ABSTRACT
There are provided N-acetyl-D-glucosamine deacetylase capable of hydrolyzing acetamide group of N-acetyl-D-glucosamine to produce D-glucosamine and acetic acid, which has the following physicochemical properties:
(1) Substrate specificity: N-acetyl-D-glucosamine monomer, not the oligomer or polymer thereof;
(2) Optimal pH: 7.8–8.2 at 37° C;
(3) Stable pH: 6.0–9.0 at 45° C;
(4) Optimal temperature: 28°–39° C;
(5) Molecular weight: 70,000–200,000 as determined using TSK-gel G-3000 SW column, and a process for preparing the same using a microorganism belonging to Vibrio sp.

N-ACETYL-D-GLUCOSAMINE DEACYLTASE AND A PROCESS FOR PREPARING THE SAME

BACKGROUND OF THE INVENTION

1. Field of the Invention

The present invention relates to an enzyme N-acetyl-D-glucosamine deacetylase capable of hydrolyzing the acetamide group of N-acetyl-D-glucosamine to produce D-glucosamine and acetic acid. More particularly, the present invention relates to a deacetylase which acts specifically on the monomer of N-acetyl-D-glucosamine, and not on the oligomers including dimer and the polymer.

The present invention also relates to a process for preparing the above described enzyme, and to a process for hydrolyzing said acetamido group using the deacetylase of the present invention.

2. Description of the Prior Art

D-glucosamine, the deacylated product of N-acetyl-D-glucosamine, is useful as pharmaceuticals, foodstuffs, and intermediates for the preparation of pharmaceuticals. In addition, oligosaccharides consisting of D-glucosamine unit have increasingly been drawing attention and becoming important as having valuable physiological activities such as antibacterial, antifungal and antitumor activities.

D-glucosamine has hitherto been prepared from N-acetyl-D-glucosamine which is prepared from purified chitin (β-1,4-poly-N-acetyl-D-glucosamine, obtained from the cuticle (crustacean such as prawn or crab by removing inorganic salts, proteins and lipids), by deacetylating with a conc. alkali or mineral acid.

However, the hydrolysis of the N-acetyl group of N-acetyl-D-glucosamine does not progress so easily and therefore, relatively hard reaction conditions are necessary to complete the hydrolysis, for example, heating for a long period of time in a concentrated acid or alkali such as 30–60% solution, leading to an increase in the formation of undesirable by-products, and the yield of the desired D-glucosamine is low. Moreover, the elimination of the acid or alkali used necessitates additional elaboration and expense.

There have been a need for developing more mild methods of deacetylating N-acetyl-D-glucosamine in a high yield without the formation of undesirable by-products, and a biological method using an enzyme capable of deacetylating N-acetyl-D-glucosamine has been investigated.

As biological deacetylation methods, there have been several references known wherein microorganisms belonging to Mucor sp., Aeromonas sp. or Colletotrichum sp. are used.

A method using a microorganism belonging to Aeromonas sp. intends to deacetylate solid chitin of high polymerization degree, and there is no disclosure of deacetylating monosaccharide [K. Shimahara, H. Iwasaki, Asahi Garasu Kogyo Gijutsu Shoreikai, 41: 299 (1982), C.A. 99:84876v (1983)].

It has now surprisingly been found that a marine microorganism belonging to Vibrio sp. produces an enzyme which is capable of splitting the acetyl group of N-acetyl-D-glucosamine and which specifically acts on the monomer of N-acetyl-D-glucosamine and not on the oligomer or polymer thereof.

The enzyme as described above having such novel substrate specificity has never been known hitherto, and represents a useful functional enzyme.

SUMMARY OF THE INVENTION

Thus the present invention relates to a novel enzyme N-acetyl-D-glucosamine deacetylase capable of hydrolyzing acetamide group of N-acetyl-D-glucosamine to produce D-glucosamine and acetic acid. More particularly, the present invention relates to N-acetyl-D-glucosamine deacetylation which has the following physicochemical properties:

1. Substrate specificity: N-acetyl-D-glucosamine monomer, not the oligomer or polymer thereof;

2. Optimal pH: 7.8–8.2 at 37°C;

3. Stable pH: 6.0–9.0 at 45°C;

4. Optimal temperature: 28°–39°C;

5. Molecular weight: 70,000–200,000 as determined using TSK-gel G-3000 SW column.

More particularly, the present invention relates to N-acetyl-D-glucosamine deacetylase as defined above, which has a molecular weight of 80,000–150,000 as determined using TSK-gel G-3000 SW column.

Furthermore, the present invention relates to N-acetyl-D-glucosamine deacetylase as described above, which is obtained from a microorganism belonging to Vibrio sp., preferably from Vibrio cholerae non-01 (IFO 15429).

The present invention also relates to a process for preparing N-acetyl-D-glucosamine deacetylase as mentioned above, by incubating a microorganism belonging to Vibrio sp. capable of producing said deacetylase in an induction medium, and isolating said deacetylase from cells separated from said medium.

This invention further relates to a process as described above wherein the microorganism is previously incubated in a nutrition medium.

This invention also relates to a process as described above wherein the microorganism is Vibrio cholerae non-01 (IFO 15429).

The present invention also relates to a process for hydrolyzing acetamido group of N-acetyl-D-glucosamine monomer using the deacetylase of the present invention.

BRIEF DESCRIPTION OF THE DRAWINGS

FIG. 1 shows the relationship between the relative activity (%) of N-acetyl-D-glucosamine deacetylation of the present invention and the pH value, at 37°C.

FIG. 2 shows the relationship between the relative activity (%) of N-acetyl-D-glucosamine deacetylation of the present invention and the temperature (°C), at pH 7.8.

FIG. 3 shows the relationship between the relative activity (%) of the N-acetyl-D-glucosamine deacetylase
the present invention and the pH value, at 37°C., after incubation at 45°C. for a period of 30 minutes. FIG. 4 shows the relationship between the relative activity (% of the N-acetyl-D-glucosamine deacetylase of the present invention and the temperature (°C), after incubation at pH 7.8 at a given temperature for a period of 30 minutes.

PREFERRED EMBODIMENT OF THE INVENTION

The physico-chemical properties of the enzyme of the present invention are described in detail hereinafter.

1) Action and substrate specificity

Acts on the amidate group of N-acetyl-D-glucosamine and hydrolyzes the latter to D-glucosamine and acetic acid, and substantially does not affect the oligomers including dimer of N-acetyl-D-glucosamine.

2) Optimal pH and stable pH

The optimal pH of the enzyme of the present invention varies widely depending on the origin of the microorganism used to produce the enzyme, but usually in the range of about 4.0-9.0. For example, the optimal pH of the enzyme derived from Vibrio sp. is in the range of 7.8-8.2 as determined colorimetrically according to indole-HCl method at pH 5.6-10.8. The buffer solution used at pH 5.6-6.0 is 100 mM CH₃COOH—CH₃COONa, at pH 6.0-9.0, 100 mM KH₂PO₄—Na₂HPO₄ is used, and at pH 9.6-10.8, 200 mM Na₂HPO₄—NaOH is used.

3) Optimal temperature range

The optimal temperature for the enzymatic activity varies widely depending on the origin of the microorganism used to produce the enzyme, but usually ranges from about 3.0 to 9.0. For example, the stable pH of the enzyme derived from Vibrio sp. is in the range of about 6.0-9.0. The relative activity after such incubation of the enzyme obtained from Vibrio sp. is shown in FIG. 3.

4) Molecular weight

The molecular weight of the enzyme of the present invention as determined by TSK-gel G-3000 SW column is 70,000-200,000. The molecular weight of the enzyme derived from Vibrio sp. is 80,000-150,000.

N-acetyl-D-glucosamine deacetylase of the present invention can be obtained by incubating a microorganism belonging to Vibrio sp. Namely, a microorganism belonging to Vibrio sp. is incubated in a medium containing an inducer. Suitable inducers include chitin, chitin hydrolysate, N-acetyl-D-glucosamine, N-acetyl-D-glucosamine oligomers. These inducers can be used alone or in combination thereof. Inducers are used in a concentration of about 0.1 g/L or above, preferably at 1.0-50 g/L.

The present invention is further described in detail referring to the production of the enzyme from a microorganism Vibrio cholerae non-01 (IFO 15429). The Vibrio sp. microorganisms are publicly known. Among them, Vibrio cholerae non-01 (IFO 15429) was deposited to INSTITUTE FOR FERMENTATION, OSAKA (IFO), 17-85, Jusohonmachi 2-chome, Yodogawa-ku, Osaka 532, Japan, under the accession number IFO 15429. The bacteriological properties of Vibrio cholerae non-01 (IFO 15429) are shown in Can. J. Microbiol., Vol.31, 711-720 (1985) and Bergey's Manual of Systematic Bacteriology Vol. 1, 518 (1957). In Bergey's Manual of Systematic Bacteriology, Vibrio Pacini corresponds to Vibrio cholerae non-01.

1) Incubation conditions

The cells of a microorganism Vibrio cholerae non-01 (IFO 15429) is at first incubated in a conventional nutrition medium which need not specifically defined. For example, such conventional medium contains glucose, maltose, xylose, sucrose, etc., as a carbon source, yeast extract, peptone, meat extract, organic nitrogen sources such as aminoacid, inorganic nitrogen sources such as ammonium sulfate, ammonium chloride, etc., as a nitrogen source, magnesium sulfate, magnesium chloride, sodium phosphate, potassium phosphate, potassium chloride, sodium chloride, calcium chloride, etc., as a mineral source, in an appropriate combinations. The pH of the medium is adjusted between 6.5-8.0 by the addition of an appropriate acid or base, and the medium is autoclaved. Incubation is conducted aerobically at 25°-40°C., preferably at 37°C., for 5-24 hours with stirring or agitation. The cells from the culture as incubated above is used for the production of N-acetyl-D-glucosamine deacetylase of the present invention by incubating said cells in an induction medium containing an inducer in addition to a carbon source, a nitrogen source and a mineral source.

For example, an induction medium contains 3 g of ammonium nitrate, 1 g of dipotassium hydrogen phosphate, 20 g of sodium chloride, 0.5 g of magnesium sulfate, 0.08 g of calcium chloride, 50 g of N-acetyl-D-glucosamine in 1 L of the medium of pH 7.4. Vibrio cholerae non-01 (IFO 15429) is aerobically incubated at 25°-40°C., preferably at 37°C, for 1-3 days while stirring or agitation.

2) Isolation of the enzyme

The enzyme of the present invention can be recovered and purified from the culture using one or more conventional methods. For example, the culture thus incubated is centrifuged to collect cells, and the cells are disrupted by sonication, to give cell extract. The extract is purified using ion exchange chromatography, adsorption chromatography, gel filtration chromatography, etc. A purification procedure comprises, for example, the following steps:

(1) the cells are disrupted by the treatment with supersonic waves and centrifuged to give cell-free extract;

(2) The cell-free extract is subjected to DEAE Bio-Gel chromatography and eluted with 10 mM phosphate buffer containing 150 mM NaCl;

(3) subjected further to hydroxyapatite column chromatography and eluted with 50 mM phosphate buffer; and

(4) subjected to HPLC using TSK-gel 3000 SW gel-filtration column.

The enrichment degree of the enzyme at each purification step is shown in Table 1 below, wherein the activity is determined by the method as described hereinafter.
As evident from Table 1, after the purification step (4), an enzyme having specific activity of 1.22 unit/mg protein (enriched 346-fold the activity of the initial value) can be obtained. Using this enzyme, enzymatic characteristics as described hereinafter is investigated.

(3) The determination of the enzymatic activity

An enzyme solution (0.1 ml) is added to 0.3 ml of 100 mM phosphate buffer (pH 7.8) containing 0.1 ml of 1% N-acyl-D-glucosamine as a substrate, and the resultant mixture is incubated at 37°C for 30 minutes. The amount of D-glucosamine formed is determined colorimetrically using indole-HCl according to the method of Z. Dische and E. Borenfreund [J. Biol. Chem., 184:517 (1950)]. One unit of the enzyme is defined as the amount of the enzyme which is capable of producing 1 µmol D-glucosamine from N-acyl-D-glucosamine per minute at 37°C.

As described above, N-acyl-D-glucosamine deacytalyase of the present invention is a novel enzyme which has not been known hitherto and which enables to deacytate monomeric N-acyl-D-glucosamine in a mild condition to produce D-glucosamine. It is possible from the substrate specificity of this enzyme to deacytate only monomeric N-acyl-D-glucosamine, among the mixture thereof with oligomers. The deacytated product D-glucosamine is useful as a starting material for the preparation of many pharmaceuticals, functional oligosaccharides, etc., and has a wide range of utility.

The present invention is further illustrated by the following EXAMPLE.

EXAMPLE

1. Incubation of Vibrio cholerae non-01 strain (IFO 15429)

Vibrio cholerae non-01 strain (IFO 15429) was incubated in a plate agar medium containing 0.6 g of ammonium nitrate, 0.2 g of dipotassium hydrogen phosphate, 2 g of sodium chloride, 0.12 g of magnesium sulfate, 0.02 g of calcium chloride, 10 g of glucose and 3 g of agar per 200ml of the medium of pH 7.4 at 37°C. For 24 hours, and the cells were collected using a spatula. The cells thus obtained were then aerobically incubated with shaking for 24 hours in the following induction medium. Induction medium: 1.5 g of ammonium nitrate, 0.5 g of dipotassium hydrogen phosphate, 10 g of sodium chloride, 0.3 g of magnesium sulfate, 0.04 g of calcium chloride, and 25 g of N-acyl-D-glucosamine in 500 ml of a liquid medium of pH 7.4.

2. Recovery and purification of the enzyme

The culture thus obtained was centrifuged at 8000 g for 20 minutes to afford 11 g of wet cells. The cells were suspended in 40 ml of physiological saline and sonicated at 0°C for 10 minutes (20 seconds operations at intervals of 20 seconds), then centrifuged to give cell-free extract containing 1.73 g of a protein having specific activity of 0.00358 unit/mg protein.

The cell-free extract as obtained above was applied to a column charged with DEAE Bio-Gel A which had been equilibrated with 0.01M phosphate buffer (pH 7.0), and eluted with a stepwise NaCl gradient eluent. Using 150 mM NaCl, 68.6 mg of a protein having specific activity of 0.0875 U/mg protein was eluted. The eluate was further applied to a hydroxypatite column and eluted with a stepwise gradient phosphate buffer. 10 ml of an eluate containing 2.45 mg of a protein having specific activity of 0.373 U/mg protein was eluted using 50 mM phosphate buffer.

The eluate (10 ml) thus obtained was concentrated to 0.4ml by ultrafiltration (exclusion limit 100,000) and subjected to HPLC using TSK gel 3000 SW column to give 0.72 mg of purified enzyme having specific activity of 1.22 U/mg protein. The enrichment degree of the activity was 346-fold of the initial value and the recovery of the enzyme was 14.2%. The molecular weight of this enzyme was 80,000-150,000.

3. Substrate specificity of the enzyme

The substrate specificity of the enzyme as obtained above was investigated using monomer and several oligomers (2-6mers) of N-acyl-D-glucosamine (SEIKAGAKU KOGYO CO. LTD. Japan), and chitin as a substrate. These substrates were added at a concentration of 0.2%, and the enzymatic reaction was allowed to take place at a temperature of 37°C and a pH of 7.8 for one hour. The amount of D-glucosamine formed was determined using indole-HCl according to the method of Z. Dische and E. Borenfreund [J. Biol. Chem., 184:517 (1950)]. The results obtained are shown in Table 2 below.

One unit of enzyme activity is defined as the amount of the enzyme required to form 1 µmole of the amino group per min at 37°C.

As seen from Table 2 above, formation of D-glucosamine from monomeric N-acyl-D-glucosamine can be observed while none of the oligomers tested (2-mer to 6-mer) and chitin show the formation of D-glucosamine.

What is claimed is:

1. N-acyl-D-glucosamine deacytalyase capable of hydrolyzing the acetamide group of N-acyl-D-glucosamine to produce D-glucosamine and acetic acid, which is obtained from Vibrio cholerae non-01 (IFO 15429) and which has the following physicochemical properties:

   substrate specificity: N-acyl-D-glucosamine monomer;
   optimal pH: 7.8-8.2 at 37°C;
   stable pH: 6.0-9.0 at 45°C;
   optimal temperature: 28°C-39°C; and
   molecular weight: 70,000-200,000.

2. N-acyl-D-glucosamine deacytalyase as claimed in claim 1 which has a molecular weight of 80,000-150,000.

* * * * *
