Titre : ANTICORPS ANTI-BIOTINE ET PROCÉDÉS D'UTILISATION CORRESPONDANTS
Title: ANTI-BIOTIN ANTIBODIES AND METHODS OF USE

Abrégé/Abstract:
The invention provides anti-biotin antibodies and methods of using the same.
Title: ANTI-BIOTIN ANTIBODIES AND METHODS OF USE

Abstract: The invention provides anti-biotin antibodies and methods of using the same.
ANTI-BIOTIN ANTIBODIES AND METHODS OF USE

FIELD OF THE INVENTION

The present invention relates to anti-biotin antibodies and anti-biotin derivative antibodies and methods of using the same.

BACKGROUND

Hapten-binding antibodies can be applied as capturing modules for therapeutic and diagnostic applications. For example, hapten-bound entities such as fluorophores, chelating reagents, peptides, nucleic acids, proteins, lipids, nanoparticles, and many other agents can react with hapten-binding antibodies and antibody derivatives. This enables effective detection of such ‘payloads’, as well as capturing, accumulation at desired locations, crosslinking and other antibody-mediated effects. Since the features and composition of haptens may influence the composition and “behavior” of hapten-bound entities (incl. size, solubility, activity, biophysical properties, PK, biological effects and more), it is highly desired to develop a variety of different hapten-binding entities. Thereby, it is possible to match a selected hapten with a given payload to generate optimized hapten conjugates. Subsequently, optimal hapten-binding entities can be combined with said conjugates to generate optimal antibody-hapten-payload complexes. It is further desired to have hapten-binding entities such as antibody derivatives which are humanized. This enables applications with significantly reduced risk of interference such as immunogenicity in therapeutic applications. The antibodies that are described here bind biotin derivatives (but not unmodified biotin). These antibodies are termed in this document ‘biotin-binding’ or ‘anti-biotin’ antibodies.

In WO 00/50088 biotinylated-chemokine antibody complexes are reported.

In WO 01/34651 antibodies binding a non-naturally occurring enantiomer (L-Biotin) and their use as targeting agents are reported.

SUMMARY

The invention provides anti-biotin antibodies and anti-biotin-derivative antibodies as well as methods of using the same.

One aspect as reported herein is a humanized anti-biotin antibody, wherein the antibody comprises (a) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11, (b) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15, and (c) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10. This antibody specifically binds to biotin.

In one embodiment the antibody further comprises (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09, (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10, and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11.

In one embodiment the antibody further comprises (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

In one embodiment the antibody comprises at position 24 of the heavy chain variable domain numbered according to Kabat the amino acid residue serine or/and comprises at position 73 of the heavy chain variable domain numbered according to Kabat the amino acid residue threonine.

In one embodiment the antibody comprises at position 60 of the heavy chain variable domain numbered according to Kabat the amino acid residue alanine and at position 61 of the heavy chain variable domain numbered according to Kabat the amino acid residue glutamine.

In one embodiment the antibody (1) comprises at position 24 of the heavy chain variable domain numbered according to Kabat the amino acid residue serine or/and
comprises at position 73 of the heavy chain variable domain numbered according to Kabat the amino acid residue threonine, (2) comprises at position 60 of the heavy chain variable domain numbered according to Kabat the amino acid residue alanine, and (3) comprises at position 61 of the heavy chain variable domain numbered according to Kabat the amino acid residue glutamine.

In one embodiment the antibody comprises (a) a VH sequence having at least 95% sequence identity to the amino acid sequence of SEQ ID NO: 12; (b) a VL sequence having at least 95% sequence identity to the amino acid sequence of SEQ ID NO: 16; or (c) a VH sequence as in (a) and a VL sequence as in (b), wherein the amino acid residue at position 24 of the heavy chain variable domain numbered according to Kabat is serine or/and the amino acid residue at position 73 of the heavy chain variable domain numbered according to Kabat is threonine and the amino acid residue at position 60 of the heavy chain variable domain numbered according to Kabat is alanine, and the amino acid residue at position 61 of the heavy chain variable domain numbered according to Kabat is glutamine.

In one embodiment the antibody comprises a VH sequence of SEQ ID NO: 12.

In one embodiment the antibody comprises a VL sequence of SEQ ID NO: 16.

One aspect as reported herein is an antibody comprising a VH sequence of SEQ ID NO: 12 and a VL sequence of SEQ ID NO: 16.

In one embodiment the antibody is a full length IgG1 antibody or a full length IgG4 antibody.

In one embodiment the antibody is a monoclonal antibody.

In one embodiment the antibody is an antibody fragment that binds biotin.

One aspect as reported herein is a pharmaceutical formulation comprising the antibody as reported herein and a pharmaceutically acceptable carrier.

One aspect as reported herein is the antibody as reported herein for use as a medicament.

One aspect as reported herein is the use of the antibody as reported herein in the manufacture of a medicament.
DESCRIPTION OF THE FIGURE

Figure 1  Expression of the humanized antibody that binds biotin and biotin derivatives with and without cys mutation for covalent payload coupling: Reducing and non-reducing SDS PAGE shows composition and homogeneity of and humanized antibodies after purification with protein A and SEC. Antibody H-chains (upper band at 50k) and L-chains (lower band at 25k) are detectable as unique bands in the SEC purified fractions of both antibody derivatives without presence of visible amounts of additional protein contaminations.

Figure 2  The protein structure of murine anti-Biotin antibody-Fab-fragment was determined in complex with biocytinamid: the complexed hapten is positioned in close proximity to a negatively charged cluster of amino acids; biotin which - as hapten - is derivatized for payload coupling at its carboxyl group binds with good efficacy as there is no charge repulsion at this position (due to the lack of the COOH group); in contrast, free (normal) biotin cannot bind efficient to the antibody because its carboxyl group would be in close proximity to this negative charge cluster, and hence becomes repulsed.

DETAILED DESCRIPTION OF EMBODIMENTS OF THE INVENTION

I. DEFINITIONS

An “acceptor human framework” for the purposes herein is a framework comprising the amino acid sequence of a light chain variable domain (VL) framework or a heavy chain variable domain (VH) framework derived from a human immunoglobulin framework or a human consensus framework, as defined below. An acceptor human framework “derived from” a human immunoglobulin framework or a human consensus framework may comprise the same amino acid sequence thereof, or it may contain amino acid sequence changes. In some embodiments, the number of amino acid changes are 10 or less, 9 or less, 8 or less, 7 or less, 6 or less, 5 or less, 4 or less, 3 or less, or 2 or less. In some embodiments, the VL acceptor human framework is identical in sequence to the VL human immunoglobulin framework sequence or human consensus framework sequence.
“Affinity” refers to the strength of the sum total of non-covalent interactions between a single binding site of a molecule (e.g., an antibody) and its binding partner (e.g., an antigen). Unless indicated otherwise, as used herein, “binding affinity” refers to intrinsic binding affinity which reflects a 1:1 interaction between members of a binding pair (e.g., antibody and antigen). The affinity of a molecule X for its partner Y can generally be represented by the dissociation constant (Kd). Affinity can be measured by common methods known in the art, including those described herein. Specific illustrative and exemplary embodiments for measuring binding affinity are described in the following.

An “affinity matured” antibody refers to an antibody with one or more alterations in one or more hypervariable regions (HVRs), compared to a parent antibody which does not possess such alterations, such alterations resulting in an improvement in the affinity of the antibody for antigen.

The terms “anti-biotin antibody” and “an antibody that binds to biotin” refer to an antibody that is capable of binding biotin with sufficient affinity such that the antibody is useful as a diagnostic and/or therapeutic agent in targeting biotin. In one embodiment, the extent of binding of an anti-biotin antibody to an unrelated, non-biotin protein is less than about 10% of the binding of the antibody to biotin as measured, e.g., by a radioimmunoassay (RIA). In certain embodiments, an antibody that binds to biotin has a dissociation constant (Kd) of ≤ 1 μM, ≤ 100 nM, ≤ 10 nM, ≤ 1 nM, ≤ 0.1 nM, ≤ 0.01 nM, or ≤ 0.001 nM (e.g., 10⁻⁸ M or less, e.g., from 10⁻⁸ M to 10⁻¹³ M, e.g., from 10⁻⁹ M to 10⁻¹³ M).

The term "antibody" herein is used in the broadest sense and encompasses various antibody structures, including but not limited to monoclonal antibodies, polyclonal antibodies, multispecific antibodies (e.g., bispecific antibodies), and antibody fragments so long as they exhibit the desired antigen-binding activity.

An "antibody fragment" refers to a molecule other than an intact antibody that comprises a portion of an intact antibody that binds the antigen to which the intact antibody binds. Examples of antibody fragments include but are not limited to Fv, Fab, Fab', Fab'-SH, F(ab')₂; diabodies; linear antibodies; single-chain antibody molecules (e.g. scFv); and multispecific antibodies formed from antibody fragments.

An “antibody that binds to the same epitope” as a reference antibody refers to an antibody that blocks binding of the reference antibody to its antigen in a
competition assay by 50% or more, and consequently, the reference antibody blocks
binding of the antibody to its antigen in a competition assay by 50% or more. An
exemplary competition assay is provided herein.

The term "chimeric" antibody refers to an antibody in which a portion of the heavy
and/or light chain is derived from a particular source or species, while the
remainder of the heavy and/or light chain is derived from a different source or
species.

The "class" of an antibody refers to the type of constant domain or constant region
possessed by its heavy chain. There are five major classes of antibodies: IgA, IgD,
IgE, IgG, and IgM, and several of these may be further divided into subclasses
(isotypes), e.g., IgG1, IgG2, IgG3, IgG4, IgA1, and IgA2. The heavy chain constant
domains that correspond to the different classes of immunoglobulins are called α,
δ, ε, γ, and μ, respectively.

The term "cytotoxic agent" as used herein refers to a substance that inhibits or
prevents a cellular function and/or causes cell death or destruction. Cytotoxic
agents include, but are not limited to, radioactive isotopes (e.g., At\(^{\text{211}}\), I\(^{\text{131}}\), I\(^{\text{125}}\),
Y\(^{\text{90}}\), Re\(^{\text{186}}\), Re\(^{\text{188}}\), Sm\(^{\text{153}}\), Bi\(^{\text{212}}\), P\(^{\text{32}}\), Pb\(^{\text{212}}\) and radioactive isotopes of Lu);
chemotherapeutic agents or drugs (e.g., methotrexate, adriamicin, vinea alkaloids
(vincristine, vinblastine, etoposide), doxorubicin, melphalan, mitomycin C,
chlorambucil, daunorubicin or other intercalating agents); growth inhibitory agents;
enzymes and fragments thereof such as nucleolytic enzymes; antibiotics; toxins
such as small molecule toxins or enzymatically active toxins of bacterial, fungal,
plant or animal origin, including fragments and/or variants thereof; and the various
antitumor or anticancer agents disclosed below.

"Effector functions" refer to those biological activities attributable to the Fc-region
of an antibody, which vary with the antibody class. Examples of antibody effector
functions include: C1q binding and complement dependent cytotoxicity (CDC); Fc
receptor binding; antibody-dependent cell-mediated cytotoxicity (ADCC);
phagocytosis; down regulation of cell surface receptors (e.g. B cell receptor); and B
cell activation.

An "effective amount" of an agent, e.g., a pharmaceutical formulation, refers to an
amount effective, at dosages and for periods of time necessary, to achieve the
desired therapeutic or prophylactic result.
The term "Fc-region" herein is used to define a C-terminal region of an immunoglobulin heavy chain that contains at least a portion of the constant region. The term includes native sequence Fc-regions and variant Fc-regions. In one embodiment, a human IgG heavy chain Fc-region extends from Cys226, or from Pro230, to the carboxyl-terminus of the heavy chain. However, the C-terminal lysine (Lys447) of the Fc-region may or may not be present. Unless otherwise specified herein, numbering of amino acid residues in the Fc-region or constant region is according to the EU numbering system, also called the EU index, as described in Kabat, E.A., et al., Sequences of Proteins of Immunological Interest, 5th ed., Public Health Service, National Institutes of Health, Bethesda, MD (1991), NIH Publication 91-3242.

"Framework" or "FR" refers to variable domain residues other than hypervariable region (HVR) residues. The FR of a variable domain generally consists of four FR domains: FR1, FR2, FR3, and FR4. Accordingly, the HVR and FR sequences generally appear in the following sequence in VH (or VL): FR1-H1(L1)-FR2-H2(L2)-FR3-H3(L3)-FR4.

The terms "full length antibody", "intact antibody", and "whole antibody" are used herein interchangeably to refer to an antibody having a structure substantially similar to a native antibody structure or having heavy chains that contain an Fc-region as defined herein.

The terms "host cell", "host cell line", and "host cell culture" are used interchangeably and refer to cells into which exogenous nucleic acid has been introduced, including the progeny of such cells. Host cells include "transformant" and "transformed cells," which include the primary transformed cell and progeny derived therefrom without regard to the number of passages. Progeny may not be completely identical in nucleic acid content to a parent cell, but may contain mutations. Mutant progeny that have the same function or biological activity as screened or selected for in the originally transformed cell are included herein.

A "human antibody" is one which possesses an amino acid sequence which corresponds to that of an antibody produced by a human or a human cell or derived from a non-human source that utilizes human antibody repertoires or other human antibody-encoding sequences. This definition of a human antibody specifically excludes a humanized antibody comprising non-human antigen-binding residues.
A “human consensus framework” is a framework which represents the most commonly occurring amino acid residues in a selection of human immunoglobulin VL or VH framework sequences. Generally, the selection of human immunoglobulin VL or VH sequences is from a subgroup of variable domain sequences. Generally, the subgroup of sequences is a subgroup as in Kabat, E.A., et al., Sequences of Proteins of Immunological Interest, 5th ed., Public Health Service, National Institutes of Health, Bethesda MD (1991), NIH Publication 91-3242, Vols. 1-3. In one embodiment, for the VL, the subgroup is subgroup kappa I as in Kabat et al., supra. In one embodiment, for the VH, the subgroup is subgroup III as in Kabat et al., supra.

A “humanized” antibody refers to a chimeric antibody comprising amino acid residues from non-human HVRs and amino acid residues from human FRs. In certain embodiments, a humanized antibody will comprise substantially all of at least one, and typically two, variable domains, in which all or substantially all of the HVRs (e.g., CDRs) correspond to those of a non-human antibody, and all or substantially all of the FRs correspond to those of a human antibody. A humanized antibody optionally may comprise at least a portion of an antibody constant region derived from a human antibody. A “humanized form” of an antibody, e.g., a non-human antibody, refers to an antibody that has undergone humanization.

The term “hypervariable region” or “HVR”, as used herein, refers to each of the regions of an antibody variable domain which are hypervariable in sequence and/or form structurally defined loops (“hypervariable loops”). Generally, native four-chain antibodies comprise six HVRs; three in the VH (H1, H2, H3), and three in the VL (L1, L2, L3). HVRs generally comprise amino acid residues from the hypervariable loops and/or from the “complementarity determining regions” (CDRs), the latter being of highest sequence variability and/or involved in antigen recognition. Exemplary hypervariable loops occur at amino acid residues 26-32 (L1), 50-52 (L2), 91-96 (L3), 26-32 (H1), 53-55 (H2), and 96-101 (H3). (Chothia, C. and Lesk, A.M., J. Mol. Biol. 196 (1987) 901-917) Exemplary CDRs (CDR-L1, CDR-L2, CDR-L3, CDR-H1, CDR-H2, and CDR-H3) occur at amino acid residues 24-34 of L1, 50-56 of L2, 89-97 of L3, 31-35B of H1, 50-65 of H2, and 95-102 of H3. (Kabat, E.A., et al., Sequences of Proteins of Immunological Interest, 5th ed. Public Health Service, National Institutes of Health, Bethesda, MD (1991), NIH Publication 91-3242.) With the exception of CDR1 in VH, CDRs generally comprise the amino acid residues that form the hypervariable loops. CDRs also comprise “specificity determining residues,” or “SDRs,” which are residues that
contact antigen. SDRs are contained within regions of the CDRs called abbreviated-CDRs, or a-CDRs. Exemplary a-CDRs (a-CDR-L1, a-CDR-L2, a-CDR-L3, a-CDR-H1, a-CDR-H2, and a-CDR-H3) occur at amino acid residues 31-34 of L1, 50-55 of L2, 89-96 of L3, 31-35B of H1, 50-58 of H2, and 95-102 of H3. (See Almagro, J.C. and Fransson, J., Front. Biosci. 13 (2008) 1619-1633). Unless otherwise indicated, HVR residues and other residues in the variable domain (e.g., FR residues) are numbered herein according to Kabat et al., supra.

An "immunoconjugate" is an antibody conjugated to one or more heterologous molecule(s), including but not limited to a cytotoxic agent.

An "individual" or "subject" is a mammal. Mammals include, but are not limited to, domesticated animals (e.g. cows, sheep, cats, dogs, and horses), primates (e.g., humans and non-human primates such as monkeys), rabbits, and rodents (e.g., mice and rats). In certain embodiments, the individual or subject is a human.

An "isolated" antibody is one which has been separated from a component of its natural environment. In some embodiments, an antibody is purified to greater than 95% or 99% purity as determined by, for example, electrophoretic (e.g., SDS-PAGE, isoelectric focusing (IEF), capillary electrophoresis) or chromatographic (e.g., ion exchange or reverse phase HPLC). For review of methods for assessment of antibody purity, see, e.g., Flatman, S., et al., J. Chrom. B 848 (2007) 79-87.

An "isolated" nucleic acid refers to a nucleic acid molecule that has been separated from a component of its natural environment. An isolated nucleic acid includes a nucleic acid molecule contained in cells that ordinarily contain the nucleic acid molecule, but the nucleic acid molecule is present extrachromosomally or at a chromosomal location that is different from its natural chromosomal location.

"Isolated nucleic acid encoding an anti-biotin antibody" refers to one or more nucleic acid molecules encoding antibody heavy and light chains (or fragments thereof), including such nucleic acid molecule(s) in a single vector or separate vectors, and such nucleic acid molecule(s) present at one or more locations in a host cell.

The term "monoclonal antibody" as used herein refers to an antibody obtained from a population of substantially homogeneous antibodies, i.e., the individual antibodies comprising the population are identical and/or bind the same epitope,
except for possible variant antibodies, e.g., containing naturally occurring mutations or arising during production of a monoclonal antibody preparation, such variants generally being present in minor amounts. In contrast to polyclonal antibody preparations, which typically include different antibodies directed against different determinants (epitopes), each monoclonal antibody of a monoclonal antibody preparation is directed against a single determinant on an antigen. Thus, the modifier “monoclonal” indicates the character of the antibody as being obtained from a substantially homogeneous population of antibodies, and is not to be construed as requiring production of the antibody by any particular method. For example, the monoclonal antibodies to be used in accordance with the present invention may be made by a variety of techniques, including but not limited to the hybridoma method, recombinant DNA methods, phage-display methods, and methods utilizing transgenic animals containing all or part of the human immunoglobulin loci, such methods and other exemplary methods for making monoclonal antibodies being described herein.

A “naked antibody” refers to an antibody that is not conjugated to a heterologous moiety (e.g., a cytotoxic moiety) or radiolabel. The naked antibody may be present in a pharmaceutical formulation.

"Native antibodies" refer to naturally occurring immunoglobulin molecules with varying structures. For example, native IgG antibodies are heterotetrameric glycoproteins of about 150,000 daltons, composed of two identical light chains and two identical heavy chains that are disulfide-bonded. From N- to C-terminus, each heavy chain has a variable region (VH), also called a variable heavy domain or a heavy chain variable domain, followed by three constant domains (CH1, CH2, and CH3). Similarly, from N- to C-terminus, each light chain has a variable region (VL), also called a variable light domain or a light chain variable domain, followed by a constant light (CL) domain. The light chain of an antibody may be assigned to one of two types, called kappa (κ) and lambda (λ), based on the amino acid sequence of its constant domain.

The term “package insert” is used to refer to instructions customarily included in commercial packages of therapeutic products, that contain information about the indications, usage, dosage, administration, combination therapy, contraindications and/or warnings concerning the use of such therapeutic products.
"Percent (%) amino acid sequence identity" with respect to a reference polypeptide sequence is defined as the percentage of amino acid residues in a candidate sequence that are identical with the amino acid residues in the reference polypeptide sequence, after aligning the sequences and introducing gaps, if necessary, to achieve the maximum percent sequence identity, and not considering any conservative substitutions as part of the sequence identity. Alignment for purposes of determining percent amino acid sequence identity can be achieved in various ways that are within the skill in the art, for instance, using publicly available computer software such as BLAST, BLAST-2, ALIGN or Megalign (DNASTAR) software. Those skilled in the art can determine appropriate parameters for aligning sequences, including any algorithms needed to achieve maximal alignment over the full length of the sequences being compared. For purposes herein, however, % amino acid sequence identity values are generated using the sequence comparison computer program ALIGN-2. The ALIGN-2 sequence comparison computer program was authored by Genentech, Inc., and the source code has been filed with user documentation in the U.S. Copyright Office, Washington D.C., 20559, where it is registered under U.S. Copyright Registration No. TXU510087. The ALIGN-2 program is publicly available from Genentech, Inc., South San Francisco, California, or may be compiled from the source code. The ALIGN-2 program should be compiled for use on a UNIX operating system, including digital UNIX V4.0D. All sequence comparison parameters are set by the ALIGN-2 program and do not vary.

In situations where ALIGN-2 is employed for amino acid sequence comparisons, the % amino acid sequence identity of a given amino acid sequence A to, with, or against a given amino acid sequence B (which can alternatively be phrased as a given amino acid sequence A that has or comprises a certain % amino acid sequence identity to, with, or against a given amino acid sequence B) is calculated as follows:

\[
100 \times \frac{X}{Y}
\]

where X is the number of amino acid residues scored as identical matches by the sequence alignment program ALIGN-2 in that program's alignment of A and B, and where Y is the total number of amino acid residues in B. It will be appreciated that where the length of amino acid sequence A is not equal to the length of amino acid sequence B, the % amino acid sequence identity of A to B will not equal the % amino acid sequence identity of B to A. Unless specifically stated otherwise, all %
amino acid sequence identity values used herein are obtained as described in the immediately preceding paragraph using the ALIGN-2 computer program.

The term "pharmaceutical formulation" refers to a preparation which is in such form as to permit the biological activity of an active ingredient contained therein to be effective, and which contains no additional components which are unacceptably toxic to a subject to which the formulation would be administered.

A “pharmaceutically acceptable carrier” refers to an ingredient in a pharmaceutical formulation, other than an active ingredient, which is nontoxic to a subject. A pharmaceutically acceptable carrier includes, but is not limited to, a buffer, excipient, stabilizer, or preservative.

The term “biotin”, as used herein, denotes 5-[(3aS,4S,6aR)-2-oxohexahydro-1H-thieno[3,4-d]imidazol-4-yl]pentanoic acid. Biotin is also known as vitamin H or coenzyme R.

As used herein, “treatment” (and grammatical variations thereof such as “treat” or “treating”) refers to clinical intervention in an attempt to alter the natural course of the individual being treated, and can be performed either for prophylaxis or during the course of clinical pathology. Desirable effects of treatment include, but are not limited to, preventing occurrence or recurrence of disease, alleviation of symptoms, diminishment of any direct or indirect pathological consequences of the disease, preventing metastasis, decreasing the rate of disease progression, amelioration or palliation of the disease state, and remission or improved prognosis. In some embodiments, antibodies of the invention are used to delay development of a disease or to slow the progression of a disease.

The term “variable region” or “variable domain” refers to the domain of an antibody heavy or light chain that is involved in binding the antibody to antigen. The variable domains of the heavy chain and light chain (VH and VL, respectively) of a native antibody generally have similar structures, with each domain comprising four conserved framework regions (FRs) and three hypervariable regions (HVRs). (See, e.g., Kindt, T.J., et al., Kuby Immunology, 6th ed., W.H. Freeman and Co., N.Y. (2007), page 91) A single VH or VL domain may be sufficient to confer antigen-binding specificity. Furthermore, antibodies that bind a particular antigen may be isolated using a VH or VL domain from an antibody that binds the antigen to screen a library of complementary VL or VH domains,

The term "vector", as used herein, refers to a nucleic acid molecule capable of propagating another nucleic acid to which it is linked. The term includes the vector as a self-replicating nucleic acid structure as well as the vector incorporated into the genome of a host cell into which it has been introduced. Certain vectors are capable of directing the expression of nucleic acids to which they are operatively linked. Such vectors are referred to herein as "expression vectors".

The term “hapten” denotes a small molecule that can elicit an immune response only when attached to a large carrier such as a protein. Exemplary haptens are aniline, o-, m-, and p-aminobenzoic acid, quinone, hydralazine, halothane, fluorescein, biotin, digoxigenin, theophylline and dinitrophenol. In one embodiment the hapten is biotin or digoxigenin or theophylline or carborane.

The term “a hapten that is conjugated to” or “haptenylated compound” denotes to a hapten which is covalently linked to a further moiety such as a polypeptide or a label. Activated hapten derivatives are often used as starting materials for the formation of such conjugates. In one embodiment the hapten is digoxigenin and it is conjugated (in one embodiment via its 3-hydroxy group) to the moiety via a linker. In one embodiment the linker comprises a) one or more (in one embodiment three to six) methylene-carboxy-methyl groups (-CH₂-C(O)-), and/or b) from 1 to 10 (in one embodiment from 1 to 5) amino acid residues (in one embodiment selected from glycine, serine, glutamate, β-alanine, γ-aminobutyric acid, ε-aminocaproic acid or lysine), and/or c) one or more (in one embodiment one or two) compounds having the structural formula NH₂-[(CH₂)ₓO]ₓCH₂-CH₂-COOH in which n is 2 or 3 and x is 1 to 10, in one embodiment 1 to 7. The last element results (at least partly) in a linker (part) of the formula -NH-[(CH₂)ₓO]ₓCH₂-CH₂-C(O)-. One example of such a compound is e.g. 12-amino-4,7,10-trioxadodecanoic acid (results in a TEG (triethylenglycol) linker). In one embodiment the linker further comprises a maleimido group. The linker has a stabilizing and solubilizing effect since it contains charges or/and can form hydrogen bridges. In addition it can sterically facilitate the binding of the anti-hapten antibody to the hapten-conjugated polypeptide. In one embodiment the linker is located at a side chain of an amino acid of the polypeptide (e.g. conjugated to a lysine or cysteine side chain via an amino or thiol group). In one embodiment the linker is located at the amino terminus or at the carboxy terminus of the polypeptide. The position of the linker
on the polypeptide is typically chosen at a region where the biological activity of the polypeptide is not affected. Therefore the attachment position of the linker depends on the nature of the polypeptide and the relevant structure elements which are responsible for the biological activity. The biological activity of the polypeptide to which the hapten attached can be tested in an in vitro assay.

The term “covalent complex formation” denotes that after the formation of a non-covalent complex, e.g. between an anti-theophylline antibody and theophylline, a covalent bond is formed between the two partners in the complex. The formation of the covalent bond takes place without the need to add further reactants.

II. COMPOSITIONS AND METHODS

In one aspect, the invention is based on antibodies that bind to biotin. These antibodies are provided herein. Antibodies of the invention are useful, e.g., as monospecific antibodies for the binding of biotinylated compounds and as multispecific antibodies for the diagnosis or treatment of all kinds of diseases by using the binding specificity to the biotinylated compound as universal payloading characteristic of the antibody.

A. Exemplary Anti-Biotin Antibodies

In one aspect, the invention provides isolated antibodies that bind to biotin. In certain embodiments the anti-biotin antibodies are humanized anti-biotin antibodies. In certain embodiments, the anti-biotin antibodies as reported herein bind to biotinylated compounds without interfering with the biological activity of the compound that is conjugated to biotin and specifically bound by the antibody via the biotin residue. Therefore these antibodies can be used to improve the pharmacokinetic properties of compounds conjugated to biotin (biotinylated compound) if the antibody is a monospecific antibody. Also these antibodies can be used for the targeted delivery of a biotinylated compound if the antibody is a bi- or multispecific antibody as one binding specificity is directed against biotin and can be used as universal payloading specificity whereas a second binding specificity specifically binds e.g. to a cell surface molecule and provides for the targeting characteristic/component of the bi- or multispecific antibody.

In one aspect, the invention provides an anti-biotin antibody comprising at least one, two, three, four, five, or six HVRs selected from (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01; (b) HVR-H2 comprising the amino acid
sequence of SEQ ID NO: 02; (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03; (d) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (e) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (f) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07.

In one aspect, the invention provides an anti-biotin antibody comprising at least one, at least two, or all three VH HVR sequences selected from (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02; and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03. In one embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03. In another embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03 and HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07. In a further embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03, HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07, and HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02. In a further embodiment, the antibody comprises (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02; and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03.

In another aspect, the invention provides an anti-biotin antibody comprising at least one, at least two, or all three VL HVR sequences selected from (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07. In one embodiment, the antibody comprises (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07.

In another aspect, an anti-biotin antibody of the invention comprises (a) a VH domain comprising at least one, at least two, or all three VH HVR sequences selected from (i) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01, (ii) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02, and (iii) HVR-H3 comprising an amino acid sequence of SEQ ID NO: 03; and (b) a VL domain comprising at least one, at least two, or all three VL HVR sequences selected from (i) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05,
(ii) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06, and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07.

In another aspect, the invention provides an anti-biotin antibody comprising (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02; (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03; (d) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (e) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (f) HVR-L3 comprising an amino acid sequence selected from SEQ ID NO: 07.

In one embodiment, the anti-biotin antibody is humanized.

In one aspect, the invention provides a humanized anti-biotin antibody comprising at least one, two, three, four, five, or six HVRs selected from (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10; (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11; (d) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (e) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (f) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

In one aspect, the invention provides a humanized anti-biotin antibody comprising at least one, at least two, or all three VH HVR sequences selected from (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10; and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11. In one embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11. In another embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11 and HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15. In a further embodiment, the antibody comprises HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11, HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15, and HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10. In a further embodiment, the antibody comprises (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10; and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11.

In another aspect, the invention provides a humanized anti-biotin antibody comprising at least one, at least two, or all three VL HVR sequences selected from
(a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15. In one embodiment, the antibody comprises (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

In another aspect, an antibody of the invention comprises (a) a VH domain comprising at least one, at least two, or all three VH HVR sequences selected from (i) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09, (ii) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10, and (iii) HVR-H3 comprising an amino acid sequence of SEQ ID NO: 11; and (b) a VL domain comprising at least one, at least two, or all three VL HVR sequences selected from (i) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13, (ii) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14, and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

In another aspect, the invention provides a humanized anti-biotin antibody comprising (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10; (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11; (d) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (e) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (f) HVR-L3 comprising an amino acid sequence selected from SEQ ID NO: 15.

In another aspect, the invention provides a humanized anti-biotin antibody comprising (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01; (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 02; (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03; (d) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (e) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (f) HVR-L3 comprising an amino acid sequence selected from SEQ ID NO: 07, wherein the amino acid residue at position 60 in the HVR-H2 is A and the amino acid residue at position 61 in the HVR-H2 is Q.

The humanized anti-biotin antibody comprises at Kabat position 60 an A and at Kabat position 61 a Q. These changes (forward mutations) were introduced to increase the binding affinity of the humanized anti-biotin antibody.
In one embodiment, a humanized anti-biotin antibody comprises HVRs as in any of the above embodiments, and further comprises an acceptor human framework, e.g. a human immunoglobulin framework or a human consensus framework. In one embodiment, a humanized anti-biotin antibody comprises a VH comprising HVR-Hs as in any of the above embodiments, and further comprises one or more of the following:

- S at position 24, and/or
- T at position 73.

Kabat position 24 corresponds to residue number 24 of SEQ ID NO: 04, 12, and 20.

Kabat position 60 corresponds to residue number 61 of SEQ ID NO: 04, 12, and 20.

Kabat position 61 corresponds to residue number 62 of SEQ ID NO: 04, 12, and 20.

Kabat position 71 corresponds to residue number 72 of SEQ ID NO: 04, 12, and 20.

These changes (forward mutations) were introduced to increase the binding affinity of the humanized anti-biotin antibody.

In another aspect, an anti-biotin antibody comprises a heavy chain variable domain (VH) sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or 100% sequence identity to the amino acid sequence of SEQ ID NO: 04. In certain embodiments, a VH sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% identity contains substitutions (e.g., conservative substitutions), insertions, or deletions relative to the reference sequence, but an anti-biotin antibody comprising that sequence retains the ability to bind to biotin.

In certain embodiments, a total of 1 to 10 amino acids have been substituted, inserted and/or deleted in SEQ ID NO: 04. In certain embodiments, substitutions, insertions, or deletions occur in regions outside the HVRs (i.e., in the FRs). Optionally, the anti-biotin antibody comprises the VH sequence in SEQ ID NO: 04, including post-translational modifications of that sequence. In a particular embodiment, the VH comprises one, two or three HVRs selected from: (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 01, (b) HVR-H2
comprising the amino acid sequence of SEQ ID NO: 02, and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 03.

In another aspect, an anti-biotin antibody is provided, wherein the antibody comprises a light chain variable domain (VL) having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or 100% sequence identity to the amino acid sequence of SEQ ID NO: 08. In certain embodiments, a VL sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% identity contains substitutions (e.g., conservative substitutions), insertions, or deletions relative to the reference sequence, but an anti-biotin antibody comprising that sequence retains the ability to bind to biotin. In certain embodiments, a total of 1 to 10 amino acids have been substituted, inserted and/or deleted in SEQ ID NO: 08. In certain embodiments, the substitutions, insertions, or deletions occur in regions outside the HVRs (i.e., in the FRs). Optionally, the anti-biotin antibody comprises the VL sequence in SEQ ID NO: 08, including post-translational modifications of that sequence. In a particular embodiment, the VL comprises one, two or three HVRs selected from (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 05; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 06; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 07.

In another aspect, an anti-biotin antibody is provided, wherein the antibody comprises a VH as in any of the embodiments provided above, and a VL as in any of the embodiments provided above. In one embodiment, the antibody comprises the VH and VL sequences in SEQ ID NO: 04 and SEQ ID NO: 08, respectively, including post-translational modifications of those sequences.

In another aspect, a humanized anti-biotin antibody comprises a heavy chain variable domain (VH) sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, 99%, or 100% sequence identity to the amino acid sequence of SEQ ID NO: 12. In certain embodiments, a VH sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% identity contains substitutions (e.g., conservative substitutions), insertions, or deletions relative to the reference sequence, but an anti-biotin antibody comprising that sequence retains the ability to bind to biotin. In certain embodiments, a total of 1 to 10 amino acids have been substituted, inserted and/or deleted in SEQ ID NO: 12. In certain embodiments, substitutions, insertions, or deletions occur in regions outside the HVRs (i.e., in the FRs). Optionally, the anti-biotin antibody comprises the VH sequence in SEQ ID NO: 12, including post-translational modifications of that
sequence. In a particular embodiment, the VH comprises one, two or three HVRs selected from: (a) HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09, (b) HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10, and (c) HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11.

In another aspect, a humanized anti-biotin antibody is provided, wherein the antibody comprises a light chain variable domain (VL) having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 100% sequence identity to the amino acid sequence of SEQ ID NO: 16. In certain embodiments, a VL sequence having at least 90%, 91%, 92%, 93%, 94%, 95%, 96%, 97%, 98%, or 99% identity contains substitutions (e.g., conservative substitutions), insertions, or deletions relative to the reference sequence, but an anti-biotin antibody comprising that sequence retains the ability to bind to biotin. In certain embodiments, a total of 1 to 10 amino acids have been substituted, inserted and/or deleted in SEQ ID NO: 16. In certain embodiments, the substitutions, insertions, or deletions occur in regions outside the HVRs (i.e., in the FRs). Optionally, the anti-biotin antibody comprises the VL sequence in SEQ ID NO: 16, including post-translational modifications of that sequence. In a particular embodiment, the VL comprises one, two or three HVRs selected from (a) HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (b) HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (c) HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

In another aspect, a humanized anti-biotin antibody is provided, wherein the antibody comprises a VH as in any of the embodiments provided above, and a VL as in any of the embodiments provided above. In one embodiment, the antibody comprises the VH and VL sequences in SEQ ID NO: 12 and SEQ ID NO: 16, respectively, including post-translational modifications of those sequences.

In a further aspect of the invention, an anti-biotin antibody according to any of the above embodiments is a monoclonal antibody, including a chimeric, humanized or human antibody. In one embodiment, an anti-biotin antibody is an antibody fragment, e.g., an Fv, Fab, Fab', scFv, diabody, or F(ab')2 fragment. In another embodiment, the antibody is a full length antibody, e.g., an intact IgG1 or IgG4 antibody or other antibody class or isotype as defined herein.

In a further aspect, an anti-biotin antibody according to any of the above embodiments may incorporate any of the features, singly or in combination, as described in Sections 1-5 below:
1. Antibody Affinity

In certain embodiments, an antibody provided herein has a dissociation constant (Kd) of ≤ 1 μM, ≤ 100 nM, ≤ 10 nM, ≤ 1 nM, ≤ 0.1 nM, ≤ 0.01 nM, or ≤ 0.001 nM (e.g. 10⁻⁸ M or less, e.g. from 10⁻⁸ M to 10⁻¹³ M, e.g., from 10⁻⁹ M to 10⁻¹³ M).

In one embodiment, Kd is measured by a radiolabeled antigen binding assay (RIA) performed with the Fab version of an antibody of interest and its antigen as described by the following assay. Solution binding affinity of FABs for antigen is measured by equilibrating Fab with a minimal concentration of (¹²⁵I)-labeled antigen in the presence of a titration series of unlabeled antigen, then capturing bound antigen with an anti-Fab antibody-coated plate (see, e.g., Chen, Y., et al., J. Mol. Biol. 293 (1999) 865-881). To establish conditions for the assay, MICROTITER® multi-well plates (Thermo Scientific) are coated overnight with 5 μg/ml of a capturing anti-Fab antibody (Cappel Labs) in 50 mM sodium carbonate (pH 9.6), and subsequently blocked with 2% (w/v) bovine serum albumin in PBS for two to five hours at room temperature (approximately 23°C). In a non-adsorbent plate (Nunc #269620), 100 pM or 26 pM [¹²⁵I]-antigen are mixed with serial dilutions of a Fab of interest (e.g., consistent with assessment of the anti-VEGF antibody, Fab-12, in Presta, L.G., et al., Cancer Res. 57 (1997) 4593-4599). The Fab of interest is then incubated overnight; however, the incubation may continue for a longer period (e.g., about 65 hours) to ensure that equilibrium is reached. Thereafter, the mixtures are transferred to the capture plate for incubation at room temperature (e.g., for one hour). The solution is then removed and the plate washed eight times with 0.1% polysorbate 20 (TWEEN-20®) in PBS. When the plates have dried, 150 μl/well of scintillant (MICROSCINT-20™; Packard) is added, and the plates are counted on a TOPCOUNT™ gamma counter (Packard) for ten minutes. Concentrations of each Fab that give less than or equal to 20% of maximal binding are chosen for use in competitive binding assays.

According to another embodiment, Kd is measured using surface plasmon resonance assays using a BIACORE®-2000 or a BIACORE®-3000 (BIAdore, Inc., Piscataway, NJ) at 25°C with immobilized antigen CM5 chips at ~10 response units (RU). Briefly, carboxymethylated dextran biosensor chips (CM5, BIACORE, Inc.) are activated with N-ethyl-N’-(3-dimethylaminopropyl)-carbodiimide hydrochloride (EDC) and N-hydroxysuccinimide (NHS) according to the supplier’s instructions. Antigen is diluted with 10 mM sodium acetate, pH 4.8, to 5 μg/ml (~0.2 μM) before injection at a flow rate of 5 μl/minute to achieve approximately
10 response units (RU) of coupled protein. Following the injection of antigen, 1 M ethanolamine is injected to block unreacted groups. For kinetics measurements, two-fold serial dilutions of Fab (0.78 nM to 500 nM) are injected in PBS with 0.05% polysorbate 20 (TWEEN-20™) surfactant (PBST) at 25°C at a flow rate of approximately 25 µl/min. Association rates (k_{on}) and dissociation rates (k_{off}) are calculated using a simple one-to-one Langmuir binding model (BIACORE ® Evaluation Software version 3.2) by simultaneously fitting the association and dissociation sensograms. The equilibrium dissociation constant (K_d) is calculated as the ratio k_{off}/k_{on}. See, e.g., Chen, Y., et al., J. Mol. Biol. 293 (1999) 865-881. If the on-rate exceeds 10^6 M^{-1} s^{-1} by the surface plasmon resonance assay above, then the on-rate can be determined by using a fluorescent quenching technique that measures the increase or decrease in fluorescence emission intensity (excitation = 295 nm; emission = 340 nm, 16 nm band-pass) at 25°C of a 20 nM anti-antigen antibody (Fab form) in PBS, pH 7.2, in the presence of increasing concentrations of antigen as measured in a spectrometer, such as a stop-flow equipped spectrophotometer (Aviv Instruments) or a 8000-series SLM-AMINCO ™ spectrophotometer (ThermoSpectronic) with a stirred cuvette.

2. Antibody Fragments

In certain embodiments, an antibody provided herein is an antibody fragment. Antibody fragments include, but are not limited to, Fab, Fab', Fab'-SH, F(ab')_2, Fv, and scFv fragments, and other fragments described below. For a review of certain antibody fragments, see Hudson, P.J., et al., Nat. Med. 9 (2003) 129-134. For a review of scFv fragments, see, e.g., Pluckthun, A., In: The Pharmacology of Monoclonal Antibodies, Vol. 113, Rosenburg and Moore (eds.), Springer-Verlag, New York (1994), pp. 269-315; see also WO 93/16185; and US 5,571,894 and US 5,587,458. For discussion of Fab and F(ab')_2 fragments comprising salvage receptor binding epitope residues and having increased in vivo half-life, see US 5,869,046.

Single-domain antibodies are antibody fragments comprising all or a portion of the heavy chain variable domain or all or a portion of the light chain variable domain of an antibody. In certain embodiments, a single-domain antibody is a human single-domain antibody (Domantis, Inc., Waltham, MA; see, e.g., US 6,248,516 B1).

Antibody fragments can be made by various techniques, including but not limited to proteolytic digestion of an intact antibody as well as production by recombinant host cells (e.g. *E. coli* or phage), as described herein.

3. Chimeric and Humanized Antibodies

In certain embodiments, an antibody provided herein is a chimeric antibody. Certain chimeric antibodies are described, e.g., in US 4,816,567; and Morrison, S.L., et al., Proc. Natl. Acad. Sci. USA 81 (1984) 6851-6855. In one example, a chimeric antibody comprises a non-human variable region (e.g., a variable region derived from a mouse, rat, hamster, rabbit, or non-human primate, such as a monkey) and a human constant region. In a further example, a chimeric antibody is a “class switched” antibody in which the class or subclass has been changed from that of the parent antibody. Chimeric antibodies include antigen-binding fragments thereof.

In certain embodiments, a chimeric antibody is a humanized antibody. Typically, a non-human antibody is humanized to reduce immunogenicity to humans, while retaining the specificity and affinity of the parental non-human antibody. Generally, a humanized antibody comprises one or more variable domains in which HVRs, e.g., CDRs, (or portions thereof) are derived from a non-human antibody, and FRs (or portions thereof) are derived from human antibody sequences. A humanized antibody optionally will also comprise at least a portion of a human constant region. In some embodiments, some FR residues in a humanized antibody are substituted with corresponding residues from a non-human antibody (e.g., the antibody from which the HVR residues are derived), e.g., to restore or improve antibody specificity or affinity.

4. Multispecific Antibodies

In certain embodiments, an antibody provided herein is a multispecific antibody, e.g. a bispecific antibody. Multispecific antibodies are monoclonal antibodies that have binding specificities for at least two different sites. In certain embodiments, one of the binding specificities is for biotin and the other is for any other antigen. In certain embodiments, bispecific antibodies may bind to two different epitopes of biotin. Bispecific antibodies may also be used to localize cytotoxic agents to cells which express biotin. Bispecific antibodies can be prepared as full length antibodies or antibody fragments.

Techniques for making multispecific antibodies include, but are not limited to, recombinant co-expression of two immunoglobulin heavy-light chain pairs having different specificities (see Milstein, C. and Cuello, A.C., Nature 305 (1983) 537-540, WO 93/08829, and Traunecker, A., et al., EMBO J. 10 (1991) 3655-3659), and “knob-in-hole” engineering (see, e.g., US 5,731,168). Multi-specific antibodies may also be made by engineering electrostatic steering effects for making antibody Fe-heterodimeric molecules (WO 2009/089004); cross-linking two or more antibodies or fragments (see, e.g., US 4,676,980, and Brennan, M., et al., Science 229 (1985) 81-83); using leucine zippers to produce bi-specific

Engineered antibodies with three or more functional antigen binding sites, including “Octopus antibodies,” are also included herein (see, e.g. US 2006/0025576).

The antibody or fragment herein also includes a “Dual Acting Fab” or “DAF” comprising an antigen binding site that binds to biotin as well as another, different antigen (see, US 2008/0069820, for example).

5. Antibody Variants

In certain embodiments, amino acid sequence variants of the antibodies provided herein are contemplated. For example, it may be desirable to improve the binding affinity and/or other biological properties of the antibody. Amino acid sequence variants of an antibody may be prepared by introducing appropriate modifications into the nucleotide sequence encoding the antibody, or by peptide synthesis. Such modifications include, for example, deletions from, and/or insertions into and/or substitutions of residues within the amino acid sequences of the antibody. Any combination of deletion, insertion, and substitution can be made to arrive at the final construct, provided that the final construct possesses the desired characteristics, e.g., antigen-binding.

a) Substitution, Insertion, and Deletion Variants

In certain embodiments, antibody variants having one or more amino acid substitutions are provided. Sites of interest for substitutional mutagenesis include the HVRs and FRs. Conservative substitutions are shown in Table 1 under the heading of "preferred substitutions". More substantial changes are provided in
Table 1 under the heading of "exemplary substitutions," and as further described below in reference to amino acid side chain classes. Amino acid substitutions may be introduced into an antibody of interest and the products screened for a desired activity, e.g., retained/improved antigen binding, decreased immunogenicity, or improved ADCC or CDC.

Amino acids may be grouped according to common side-chain properties:

1. hydrophobic: Norleucine, Met, Ala, Val, Leu, Ile;
2. neutral hydrophilic: Cys, Ser, Thr, Asn, Gln;
3. acidic: Asp, Glu;
(4) basic: His, Lys, Arg;
(5) residues that influence chain orientation: Gly, Pro;
(6) aromatic: Trp, Tyr, Phe.

Non-conservative substitutions will entail exchanging a member of one of these classes for another class.

One type of substitutitional variant involves substituting one or more hypervariable region residues of a parent antibody (e.g. a humanized or human antibody). Generally, the resulting variant(s) selected for further study will have modifications (e.g., improvements) in certain biological properties (e.g., increased affinity, reduced immunogenicity) relative to the parent antibody and/or will have substantially retained certain biological properties of the parent antibody. An exemplary substitutional variant is an affinity matured antibody, which may be conveniently generated, e.g., using phage display-based affinity maturation techniques such as those described herein. Briefly, one or more HVR residues are mutated and the variant antibodies displayed on phage and screened for a particular biological activity (e.g. binding affinity).

Alterations (e.g., substitutions) may be made in HVRs, e.g., to improve antibody affinity. Such alterations may be made in HVR “hotspots,” i.e., residues encoded by codons that undergo mutation at high frequency during the somatic maturation process (see, e.g., Chowdhury, P.S., Methods Mol. Biol. 207 (2008) 179-196), and/or SDRs (a-CDRs), with the resulting variant VH or VL being tested for binding affinity. Affinity maturation by constructing and reselecting from secondary libraries has been described, e.g., in Hoogenboom, H.R., et al. in Methods in Molecular Biology 178 (2002) 1-37. In some embodiments of affinity maturation, diversity is introduced into the variable genes chosen for maturation by any of a variety of methods (e.g., error-prone PCR, chain shuffling, or oligonucleotide-directed mutagenesis). A secondary library is then created. The library is then screened to identify any antibody variants with the desired affinity. Another method to introduce diversity involves HVR-directed approaches, in which several HVR residues (e.g., 4-6 residues at a time) are randomized. HVR residues involved in antigen binding may be specifically identified, e.g., using alanine scanning mutagenesis or modeling. CDR-H3 and CDR-L3 in particular are often targeted.
In certain embodiments, substitutions, insertions, or deletions may occur within one or more HVRs so long as such alterations do not substantially reduce the ability of the antibody to bind antigen. For example, conservative alterations (e.g., conservative substitutions as provided herein) that do not substantially reduce binding affinity may be made in HVRs. Such alterations may be outside of HVR “hotspots” or SDRs. In certain embodiments of the variant VH and VL sequences provided above, each HVR either is unaltered, or contains no more than one, two or three amino acid substitutions.

A useful method for identification of residues or regions of an antibody that may be targeted for mutagenesis is called "alanine scanning mutagenesis" as described by Cunningham, B.C. and Wells, J.A., Science 244 (1989) 1081-1085. In this method, a residue or group of target residues (e.g., charged residues such as arg, asp, his, lys, and glu) are identified and replaced by a neutral or negatively charged amino acid (e.g., alanine or polyalanine) to determine whether the interaction of the antibody with antigen is affected. Further substitutions may be introduced at the amino acid locations demonstrating functional sensitivity to the initial substitutions. Alternatively, or additionally, a crystal structure of an antigen-antibody complex to identify contact points between the antibody and antigen. Such contact residues and neighboring residues may be targeted or eliminated as candidates for substitution. Variants may be screened to determine whether they contain the desired properties.

Amino acid sequence insertions include amino- and/or carboxyl-terminal fusions ranging in length from one residue to polypeptides containing a hundred or more residues, as well as intrasequence insertions of single or multiple amino acid residues. Examples of terminal insertions include an antibody with an N-terminal methionyl residue. Other insertional variants of the antibody molecule include the fusion to the N- or C-terminus of the antibody to an enzyme (e.g. for ADEPT) or a polypeptide which increases the serum half-life of the antibody.

One preferred variant is a single cysteine variant wherein the amino acid residue at position 53 according to Kabat in the heavy chain variable domain is cysteine.

b) Glycosylation variants

In certain embodiments, an antibody provided herein is altered to increase or decrease the extent to which the antibody is glycosylated. Addition or deletion of glycosylation sites to an antibody may be conveniently accomplished by altering
the amino acid sequence such that one or more glycosylation sites is created or removed.

Where the antibody comprises an Fc-region, the carbohydrate attached thereto may be altered. Native antibodies produced by mammalian cells typically comprise a branched, biantennary oligosaccharide that is generally attached by an N-linkage to Asn297 of the CH2 domain of the Fc-region. See, e.g., Wright, A. and Morrison, S.L., TIBTECH 15 (1997) 26-32. The oligosaccharide may include various carbohydrates, e.g., mannose, N-acetyl glucosamine (GlcNAc), galactose, and sialic acid, as well as a fucose attached to a GlcNAc in the “stem” of the biantennary oligosaccharide structure. In some embodiments, modifications of the oligosaccharide in an antibody of the invention may be made in order to create antibody variants with certain improved properties.

In one embodiment, antibody variants are provided having a carbohydrate structure that lacks fucose attached (directly or indirectly) to an Fc-region. For example, the amount of fucose in such antibody may be from 1% to 80%, from 1% to 65%, from 5% to 65% or from 20% to 40%. The amount of fucose is determined by calculating the average amount of fucose within the sugar chain at Asn297, relative to the sum of all glycostructures attached to Asn 297 (e. g. complex, hybrid and high mannose structures) as measured by MALDI-TOF mass spectrometry, as described in WO 2008/077546, for example. Asn297 refers to the asparagine residue located at about position 297 in the Fc-region (EU numbering of Fc-region residues); however, Asn297 may also be located about ± 3 amino acids upstream or downstream of position 297, i.e., between positions 294 and 300, due to minor sequence variations in antibodies. Such fucosylation variants may have improved ADCC function. See, e.g., US 2003/0157108; US 2004/0093621. Examples of publications related to “defucosylated” or “fucose-deficient” antibody variants include: US 2003/0157108; WO 2000/61739; WO 2001/29246; US 2003/0115614; US 2002/0164328; US 2004/0093621; US 2004/0132140; US 2004/0110704; US 2004/0110282; US 2004/0109865; WO 2003/085119; WO 2003/084570; WO 2005/035586; WO 2005/035778; WO 2005/053742; WO 2002/031140; Okazaki, A., et al., J. Mol. Biol. 336 (2004) 1239-1249; Yamane-Ohnuki, N., et al., Biotech. Bioeng. 87 (2004) 614-622. Examples of cell lines capable of producing defucosylated antibodies include Lec13 CHO cells deficient in protein fucosylation (Ripka, J., et al., Arch. Biochem. Biophys. 249 (1986) 533-545; US 2003/0157108; and WO 2004/056312, especially at Example 11), and knockout cell lines, such as alpha-1,6-fucosyltransferase gene, FUT8, knockout CHO cells (see, e.g., Yamane-
Antibodies variants are further provided with bisected oligosaccharides, e.g., in which a biantennary oligosaccharide attached to the Fc-region of the antibody is bisected by GlcNAc. Such antibody variants may have reduced fucosylation and/or improved ADCC function. Examples of such antibody variants are described, e.g., in WO 2003/011878; US 6,602,684; and US 2005/0123546. Antibody variants with at least one galactose residue in the oligosaccharide attached to the Fc-region are also provided. Such antibody variants may have improved CDC function. Such antibody variants are described, e.g., in WO 1997/30087; WO 1998/58964; and WO 1999/22764.

c) Fc-region variants

In certain embodiments, one or more amino acid modifications may be introduced into the Fc-region of an antibody provided herein, thereby generating an Fc-region variant. The Fc-region variant may comprise a human Fc-region sequence (e.g., a human IgG1, IgG2, IgG3 or IgG4 Fc-region) comprising an amino acid modification (e.g. a substitution) at one or more amino acid positions.

In certain embodiments, the invention contemplates an antibody variant that possesses some but not all effector functions, which make it a desirable candidate for applications in which the half-life of the antibody in vivo is important yet certain effector functions (such as complement and ADCC) are unnecessary or deleterious. In vitro and/or in vivo cytotoxicity assays can be conducted to confirm the reduction/depletion of CDC and/or ADCC activities. For example, Fe receptor (FcR) binding assays can be conducted to ensure that the antibody lacks FcγR binding (hence likely lacking ADCC activity), but retains FcRn binding ability. The primary cells for mediating ADCC, NK cells, express Fc(RIII only, whereas monocytes express FcγRI, FcγRII and FcγRIII. FcR expression on hematopoietic cells is summarized in Table 3 on page 464 of Ravetch, J.V. and Kinet, J.P., Annu. Rev. Immunol. 9 (1991) 457-492. Non-limiting examples of in vitro assays to assess ADCC activity of a molecule of interest is described in US 5,500,362 (see, e.g. Hellstrom, I., et al., Proc. Natl. Acad. Sci. USA 83 (1986) 7059-7063; and Hellstrom, I., et al., Proc. Natl. Acad. Sci. USA 82 (1985) 1499-1502); US 5,821,337 (see Bruggemann, M., et al., J. Exp. Med. 166 (1987) 1351-1361). Alternatively, non-radioactive assays methods may be employed (see, for example,
ACTI™ non-radioactive cytotoxicity assay for flow cytometry (CellTechnology, Inc. Mountain View, CA; and CytoTox 96® non-radioactive cytotoxicity assay (Promega, Madison, WI). Useful effector cells for such assays include peripheral blood mononuclear cells (PBMC) and Natural Killer (NK) cells. Alternatively, or additionally, ADCC activity of the molecule of interest may be assessed in vivo, e.g., in an animal model such as that disclosed in Clynes, R., et al., Proc. Natl. Acad. Sci. USA 95 (1998) 652-656. C1q binding assays may also be carried out to confirm that the antibody is unable to bind C1q and hence lacks CDC activity. See, e.g., C1q and C3c binding ELISA in WO 2006/029879 and WO 2005/100402. To assess complement activation, a CDC assay may be performed (see, for example, Gazzano-Santoro, H., et al., J. Immunol. Methods 202 (1996) 163-171; Cragg, M.S., et al., Blood 101 (2003) 1045-1052; and Cragg, M.S. and M.J. Glennie, Blood 103 (2004) 2738-2743). FcRn binding and in vivo clearance/half-life determinations can also be performed using methods known in the art (see, e.g., Petkova, S.B., et al., Int. Immunol. 18 (2006) 1759-1769).

Antibodies with reduced effector function include those with substitution of one or more of Fc-region residues 238, 265, 269, 270, 297, 327 and 329 (US 6,737,056). Such Fc mutants include Fc mutants with substitutions at two or more of amino acid positions 265, 269, 270, 297 and 327, including the so-called “DANA” Fc mutant with substitution of residues 265 and 297 to alanine (US 7,332,581).

In certain embodiments, an antibody variant comprises an Fc-region with one or more amino acid substitutions which improve ADCC, e.g., substitutions at positions 298, 333, and/or 334 of the Fc-region (EU numbering of residues).

In some embodiments, alterations are made in the Fc-region that result in altered (i.e., either improved or diminished) C1q binding and/or Complement Dependent Cytotoxicity (CDC), e.g., as described in US 6,194,551, WO 99/51642, and Idusogie, E.E., et al., J. Immunol. 164 (2000) 4178-4184.

Antibodies with increased half-lives and improved binding to the neonatal Fc receptor (FcRn), which is responsible for the transfer of maternal IgGs to the fetus (Guyer, R.L., et al., J. Immunol. 117 (1976) 587-593, and Kim, J.K., et al., J. Immunol. 24 (1994) 2429-2434), are described in US 2005/0014934. Those
antibodies comprise an Fc-region with one or more substitutions therein which improve binding of the Fc-region to FcRn. Such Fc variants include those with substitutions at one or more of Fc-region residues: 238, 256, 265, 272, 286, 303, 305, 307, 311, 312, 317, 340, 356, 360, 362, 376, 378, 380, 382, 413, 424 or 434, e.g., substitution of Fc-region residue 434 (US 7,371,826).

d) Cysteine engineered antibody variants

In certain embodiments, it may be desirable to create cysteine engineered antibodies, e.g., “thioMAbs,” in which one or more residues of an antibody are substituted with cysteine residues. In particular embodiments, the substituted residues occur at accessible sites of the antibody. By substituting those residues with cysteine, reactive thiol groups are thereby positioned at accessible sites of the antibody and may be used to conjugate the antibody to other moieties, such as drug moieties or linker-drug moieties, to create an immunoconjugate, as described further herein. In certain embodiments, any one or more of the following residues may be substituted with cysteine: V205 (Kabat numbering) of the light chain; A118 (EU numbering) of the heavy chain; and S400 (EU numbering) of the heavy chain Fc-region. Cysteine engineered antibodies may be generated as described, e.g., in US 7,521,541.

e) Antibody Derivatives

In certain embodiments, an antibody provided herein may be further modified to contain additional non-proteinaceous moieties that are known in the art and readily available. The moieties suitable for derivatization of the antibody include but are not limited to water soluble polymers. Non-limiting examples of water soluble polymers include, but are not limited to, polyethylene glycol (PEG), copolymers of ethylene glycol/propylene glycol, carboxymethylcellulose, dextran, polyvinyl alcohol, polyvinyl pyrrolidone, poly-1, 3-dioxolane, poly-1,3,6-trioxane, ethylene/maleic anhydride copolymer, polyaminoacids (either homopolymers or random copolymers), and dextran or poly(n-vinyl pyrrolidone)polyethylene glycol, propylene glycol homopolymers, propylene oxide/ethylene oxide co-polymers, polyoxyethylated polyols (e.g., glycerol), polyvinyl alcohol, and mixtures thereof. Polyethylene glycol propionaldehyde may have advantages in manufacturing due to its stability in water. The polymer may be of any molecular
weight, and may be branched or unbranched. The number of polymers attached to the antibody may vary, and if more than one polymer is attached, they can be the same or different molecules. In general, the number and/or type of polymers used for derivatization can be determined based on considerations including, but not limited to, the particular properties or functions of the antibody to be improved, whether the antibody derivative will be used in a therapy under defined conditions, etc.

In another embodiment, conjugates of an antibody and non-proteinaceous moiety that may be selectively heated by exposure to radiation are provided. In one embodiment, the non-proteinaceous moiety is a carbon nanotube (Kam, N.W., et al., Proc. Natl. Acad. Sci. USA 102 (2005) 11600-11605). The radiation may be of any wavelength, and includes, but is not limited to, wavelengths that do not harm ordinary cells, but which heat the non-proteinaceous moiety to a temperature at which cells proximal to the antibody-non-proteinaceous moiety are killed.

**B. Recombinant Methods and Compositions**

Antibodies may be produced using recombinant methods and compositions, e.g., as described in US 4,816,567. In one embodiment, isolated nucleic acid encoding an anti-biotin antibody described herein is provided. Such nucleic acid may encode an amino acid sequence comprising the VL and/or an amino acid sequence comprising the VH of the antibody (e.g., the light and/or heavy chains of the antibody). In a further embodiment, one or more vectors (e.g., expression vectors) comprising such nucleic acid are provided. In a further embodiment, a host cell comprising such nucleic acid is provided. In one such embodiment, a host cell comprises (e.g., has been transformed with): (1) a vector comprising a nucleic acid that encodes an amino acid sequence comprising the VL of the antibody and an amino acid sequence comprising the VH of the antibody, or (2) a first vector comprising a nucleic acid that encodes an amino acid sequence comprising the VL of the antibody and a second vector comprising a nucleic acid that encodes an amino acid sequence comprising the VH of the antibody. In one embodiment, the host cell is eukaryotic, e.g. a Chinese Hamster Ovary (CHO) cell or lymphoid cell (e.g., Y0, NS0, Sp20 cell). In one embodiment, a method of making an anti-biotin antibody is provided, wherein the method comprises culturing a host cell comprising a nucleic acid encoding the antibody, as provided above, under conditions suitable for expression of the antibody, and optionally recovering the antibody from the host cell (or host cell culture medium).
For recombinant production of an anti-biotin antibody, nucleic acid encoding an antibody, e.g., as described above, is isolated and inserted into one or more vectors for further cloning and/or expression in a host cell. Such nucleic acid may be readily isolated and sequenced using conventional procedures (e.g., by using oligonucleotide probes that are capable of binding specifically to genes encoding the heavy and light chains of the antibody).

Suitable host cells for cloning or expression of antibody-encoding vectors include prokaryotic or eukaryotic cells described herein. For example, antibodies may be produced in bacteria, in particular when glycosylation and Fc effector function are not needed. For expression of antibody fragments and polypeptides in bacteria, see, e.g., US 5,648,237, US 5,789,199, and US 5,840,523. (See also Charlton, K.A., In: Methods in Molecular Biology, Vol. 248, Lo, B.K.C. (ed.), Humana Press, Totowa, NJ (2003), pp. 245-254, describing expression of antibody fragments in E. coli.) After expression, the antibody may be isolated from the bacterial cell paste in a soluble fraction and can be further purified.

In addition to prokaryotes, eukaryotic microbes such as filamentous fungi or yeast are suitable cloning or expression hosts for antibody-encoding vectors, including fungi and yeast strains whose glycosylation pathways have been “humanized,” resulting in the production of an antibody with a partially or fully human glycosylation pattern. See Gerngross, T.U., Nat. Biotech. 22 (2004) 1409-1414; and Li, H., et al., Nat. Biotech. 24 (2006) 210-215.

Suitable host cells for the expression of glycosylated antibody are also derived from multicellular organisms (invertebrates and vertebrates). Examples of invertebrate cells include plant and insect cells. Numerous baculoviral strains have been identified which may be used in conjunction with insect cells, particularly for transfection of Spodoptera frugiperda cells.

Plant cell cultures can also be utilized as hosts. See, e.g., US 5,959,177; US 6,040,498; US 6,420,548; US 7,125,978; US 6,417,429 (describing PLANTIBODIES™ technology for producing antibodies in transgenic plants).

Vertebrate cells may also be used as hosts. For example, mammalian cell lines that are adapted to grow in suspension may be useful. Other examples of useful mammalian host cell lines are monkey kidney CV1 line transformed by SV40 (COS-7); human embryonic kidney line (293 or 293 cells as described, e.g., in Graham, F.L., et al., J. Gen Virol. 36 (1977) 59-74); baby hamster kidney cells
(BHK); mouse sertoli cells (TM4 cells as described, e.g., in Mather, J.P., Biol.
Reprod. 23 (1980) 243-252); monkey kidney cells (CV1); African green monkey
kidney cells (VERO-76); human cervical carcinoma cells (HELA); canine kidney
cells (MDCK); buffalo rat liver cells (BRL 3A); human lung cells (W138); human
liver cells (Hep G2); mouse mammary tumor (MMT 060562); TRI cells, as
MRC 5 cells; and FS4 cells. Other useful mammalian host cell lines include
Chinese hamster ovary (CHO) cells, including DHFR CHO cells (Urlaub, G., et
al., Proc. Natl. Acad. Sci. USA 77 (1980) 4216-4220); and myeloma cell lines such
as Y0, NS0 and Sp2/0. For a review of certain mammalian host cell lines suitable
for antibody production, see, e.g., Yazaki, P. and Wu, A.M., Methods in Molecular
268.

C. Assays

Anti-biotin antibodies provided herein may be identified, screened for, or
characterized for their physical/chemical properties and/or biological activities by
various assays known in the art.

Binding assays and other assays

In one aspect, an antibody of the invention is tested for its antigen binding activity,
e.g., by known methods such as ELISA, Western blot, etc.

In another aspect, competition assays may be used to identify an antibody that
competes with the antibodies as reported herein for binding to biotin.

In an exemplary competition assay, immobilized biotin is incubated in a solution
comprising a first labeled antibody that binds to biotin and a second unlabeled
antibody that is being tested for its ability to compete with the first antibody for
binding to biotin. The second antibody may be present in a hybridoma supernatant.
As a control, immobilized biotin is incubated in a solution comprising the first
labeled antibody but not the second unlabeled antibody. After incubation under
conditions permissive for binding of the first antibody to biotin, excess unbound
antibody is removed, and the amount of label associated with immobilized biotin is
measured. If the amount of label associated with immobilized biotin is substantially
reduced in the test sample relative to the control sample, then that indicates that the
second antibody is competing with the first antibody for binding to biotin. See

D. Immunoconjugates

The invention also provides immunoconjugates comprising an anti-biotin antibody herein conjugated to one or more cytotoxic agents, such as chemotherapeutic agents or drugs, growth inhibitory agents, toxins (e.g., protein toxins, enzymatically active toxins of bacterial, fungal, plant, or animal origin, or fragments thereof), or radioactive isotopes.

In another embodiment, an immunoconjugate comprises an antibody as described herein conjugated to an enzymatically active toxin or fragment thereof, including but not limited to diphtheria A chain, nonbinding active fragments of diphtheria toxin, exotoxin A chain (from Pseudomonas aeruginosa), ricin A chain, abrin A chain, modeccin A chain, alpha-sarcin, Aleurites fordii proteins, dianthin proteins, Phytolaca americana proteins (PAPI, PAPII, and PAP-S), momordica charantia inhibitor, curcin, crotin, sapoanaria officinalis inhibitor, gelonin, mitogellin, restrictocin, phenomycin, enomycin, and the tricothecenes.
In another embodiment, an immunoconjugate comprises an antibody as described herein conjugated to a radioactive atom to form a radioconjugate. A variety of radioactive isotopes are available for the production of radioconjugates. Examples include At$^{211}$, I$^{131}$, I$^{125}$, Y$^{90}$, Re$^{186}$, Re$^{188}$, Sm$^{153}$, Bi$^{212}$, P$^{32}$, Pb$^{212}$ and radioactive isotopes of Lu. When the radioconjugate is used for detection, it may comprise a radioactive atom for scintigraphic studies, for example TC$^{99m}$ or I$^{123}$, or a spin label for nuclear magnetic resonance (NMR) imaging (also known as magnetic resonance imaging, MRI), such as iodine-123 again, iodine-131, indium-111, fluorine-19, carbon-13, nitrogen-15, oxygen-17, gadolinium, manganese or iron.

Conjugates of an antibody and cytotoxic agent may be made using a variety of bifunctional protein coupling agents such as N-succinimidyl-3-(2-pyridyldithio) propionate (SPDP), succinimidyl-4-(N-maleimidomethyl) cyclohexane-1-carboxylate (SMCC), iminothiolane (IT), bifunctional derivatives of imidoesters (such as dimethyl adipimide HCl), active esters (such as disuccinimidyl suberate), aldehydes (such as glutaraldehyde), bis-azo compounds (such as bis (p-azidobenzoyl) hexanediamine), bis-diazoimium derivatives (such as bis-(p-diazoniumbenzoyl)-ethylenediamine), diisocyanates (such as toluene 2,6-diisocyanate), and bis-active fluorine compounds (such as 1,5-difluoro-2,4-dinitrobenzene). For example, a ricin immunotoxin can be prepared as described in Vitetta, E.S., et al., Science 238 (1987) 1098-1104. Carbon-14-labeled 1-isothiocyanatobenzyl-3-methylidioethylene triamine pentaacetic acid (MX-DTPA) is an exemplary chelating agent for conjugation of radionuclide to the antibody. See WO 94/11026. The linker may be a “cleavable linker” facilitating release of a cytotoxic drug in the cell. For example, an acid-labile linker, peptidase-sensitive linker, photolabile linker, dimethyl linker or disulfide-containing linker (Chari, R.V., et al., Cancer Res. 52 (1992) 127-131; US 5,208,020) may be used.

The immunoconjugates or ADCs herein expressly contemplate, but are not limited to such conjugates prepared with cross-linker reagents including, but not limited to, BMPS, EMCS, GMBS, HBVS, LC-SMCC, MBS, MPBH, SBAP, SIA, SIAB, SMCC, SMPB, SMPH, sulfo-EMCS, sulfo-GMBS, sulfo-KMUS, sulfo-MBS, sulfo-SIAB, sulfo-SMCC, and sulfo-SMPB, and SVSB (succinimidyl-(4-vinylsulfone)benzoate) which are commercially available (e.g., from Pierce Biotechnology, Inc., Rockford, IL, U.S.A.).
E. Methods and Compositions for Diagnostics and Detection

The term “detecting” as used herein encompasses quantitative or qualitative detection.

In one embodiment, an anti-biotin antibody for use in a method of diagnosis or detection is provided. Such method may be an in vitro or in vivo method.

In certain embodiments, labeled anti-biotin antibodies are provided. Labels include, but are not limited to, labels or moieties that are detected directly (such as fluorescent, chromophoric, electron-dense, chemiluminescent, and radioactive labels), as well as moieties, such as enzymes or ligands, that are detected indirectly, e.g., through an enzymatic reaction or molecular interaction. Exemplary labels include, but are not limited to, the radioisotopes $^{32}$P, $^{14}$C, $^{125}$I, $^{3}$H, and $^{131}$I, fluorophores such as rare earth chelates or fluorescein and its derivatives, rhodamine and its derivatives, dansyl, umbelliferone, luciferases, e.g., firefly luciferase and bacterial luciferase (US 4,737,456), luciferin, 2,3-dihydrophthalazinesediones, horseradish peroxidase (HRP), alkaline phosphatase, β-galactosidase, glucoamylase, lysozyme, saccharide oxidases, e.g., glucose oxidase, galactose oxidase, and glucose-6-phosphate dehydrogenase, heterocyclic oxidases such as uricase and xanthine oxidase, coupled with an enzyme that employs hydrogen peroxide to oxidize a dye precursor such as HRP, lactoperoxidase, or microperoxidase, biotin/avidin, spin labels, bacteriophage labels, stable free radicals, and the like.

F. Pharmaceutical Formulations

Pharmaceutical formulations of an anti-biotin antibody as described herein are prepared by mixing such antibody having the desired degree of purity with one or more optional pharmaceutically acceptable carriers (Osol, A. (ed.) Remington's Pharmaceutical Sciences, 16th edition (1980)), in the form of lyophilized formulations or aqueous solutions. Pharmaceutically acceptable carriers are generally nontoxic to recipients at the dosages and concentrations employed, and include, but are not limited to: buffers such as phosphate, citrate, and other organic acids; antioxidants including ascorbic acid and methionine; preservatives (such as octadecyl dimethylbenzyl ammonium chloride; hexamethonium chloride; benzalkonium chloride; benzethonium chloride; phenol, butyl or benzyl alcohol; alkyl parabens such as methyl or propyl paraben; catechol; resorcinol; cyclohexanol; 3-pentanol; and m-cresol); low molecular weight (less than about 10
residues) polypeptides; proteins, such as serum albumin, gelatin, or immunoglobulins; hydrophilic polymers such as poly(vinylpyrrolidone); amino acids such as glycine, glutamine, asparagine, histidine, arginine, or lysine; monosaccharides, disaccharides, and other carbohydrates including glucose, mannose, or dextrins; chelating agents such as EDTA; sugars such as sucrose, mannitol, trehalose or sorbitol; salt-forming counter-ions such as sodium; metal complexes (e.g. Zn-protein complexes); and/or non-ionic surfactants such as polyethylene glycol (PEG). Exemplary pharmaceutically acceptable carriers herein further include interstitial drug dispersion agents such as soluble neutral-active hyaluronidase glycoproteins (sHASEGP), for example, human soluble PH-20 hyaluronidase glycoproteins, such as rhuPH20 (HYLENEX®, Baxter International, Inc.). Certain exemplary sHASEGP and methods of use, including rhuPH20, are described in US 2005/0260186 and US 2006/0104968. In one aspect, a sHASEGP is combined with one or more additional glycosaminoglycanases such as chondroitinases.

Exemplary lyophilized antibody formulations are described in US 6,267,958. Aqueous antibody formulations include those described in US 6,171,586 and WO 2006/044908, the latter formulations including a histidine-acetate buffer.

The formulation herein may also contain more than one active ingredients as necessary for the particular indication being treated, preferably those with complementary activities that do not adversely affect each other. For example, it may be desirable to further provide [[list drugs that might be combined with the anti-biotin antibody]]. Such active ingredients are suitably present in combination in amounts that are effective for the purpose intended.

Active ingredients may be entrapped in microcapsules prepared, for example, by coacervation techniques or by interfacial polymerization, for example, hydroxymethylcellulose or gelatin-microcapsules and poly-(methyl methacrylate) microcapsules, respectively, in colloidal drug delivery systems (for example, liposomes, albumin microspheres, microemulsions, nano-particles and nanocapsules) or in macroemulsions. Such techniques are disclosed in Remington's Pharmaceutical Sciences, 16th edition, Osol, A. (ed.) (1980).

Sustained-release preparations may be prepared. Suitable examples of sustained-release preparations include semi-permeable matrices of solid hydrophobic
polymers containing the antibody, which matrices are in the form of shaped articles, e.g. films, or microcapsules.

The formulations to be used for in vivo administration are generally sterile. Sterility may be readily accomplished, e.g., by filtration through sterile filtration membranes.

**G. Therapeutic Methods and Compositions**

Any of the anti-biotin antibodies provided herein may be used in therapeutic methods.

In one aspect, an anti-biotin antibody for use as a medicament is provided. In certain embodiments, an anti-biotin antibody for use in a method of treatment is provided.

In a further aspect, the invention provides for the use of an anti-biotin antibody in the manufacture or preparation of a medicament.

In a further aspect, the invention provides pharmaceutical formulations comprising any of the anti-biotin antibodies provided herein. In one embodiment, a pharmaceutical formulation comprises any of the anti-biotin antibodies provided herein and a pharmaceutically acceptable carrier.

Antibodies of the invention can be used either alone or in combination with other agents in a therapy. For instance, an antibody of the invention may be co-administered with at least one additional therapeutic agent.

Such combination therapies noted above encompass combined administration (where two or more therapeutic agents are included in the same or separate formulations), and separate administration, in which case, administration of the antibody of the invention can occur prior to, simultaneously, and/or following, administration of the additional therapeutic agent and/or adjuvant. Antibodies of the invention can also be used in combination with radiation therapy.

An antibody of the invention (and any additional therapeutic agent) can be administered by any suitable means, including parenteral, intrapulmonary, and intranasal, and, if desired for local treatment, intralesional administration. Parenteral infusions include intramuscular, intravenous, intraarterial, intraperitoneal, or subcutaneous administration. Dosing can be by any suitable
route, e.g. by injections, such as intravenous or subcutaneous injections, depending in part on whether the administration is brief or chronic. Various dosing schedules including but not limited to single or multiple administrations over various time-points, bolus administration, and pulse infusion are contemplated herein.

Antibodies of the invention would be formulated, dosed, and administered in a fashion consistent with good medical practice. Factors for consideration in this context include the particular disorder being treated, the particular mammal being treated, the clinical condition of the individual patient, the cause of the disorder, the site of delivery of the agent, the method of administration, the scheduling of administration, and other factors known to medical practitioners. The antibody need not be, but is optionally formulated with one or more agents currently used to prevent or treat the disorder in question. The effective amount of such other agents depends on the amount of antibody present in the formulation, the type of disorder or treatment, and other factors discussed above. These are generally used in the same dosages and with administration routes as described herein, or about from 1 to 99% of the dosages described herein, or in any dosage and by any route that is empirically/clinically determined to be appropriate.

For the prevention or treatment of disease, the appropriate dosage of an antibody of the invention (when used alone or in combination with one or more other additional therapeutic agents) will depend on the type of disease to be treated, the type of antibody, the severity and course of the disease, whether the antibody is administered for preventive or therapeutic purposes, previous therapy, the patient's clinical history and response to the antibody, and the discretion of the attending physician. The antibody is suitably administered to the patient at one time or over a series of treatments. Depending on the type and severity of the disease, about 1 μg/kg to 15 mg/kg (e.g. 0.5 mg/kg - 10 mg/kg) of antibody can be an initial candidate dosage for administration to the patient, whether, for example, by one or more separate administrations, or by continuous infusion. One typical daily dosage might range from about 1 μg/kg to 100 mg/kg or more, depending on the factors mentioned above. For repeated administrations over several days or longer, depending on the condition, the treatment would generally be sustained until a desired suppression of disease symptoms occurs. One exemplary dosage of the antibody would be in the range from about 0.05 mg/kg to about 10 mg/kg. Thus, one or more doses of about 0.5 mg/kg, 2.0 mg/kg, 4.0 mg/kg or 10 mg/kg (or any combination thereof) may be administered to the patient. Such doses may be administered intermittently, e.g. every week or every three weeks (e.g. such that
the patient receives from about two to about twenty, or e.g. about six doses of the antibody). An initial higher loading dose, followed by one or more lower doses may be administered. The progress of this therapy is easily monitored by conventional techniques and assays.

It is understood that any of the above formulations or therapeutic methods may be carried out using an immunoconjugate of the invention in place of or in addition to an anti-biotin antibody.

III. Articles of Manufacture

In another aspect of the invention, an article of manufacture containing materials useful for the treatment, prevention and/or diagnosis of the disorders described above is provided. The article of manufacture comprises a container and a label or package insert on or associated with the container. Suitable containers include, for example, bottles, vials, syringes, IV solution bags, etc. The containers may be formed from a variety of materials such as glass or plastic. The container holds a composition which is by itself or combined with another composition effective for treating, preventing and/or diagnosing the condition and may have a sterile access port (for example the container may be an intravenous solution bag or a vial having a stopper pierceable by a hypodermic injection needle). At least one active agent in the composition is an antibody of the invention. The label or package insert indicates that the composition is used for treating the condition of choice.

Moreover, the article of manufacture may comprise (a) a first container with a composition contained therein, wherein the composition comprises an antibody of the invention; and (b) a second container with a composition contained therein, wherein the composition comprises a further cytotoxic or otherwise therapeutic agent. The article of manufacture in this embodiment of the invention may further comprise a package insert indicating that the compositions can be used to treat a particular condition. Alternatively, or additionally, the article of manufacture may further comprise a second (or third) container comprising a pharmaceutically-acceptable buffer, such as bacteriostatic water for injection (BWFI), phosphate-buffered saline, Ringer's solution and dextrose solution. It may further include other materials desirable from a commercial and user standpoint, including other buffers, diluents, filters, needles, and syringes.
It is understood that any of the above articles of manufacture may include an immunonoconjugate of the invention in place of or in addition to an anti-biotin antibody.

IV. EXAMPLES

The following are examples of methods and compositions of the invention. It is understood that various other embodiments may be practiced, given the general description provided above.

Example 1

**Isolation and characterization of cDNAs encoding the VH and VL domains of a murine anti-biotin antibody of IgG1 class with kappa light chain from mouse hybridoma**

The protein and (DNA) sequence information of the VH and VL domains of the murine hapten-biotin antibody was obtained directly from hybridoma clones. The experimental steps performed subsequently were (i) the isolation of RNA from antibody producing hybridoma cells, (ii) conversion of this RNA into cDNA, the transfer into VH and VL harboring PCR fragments, and (iii) integration of these PCR fragments into plasmids vectors for propagation in E.coli and determination of their DNA (and deduced protein) sequences.

**RNA preparation from hybridoma cells:**

RNA was prepared from $5 \times 10^6$ antibody expressing hybridoma cells applying the RNeasy-Kit (Qiagen). Briefly, the sedimented cells were washed once in PBS and sedimented and subsequently resuspended for lysis in 500 µl RLT-Puffer (+ß-ME). The cells were completely lysed by passing through a Qiashredder (Qiagen) and then subjected to the matrix-mediated purification procedure (ETOH, RNeasy columns) as described in the manufacturer’s manual. After the last washing step, RNA was recovered from the columns in 50 µl RNase-free water. The concentration of the recovered RNA was determined by quantify A260 and A280 of 1:20 diluted samples. The integrity (quality, degree of degradation) of the isolated RNA samples was analyzed by denaturing RNA gel electrophoresis on Formamide-Agarose gels (see Maniatis Manual). Discrete bands representing the intact 18s and 28 s ribosomal RNAs were obtained and intactness (and approx. 2:1 intensity ratios) of these bands indicated a good quality of the RNA preparations. The isolated RNAs from hybridoma were frozen and stored at -80 C in aliquots.
Generation of DNA fragments encoding VH and VH by RACE PCR, cloning of these DNA fragments into plasmids and determination of their DNA- and amino acid sequences:

The cDNA for subsequent (RACE-) PCR reactions were prepared from RNA preparations by applying the technologies as described in International patent application PCT/EP2011/074273. Subsequently, the VH and VL-encoding PCR fragments were isolated by agarose gel extraction and subsequent purification by standard molecular biology techniques. PWO-generated purified PCR fragments were inserted into the vector pCR bluntII topo by applying the pCR bluntII topo Kit (Invitrogen) exactly following the manufacturer’s instructions. The Topo-ligation reactions were transformed into E.coli Topo10-one-shot competent cells. Thereafter, E.coli clones that contained vectors with either VL- or VH containing inserts were identified as colonies on LB-Kanamycin agar plates. Plasmids were prepared from these colonies and the presence of the desired insert in the vector was confirmed by restriction digestion with EcoRI. Because the vector backbone contains EcoRI restriction recognition sites flanking each side of the insert, plasmids harboring inserts were defined by having EcoRI-releasable inserts of approx. 800bp (for VL) or 600 bp (for VH). The DNA sequence and the deduced protein sequence of the VL and VH were determined by automated DNA sequencing on multiple clones for VH and VL.

The murine VL sequence of the anti-biotin antibody is depicted in SEQ ID NO: 08. The murine VH sequence of the anti-biotin antibody is depicted in SEQ ID NO: 04.

**Example 2**

**Humanization of the VH and VL domains of murine anti-biotin antibody**

The murine biotin-binding antibody muM33 was humanized as follows: The generation and characterization of encoding sequences and amino acid sequences that comprise the VH and VL domains of a murine anti-biotin antibody of the IgG1 class with kappa light chain from mouse hybridoma are described in WO 2011/003557 & WO 2011/003780. Based upon this information, a corresponding humanized anti-biotin antibody was generated (huM33) based on the human germline framework IGHV1-69-02 and IGKV1-27-01 combination. For VL, it was not necessary to integrate any backmutation in the framework of the human IGKV1-27-01 and the human J element of the IGKJ2-01 germline. The humanized VH is based on the human IGHV1-69-02 germline and the human J
element of the IGHJ4-01-3 germline. Two backmutations in framework region 1 at position 24 (A24S) and in framework region 3 at position 73 (K73T) were introduced. The amino acid sequence of the humanized VH is depicted in SEQ ID NO: 12 and the amino acid sequence of the humanized VL is shown in SEQ ID NO: 16.

**Example 3**

**Crystallization and X-ray structure determination of the binding region of the murine anti-biotin Fv region in the presence of biotin**

The structure of the murine anti-biotin antibody was determined. Therefore, Fab fragments were generated by protease digestion of the purified IgGs and subsequently purified, applying well known state of the art methods (papain digestion).

For crystallization of the apo Fab fragment (purified Fabs) in 20 mM His-HCl, 140 mM NaCl, pH 6.0 were concentrated to 13 mg/ml. Crystallization droplets were set up at 21 °C by mixing 0.2 µl of protein solution with 0.2 µl reservoir solution in vapor diffusion sitting drop experiments. Crystals appeared out of 0.1 M Tris pH 8.5, 0.01 M cobalt chloride, 20 % polyvinylpyrrolidone K15 within 5 days and grew to a final size of 0.3 mm x 0.06 mm x 0.03 mm within 8 days.

Crystals were harvested with 15 % Glycerol as cryoprotectant and then flash frozen in liquid N2. Diffraction images were collected with a Pilatus 6M detector at a temperature of 100K at the beam line X10SA of the Swiss Light Source and processed with the programs XDS [Kabsch, W., J. Appl. Cryst. 26 (1993) 795-800] and scaled with SCALA [obtained from BRUKER AXS], yielding data to 2.22Å resolution. This Fab fragment crystal belongs to monoclinic space group P21 with cell dimensions of a=90.23Å, b=118.45Å, c=96.79Å and β=117.53° and contains four Fab molecules per crystallographic asymmetric unit (see Table 2).

Standard crystallographic programs from the CCP4 software suite were used to solve the structure by molecular replacement with the PDB entry 3PQP as search model, to calculate the electron density, and to refine the x-ray structure [CCP4 (Collaborative Computational Project, N. The CCP4 suite: programs for protein crystallography. Acta Crystallogr. D (1994) 760-763]. The structural models were rebuilt into the electron density using COOT (Emsley, P., et al., Acta Crystallogr. D Biol. Crystallogr. 60 (2010) 486-501). Coordinates were refined with

\(^4\) \(R_{\text{free}}\) was calculated based on 5% of the total data omitted during refinement.  

For the crystallization of Fab-fragment in complex with a biotin-derivative apo Crystals of the Fab fragment used for soaking experiments were derived out of 0.8 M Succinic Acid within 3 days after screening and grew to a final size of 0.25 mm x 0.04 mm x 0.04 mm within 5 days. Biocytinamid was dissolved at 100 mM in water. Subsequently, the compound was diluted to 10 mM working concentration in crystallization solution and applied to the crystals in the crystallization droplet.
Crystals were washed three times with 2 μl of 10 mM compound solution and were finally incubated for 16 h with biocytinamid at 21°C.

Crystals were harvested with 15 % glycerol as cryoprotectant and then flash frozen in liquid N₂. Diffraction images were collected with a Pilatus 6M detector at a temperature of 100 K at the beam line X10SA of the Swiss Light Source and processed with the programs XDS [Kabsch, W., J. Appl. Cryst. 26 (1993) 795-800] and scaled with SCALA [obtained from BRUKER AXS], yielding data to 2.35 Å resolution. ThisFab fragment crystal belongs to monoclinic space group P2₁ with cell dimensions of a=89.09Å b=119.62Å c=96.18Å and β=117.15° and contains four Fab molecules per crystallographic asymmetric unit (see Table 3).

Standard crystallographic programs from the CCP4 software suite were used to solve the structure by molecular replacement with the coordinates of the apo Fab fragment as search model, to calculate the electron density, and to refine the x-ray structure to a resolution of 2.5Å [CCP4 (Collaborative Computational Project)]. The structural models were rebuilt into the electron density using COOT (Emsley, P., et al., Acta Crystallogr. D Biol. Crystallogr. 60 (2010) 486-501). Coordinates were refined with REFMAC5 (Murshudov, G.N., et al., Acta Crystallogr. D Biol. Crystallogr. 53 (1997) 240-255) and with autoBUSTER (Global Phasing Ltd.).

¹ Values in parentheses refer to the highest resolution bins.
² $R_{\text{merge}} = \sum |I_\text{obs} - \langle I \rangle | / \Sigma I$ where $I$ is intensity.
³ $R_{\text{cryst}} = \sum |F_\text{o} - F_\text{c}| / \Sigma F_\text{o}$ where $F_\text{o}$ is the observed and $F_\text{c}$ is the calculated structure factor amplitude.
⁴ $R_{\text{free}}$ was calculated based on 5% of the total data omitted during refinement.

The crystal form of the complex contained four independent biocytinamid:antibiotin Fab complexes in the asymmetric unit, with biocytinamid bound similarly by all Fab molecules. Biocytinamid is bound in a pocket formed by CDRs 1 and 3 of the heavy chain and all 3 light chain CDRs. The binding pocket of the ligand is defined by residues ASN29, ASP31, THR32, PHE33, GLN35, TRP99 and TRP106 from the heavy chain and ASN31, TYR32, LEU33, SER34, TYR49, SER50, PHE91 and TYR96 from the light chain. The biotin head group forms hydrogen bonds with residues of CDR2 and CDR1 at one end of the pocket: N3 of biocytinamid is interacting with the hydroxyl-oxygen of Ser50 whereas O22 is in contact with the backbone-amide nitrogen of the same residue. In addition, O22 of biocytinamid is also hydrogen-bonded to the hydroxyl-group oxygen of Ser34. In addition to that, hydrophobic interactions are observed between biocytinamid and the aromatic side chains lining the binding pocket. The amide bond at the end of the (CH$_2$)$_4$ aliphatic tail of biotin stacks onto PHE33 of heavy chain CDR1 and is stabilized by an additional hydrogen bond to the backbone amide nitrogen of PHE33 and to Asp31. This positions the amide nitrogen, which is the site of linkage to the active entity, in a way that atoms that are following the nitrogen are pointing away from the binding pocket towards the solvent.

The results of the experimental determination of the binding region at a resolution of 2.5 Å enables the characterization of the binding mode of the ligand to its antibody, which is a prerequisite for detailed modeling and further improvement via protein engineering of recombinant biotin binding modules.
Example 4
Composition, expression and purification of recombinant anti-biotin antibodies

Murine and humanized anti-biotin antibody variable regions were combined with constant regions of human origin to form mono- or bispecific chimeric or humanized antibodies.

The generation of monospecific humanized anti-biotin antibodies and bispecific humanized anti-biotin antibodies that specifically bind biotin as well as a different non-biotin target (e.g. receptor tyrosine kinases or IGF-1R) required (i) design and definition of amino- and nucleotide sequences for such molecules, (ii) expression of these molecules in transfected cultured mammalian cells, and (iii) purification of these molecules from the supernatants of transfected cells. These steps were performed as previously described in PCT/EP2011/074273.

In general, to generate a humanized antibody of the IgG class that has the binding specificity of the (original) murine anti-biotin antibody, the humanized VH sequence was fused in frame to the N-terminus of CH1-hinge-CH2-CH3 of a human Fc-region of the subclass IgG1. Similarly, the humanized VL sequence was fused in frame to the N-terminus of human CL kappa constant region.

To generate bispecific antibody derivatives that contain the biotin-binding specificity as well as specificities to other targets, the anti-biotin antibody, a scFv or Fab fragment was fused in frame to the C-terminus of the heavy chain of previously described antibodies. In many cases, the applied anti-hapten scFv was further stabilized by introduction of a VH44-VL100 disulfide bond which has been previously described (e.g. Reiter, Y., et al., Nature biotechnology 14 (1996) 1239-1245).

Expression plasmids:

Expression plasmids comprise expression cassettes for the expression of the heavy and light chains were separately assembled in mammalian cell expression vectors.

Thereby the gene segments encoding the individual elements were joined as outlined above.

General information regarding the nucleotide sequences of human light and heavy chains from which the codon usage can be deduced is given in: Kabat, E.A., et al.,

The transcription unit of the κ-light chain is composed of the following elements:
- the immediate early enhancer and promoter from the human cytomegalovirus (hCMV),
- a synthetic 5'-UT including a Kozak sequence,
- a murine immunoglobulin heavy chain signal sequence including the signal sequence intron,
- the cloned variable light chain cDNA arranged with a unique BsmI restriction site at the 5' end and a splice donor site and a unique NotI restriction site at the 3' end,
- the genomic human κ-gene constant region, including the intron 2 mouse Ig-κ enhancer (Picard, D., and Schaffner, W. Nature 307 (1984) 80-82), and
- the human immunoglobulin κ-polyadenylation ("poly A") signal sequence.

The transcription unit of the γl-heavy chain is composed of the following elements:
- the immediate early enhancer and promoter from the human cytomegalovirus (hCMV),
- a synthetic 5'-UT including a Kozak sequence,
- a modified murine immunoglobulin heavy chain signal sequence including the signal sequence intron,
- the cloned monospecific variable heavy chain cDNA or the cloned bispecific fusion scFv-variable heavy chain cDNA arranged with a unique BsmI restriction site at the 5' and a splice donor site and a unique NotI restriction site at the 3' end,
- the genomic human γl-heavy gene constant region, including the mouse Ig μ-enhancer (Neuberger, M.S., EMBO J. 2 (1983) 1373-1378), and
- the human γl-immunoglobulin polyadenylation ("polyA") signal sequence.

Besides the κ-light chain or γl-heavy chain expression cassette these plasmids contain
- a hygromycin resistance gene,
- an origin of replication, oriP, of Epstein-Barr virus (EBV),
- an origin of replication from the vector pUC18 which allows replication of this plasmid in E. coli, and
- a β-lactamase gene which confers ampicillin resistance in E. coli.
Recombinant DNA techniques:

Cloning was performed using standard cloning techniques as described in Sambrook, J., et al., Molecular Cloning: A Laboratory Manual, second edition, Cold Spring Harbor Laboratory Press (1989). All molecular biological reagents were commercially available (if not indicated otherwise) and were used according to the manufacturer’s instructions.

DNA that contains coding sequences, mutations or further genetic elements was synthesized by Geneart AG, Regensburg.

DNA sequences were determined by double strand sequencing performed at SeqiServe (SeqiServe GmbH, Germany).

DNA and protein sequence analysis and sequence data management:

The Vector NTI Advance suite version 9.0 was used for sequence creation, mapping, analysis, annotation, and illustration.

Expression of anti-biotin antibodies and derivatives:

The anti-biotin antibodies were expressed by transient transfection of human embryonic kidney 293 (HEK293) cells in suspension. For that, light and heavy chains of the corresponding mono- or bispecific antibodies were constructed in expression vectors carrying prokaryotic and eukaryotic selection markers as outlined above. These plasmids were amplified in E.coli, purified, and subsequently applied for transient transfections. Standard cell culture techniques were used for handling of the cells as described in Current Protocols in Cell Biology (2000), Bonifacino, J.S., Dasso, M., Harford, J.B., Lippincott-Schwartz, J. and Yamada, K.M. (eds.), John Wiley & Sons, Inc.

The cells were cultivated in appropriate expression medium at 37 °C/8 % CO₂. On the day of transfection the cells were seeded in fresh medium at a density of 1-2 x 10⁶ viable cells/ml. The DNA-complexes with transfection reagents were prepared in Opti-MEM I medium (Invitrogen, USA) comprising 250 μg of heavy and light chain plasmid DNA in a 1:1 molar ratio for a 250 ml final transfection volume. The monospecific or bispecific antibody containing cell culture supernatants were clarified 7 days after transfection by centrifugation at 14,000 g for 30 minutes and filtration through a sterile filter (0.22 μm). Supernatants were stored at -20 °C until purification.
To determine the concentration of antibodies and derivatives in the cell culture supernatants, affinity HPLC chromatography was applied. For that, the cell culture supernatant containing mono- or bispecific antibody or derivatives thereof that bind to protein-A was applied to an Applied Biosystems Poros A/20 column in a solution comprising 200 mM KH₂PO₄, 100 mM sodium citrate, at pH 7.4. Elution from the chromatography material was performed by applying a solution comprising 200 mM NaCl, 100 mM citric acid, at pH 2.5. An UltiMate 3000 HPLC system (Dionex) was used. The eluted protein was quantified by UV absorbance and integration of peak areas. A purified IgG1 antibody served as a standard.

Purification of anti-biotin antibodies:

Seven days after transfection the HEK 293 cell supernatants were harvested. The recombinant antibody contained therein were purified from the supernatant in two steps by affinity chromatography using protein A-Sepharose™ affinity chromatography (GE Healthcare, Sweden) and Superdex200 size exclusion chromatography. Briefly, the antibody containing clarified culture supernatants were applied on a MabSelectSuRe Protein A (5-50 ml) column equilibrated with PBS buffer (10 mM Na₂HPO₄, 1 mM KH₂PO₄, 137 mM NaCl and 2.7 mM KCl, pH 7.4). Unbound proteins were washed out with equilibration buffer. The antibodies (or -derivatives) were eluted with 50 mM citrate buffer, pH 3.2. The protein containing fractions were neutralized with 0.1 ml 2 M Tris buffer, pH 9.0. Then, the eluted protein fractions were pooled, concentrated with an Amicon Ultra centrifugal filter device (MWCO: 30 K, Millipore) and loaded on a Superdex200 HiLoad 26/60 gel filtration column (GE Healthcare, Sweden) equilibrated with 20 mM histidine, 140 mM NaCl, at pH 6.0. The protein concentration of purified antibodies and derivatives was determined by determining the optical density (OD) at 280 nm with the OD at 320 nm as the background correction, using the molar extinction coefficient calculated on the basis of the amino acid sequence according to Pace, et al., Protein Science 4 (1995) 2411-2423. Monomeric antibody fractions were pooled, snap-frozen and stored at -80 °C. Part of the samples was provided for subsequent protein analytics and characterization.

The homogeneity of the antibodies was confirmed by SDS-PAGE in the presence and absence of a reducing agent (5 mM 1,4-dithiotreitol) and staining with Coomassie brilliant blue. The NuPAGE® Pre-Cast gel system (Invitrogen, USA) was used according to the manufacturer’s instruction (4-20% Tris-Glycine gels).
Under reducing conditions, polypeptide chains related to the IgG showed upon SDS-PAGE at apparent molecular sizes analogous to the calculated molecular weights. Expression levels of all constructs were analyzed by protein-A. Average protein yields were between 6 mg and 35 mg of purified protein per liter of cell-culture supernatant in such non-optimized transient expression experiments.

Figure 1 shows the results of expression and purification of the humanized antibody that binds biotin and biotin derivatives. Reducing and non-reducing SDS PAGE shows composition and homogeneity of humanized antibodies with and without cysteine at position 53 according to Kabat after purification with protein A (MabSelect) and SEC. The molecular weight marker is in the non-labeled lanes. Antibody H-chains (upper band at 50k) and L-chains (lower band at 25k) are detectable under reduced conditions as unique bands without presence of visible amounts of additional protein contaminants.

Example 5

**Binding of recombinant humanized anti-biotin antibody to biotin-labeled compound (biotinylated compound)**

The binding properties of the recombinant chimeric and humanized anti-biotin antibody and a variant thereof, which has a cysteine at position 53 in the HVR-H2 according to the numbering of Kabat, were analyzed by biolayer interferometry (BLI) technology using an Octet QK instrument (Fortebio Inc.). This system is well established for the study of molecule interactions. BLI-technology is based on the measurement of the interference pattern of white light reflected from the surface of a biosensor tip and an internal reference. Binding of molecules to the biosensor tip is resulting in a shift of the interference pattern which can be measured. To analyze if the humanization procedure described above diminished the ability of the anti-biotin antibody to bind to biotin, the properties of the chimeric and the humanized versions of the antibody in their ability to bind to a biotinylated protein were compared directly. Binding studies were performed by capturing anti-biotin antibody on anti-huIgG Fc antibody Capture (AHC) Biosensors (Fortebio Inc.).

First, biosensors were incubated in an antibody solution with a concentration of 0.5 mg/ml in 20 mM histidine, 140 mM NaCl, pH 6.0 for 1 min. Thereafter, the biosensors were incubated for 1 min. in 1x PBS pH 7.4 to reach a stable baseline. Binding was measured by incubating the antibody-coated biosensors in a solution containing biotinylated protein with a concentration of 0.06 mg/ml in 20 mM histidine, 140 mM NaCl, pH 6.0 for 5 min. Dissociation was monitored for 5 min.
in 1x PBS pH 7.4. The resulting binding curves for chimeric and humanized anti-biotin antibodies were compared directly.

The humanized version of the antibody showed equal or even better binding of the biotinylated antigen than the chimeric antibody. The same is true for the humanized antibody with the Cys mutation at Kabat position VH53. The biotinylated protein showed residual unspecific binding to the biosensors which was reduced when the biosensors were coated with Herceptin, which does not bind biotin. Thus, the functionality of the anti-biotin antibody was retained in its humanized variant (which is defined by the sequences as depicted in SEQ ID NO: 12 and 16, SEQ ID NO: 20 and 24).

**Surface plasmon resonance:**

Surface plasmon resonance measurement was performed on a BIAcore® T200 instrument (GE Healthcare Biosciences AB, Sweden) at 25°C. Around 4300 resonance units (RU) of the capturing system (10 µg/ml Anti-human Capture (IgG Fc) from Human Antibody Capture Kit, BR-1008-39, GE Healthcare Biosciences AB, Sweden) were coupled on a CM3 chip (GE Healthcare, BR-1005-36) at pH 5.0 by using the standard amine coupling kit supplied by GE Healthcare (BR-1000-50). The running buffer for amine coupling was HBS-N (10 mM HEPES, pH 7.4, 150 mM NaCl, GE Healthcare, BR-1006-70). Running and dilution buffer for the followed binding study was PBS-T (10 mM phosphate buffered saline including 0.05% Tween 20) pH 7.4. The humanized anti-biotin antibody was captured by injecting a 2 nM solution for 60 sec at a flow rate of 5 µl/min. Biotinylated siRNA was diluted with PBS-T at concentrations of 0.14 - 100 nM (1:3 dilution series). Binding was measured by injecting each concentration for 180 sec at a flow rate of 30µl/min, dissociation time 600 sec. The surface was regenerated by 30 sec washing with a 3 M MgCl₂ solution at a flow rate of 5 µl/min. The data were evaluated using BIAevaluation software (GE Healthcare Biosciences AB, Sweden). Bulk refractive index differences were corrected by subtracting the response obtained from an anti-human IgG Fc surface. Blank injections were also subtracted (= double referencing). For calculation of KD and kinetic parameters the Langmuir 1:1 model was used.

Kinetic binding analysis by surface plasmon resonance (SPR) was carried out for humanized anti-biotin antibody SEQ ID NO: 12 and 16 and humanized anti-biotin antibody VH53C SEQ ID NO: 20 and 24. Anti-biotin antibodies at a concentration
of 2 nM were captured by anti-human IgG Fc antibody which was bound to a CM3 sensor chip. Binding of biotinylated siRNA (Mw: 13868 Da) was recorded at the concentrations 0.41, 1.23, 3.7, 11.1, 33.3, 100 and 300 nM. Measurements were carried out in duplicates. The calculated $K_D$ for humanized anti- biotin antibody and humanized anti-biotin antibody VH53C were 0.633 nM and 0.654 nM, respectively.

**Example 6**

**Generation of non-covalent complexes of biotinylated compounds with anti-biotin antibodies**

**General method:**

The generation of complexes of anti-biotin antibodies with biotinylated compounds (= biotin conjugated to a payload) shall result in defined complexes and it shall be assure that the compound (= payload) in these complexes retains its activity. For the generation of complexes of biotinylated compounds with the anti-biotin antibody the biotinylated compound was dissolved in H$_2$O to a final concentration of 1mg/ml. The antibody was concentrated to a final concentration of 1 mg/ml (4.85 μM) in 20 mM histidine buffer, 140 mM NaCl, pH=6.0. Biotinylated payload and antibody were mixed to a 2:1 molar ratio (compound to antibody) by pipetting up and down and incubated for 15 minutes at RT.

Alternatively, the biotinylated compound was dissolved in 100% DMF to a final concentration of 10 mg/ml. The antibody was concentrated to a final concentration of 10 mg/ml in 50 mM Tris-HCl, 1 mM EDTA, pH=8.2. Biotinylated compound and antibody were mixed to a 2.5:1 molar ratio (compound to antibody) by pipetting up and down and incubated for 60 minutes at RT and 350 rpm.

**Exemplary method for the formation of complexes of biotinylated fluorescent dyes and anti-biotin antibodies – Biotin-Cy5 / chimeric anti-biotin antibody (human IgG subclass) complex:**

For the generation of complexes of biotin-derivatized-Cy5 (Biotin-Cys-Cy5) containing a cysteinyalted linker, 0.16 mg of Biotin-Cys-Cy5 were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the antibody was used in a concentration of 10.1 mg/ml (about 69 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Biotin-Cys-Cy5 and antibody were mixed at a 2.5:1 molar ratio (Biotin-Cys-Cy5 to antibody) and incubated for 60 min at RT, shaken
at 350 rpm. The resulting conjugate was analyzed by SDS-PAGE as described in Example 7. Detection of fluorescence was carried out as described in Example 7.

Exemplary method for the formation of complexes of biotinylated fluorescent dyes and anti-biotin antibodies – Biotin-Cys-Cy5/ humanized anti-biotin antibody:

For the generation of complexes of biotin-derivatized-Cy5 (Biotin-Cys-Cy5) containing a cysteinylated linker, 0.16 mg of Biotin-Cys-Cy5 were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the antibody was used in a concentration of 5.5 mg/ml (about 38 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Biotin-Cys-Cy5 and antibody were mixed at a 2.5:1 molar ratio (Biotin-Cys-Cy5 to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by SDS-PAGE as described in Example 7. Detection of fluorescence was carried out as described in Example 7.

Exemplary method for the formation of complexes of biotinylated polypeptides and anti-biotin antibodies - Ac-PYY-PEG3-Cys-β-Ala-Biotin / chimeric anti-biotin antibody complex:

For the generation of non-covalent complexes of biotinylated-PYY-polypeptide containing a cysteinylated linker, 0.19 mg of Ac-PYY-PEG3-Cys-β-Ala-Biotin were dissolved in 100% DMF to a concentration of 10 mg/ml. The antibody was used in a concentration of 10.7 mg/ml (about 73 μM) in a buffer composed of 50 mM Tris-HCl, 1mM EDTA, pH 8.2. Ac-PYY-PEG3-Cys-β-Ala-Biotin and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY-PEG3-Cys-β-Ala-Biotin to antibody) and incubated for 60 min at RT and 350 rpm. The resulting complex was defined as monomeric IgG-like molecule via the occurrence of a single peak in a size exclusion chromatography (95% monomer). The resulting complex was further analyzed by SDS-PAGE and subsequent Western Blot analysis. 10 μg of the complex were mixed with 4x LDS sample buffer (Invitrogen) and incubated at 95°C for 5 min. The sample was applied to a 4-12% Bis-Tris polyacrylamide-gel (NuPAGE, Invitrogen) which was run for 35 min at 200V and 120 mA. Molecules that were separated in the polyacrylamide-gel were transferred to a PVDF membrane (0.2 μm pore size, Invitrogen) for 40 min at 25V and 160 mA. The membrane was blocked in 1% (w/v) skim milk in 1x PBST (1x PBS + 0.1 % Tween20) for 1h at RT. The membrane was washed 3x for 5 min in 1x PBST and subsequently incubated with a streptavidin-POD-conjugate (2900 U/ml, Roche) which was used in a 1:2000 dilution. Detection of streptavidin-POD bound to
biotin on the membrane was carried out using Lumi-Light Western Blotting Substrate (Roche).

**Exemplary method for the formation of complexes of biotinylated polypeptides and anti-biotin antibodies - Ac-PYY-PEG3-Cys-PEG2-Biotin / chimeric anti-biotin antibody complex:**

For the generation of non-covalent complexes of biotinylated-PYY-polypeptide containing a cysteinylated linker, 0.16 mg of Ac-PYY-PEG3-Cys-PEG2-Biotin were dissolved in 100% DMF to a concentration of 10 mg/ml. The antibody was used in a concentration of 10.7 mg/ml (about 73 μM) in a buffer composed of 50 mM Tris-HCl, 1mM EDTA, pH 8.2. Ac-PYY-PEG3-Cys-PEG2-Biotin and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY-PEG3-Cys-PEG2-Biotin to antibody) and incubated for 60 min at RT and 350 rpm. The resulting complex was defined as 63% monomeric IgG-like molecule and 37% dimeric soluble aggregates via size exclusion chromatography. The resulting complex was further analyzed by SDS-PAGE and subsequent Western Blot analysis. 10 μg of the complex were mixed with 4x LDS sample buffer (Invitrogen) and incubated at 95°C for 5 min. The sample was applied to a 4-12% Bis-Tris polyacrylamide-gel (NuPAGE, Invitrogen) which was run for 35 min at 200V and 120 mA. Molecules that were separated in the polyacrylamide-gel were transferred to a PVDF membrane (0.2 μm pore size, Invitrogen) for 40 min at 25V and 160 mA. The membrane was blocked in 1 % (w/v) skim milk in 1x PBST (1x PBS + 0.1% Tween20) for 1h at RT. The membrane was washed 3x for 5 min in 1x PBST and subsequently incubated with a streptavidin-POD-conjugate (2900 U/ml, Roche) which was used in a 1:2000 dilution. Detection of streptavidin-POD bound to biotin on the membrane was carried out using Lumi-Light Western Blotting Substrate (Roche).

**Generation of defined covalent conjugates of haptenylated dyes and polypeptides with an anti-hapten antibody VH53C in the absence of redox agents**

For the generation of covalent anti-biotin antibody/biotinylated polypeptide or biotinylated dye disulfide-linked conjugates it is necessary to (i) couple biotin via a suitable a reactive group (such as e.g. cysteine, maleimide) containing linkers to the polypeptide or dye that allows the polypeptide to be exposed above the antibody surface and hence to retain its activity, and (ii) generate covalent site specific conjugates of the biotinylated polypeptides with the anti-biotin antibody
with a cysteine mutation (= antibody VH52bC/VH53C) in which the biological activity of the polypeptide is retained, and (iii) to carry out the reaction in the absence of a reducing agent in order to avoid the reduction of antibody inter-chain disulfide bridges.

5 General method:

The generation of conjugates of anti-biotin antibodies with biotinylated compounds shall result in conjugates with defined stoichiometry and it shall be assured that the compound in these conjugates retains its activity. For the generation of conjugates of biotinylated compounds with the anti-biotin antibody the biotinylated compound was dissolved in 100% DMF to a final concentration of 10 mg/ml. The anti-biotin antibody VH52bC/VH53C was brought to a concentration of 10 mg/ml in 50 mM Tris-HCl, 1 mM EDTA, pH=8.2. Biotinylated compound and anti-biotin antibody VH52bC/VH53C were mixed in a 2.5:1 molar ratio (compound to antibody) by pipetting up and down and incubated for 60 minutes at RT and 350 rpm.

10 A polypeptide conjugated to biotin via a cysteine containing linker is termed biotin-Cys-polypeptide or polypeptide-Cys-biotin in the following. The polypeptide may either have a free N-terminus or a capped N-terminus e.g. with an acetyl-group (Ac-polypeptide-Cys-biotin) or a PEG-residue (PEG-polypeptide-Cys-biotin).

15 A fluorescent dye conjugated to biotin via a cysteine containing linker is termed dye-Cys-biotin or biotin-Cys-dye in the following.

Exemplary method for the formation of conjugates of biotinylated fluorescent dyes and anti-biotin antibodies – Biotin-Ser-Cy5/ humanized anti-biotin antibody:

For the generation of complexes of biotin-derivatized-Cy5 (Biotin-Ser-Cy5) containing a serine residue within the linker, 0.61 mg of Biotin-Ser-Cy5 were dissolved in 20 mM histidine, 140 mM NaCl, pH 6.0 to a concentration of 10 mg/ml. 18.5 mg of the humanized anti-biotin antibody was used in a concentration of 10 mg/ml (about 69 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Biotin-Ser-Cy5 and antibody were mixed at a 2.5:1 molar ratio (Biotin-Ser-Cy5 to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The sample was then subjected to size exclusion chromatography using Superdex 200 16/60 high load prep grade column (GE Healthcare) with a flow rate of 1.5 ml/min and 20 mM histidine, 140 mM NaCl, pH 6.0 as the mobile phase. Peak
fractions were collected and analyzed by SDS-PAGE for purity. The dye to antibody ratio was calculated by (1) measuring the absorbance of the samples at the wavelength 280 nm (protein) and 650 nm (Cy5); (2) using the formula: $A_{650}$ of labeled protein/$\varepsilon$(Cy5)*protein concentration (M) = moles dye per mole protein, where $\varepsilon$(Cy5) = 250000 M$^-1$cm$^1$, $A_{650}$ of the complex = 47.0 and the protein concentration is 86.67 μM. The resulting ratio of dye to antibody molecule was 2.17 which suggests that all antibody paratopes are saturated with Biotin-Cy5 molecules.

**Exemplary method for the formation of conjugates of biotinylated fluorescent dyes and anti-biotin antibodies – Biotin-Cys-Cy5/ chimeric anti-biotin antibody VH53C:**

For the generation of conjugates of biotin-derivatized-Cy5 containing a cysteinylated linker, 0.16 mg of Biotin-Cys-Cy5 were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the anti-biotin antibody VH53C was used in a concentration of 9.7 mg/ml (about 68 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Biotin-Cys-Cy5 and antibody were mixed at a 2.5:1 molar ratio (Ac-Biotin-Cys-Cy5 to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by SDS-PAGE as described in Example 7. Detection of fluorescence was carried out as described in Example 7.

**Exemplary method for the formation of conjugates of biotinylated fluorescent dyes and anti-biotin antibodies – Biotin-Cys-Cy5/ humanized anti-biotin antibody VH53C:**

For the generation of conjugates of biotin-derivatized-Cy5 containing a cysteinylated linker, 0.16 mg of Biotin-Cys-Cy5 were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the humanized anti-biotin antibody VH53C was used in a concentration of 7.4 mg/ml (about 51 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Biotin-Cys-Cy5 and antibody were mixed at a 2.5:1 molar ratio (Ac-Biotin-Cys-Cy5 to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by SDS-PAGE as described in Example 7. Detection of fluorescence was carried out as described in Example 7.
Exemplary method for the formation of conjugates of biotinylated polypeptides and anti-biotin antibodies – Ac-PYY(PEG3-Cys-βAla-Biotin) / chimeric anti-biotin antibody VH53C:

For the generation of conjugates of biotin-derivatized-PYY-polypeptide containing a cysteinylated linker, 0.19 mg of Ac-PYY(PEG3-Cys-βAla-Biotin) were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the chimeric anti-biotin antibody VH53C was used in a concentration of 9.7 mg/ml (about 67 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Ac-PYY(PEG3-Cys-βAla-Biotin) and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY(PEG3-Cys-βAla-Biotin) to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by mass spectrometry. 87.7% of the detected species was identified as antibody coupled to 2 peptide molecules, 12.3% was identified as antibody coupled to 1 peptide molecule.

Exemplary method for the formation of conjugates of biotinylated polypeptides and anti-biotin antibodies – Ac-PYY(PEG3-Cys-PEG2-Biotin)/chimeric anti-biotin antibody VH53C:

For the generation of conjugates of biotin-derivatized-PYY-polypeptide containing a cysteinylated linker, 0.16 mg of Ac-PYY(PEG3-Cys-PEG2-Biotin) were dissolved in 100% DMF to a concentration of 10 mg/ml. 1 mg of the chimeric anti-biotin antibody VH53C was used in a concentration of 9.9 mg/ml (about 68 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Ac-PYY(PEG3-Cys-PEG2-Biotin) and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY(PEG3-Cys-PEG2-Biotin) to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by mass spectrometry. 100% of the detected species was identified as antibody coupled to 2 peptide molecules.

Exemplary method for the formation of conjugates of biotinylated polypeptides and anti-biotin antibodies – Ac-PYY(PEG3-Cys-βAla-Biotin)/humanized anti-biotin antibody VH53C:

For the generation of conjugates of biotin-derivatized-PYY-polypeptide containing a cysteinylated linker, 0.06 mg of Ac-PYY(PEG3-Cys-βAla-Biotin) were dissolved in 100% DMF to a concentration of 10 mg/ml. 0.8 mg of the humanized anti-biotin antibody VH53C was used in a concentration of 9 mg/ml (about 62 μM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Ac-PYY(PEG3-Cys-βAla-Biotin) and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY(PEG3-Cys-βAla-
Biotin) to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by mass spectrometry. 62.2% of the detected species was identified as antibody coupled to 2 peptide molecules, 33.9% was identified as antibody coupled to 1 peptide molecule and 3.9% was identified as uncoupled antibody.

Exemplary method for the formation of conjugates of biotinylated polypeptides and anti-biotin antibodies – Ac-PYY(PEG3-Cys-PEG2-Biotin)/humanized anti-biotin antibody VH53C

For the generation of conjugates of biotin-derivatized-PYY-polypeptide containing a cysteiny lated linker, 0.08 mg of Ac-PYY(PEG3-Cys-PEG2-Biotin) were dissolved in 100% DMF to a concentration of 10 mg/ml. 0.8 mg of the humanized anti-biotin antibody VH53C was used in a concentration of 9 mg/ml (about 62 µM) in a buffer composed of 50 mM Tris-HCl, 1 mM EDTA, pH 8.2. Ac-PYY(PEG3-Cys-PEG2-Biotin) and antibody were mixed at a 2.5:1 molar ratio (Ac-PYY(PEG3-Cys-PEG2-Biotin) to antibody) and incubated for 60 min at RT, shaken at 350 rpm. The resulting conjugate was analyzed by mass spectrometry. 71.4% of the detected species was identified as antibody coupled to 2 peptide molecules, 26% was identified as antibody coupled to 1 peptide molecule and 2.5% was identified as uncoupled antibody.

Example 7
Detection methods

SDS-gel electrophoresis:

For SDS gel electrophoresis, 4x LDS sample buffer (Invitrogen) was added to the samples. For each sample also a reduced version was prepared by adding 10x NuPAGE sample reducing agent (Invitrogen). All samples were incubated at 70°C for 5 min before electrophoresis on a 4-12% Bis-Tris polyacrylamide gel (NuPAGE, Invitrogen) with 1x MOPS buffer (Invitrogen).

Fluorescence detection:

Cy5-related fluorescence in the gel was detected with a LumiImager F1 device (Roche) at an excitation wavelength of 645 nm. After detection of fluorescence, the gel was stained with SimplyBlue SafeStain (Invitrogen).
Example 8
Serum stability

Serum stability of complexes of biotinylated Cy5 with humanized anti-biotin antibody in comparison to covalent conjugates of biotinylated Cy5 with humanized anti-biotin antibody VH53C.

The objective of the described peptide modification technology is to improve the therapeutic applicability of peptides. Major bottlenecks for therapeutic application of peptides are currently limited stability in vivo and/or short serum half-life and fast clearance. The PK parameters of antibody conjugates of fluorophores were determined in vivo and compare with the PK of non-covalent antibody-fluorophore complexes. Therefore, (i) the anti-biotin antibody VH53C was covalently conjugated to the biotinylated fluorophore Biot-Cys-Cy5, (ii) a non-covalent complex of the anti-biotin antibody with biotinylated fluorophore Biot-Cy5 was generated, (iii) the covalently conjugated and the non-covalently complexed compounds were applied to animals and (iv) the serum concentrations of the compounds over time in these animals was analyzed.

Experimental procedure:

To analyze the influence on PK parameters of antibody-complexation of a small fluorescent substrate, 13 nmol of Cy5-Biotin/humanized anti-biotin antibody disulfide-linked conjugate or of the corresponding antibody non-covalently complexed compound in 20 mM histidine / 140 mM NaCl, pH 6.0 are applied to six female mice (strain NRMI) for each substance. About 0.1 ml blood samples are collected after the following time points: 0.08 h, 8 h and 48 h for Mouse 1 and 2 and 0.08 h, 24 h and 48 h for Mouse 3 and 4 and 0.08h, 36 h and 48h for Mouse 5 and 6. Serum samples of at least 40 µl are obtained after 1 h at RT by centrifugation (9,300 x g, 3 min, 4 °C). Serum samples are stored at -80 °C.

To determine the amount of compound in the serum at the given time points the fluorescent properties of Cy5 are used: Cy5 related fluorescence in serum samples are measured in 120µl quartz cuvettes at room temperature using a Cary Eclipse Fluorescence Spectrophotometer (Varian). Excitation wavelength is 649 nm, Emission is measured at 670 nm. Serum samples are diluted in 1 x PBS to reach an appropriate range of Emission intensity. Blood serum of an untreated mouse in the same dilution in 1 x PBS as the respective sample is used as a blank probe.
Although the foregoing invention has been described in some detail by way of illustration and example for purposes of clarity of understanding, the descriptions and examples should not be construed as limiting the scope of the invention. The disclosures of all patent and scientific literature cited herein are expressly incorporated in their entirety by reference.

**Example 9**

**X-ray structure determination of murine anti-Biotin antibody-Fab-fragments in complex with biocytinamide**

The protein structure of murine anti-Biotin antibody Fab-fragment was determined in complex with biocytinamide. Therefore, crystals of the Fab-fragment were grown in 0.8 M Succinic Acid, followed by charging of the antibody crystals with Biocytidinamide (diluted to 10 mM working concentration in crystallization solution, applied to the crystals in the crystallization droplet). Crystals were washed three times with 2 µl of 10 mM Biocytidinamide solution and were finally incubated for 16 hrs. with Biocytidinamide at 21 °C, harvested with 15 % Glycerol as cryoprotectant and flash frozen in liquid nitrogen. Processed diffraction images yielded a protein structure at 2.5 Å resolution. The structure and charge composition of the biotin-binding variable region is shown in Figure 2: Biotin binds into a surface pocket which is flanked by charged regions that composed of amino acids from the CDR regions. The complexed hapten is positioned in close proximity to a negatively charged cluster of amino acids. Biotin which -as hapten- is derivatized for payload coupling at its carboxyl group binds with good efficacy as there is no charge repulsion at this position (due to the lack of the COOH group). In contrast, free (normal) biotin cannot bind efficient to the antibody because its carboxyl group would be in close proximity to this negative charge cluster, and hence becomes repulsed.
Patent Claims

1. A humanized anti-biotin antibody, wherein the antibody comprises (a) a HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11, (b) a HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15, and (c) a HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10.

2. The antibody of claim 1, wherein the antibody comprises (a) a HVR-H1 comprising the amino acid sequence of SEQ ID NO: 09, (b) a HVR-H2 comprising the amino acid sequence of SEQ ID NO: 10, and (c) a HVR-H3 comprising the amino acid sequence of SEQ ID NO: 11.

3. The antibody according to any one of the preceding claims, wherein the antibody comprises (a) a HVR-L1 comprising the amino acid sequence of SEQ ID NO: 13; (b) a HVR-L2 comprising the amino acid sequence of SEQ ID NO: 14; and (c) a HVR-L3 comprising the amino acid sequence of SEQ ID NO: 15.

4. The antibody according to any one of the preceding claims, characterized in that it comprises at position 24 of the heavy chain variable domain numbered according to Kabat the amino acid residue serine or/and that it comprises at position 73 of the heavy chain variable domain numbered according to Kabat the amino acid residue threonine.

5. The antibody according to any one of the preceding claims, characterized in that it comprises at position 60 of the heavy chain variable domain numbered according to Kabat the amino acid residue alanine and at position 61 of the heavy chain variable domain numbered according to Kabat the amino acid residue glutamine.

6. The antibody according to any one of the preceding claims, comprising

(a) a VH sequence having at least 95% sequence identity to the amino acid sequence of SEQ ID NO: 12;

(b) a VL sequence having at least 95% sequence identity to the amino acid sequence of SEQ ID NO: 16; or

(c) a VH sequence as in (a) and a VL sequence as in (b),
wherein the amino acid residue at position 24 of the heavy chain variable domain numbered according to Kabat is serine or/and the amino acid residue at position 73 of the heavy chain variable domain numbered according to Kabat is threonine.

7. The antibody of claim 4, comprising a VH sequence of SEQ ID NO: 12.

8. The antibody of any one of claim 4 or 7, comprising a VL sequence of SEQ ID NO: 16.

9. An antibody comprising a VH sequence of SEQ ID NO: 12 and a VL sequence of SEQ ID NO: 16.

10. The antibody of claim 1, which is a full length IgG1 antibody or a full length IgG4 antibody.

11. The antibody according to any one of the preceding claims, which is a monoclonal antibody.

12. The antibody according to any one of the preceding claims, which is an antibody fragment that binds biotin.

13. A pharmaceutical formulation comprising the antibody according to any one of the preceding claims and a pharmaceutically acceptable carrier.

14. The antibody of any one of claims 1 to 12 for use as a medicament.

15. Use of the antibody of any one of claims 1 to 12 in the manufacture of a medicament.
