may also include non-private elements, 25 e.g., an identifier (ID) of the device, public elliptic curve points, and optionally a public isogeny. Provisioning is described primarily with respect to node 210, but the other nodes may be provisioned similarly.

Key pre-distribution device 110 comprises a communication interface 120 arranged to configure the network node with the private elliptic curve point. The

communication interface may be of the same type as used between the network nodes (see below), but may also be of a different type. For example, communication interface 120 may be a wired interface, e.g., a wired connection made in a testing and provisioning device during manufacture of network nodes 210, 211, etc. For example, communication interface 5 120 may comprise a connection pad or connection port. Communication interface 120 may also be digital wired network connection, or a wireless network connection, or a hybrid, etc. For example, communication interface 120 may comprise an antenna.

Key pre-distribution device 110 comprises a storage 130. Storage 130 comprises a representation of a first elliptic curve 131 and a second elliptic curve 132. 10 Elliptic curves 131 and 132 are different curves, e.g., they may be defined by a different formula. An elliptic curve may be defined by the coefficients of a formula that defines it, e.g., in some canonical form. One such form is $Y^2 = X^3 + AX + B$, in which A and B are integers that define the elliptic curve. For example, storage 130 may store the coefficients A and B for the two elliptic curves. Alternatively, the two numbers may be hard coded in algorithms that 15 employ them, e.g., curve multiplication or elliptic hash functions (see further below).

In an embodiment, the first and second elliptic curves are both defined over a field F_q of characteristic p . For example, one may take $q=p^k$. In an embodiment, $p=2$. Along with curves 131, 132 information over the field for which they are defined can be stored. Note that the two curves are defined over the same field.

20 In an embodiment, the elliptic curves 131 and 132 are so-called ordinary (not super singular) curves. For example, one may take elliptic curves from “Recommended Elliptic Curves For Federal Government Use”, a collection of elliptic curves is recommended for Federal government use. In an embodiment, the elliptic curves 131 and 132 are so-called super singular curves. Examples of super singular curves include: if K is a field of 25 characteristic 2, every curve defined by an equation of the form $y^2 + a_3y = x^3 + a_4x + a_0$, with a_3 nonzero; if K is a field of characteristic 3, every curve defined by an equation of the form $y^2 = x^3 + a_4x + a_6$, with a_4 nonzero. Other examples are known.

Key distribution device 110 comprises an elliptic hash unit 140. Elliptic hash unit 140 is arranged to obtain a digital identifier (*ID*) for network node 210. The digital 30 identifier may be received from network node 210, e.g., through communication interface 120. For example, network node 210 may send key pre-distribution device 110 an identifier. The identifier may also be assigned by key pre-distribution device 110, e.g., by hash unit 140. For example, the identifier may comprise a serial number of network node 210, a random number, a nonce, etc. For example, the identifier may comprise a digital computer address of

the network node, e.g., an IP address, a MAC address, etc. The identifier may comprise a common name of the network node 210 or a name of a user of network node 210. The identifier may comprise information regarding roles or authorizations of the user. The latter options are useful for implicit authentication; for example, device 110 may assign or verify
5 the roles.

Hash unit 140 is configured with two hash functions: a first hash function 147 and a second hash function 148. First hash function 147, H_1 maps the digital identifier of network node 210 to a first public point 141, $H_1(ID)$ on first elliptic curve 131. Second hash function 148, H_2 maps the digital identifier of network node 210 to a second public point 142,
10 $H_2(ID)$ on second elliptic curve 132. The hash functions may include additional information together with the ID, e.g., an identification of key pre-distribution device 110, e.g., a salt, e.g., additional information on network node 210, e.g., a timestamp of the time of creating the local key material.

The public points 141 and 142 are part of the public key material 145 for
15 network node 210. Generally speaking, there are two approaches to the public key material 145. Public key material 145 may be stored on network node 210, e.g., together with the private key material. In this case, the nodes may use a public point of another node and a private point of themselves to obtain a shared key. This avoids the need to compute the elliptic hash functions 147 and 148 at the node. In fact, the identifier of a network node is not
20 even needed at the node in this case; key pre-distribution device 110 may just take a random number for it. On the other hand, the network nodes may also be configured to compute the public points 141 and 142 for another node from the identifier of that node. If any additional information is used, in addition to the identifier, then that additional information should be known to the node that computes public points 141 and 142. These embodiments can provide
25 implicit authentication, but do require additional computations. Both approaches may be combined, e.g., some nodes compute the hashes themselves, some nodes use a pre-computed public point. In an embodiment, the public information comprises the identifier, and optionally any additional information that may be part of the public key material, but not the public points 141 and 142. In an embodiment, the public information comprises the public
30 points 141 and 142, but not the identifier. In embodiment, the public information comprises the public points 141 and 142, and also the identifier, and optionally any additional information.

The hash functions 147 and 148 map a bit string such as a digital identifier to a point on an elliptic curve. Preferably, the hash functions are cryptographically collision

resistant, i.e., it is hard to find two identifiers that map to the same elliptic curve point, but statistical collision resistance may be sufficient in embodiments, i.e., it is unlikely that two random identifiers map to the same elliptic curve point. Elliptic hashes may be constructed from conventional hash functions, such as a hash function from the SHA family, e.g., SHA-

5 256, etc. For example, one may hash the ID and map it to a value in the field over which the elliptic curve is defined. Next substitute the value as the X value in the canonical representation of the elliptic curve (e.g. the coordinate with a cube power) and finally compute the value of Y. Which value of Y to choose (generally there are two solutions) may be decided by some bit of the hash of the identifier, or by a bit from a further hash of the
10 identifier, etc. The hashes may be distinguished for the first and second curve by adding a curve identifier to the identifier, e.g., a magic number, e.g. 1 for curve 131 and 2 for curve 132. The two public points 141 and 142 lie on different ones of the first and second elliptic curves. For example, point 141 may lie on curve 131 and point 142 on curve 132.

Key pre-distribution device 110 comprises an isogeny unit 150. Isogeny unit
15 150 takes the public points computed by hash unit 140 and computes private elliptic curve points from them by applying isogenies on them. Storage 130 further comprises information 135 representing a first secret isogeny for first elliptic curve 131 and a second secret isogeny for second elliptic curve 132. Knowledge of these isogenies would break the entire system. For this reason, they are kept secret from anyone who cannot be trusted to protect the system.

20 Isogeny unit 150 is configured to apply the first secret isogeny to first public elliptic curve point 141 obtaining a first private elliptic curve point 151 and to apply the second secret isogeny to second public elliptic curve point 142 obtaining a second private elliptic curve point 152. First private elliptic curve point 151 lies on one of the elliptic curves 131, 132, and second private elliptic curve point 152 lies on the other one of the elliptic
25 curves 131, 132. In some embodiments, the elliptic curve points 141 and 151 lie on the same curve, in some embodiments the elliptic curve points 141 and 151 lie on a different elliptic curve. The secret isogenies map point on an elliptic curve to a point on an elliptic curve. Various examples of storage 130 and isogeny unit 150 are illustrated with respect to Figs. 2a-2c.

30 Fig. 2a schematically shows an example of an embodiment of a storage 161 of a key pre-distribution device. Storage 161 may be used in the key pre-distribution device 110 in the place of storage 130. Storage 161 may be used in embodiment of the first type as discussed above. In storage 161 the isogeny information 135 comprises a first isogeny 162 and a second isogeny 163.

First isogeny 162, φ is a mapping from first elliptic curve 131 to second elliptic curve 132. Second isogeny 163 is the dual of first isogeny 162, φ' and maps from second elliptic curve 132 to first elliptic curve 131. One may take the dual isogeny as the unique isogeny such that the composition $\varphi' \cdot \varphi$ is the multiplication on the first elliptic curve 5 with the degree of the first isogeny. In an embodiment, the degree of first isogeny 162 is at least 2^{80} , at least 2^{128} , or at least 2^{256} , etc. A large degree of the isogeny avoids exhaustive search attacks, since the elliptic curves that are used are public.

In this embodiment, the elliptic curve points 141 and 151 lie on different curves, and so do points 142 and 152. Isogeny unit 150 applies first isogeny 162 to point 141 10 and the second, dual isogeny 163 to point 142. This embodiment may in particular use the techniques disclosed in “Evaluating large degree isogenies and applications to pairing based 15 cryptography” by Reinier Bröker, Denis Charles, and Kristin Lauter.

Fig. 2b schematically shows an example of an embodiment of a storage 167 of 20 a key pre-distribution device. Storage 167 may be used in the key pre-distribution device 110 in the place of storage 130. Storage 167 may be used in an embodiment according to the second type. Storage 167 stores a secret integer 164, s . The first isogeny may be defined as a point multiplication on first curve 131 by s . The second isogeny may be defined as a point multiplication on second curve 132 also by s . In this embodiment, the elliptic curve points 141 and 151 lie on the same curve, and so do points 142 and 152. This embodiment may use conventional point multiplication algorithms.

Fig. 2c schematically shows an example of an embodiment of a storage 168 of 25 a key pre-distribution device. Storage 168 may be used in the key pre-distribution device 110 in the place of storage 130. Storage 168 may be used in an embodiment according to the second type. Storage 168 stores two secret integers 165, 166, s_1, s_2 . The first isogeny may be defined as a point multiplication on first curve 131 by s_1 . The second isogeny may be defined as a point multiplication on second curve 132 by s_2 . In this embodiment, the elliptic curve points 141 and 151 lie on the same curve, and so do points 142 and 152. This embodiment may use conventional point multiplication algorithms.

In an embodiment, hash unit 140 is modified to also include a point 30 multiplication. First public point 141 is computed as $a_1 H_1 (ID)$ and second public point as $a_2 H_2 (ID)$. The parameters are chosen such that $a_1 s_2 = a_2 s_1$. In an embodiment, the integers a_1 and a_2 could be public, although this could be avoided by using the public points instead of the hash functions in the network nodes; that a node received one of the other party’s public points instead of its ID.

In an embodiment, all points that can be used have an order that divides a common number m. In this case, the case of figure 2c can be reduced by re-defining H1,H2 and setting $s = s_1/a_1 = s_2/a_2$, where / is modular m division.

Returning to Fig. 1. First private elliptic curve point 151 and second private elliptic curve point 152 are part of private key material 155 for the network node 210. Key pre-distribution device 110 is configured to write at least the private key material 155 to network node 210. In addition, either the identifier for network node 210 or the public points 141 and 142, e.g., public key material 145 is written to network node 210. Writing both is also possible.

Fig. 3a schematically shows an example of an embodiment of a key agreement system 200. Key agreement system 200 comprises multiple nodes that have been configured for key sharing by a key pre-distribution device, such as key pre-distribution device 110. The multiple nodes in system 200 can communicate with each other through protected communication, protected using a shared key which each node can compute for any of the other nodes. Key pre-distribution device 110 may also be part of system 200, e.g., to dynamically add new nodes, even after system 200 is operational. This is not necessary; In an embodiment, key pre-distribution device 110 is discarded after all nodes are provisioned with local key material.

With respect to Fig. 3a embodiments of the first type are illustrated. First network node 210 is arranged for a key agreement protocol with multiple network nodes. The key agreement protocol is illustrated with respect to a second network node 211. The structure of second network node 211 is largely the same as that of first network node 210, except where they have a sender-receiver relationship.

Network node 210 comprises a storage 230. Storage 230 comprises some means with which second node 211 can obtain a public point for network node 210. For example, storage 230 may store a digital identifier 234, ID_1 for the first network node. The digital identifier is the same as the identifier used to compute the private key material for node 210. Instead of the digital identifier, storage 230 may store a first public elliptic curve point 241 and second public elliptic curve point 242. The points may correspond to public points 141 and 142. Using the identifier has the advantage that implicit authentication is possible. Using the public points has the advantage that some computations are avoided at the nodes. First and second public elliptic curve point 241, 242 lie on a first and second elliptic curve respectively.

Storage 230 also stores a first private elliptic curve point 251 and a second private elliptic curve point 252. First private elliptic curve point 251 and a second private elliptic curve point 252 correspond to the first public elliptic curve point 241 and the second public elliptic curve point 242 through a first and second secret isogeny. First public elliptic 5 curve point 241 and the second public elliptic curve point 242 in turn correspond to digital identifier 234 through a first and second hash function 147, 148.

In this embodiment, the first isogeny may be isogeny 162, and the second isogeny may be isogeny 163. Points 241 and 251 do not lie on the same curve, just as points 242 and 252.

10 Storage 230 may store the first elliptic curve 231 and second elliptic curve 232 on which the points in the public and private data lie. The curves may be represented, e.g., by coefficients of an equation for the curve. The curve can also be present implicitly, e.g., hard coded in the algorithm the bilinear map and the like.

15 The first and second network node 210, 211 each comprise a communication interface 220. Communication interface 220 of first network node 210 is arranged for digital communication with second network node 211. Typically, Communication interface 120 is arranged to communicate with many of the other nodes in system 200.

20 The communication interfaces may be arranged for digital communication with the other nodes in the key agreement system. It is not necessary though that all nodes in the system can be reached at all times. Communication interface 220 is arranged for digital communication. For example, the communication interfaces may be arranged to communicate over a computer network. For example, the communication interface may be arranged for wireless, e.g., Wi-Fi, ZigBee, Bluetooth and the like, and/or wired communication, e.g., Ethernet, USB, and the like. The communication between nodes 210 and 211 may also be a combination of wired and wireless connections. For example, the nodes in system 200, including nodes 210 and 211 may comprise an electronic storage that contains a communication identifier, which uniquely identifies the node within system 200. For example, the communication identifier may be included in digital messages exchanged between nodes 210 and 211, e.g., to address the message. For example, the communication 25 identifier may an IP address, a MAC address, and the like. Advantageously, the same communication identifier may be comprised in the digital identifier 234 and used to compute the local key material.

30 Network node 210 comprises a shared key unit 260. Shared key unit 260 is configured to obtain a public elliptic curve point for the second network node (e.g. the point

$H_2(ID_2)$, with ID_2 is the ID of the second network node), the public elliptic curve point lying on a first one of the first and second elliptic curves. As pointed out, there are different options to do this. For example, second network node 210 may send the public elliptic curve point ($H_2(ID_2)$) directly to first network node 210, e.g., through the communication interface 220.

- 5 On the other hand, the second network node 211 may send its identifier ID_2 instead. In that case shared key unit 260 may apply one of the hash functions 147 and 148, e.g., the second hash function 148 to obtain a public point for second network node 211. Shared key unit 260 also selects a private elliptic curve point from the first and second private elliptic curve points lying on the same elliptic curve as the received public point, e.g., $\varphi(H_1(ID_1))$. In the end,
- 10 shared key unit 260 obtains two elliptic curve points on the same curve: e.g., one public point obtained from second node 211 and one private point selected from storage 230. For example, the points used by shared key unit 260 may be $H_2(ID_2)$ and $\varphi(H_1(ID_1))$. To these two points a bilinear mapping e is applied by shared key unit 260, e.g., $e(H_2(ID_2), \varphi(H_1(ID_1)))$. The bilinear map may be the Weil pairing or the Tate pairing, etc. The outcome of the bilinear map may be used as the shared key. The output may also be further processed, e.g., using a key derivation function (KDF). In an embodiment, all output bits of the bilinear maps are input to a key derivation function (KDF), e.g., a cryptographic hash function. An example of a KDF is given in e.g., the CMLA_KDF from CMLA Technical Specification, Version:
- 15 V1.43-20131218, or the KDF function defined in “DRM specification”, OMA-TS-DRM-DRM-V2_0_2-20080723-A, Open Mobile Alliance™, Version 2.0.2, section 7.1.2, etc.

Second network node 211 also has a shared key unit which computes the corresponding computation $e'(H_1(ID_1), \varphi'(H_2(ID_2)))$. Which computation to use may be hard wired to the party that initiated or responds. For example, it may be agreed that the initiating node uses a public point for the responding node on the second curve, and also a private point on the second curve; whereas the responding party takes a public point for the initiating node on the first curve, and a secret private point on the first curve. This could also be vice versa. In embodiment of this type, one node computes the bilinear map e' on the first curve while the other node computes the bilinear map e on the second curve. This works since, given the two bilinear maps on the two curves, and the isogeny, the dual isogeny is obtained.

- 30 Optionally, network node 210 may comprise a key confirmation unit 280. Key confirmation unit 280 is arranged to compute key confirmation data from the cryptographic key, and send the key confirmation data to the second network node. The key confirmation data may be some authentication token, e.g., an encrypted timestamp, e.g., an encrypted challenge from the second node, etc. The key confirmation data gives implicit authentication,

in the sense that it proves to the second network node that the first network node must have valid key material, which in turn means that it registered with a key pre-distribution device 110. Alternatively, or in addition, key confirmation unit 280 may be arranged to receive key confirmation data for the cryptographic key from the second node, and verify the key 5 confirmation data using the derived shared key. This verifies that the second network node correctly computed the cryptographic key, and thus provides implicit authentication.

The key agreement/distribution scheme illustrated with respect to Fig. 3a is suitable for application such as the Internet of Things, due to the non-interactive nature of key-establishment between nodes and the lightweight operations based on cryptographic 10 pairings over elliptic curves. Isogenies are only carried out by the TTP, which may possess more resources and is therefore capable of carrying out such operations. The secret key-materials of each node can be securely provided by the TTP to the nodes, e.g., during node-bootstrapping. The security model considered while evaluating attacks is a collusion-based security model by default and takes into consideration attackers who can compromise the IoT 15 nodes in the field and use their compromised key-materials to mount attacks on the rest of the network, and in particular on the TTP.

An advantage of the protocol implemented in node 210 is that shared key can be computed without exchanging any messages, so long the digital identifier of the other node is known. The derived key can then be used to derive a key for symmetric encryption 20

Fig. 3b schematically shows an example of an embodiment of a key agreement system 201. System 201 is similar to system 200 except that it uses key pre-distribution of the second type. System 201 comprises multiple network nodes; shown are nodes 215 and 216.

As network node 210, node 215 comprises a storage 230. Storage 230 25 comprises public key material 245, private key material 255, first elliptic curve 231, second elliptic curve 232, and digital identifier 234. As in node 210 some of this is optional, e.g., only one of digital identifier 234 and public material 245 is needed. The first elliptic curve 231 and second elliptic curve 232 need not be explicit but may be implicit, e.g., hard coded in algorithms for point multiplication, bilinear maps and the like.

A difference with node 210 is that in node 215 the first public point 241 and 30 first private point 251 lie on the same elliptic curve, and that the second public point 242 and second private point 252 lie on the other elliptic curve. Furthermore, storage 230 of Fig. 3b comprises a public isogeny 235. The public isogeny 235 is a mapping from the first elliptic curve to the second elliptic curve (or vice versa). Preferably, public isogeny 235 is a low

degree isogeny. Interestingly, the degree of the isogeny adds little to the security as the isogeny is public, however, a lower degree allows easier implementation at the nodes. In embodiments of this type, the public isogeny ensures that each node executes the bilinear map on the same curve; in case the public isogeny maps from the first to the second curve, 5 both the first and second node compute the bilinear map on the second curve.

Node 215 comprises an isogeny unit 270 configured to apply the public isogeny defined by information 235 to a point on the first curve 231. In particular, isogeny unit 270 will be applied to a public point on the first curve that is received from the second node, or computed for the second node from its digital identifier, or isogeny unit 270 will be 10 applied to the private point 251 of node 215 itself on the first curve. Isogeny unit 270 in an embodiment of the second type may use a similar design as isogeny unit 150 in an embodiment of the first type, except that isogeny unit 270 does not need to evaluate any dual isogenies.

Shared key unit 260 is arranged to obtain a public elliptic curve point for the 15 second network node, the public elliptic curve point may lie on any one of the first and second elliptic curves. Shared key unit 260 could compute the public elliptic curve point for the second network node or receive it. Shared key unit 260 also selects a private elliptic curve point from storage 230 of Fig. 3b, which lies on the other elliptic curve than the public point for node 216. At this point shared key unit 260 has obtained two elliptic curve points, one on 20 each of the two curves, one of which is private for node 215, and one of which is public for node 216. Next shared key unit 260 applies isogeny unit 270 to the point that lies on the first elliptic curve, this may be a public or a private point. The result is that two points are now obtained on the second elliptic curve. Finally, shared key unit 270 evaluates the bilinear map e for the second elliptic curve and the two points on it.

25 As for node 210, from the result of the bilinear map the shared key may be derived, e.g., using a KDF. In case of point compression, the trace of the result of the bilinear map may be used to derive the shared key from.

The nodes may be configured depending on who is the initiating node, which 30 point to use. For example, the initiator may use the first public point for the responding node, whereas the responder uses the second public point of the initiator.

In the various embodiments, e.g., with respect to key pre-distribution device 110, or network node 210, 215 the communication interface may be selected from various alternatives. For example, a communication interface may be a network interface to a local or

wide area network, e.g., the Internet, a storage interface to an internal or external data storage. The communication interface may be a card reader, etc.

Storage 130, 230 may be implemented as an electronic memory, say a flash memory, or magnetic memory, say hard disk or the like. Storage 130, 230 may comprise 5 multiple discrete memories together making up the storage. Storage 130, 230 may also be a temporary memory, say a RAM, but in case of a temporary storage, the storage contains some means to obtain the parameters before use, say by obtaining them over an optional network connection (not shown).

Typically, the devices 110, 210, and 215 each comprise a microprocessor (not 10 separately shown) which executes appropriate software stored at the devices 110, 210, and 215; for example, that software may have been downloaded and/or stored in a corresponding memory, e.g., a volatile memory such as RAM or a non-volatile memory such as Flash (not separately shown). Alternatively, the devices 110, 210, and 215 may, in whole or in part, be implemented in programmable logic, e.g., as field-programmable gate array (FPGA). Devices 15 110, 210, and 215 may be implemented, in whole or in part, as a so-called application-specific integrated circuit (ASIC), i.e. an integrated circuit (IC) customized for their particular use. For example, the circuits may be implemented in CMOS, e.g., using a hardware description language such as Verilog, VHDL etc.

In an embodiment, key pre-distribution device 110 comprises a 20 communication interface circuit, a storage circuit, an elliptic hash unit circuit, an isogeny unit circuit. In an embodiment, network node 210 comprises a communication interface circuit, a storage circuit, a shared key unit circuit, and an optional key confirmation unit circuit. Network node 215 may also comprise an isogeny unit circuit. The circuits may be a processor circuit and storage circuit, the processor circuit executing instructions represented 25 electronically in the storage circuits.

A processor circuit may be implemented in a distributed fashion, e.g., as 30 multiple sub-processor circuits. A storage may be distributed over multiple distributed sub-storages. Part or all of the memory may be an electronic memory, magnetic memory, etc. For example, the storage may have volatile and a non-volatile part. Part of the storage may be read-only.

Fig. 4 schematically is a simplified sequence diagram that illustrates an example of an embodiment of a key agreement method. A shared key is established between network nodes 210 and 211 as in Fig. 3a. However, a similar method is applicable to nodes

215 and 215 of Fig. 3b. The message sequence 400 that is shown in Fig. 4 comprises multiple messages exchanged between the nodes, shown are messages 410, 420, and 430.

In a first message 410, node 210 sends a key agreement request to node 211. The request includes the digital identifier ID_1 of node 210. A second message 420, sent from 5 node 211 to node 210, comprises the digital identifier ID_2 of node 211.

At this point, node 210 computes the second public point of node 211: $H_2(ID_2)$ and selects his own first private point $\varphi(H_1(ID_1))$. Node 210 computes the bilinear map $e(H_2(ID_2), \varphi(H_1(ID_1)))$ and derives the shared key from the result.

10 All or part of message 430, send from node 210 to 211, is protected, e.g., encrypted and/or authenticated, e.g., using a block cipher or a message authentication code (MAC) using the obtained shared key. The contents of the protected part may be unrelated to the key agreement protocol, e.g., to serve some further communication need of nodes 210, and 211, e.g., to exchange sensor values, etc.

15 Before or after receiving message 430, Node 211 computes the first public point of node 210: $H_1(ID_1)$ and selects his own second private point $\varphi'(H_2(ID_2))$. Node 210 computes the bilinear map $e(H_1(ID_1), \varphi'(H_2(ID_2)))$ and derives the shared key from the result. The shared key can then be used by node 211 to decrypt and/or verify message 430 or part thereof.

20 If the nodes 210 and 211 already know the digital identifier of the other node, then messages 410 and 420 may be cancelled. Message 430 may comprise a key confirmation token, computed by node 210. Message 420 may comprise a challenge from node 211, e.g., a nonce, which is to be encrypted by node 210. Message 430 may comprise a challenge to node 211. A further message from node 211 to node 210 may comprise a key confirmation token computed by node 211.

25 An application of the key agreement protocol is in messaging applications. For example, in such an application it may be assumed that the sender already has an identifier of receiver. For example, a first network node may send a message to a second network node including: The identifier of the first network node, a protected message. For example, the identifier of the first network node may be a (mobile) telephone number, an email address, a 30 computer address, e.g., an IP address, and the like. The first node is able to compute shared key in advance since it known the identifier, e.g., the telephone number, of the second node for which the message is intended. The message may be directly send to second node identifier by the identifier, e.g., in the case of an email address or a computer address. The message may also be send by an intermediary, e.g., a routing service, that sends the message

over a computer network to a device associated with the identifier, e.g., a telephone number. In the latter case, the nodes may use the telephone number during registration to obtain local key material, and include a computer address for routing messages. Interestingly, the first node can send a message even if the second node is currently offline and not able to

5 interactively participate in a key agreement protocol. The message of the first node may be kept in a buffer, e.g., by a routing device, until the second device is online.

Fig. 5 schematically shows an example of an embodiment of a key pre-distribution method 500. Method 500 for key pre-distribution configures multiple network nodes such as nodes 210 and 211 or nodes 215 and 216 with local key information, Key pre-distribution method 500 comprises:

- storing 510 information 135 representing a first secret isogeny φ ; s for a first elliptic curve 131; E_1 and a second secret isogeny φ' ; s for a second elliptic curve 132; E_2 , an isogeny being arranged to receive a point on an elliptic curve and to produce a point on an elliptic curve as output,
- 15 - obtaining 520 a digital identifier ID for a network node 210,
- applying 530 at least a first hash function 147 and a second hash function 148 to the digital identifier, the first and second hash functions mapping the digital identifier to a first public point 141; $H_1(ID)$ and a second public point 142; $H_2(ID)$ on a first elliptic curve 131 and second elliptic curve 132, the first elliptic curve being different from the second elliptic curve, the first and second public point being part of public key material 145 for the network node 210,
- 20 - applying 540 the first and second secret isogeny 135 to the first and second public elliptic curve point 141, 142, thus obtaining a first private elliptic curve point 151 and second private elliptic curve point 152 being part of private key material 155 for the network node 210, and
- configuring 550 the network node with the private elliptic curve point over a communication interface.

Fig. 6 schematically shows an example of an embodiment of a key agreement method 600. Method 600 establishes a shared key between two network nodes, such as first network node 210 and a second network; or first network node 215 and a second network node 216. Method 600 comprises

- storing 610

- a digital identifier 234; ID for the first network node and/or a first and second public elliptic curve point, the first and second public elliptic curve point lying on a first and second elliptic curve, and

- a first private elliptic curve point 251 and second private elliptic

5 curve point 252 corresponding to the first public elliptic curve point 241 and the second public elliptic curve point 242 through a first and second secret isogeny 135, the first public elliptic curve point 241 and the second public elliptic curve point 242 corresponding to the digital identifier 234 of the network node 210 through a first and second hash function 147, 148, the first and second private elliptic curve points being computed by a key pre-

10 distribution device 110,

- obtaining 620 a public elliptic curve point $H_2(ID_R)$ for the second network node, the public elliptic curve point lying on a first one of the first and second elliptic curves,

- selecting 630 a private elliptic curve point from the first and second private elliptic curve points lying on a second one of the first and second elliptic curves, the first one 15 and the second one being different,

- applying 640 a bilinear map e to the selected private point of the first network node, and the obtained public elliptic curve point of the second network node or the public elliptic curve point of the second network node to which a public isogeny has been applied by the first node,

20 - deriving 650 a cryptographic key from the result of the bilinear map.

Many different ways of executing methods 500 and 500 are possible, as will be apparent to a person skilled in the art. For example, the order of the steps can be varied or some steps may be executed in parallel. Moreover, in between steps other method steps may be inserted. The inserted steps may represent refinements of the method such as described herein, or may be unrelated to the method. Moreover, a given step may not have finished 25 completely before a next step is started.

A method according to the invention may be executed using software, which comprises instructions for causing a processor system to perform method 500 or 600.

Software may only include those steps taken by a particular sub-entity of the system. The

30 software may be stored in a suitable storage medium, such as a hard disk, a floppy, a memory, an optical disc, etc. The software may be sent as a signal along a wire, or wireless, or using a data network, e.g., the Internet. The software may be made available for download and/or for remote usage on a server. A method according to the invention may be executed

using a bitstream arranged to configure programmable logic, e.g., a field-programmable gate array (FPGA), to perform the method.

It will be appreciated that the invention also extends to computer programs, particularly computer programs on or in a carrier, adapted for putting the invention into practice. The program may be in the form of source code, object code, a code intermediate source, and object code such as partially compiled form, or in any other form suitable for use in the implementation of the method according to the invention. An embodiment relating to a computer program product comprises computer executable instructions corresponding to each of the processing steps of at least one of the methods set forth. These instructions may be subdivided into subroutines and/or be stored in one or more files that may be linked statically or dynamically. Another embodiment relating to a computer program product comprises computer executable instructions corresponding to each of the means of at least one of the systems and/or products set forth.

Fig. 7a shows a computer readable medium 1000 having a writable part 1010 comprising a computer program 1020, the computer program 1020 comprising instructions for causing a processor system to perform a method of key pre-distribution or key agreement, according to an embodiment. The computer program 1020 may be embodied on the computer readable medium 1000 as physical marks or by means of magnetization of the computer readable medium 1000. However, any other suitable embodiment is conceivable as well. Furthermore, it will be appreciated that, although the computer readable medium 1000 is shown here as an optical disc, the computer readable medium 1000 may be any suitable computer readable medium, such as a hard disk, solid state memory, flash memory, etc., and may be non-recordable or recordable. The computer program 1020 comprises instructions for causing a processor system to perform said method of key pre-distribution or key agreement.

Fig. 7b shows in a schematic representation of a processor system 1140 according to an embodiment. The processor system comprises one or more integrated circuits 1110. The architecture of the one or more integrated circuits 1110 is schematically shown in Fig. 7b. Circuit 1110 comprises a processing unit 1120, e.g., a CPU, for running computer program components to execute a method according to an embodiment and/or implement its modules or units. Circuit 1110 comprises a memory 1122 for storing programming code, data, etc. Part of memory 1122 may be read-only. Circuit 1110 may comprise a communication element 1126, e.g., an antenna, connectors or both, and the like. Circuit 1110 may comprise a dedicated integrated circuit 1124 for performing part or all of the processing defined in the method. Processor 1120, memory 1122, dedicated IC 1124 and communication

element 1126 may be connected to each other via an interconnect 1130, say a bus. The processor system 1110 may be arranged for contact and/or contact-less communication, using an antenna and/or connectors, respectively.

For example, in an embodiment, the key pre-distribution device or key agreement device, e.g., a network node, may comprise a processor circuit and a memory circuit, the processor being arranged to execute software stored in the memory circuit. For example, the processor circuit may be an Intel Core i7 processor, ARM Cortex-R8, etc. In an embodiment, the processor circuit may be ARM Cortex M0. The memory circuit may be an ROM circuit, or a non-volatile memory, e.g., a flash memory. The memory circuit may be a 10 volatile memory, e.g., an SRAM memory. In the latter case, the device may comprise a non-volatile software interface, e.g., a hard drive, a network interface, etc., arranged for providing the software.

It should be noted that the above-mentioned embodiments illustrate rather than limit the invention, and that those skilled in the art will be able to design many alternative 15 embodiments.

In the claims, any reference signs placed between parentheses shall not be construed as limiting the claim. Use of the verb "comprise" and its conjugations does not exclude the presence of elements or steps other than those stated in a claim. The article "a" or "an" preceding an element does not exclude the presence of a plurality of such elements. The 20 invention may be implemented by means of hardware comprising several distinct elements, and by means of a suitably programmed computer. In the device claim enumerating several means, several of these means may be embodied by one and the same item of hardware. The mere fact that certain measures are recited in mutually different dependent claims does not indicate that a combination of these measures cannot be used to advantage.

25 In the claims references in parentheses refer to reference signs in drawings of exemplifying embodiments or to formulas of embodiments, thus increasing the intelligibility of the claim. These references shall not be construed as limiting the claim.

CLAIMS:

1. An electronic key pre-distribution device (110) for configuring multiple network nodes (210, 211) with local key information, the key pre-distribution device comprising

- a storage (130) comprising information (135) representing a first secret isogeny ($\varphi; s$) for a first elliptic curve (131; E_1) and a second secret isogeny ($\varphi'; s$) for a second elliptic curve (132; E_2), an isogeny being arranged to receive a point on an elliptic curve and to produce a point on an elliptic curve as output,

- a processor circuit configured to

- obtain a digital identifier (ID) for a network node (210),

- apply at least a first hash function (147) and a second hash function (148) to the digital identifier, the first and second hash functions mapping the digital identifier to a first public point (141; $H_1(ID)$) and a second public point (142; $H_2(ID)$) on a first elliptic curve (131) and second elliptic curve (132), the first elliptic curve being different from the second elliptic curve, the first and second public point being part of public key material (145) for the network node (210),

- apply the first and second secret isogeny (135) to the first and second public elliptic curve point (141, 142), thus obtaining a first private elliptic curve point (151) and second private elliptic curve point (152) being part of private key material (155) for the network node (210), and

20 - a communication interface (120) arranged to configure the network node with the first and second private elliptic curve point.

2. A key pre-distribution device as in Claim 1, wherein the first and second public point lie on different ones of the first and second elliptic curves, and wherein the first and second private point lie on different ones of the first and second elliptic curves.

25 3. A key pre-distribution device as in Claim 1 or 2, wherein

- the first isogeny (162) is a mapping from the first elliptic curve (131, E_1) to the second elliptic curve (132, E_2), and wherein the second isogeny (163) is the dual of the first

isogeny, the first public point being a point on the first elliptic curve, the first private point being a point on the second elliptic curve, the second public point being a point on the second elliptic curve, the second private point being a point on the first elliptic curve.

5 4. A key pre-distribution device as in any one of the preceding claims, wherein the first and second elliptic curves are defined by different formula.

5. A key pre-distribution device as in Claim 1, wherein

- the first and second secret isogenies (164; 165, 166) mapping from an elliptic curve to itself, the first and second secret isogenies comprises an elliptic curve scalar multiplication of an input point (P) on the elliptic curve with a secret integer ($s; s_1, s_2$), said information representing the secret isogenies comprising the secret integer.

6. A first electronic network node (210; 215) arranged for a key agreement

15 protocol with a second network node (211), the network node comprising

- a storage comprising

- a digital identifier (234; ID) for the first network node and/or a first and second public elliptic curve point, the first and second public elliptic curve point lying on a first and second elliptic curve, and

20 - a first private elliptic curve point (251) and second private elliptic curve point (252) corresponding to the first public elliptic curve point (241) and the second public elliptic curve point (242) through a first and second secret isogeny (135), the first public elliptic curve point (241) and the second public elliptic curve point (242) corresponding to the digital identifier (234) of the network node (210) through a first and second hash function (147, 148), the first and second private elliptic curve points being computed by a key pre-distribution device (110),

- the processor circuit is configured to

- obtain a public elliptic curve point ($H_2(ID_R)$) for the second network node, the public elliptic curve point lying on a first one of the first and second elliptic curves,

25 - selecting a private elliptic curve point from the first and second private elliptic curve points lying on a second one of the first and second elliptic curves, the first one and the second one being different,

- apply a bilinear map (e) to the selected private point of the first network node, and the obtained public elliptic curve point of the second network node or the

public elliptic curve point of the second network node to which a public isogeny has been applied by the first node,

- deriving a cryptographic key from the result of the bilinear map.

- 5 7. A first electronic network node as in Claim 6, wherein
- the processor circuit is configured to
 - obtain for the second network node a public elliptic curve point on the first elliptic curve ($H_1(ID)$) or a public elliptic curve point on the second elliptic curve ($H_2(ID)$),
 - apply a bilinear map (e) to
 - a public elliptic curve point on the first elliptic curve ($H_1(ID)$) for the second network node and the second private elliptic curve point on the first elliptic curve or to
 - a public elliptic curve point on the second elliptic curve ($H_1(ID)$) for the second network node and the first private elliptic curve point on the second elliptic curve.

- 10 15 8. A first electronic network node as in Claim 6, wherein first public point and the first private points are on the first elliptic curve, and the second public point and the second private points are on the second elliptic curve, the processor circuit being configured to apply a public isogeny to the public elliptic curve point before applying the bilinear map (e), said public isogeny mapping from the first elliptic curve to the second elliptic curve or from the second elliptic curve to the first elliptic curve.

- 20 25 9. A first electronic network node as any one of claims 6-8, wherein the
- the processor circuit is configured to
 - compute key confirmation data from the cryptographic key to allow the second node to verify that the first network node correctly computed the cryptographic key, and/or
 - receive key confirmation data for the cryptographic key from the second node, and verify the key confirmation data to verify that the second network node correctly computed the cryptographic key.

- 30 10. A first electronic network node as in any one of the Claim 6-9 wherein the processor circuit is configured to encrypt a digital message with the cryptographic key and

send the encrypted message to the second node and/or to decrypt an encrypted message with the cryptographic key which is received from the second node.

11. An electronic method 500 for key pre-distribution configuring multiple

5 network nodes (210, 211) with local key information, the key pre-distribution method comprising

- storing (510) information (135) representing a first secret isogeny ($\varphi; s$) for a

first elliptic curve (131; E_1) and a second secret isogeny ($\varphi'; s$) for a second elliptic curve

(132; E_2), an isogeny being arranged to receive a point on an elliptic curve and to produce a

10 point on an elliptic curve as output,

- obtaining (520) a digital identifier (ID) for a network node (210),

- applying (530) at least a first hash function (147) and a second hash function

(148) to the digital identifier, the first and second hash functions mapping the digital

identifier to a first public point (141; $H_1(ID)$) and a second public point (142; $H_2(ID)$) on a first

15 elliptic curve (131) and second elliptic curve (132), the first elliptic curve being different

from the second elliptic curve, the first and second public point being part of public key

material (145) for the network node (210),

- applying (540) the first and second secret isogeny (135) to the first and second

public elliptic curve point (141, 142), thus obtaining a first private elliptic curve point (151)

20 and second private elliptic curve point (152) being part of private key material (155) for the

network node (210), and

- configuring (550) the network node with the private elliptic curve point over a

communication interface.

25 12. An electronic method (600) for establishing a shared key between a first

network node (210; 215) and a second network node (211; 216), the method comprising

- storing (610)

- a digital identifier (234; ID) for the first network node and/or a first

and second public elliptic curve point, the first and second public elliptic curve point lying on

30 a first and second elliptic curve, and

- a first private elliptic curve point (251) and second private elliptic

curve point (252) corresponding to the first public elliptic curve point (241) and the second

public elliptic curve point (242) through a first and second secret isogeny (135), the first

public elliptic curve point (241) and the second public elliptic curve point (242)

corresponding to the digital identifier (234) of the network node (210) through a first and second hash function (147, 148), the first and second private elliptic curve points being computed by a key pre-distribution device (110),

- obtaining (620) a public elliptic curve point ($H_2(ID_R)$) for the second network node, the public elliptic curve point lying on a first one of the first and second elliptic curves,
- selecting (630) a private elliptic curve point from the first and second private elliptic curve points lying on a second one of the first and second elliptic curves, the first one and the second one being different,
- applying (640) a bilinear map (e) to the selected private point of the first network node, and the obtained public elliptic curve point of the second network node or the public elliptic curve point of the second network node to which a public isogeny has been applied by the first node,
- deriving (650) a cryptographic key from the result of the bilinear map.

- 15 13. A computer readable medium (1000) comprising transitory or non-transitory data (1020) representing instructions to cause a processor system to perform the method according to claim 11 or 12.
