**RIFAXIMIN POWDER, PROCESS FOR PREPARING THE
SAME AND CONTROLLED RELEASE COMPOSITIONS
CONTAINING SAID RIFAXIMIN USEFUL FOR OBTAINING A
LONG-LASTING EFFECT**

(57) Abstract:

The present invention describes rifaximin powder and to a process for preparing the same. The invention relates also to a pharmaceutical composition in solid form comprising said rifaximin, pharmaceutically acceptable excipients and optionally other ingredients. The compositions according to the invention are suitable for oral administration and are characterized by producing a controlled release of rifaximin, whereby a long-lasting effect is obtained in a patient.

**RIFAXIMIN POWDER, PROCESS FOR PREPARING THE SAME AND
CONTROLLED RELEASE COMPOSITIONS CONTAINING SAID
RIFAXIMIN USEFUL FOR OBTAINING A LONG-LASTING EFFECT**

5 The present invention concerns rifaximin powder, a process for preparing the same, solid compositions comprising said rifaximin, and their use as a medicament.

State of the art

 Rifaximin (INN; see The Merck Index, XIII Ed., 8304, CAS no. 80621-81-
10 4), IUPAC nomenclature (2S,16Z,18E,20S,21S,22R, 23R,24R,25S,26S,27S,28E)-
5,6,21,23,25 pentahydroxy-27-methoxy-2,4,11,16,20,22,24,26-octamethyl-2,7-
(epoxypentadeca-(1,11,13) trienimino) benzofuro (4,5-e) pyrido(1,2,-a) benzimi-
dazole-1,15(2H)-dione,25-acetate) is a semi-synthetic antibiotic belonging to the
rifamycin class of antibiotics. More precisely rifaximin is a pyrido-imidazo
15 rifamycin described in the Italian patent IT 1154655, whereas the European patent
EP 0161534 discloses a process for rifaximin production using rifamycin O as
starting material (The Merck Index, XIII Ed., 8301).

 US 7,045,620, US 2008/0262220, US 7, 612,199, US 2009/0130201 and
Cryst. Eng. Comm., 2008, 10 1074-1081 (2008) disclose new forms of rifaximin.

20 Rifaximin, characterized by a systemic adsorption depending by the solid forms, in particular by the crystalline or amorphous forms, is known for its antibacterial activity exerted, for example, against bacteria localized in the gastrointestinal tract that cause, for instance, infectious bowel diseases, diarrhoea, irritable bowel syndrome (IBS), small intestinal bacterial overgrowth (SIBO),
25 Crohn's disease (CD), pancreatic insufficiency, enteritis, fibromyalgia.

 Antibiotics or combinations of antibiotics such as, for instance, neomycin, metronidazole, ciprofloxacin, doxycycline, tetracycline, penicillin, ampicillin,

kanamycin, rifamycin, vancomycin and rifaximin are used in the therapy against bacterial bowel infections. Among them the antibiotics having a low systemic adsorption are preferred, such as, for instance, some crystalline forms of rifaximin. Antibiotics having a low systemic adsorption typically have an adsorption lower
5 than 10%, and in particular between 0.05% and 1% of the nominal concentration.

The intestinal apparatus is subject to various inflammatory pathologies, generally termed as bowel diseases, known in the literature as “intestinal bowel disease” (IBD), and among them a particular relevance is given to IBS and CD.

IBS is a bowel disease affecting 10-20% of the adult population in Western
10 countries. It is a disease characterized by a chronic recurrence of symptoms such as abdominal pain, swelling, meteorism, feelings of urgency or incomplete evacuation, and it is associated to alterations of the intestinal activity.

CD is a chronic inflammatory disease affecting various levels of the digestive tract, from the mouth to the anus. It is prevalingly localized in the last
15 part of the small intestine, called ileum, thus taking the name of terminal ileitis, or in the colon, thus taking the name of colitis, or in both regions (thus taking the name of ileocolitis), but sometimes only in the colon mucosa and in the anal region. The affected intestinal tracts show inflammation, swelling and ulcerations in the whole intestinal wall, often causing stenosis and bleeding ulcers, whereas
20 the tissue interposed between the sick areas appears normal. There is an alternation of periods with inflammatory manifestations of variable gravity and of periods of remission, wherein the main symptoms are represented by diarrhoea, abdominal pain and weight loss, often accompanied by rhagades or perirectal fistulas, frequently requiring a surgical treatment.

25 Although, generally speaking, the aetiology of inflammatory diseases is still in need of further investigations, some genetic, inflammatory, infective,

nutritional, immune-mucosal and neuro-immune-mucosal factors have been found out. However, three theories have been most successful: the presence of a chronic infectious stimulus, a defect of the mucosal barrier and an altered response of the membrane immune system to autologous antigens.

5 The role of the intestinal bacterial flora in the aetiopathogenesis of intestinal inflammatory pathologies, and in particular in Crohn's disease, is remarked by a series of unmistakable signs: the disease is more frequently localized in areas with high bacterial concentrations, as described by Janowitz H. D. et al. in *Inflamm. Bowel Dis.* 1998, 4, 29-39; the diversion of the faecal flow leads to the remission
10 of the endoscopic lesions which reappear again at restoration of the canalization, as described by Rutgeerts P. et al. in *Lancet*, 1991, 338, 771-774; in experimental models of knockout mouse for the IL-10 gene or others, the spontaneous colitis does not develop if the "germ-free" condition is maintained, as described by Blumberg R.S. et al. in *Curr. Opin. Immunol.*, 1999, 11(6), 648-56; the
15 inflammation of the intestinal mucous membrane develops as a consequence of the contact with the faecal material, as described by Harper P.H. et al. in *Gut*, 1985, 26(3), 279-84; in the case of patients submitted to a surgical "curative" therapy consisting of ileocolic anastomosis, the antibiotics treatment delays the development of both endoscopic and clinic relapses, as described by Cameron J.L.
20 et al. in *Ann. Surg.*, 1992, 215, 546-52; the presence of fistulas or abscess-sacs further points out the bacterial contribution to the disease development.

 In medical therapy, medicaments able to reduce or control the inflammation such as cortisones, salazopirine, mesalazine, immunosuppressants, specific chemotherapeutics, antibiotics and protein inhibitors of the actions of the Tumor
25 Necrosis Factor (TNF) or of the adhesion of leucocytes, are largely used.

 During the treatment of the acute phase of the inflammatory bowel disease,

stronger treatments, such as parenteral alimentation, are often necessary to reconstitute the loss of proteins, liquids and salts, and above all to permit the intestine to rest in order to facilitate the cicatrization of ulcers.

The purpose of the therapy is to decrease the frequency of the reappearance
5 of symptoms and to reduce the seriousness of the acute episodes when they appear.

However, with current therapies, acute episodes respond in about 50-70% of the cases, but relapses occur in 80% of the patients.

Antibiotics are largely used to decrease the growth of the luminal bacteria and therefore to decrease the inflammatory state sustained as a result of the
10 bacterial growth; to reduce symptoms of the acute phase of the disease, e.g., diarrhoea, intestinal pain and meteorism; and to prevent and to cure septic complications, such as abscesses, fistulas and toxic state.

The most frequently used antibiotics are systemically absorbed, for example, metronidazole, active against some parasites and many anaerobic
15 bacteria, and ciprofloxacin, active against such bacteria as E. Coli and aerobic enterobacteriaceae.

Metronidazole has been used at a dose of 10-20 mg/kg/day for 4 months, as described by Sunterland, L. Gut, 1991 32, 1071-5, while ciprofloxacin has been used at a dose of 1000 mg/day for 6 weeks, as described by Colombel J.F. in Am.
20 J. Gastroenterol., 1999, 94, 674-8, while Prantera C. et al. in Am. J. Gastroenterol., 1996, 91, 328-32, adopted the combination of the two aforesaid antibiotics using metronidazole at the dose of 1000 mg/day and ciprofloxacin at the dose of 1000 mg/day for 12 weeks.

Unfortunately, the high systemic bioavailability of these antibiotics is at the
25 basis of their high incidence of side effects registered in long-term therapies, which negatively impacts their use.

It is advantageous for a pharmaceutical preparation based on antibiotics used for efficaciously treating inflammatory bowel diseases to have one or more of the following characteristics: intestinal level activity, bacteria level control in the intestinal lumen, wide spectrum of actions against the microbes (e.g., intestinal
5 Gram-positive, Gram-negative, aerobic and anaerobic components), possibility of long term therapy without severe side effects, ease of administration to facilitate compliance even with the potential of high dosage necessity.

An antibiotic possessing several of these characteristics is rifaximin, which is characterized by a wide spectrum of actions against many Gram- positive and
10 Gram-negative bacteria, including aerobic and anaerobic bacteria. Bioavailability studies in healthy volunteers have shown that, when administered orally, less than 1% of rifaximin is absorbed and it concentrates in the intestinal lumen and in the faeces. This has been confirmed in patients affected by chronic bowel disease by Rizzello F. et al., Eur. J. Clin. Pharmacol. (1998) 54, 91-93.

15 The low systemic absorption of rifaximin reduces the incidence of side effects, adverse events and the unwanted risk of pharmacological interactions. Thus, rifaximin may be considered useful in the therapy of inflammatory chronic bowel disease.

Presently, rifaximin is approved for the treatment of pathologies whose
20 aetiology is in part or totally due to intestinal acute and chronic infections sustained by Gram-positive and Gram-negative bacteria, with diarrhoea syndromes, altered intestinal microbial flora diarrhoea like summer diarrhoeic episodes, traveller's diarrhoea, enterocolitis, pre- and post- surgery prophylaxis of the infective complications in gastro intestinal surgery and as coadjutant in the
25 hyperammonaemia therapy.

Rifaximin is currently marketed as tablets and capsules in ready-to-use

preparations for a suspension, or as ointment for the treatment of topical infections, or as collyrium against ocular infections.

The use of antibiotic in the clinical practice is directed by stringent control of dosage, both as amount of administered antibiotic and frequency of administration. Generally speaking, the target in antibiotic therapy is to provide plasma concentrations of antibiotics which never go below therapeutically significant thresholds over a time period of 3-7 days.

Usually these thresholds are established on the basis of the measure of the microbial inhibitory concentrations (MICs), which represent the lowest concentration of antibiotics to completely inhibit visible growth of microbial agents over a time period of about 18-24 hours at an incubation temperature of about 35° C. Sometimes reference is made to MIC50 and MIC90 values, which are defined as the lowest concentrations capable of inhibiting the growth of 50% and 90% of microbial isolates.

Regarding possible adverse events connected to the use of antibiotics, the problem of bacterial resistance to the antibiotic in use is well known. Also in the hospital setting, the use of antibiotics is often associated with an increase in the frequency of antibiotic resistance, whereas a reduced consumption of antibiotics may be followed by a reduction of resistance to specific drugs, as described by Guillemot D. et al., *Current Opinion in Microbiology*, 1999, 2:494–498.

The purpose of choosing the antibiotic dosage is that of maintaining their plasma concentration never below some threshold values in order to guarantee the eradication of pathogenic microorganisms. In fact, if the plasmatic antibiotic concentrations were lower than those able to inhibit the bacterial growth, or in case of periods of therapy in which the antibiotic is absent, the eradication of pathogens would not be guaranteed and, with an even more dramatic effect, the generation of

bacteria resistant to antibiotics could be favoured. In the presence of concentrations lower than MICs, or when the antibiotic is not present, bacteria are in fact able to reproduce and to adapt, thus making the antibiotic action ineffective.

In the case of rifaximin it must be remarked that it is a locally-acting agent, which acts against pathogens which are present in the gastro-intestinal tract, on the mucosa surface or on the intestinal mucosa.

One of the mechanisms of action of rifaximin is the alteration of virulence factor of the enteric bacteria pathogens. This mechanism occurs at supra-, but most importantly, also at sub-inhibitory concentrations of rifaximin such 32-folds lower than the MIC values. It is concluded by Debbia et al., J. Chemother. 20 (2), 186-94, 2008 that this lethal effect mainly depends on the time in which the antibiotic is in contact with the bacteria and does not appear to be influenced by the antibiotic concentration.

The relevance of rifaximin contact with bacteria in the mechanism of action is also supported by Jiang Z.D. et al. in Int. J. Antimicrob. Agents 35(3), 278-81, 2010, who shows that rifaximin is effective in the alteration of the virulence of enterotoxogenic Escherichia coli isolates even at a concentration 8-fold lower than MIC, at the condition of providing the continuous contact of rifaximin with the pathogens at such concentration for at least 24 hours. On the contrary, if the contact is maintained only for 8 hours, the virulence of the pathogens is not abolished.

The evidence reported by Jiang Z.D. stresses the importance of providing a continuous presence of rifaximin in both the small and large bowel during therapies treating pathologies wherein bacterial agents in the intestinal tract are the cause of the disease.

Combining the importance of the contact time of rifaximin with pathogens

to be effective with the fact that these pathogens are localised in the bowel, it can be inferred that drugs which can provide a more lasting residence time of rifaximin in the bowel could result to be more effective.

In this respect it is therefore important to determine the rifaximin time of
5 contact with pathogenic bacteria in the intestinal tract.

However, this information is hardly obtainable. In fact, as rifaximin is negligibly soluble in water, any in-vitro models do not accurately reproduce the complex intestinal environment. On the contrary, in-vivo studies on humans should foresee the use of a product marked with a radioactive isotope with the
10 relative problems of formulation implied by the use of radioactive materials.

However, useful information on rifaximin bowel residence time can be indirectly obtained by speculating on the pharmacokinetic (PK) profile of rifaximin in humans, in which the concentration of the active ingredient or active moiety in biological fluid (blood, plasma, serum and/or urine) is measured as a
15 function of time. Generally speaking, it can be stated that the PK profile of an orally administered compound has to be considered dependent by the transient amount of the compound in the small intestine, which is the main absorptive site. An increase in the amount of the compound in the small intestine or a prolonged residence time are both factors favouring the systemic absorption.

20 The contemporaneous presence of a compound in blood and in the small intestine does not necessarily occur, since a compound requires a certain period of time for passing from the intestine to the blood; period of time depending both from the characteristics of the compound and from the physiologic or pathologic characteristics of the subject. In a healthy subject, this period of time is usually
25 approximately one hour.

The correlation between the systemic concentrations of a compound and the

availability of the same in the small intestine is well known and largely exploited by pharmaceutical technology. In fact, in order to favour the absorption, measures are taken for increasing the presence of the compound in the small intestine. On the contrary, in order to oppose the systemic concentration, measures are taken for
5 hindering the release of the compound in the small intestine, for instance employing colonic release technologies.

In conclusion, the systemic bioavailability of an orally administered compound also depends on all those characteristics of a drug which can affect the release and the duration of the permanence of the active ingredient in the intestine,
10 such as the characteristics of the active ingredient, the drug composition comprising the active ingredient, and the form of the administered drug (e.g. tablets, capsules, suspensions, gastro-resistant preparations or controlled-release preparations).

Also, the drug preparation process has a particular relevance. In fact,
15 through the preparation method both the dissolution profile and the disaggregation profile of the drug can be modulated, thus making the active ingredient more or less available.

These concepts are entirely applicable to rifaximin. Therefore, a rifaximin concentration detectable in the plasma at a certain time must correspond to a
20 rifaximin amount present in the small intestine at an earlier time. The correlation between the rifaximin amount in the intestine and the following plasma concentrations depends on the absorption of rifaximin and on the time of passage into the small intestine.

Therefore, it can be stated that a maximum plasma concentration of
25 rifaximin, measured at a certain time, corresponds to a maximum amount of rifaximin present in the small intestine. Obviously, the absence of rifaximin in the

plasma at a certain time should be an indication that there was a period of time in which rifaximin was not present in the small intestine.

PK data of rifaximin after oral administration of 400 mg tablets in humans are reported by Descombe J.J. et al. in Int. J. Clin. Pharmacol. Res., 14 (2), 51-56, 5 (1994). In particular, this document reports in Table II, that in most cases, sixteen out of eighteen subjects, no amount of rifaximin is detectable in the blood 4 hours after the administration, and in all cases there is no detectable amount 8 hours after the administration.

Since the product commercialized in the USA with the trademark 10 XIFAXAN® containing rifaximin foresees the administration of a 200 mg tablet every 8 hours for the treatment of the “traveller’s diarrhoea”, it can be deduced from the aforesaid that the approved administration schedule does not guarantee a constant presence of rifaximin in the small intestine and therefore an optimal antibiotic activity.

15 It follows that any pharmaceutical composition comprising rifaximin which were able to release rifaximin with extended time of residence in the small intestine, would be considered an improvement to the therapeutic efficiency of rifaximin.

There thus exists the need for improved compositions able to release 20 constant quantity of rifaximin, thereby maintaining a constant level of this antibiotic in plasma for a prolonged time.

Brief description of the invention

It has been surprisingly found that compositions containing rifaximin in a solid powder form obtained by a spray drying process with pharmaceutically 25 acceptable excipients and optionally other ingredients, provides a controlled release of rifaximin and a long-lasting antibiotic effect in a patient.

Another aspect of the present invention is rifaximin powder obtained by a spray drying process. Said rifaximin powder is characterized by particular particle size distribution, porosity and surface area values as defined in the appended claims.

5 Another aspect of the invention is the spray-drying process used for preparing the rifaximin defined above, which is obtained using a solution of crystalline or amorphous rifaximin or their mixtures.

Another aspect of the invention is rifaximin obtained by spray drying for use as medicine.

10 Another aspect of the invention is composition rifaximin by spray drying - containing composition.

Another aspect of the invention is the composition containing rifaximin by spray drying for the treatment of pathologies like inflammatory disease and bacterial infections.

15 Another aspect of the invention is the composition containing rifaximin by spray drying for preventing pathologies like bacterial infections and the method of treatment in human and animal.

Another aspect of the invention of the invention is composition comprising other active ingredients and / or other forms of rifaximin.

Detailed description of the invention

The present invention concerns rifaximin powder, a process for preparing
 10 the same, pharmaceutical compositions or pharmaceutical preparations comprising
 said rifaximin, and the use of these compositions and/or preparations for treating
 bowel diseases such as, for example, inflammatory bowel diseases, traveller's
 diarrhoea, IBS, SIBO, CD, hyperammonaemia therapy, hepatic encephalopathy,
 ulcerative colitis, enteritis, chronic pancreatitis, pancreatic insufficiency, colitis,
 15 diverticular disease, fibromyalgia, systemic lupus erythematosus and/or pouchitis.

Rifaximin is a compound represented by the formula

The present invention also concerns compositions containing 4-deoxy-4'-
 20 methyl-pyrido [1',2'-1,2] imidazo [5,4-c]rifamycin SV and 4-deoxy-pyrido

[1',2':1,2] imidazo [5,4-c] rifamycin SV.

Rifaximin is approved and commercialized in several countries for the treatment of bowel infections, for the treatment of diarrhoea due to infection, for the prevention of post-surgical infections, for the treatment of hyperammonaemia
5 and of hepatic encephalopathy. In particular in the USA, UK, Denmark and in Germany, rifaximin is approved for the treatment of bowel diseases called traveller's diarrhoea with a treatment schedule which foresees the administration of a 200 mg tablet three times a day for three days in a row.

Subjects affected by bowel diseases (BD), subjects suffering under active
10 or acute diseases or syndromes and subjects in remission after one or more bowel diseases can benefit by a rifaximin treatment. The term bowel diseases includes, for example, irritable bowel syndrome (IBS), uncontrolled diarrhoea-associated Irritable Bowel Syndrome (dIBS), Crohn's disease, traveller's diarrhoea, ulcerative colitis, enteritis, small intestinal bacterial overgrowth, chronic pancreatitis,
15 pancreatic insufficiency, colitis, diverticular disease, fibromyalgia, systemic lupus erythematosus or hepatic encephalopathy.

In particular, the subjects who can benefit by this treatment are those suffering from or being susceptible to forms of bowel diseases.

The term "rifaximin" indicates solvates and crystalline and amorphous
20 forms of rifaximin. These polymorphous rifaximin forms are described in US 7,045,620, US 2008/0262220, US 7,612,199, US 2009/0130201 e in Cryst. Eng. Comm., 2008, 10 1074-1081.

The term "polymorphous/polymorphism" here indicates different crystalline forms of the compound in a hydrated state as property of some compounds and
25 complexes, salts, solvates and amorphous.

A single compound can exist in a variety of polymorphic forms, which,

though having the same molecular formula, have different physical properties, such as solubility, fusion temperature, hygroscopicity, size of particles, density and X-ray diffraction spectra. Moreover, the solubility of each polymorphous form can vary, thus varying also its bioavailability. That is the reason why the identification
5 of pharmaceutical polymorphous forms is relevant for obtaining pharmaceutical forms with foreseeable solubility profiles. The polymorphic forms of a compound can be determined by X-ray diffraction spectroscopy and by means of other methods like IR spectroscopy.

The object of the present invention is represented by pharmaceutical
10 composition comprising a rifaximin solid preparation specifically prepared for conferring improved solubility, the method for obtaining said rifaximin preparation, the pharmaceutical composition containing said rifaximin preparation suitable for guaranteeing a prolonged release in the time of rifaximin, the process for their preparation and the use in pathologies like bacterial infections and method
15 of treatment.

The combination of properties of the rifaximin powder according to the invention and of the pharmaceutical composition comprising said rifaximin ensures that the composition, in particular in the form of tablets, releases rifaximin at predictable and controlled release. Advantageously the solid composition
20 according to the invention maintains an effective rifaximin concentration in plasma during the treatment.

The composition contains rifaximin alone or in a mixture with other polymorphic forms of rifaximin to modulate the in vivo absorption.

Another aspect of the present invention is represented by the rifaximin solid
25 preparation comprised in the pharmaceutical composition.

In a preferred aspect the composition for oral use is in the form of tablets or

capsules containing an amount of rifaximin comprised between 20 and 800 mg. The amount of rifaximin in the pharmaceutical composition may thus be varied so as to obtain an amount suitable to achieve the desired therapeutic response in a patient, without causing any toxic effect on the subject.

5 For rifaximin a typical dose range is from 25 to 3000 mg per day, without causing any toxicity or other side effects. Rifaximin in pharmaceutical composition is administered at a concentration of about 1 mg to about 200 mg per kilogram of body of a patient.

The composition of the present invention provides by a high therapeutic
10 effectiveness thanks to a longer time of permanence of the antibiotic activity in the site of infection.

The composition object of the present invention is useful in the treatment of human or animal subjects affected by bowel diseases or other diseases treatable with an antibiotic belonging to the rifamycin class, like rifaximin, or in the
15 treatment of subjects who could benefit by the administration of said antibiotics, or who could be in danger of developing a bowel disease, or subjects in remission from a bowel disease, or subjects in relapse to bowel diseases, for instance subjects affected by immunosuppression, subjects exposed to bacterial infections, familiar with bowel syndromes, subjects suffering under hepatic damages, subjects with
20 past episodes of HE.

Another aspect of the present invention is represented by methods of treating, preventing, or alleviating bowel related disorders comprising administering to a subject in need thereof an effective amount of solid dispersion compositions of rifaximin. Bowel related disorders include one or more of irritable
25 bowel syndrome, diarrhoea, microbe associated diarrhoea, *Clostridium difficile* associated diarrhoea, travelers' diarrhoea, small intestinal bacterial overgrowth,

Crohn's disease, diverticular disease, chronic pancreatitis, pancreatic insufficiency, enteritis, colitis, hepatic encephalopathy.

The length of treatment for a particular bowel disorder will depend in part on the disorder. For example, traveler's diarrhoea may only require treatment
5 duration of 12 to about 72 hours, while Crohn's disease may require treatment durations from about 2 days to 3 months.

Rifaximin in pharmaceutical composition is useful for the prophylactic treatment for intestinal infections.

Rifaximin obtained by the process of the present invention can be used for
10 the preparation of pharmaceutical composition without any limitation, such as vaginal infections or topical infections.

Pharmaceutical compositions of the present invention can be used to treat gastric dyspepsia, including gastritis, gastroduodenitis, antral gastritis, antral erosions, erosive duodenitis and peptic ulcers.

15 A particular aspect of the present invention is represented by pharmaceutical compositions in form of tablets comprising rifaximin obtained by spray drying with pharmaceutically acceptable excipients.

The pharmaceutical excipients can comprise, for example, one or more of a diluting agent, binding agent, lubricating agent, disintegrating agent, glidants,
20 colouring agent, flavouring agent or sweetening agent. The composition may be formulated for selected coated and uncoated tablets, hard and soft gelatin capsules, sugar-coated pills, lozenges, wafer sheets, pellets, and powders in sealed packet. Solid composition are not limiting and rifaximin prepared by spray-drying may be formulated for topical use, for example, ointments, pomades, creams, gels and
25 lotions, suspension in an aqueous or non-aqueous emulsion, elixir or syrup containing a predetermined amount of a rifaximin preparation by spray drying.

According to the invention rifaximin is administered to the subject by using a pharmaceutically acceptable composition that provides prolonged release the rifaximin to a subject.

Rifaximin powder according to the present invention is described in
5 Example 1, wherein the present rifaximin is prepared by using a spray-drying technique starting from crystalline or amorphous forms of rifaximin, or from mixtures thereof. Said process allows to obtain solid powders having characteristics described below and in particular characteristic of amorphous form.

The starting crystalline or amorphous forms of rifaximin, or their mixtures,
10 are charged in a spray drying apparatus, such as a fluid bed equipment, previously heated, such as, for instance, a Glatt GPCG 60, provided with e.g. an 18-inch Wurster system and a spraying nozzle, with an amount of organic solvent comprised between 1 and 40 litres per kg of rifaximin. The obtained suspension is then kept under stirring till complete dissolution of rifaximin.

15 Any suitable organic solvent can be used. For example alcohols C1- C4 can be used, ethanol or methanol being preferred.

The rifaximin containing solution is then sprayed inside the fluid bed apparatus at a pressure comprised between 0.5 and 2.5 bar under a flow of warm air. Then the solid rifaximin, dried until reaching constant weight at a temperature
20 comprised between 20°C and 120°C, preferably 35°C and 110°C, and the formed particles are dried in a temperature range comprised between 20°C and 120°C, preferably between 35°C and 110°C, until reaching constant weight.

The solid powder obtained after drying is analyzed by X-ray diffraction spectroscopy. The X-ray diffractogram obtained does not show any peaks
25 characterizing the cristallinity, as reported in the analytical characterization below.

Figure 3 shows the X-ray diffractogram, Figures 4 show the ¹³C-NMR

spectrum, and Figure 5 shows the FT-IR spectra of the rifaximin obtained by spray drying. The obtained rifaximin in powder form is stable after three months in a temperature range comprised between 30°C and 40°C, with a humidity degree higher than 50%, which demonstrates that this active ingredient can be prepared
5 and stored until its use.

A solid powder of rifaximin in a substantially amorphous form can be prepared also by a milling process, wherein the milling can be performed manually or automatically.

A rifaximin solid powder having characteristics of amorphous form
10 obtained by spray drying was compared with a rifaximin solid powder obtained by milling. A comparative analysis of the X-ray diffractogram, particle size distribution (PSD), scanning electron microscope (SEM), specific surface area (BET), density and solubility, is reported in Example 2.

Figure 3 and Figure 6 show X-ray diffractograms of rifaximin obtained by
15 spray drying and by milling, respectively. Both the solid forms are characterized by a non-crystalline profile in which the absence of sharp peaks indicates the presence of amorphous forms of rifaximin. The X-ray powder diffraction peaks in Figure 3 and 6 are distinct, and in particular rifaximin by spray drying is characterized by the halo- peaks with maximum at about $7.75^{\circ} \pm 0.2$, $14.54^{\circ} \pm 0.2$
20 and $18.33^{\circ} \pm 0.2$, 2θ ; rifaximin by milling is characterized by the halo-peaks with maximum at $7.44^{\circ} \pm 0.2$, $14.40^{\circ} \pm 0.2$; $17.19^{\circ} \pm 0.2$, 2θ .

The particle size distribution (PSD) analysis shows that the solid form of rifaximin obtained by spray drying has a particles size distribution more homogeneous in respect to the rifaximin powder obtained by the milling process,
25 as shown in Figure 7 and in Figure 8.

In particular, rifaximin prepared by spray drying is characterized by a

substantially symmetric profile of the particle size distribution around 20 micrometers particles diameter, wherein the measure of d_{90} , (percentage of 90% of the particles diameter) is comprised between 40 and 120 micrometers, d_{50} (percentage of 50% of the particles diameter) is comprised between 15 and 30 micrometers and d_{10} , (percentage of 10% of the particles diameter) is comprised between 2 and 10 micrometers. Rifaximin obtained by milling process is characterized by a non symmetric profile, wherein d_{90} is comprised between 10 and 20 micrometers, d_{50} is comprised between 6 and 12 micrometers, and d_{10} is comprised between 0.5 and 4 micrometers.

Scanning electron microscopy (SEM) analysis shows that the rifaximin powder obtained by spray drying shows aggregates having dimension between about 10 μm and 40 μm , while SEM of rifaximin obtained by milling process shows aggregates having dimension between about 3 and 15 micrometers. Visual inspection of the images obtained and reported in Figure 7 and Figure 8 demonstrate these differences in the powder form.

Bulk density of rifaximin solid forms prepared by spray drying was measured in respect to the solid rifaximin by milling corresponding to their mass per unit volume. The bulk density measure of particles is an important physical characteristic of the pharmaceutical powder and the density of a solid depends on its assembly and therefore varies with the crystal structure and degree of crystallinity. In particular when a solid is amorphous or partially amorphous, its density may further depend upon the preparation, treatment and storage.

Three measures with three different samples were done for rifaximin by spray drying and for rifaximin by milling and the density calculated in grams per milliliter using a 10 ml volumetric flask.

The bulk density of rifaximin by spray drying is between 0.1 and 0.5 g/ml

and the density of rifaximin by milling is between 0.3 and 0.6 g/ml.

The measure of specific surface area (BET) based on the physical absorption of inert gas, such as nitrogen on the rifaximin surface permits to show the difference in the particle size of rifaximin obtained by spray drying in respect to the rifaximin obtained by milling. From this technique it results that rifaximin by milling has a specific surface greater than rifaximin by spray drying. In particular BET of powder particle size of rifaximin by milling can range from 5 to 20 m²/g, and more particularly between 9 to 12 m²/g, while the BET of rifaximin by spray drying is between 0.01 to 10 m²/g and more particularly between 5 to 8 m²/g.

Comparative dissolution tests for rifaximin powders prepared by spray drying and by milling are reported in Example 2. The test was carried out in phosphate buffer at pH 6.8 at a temperature of 30±0.5°C. The results reported in Table 5 show that the rifaximin obtained by spray drying has a higher dissolution capacity if compared, for instance, to the rifaximin form prepared by milling and the concentration of solubilised rifaximin can range from 1.1 to 3 times with respect to the rifaximin obtained by milling.

The comparative analysis demonstrate that X-ray powder diffraction spectrum, PSD, BET, bulk density and solubility of rifaximin prepared by spray drying are features derived by the morphology of the powder, which in turn is determined by the preparation process.

The method of preparation of rifaximin by the spray drying process confers to the rifaximin preparation particular chemical -physical properties, different from other amorphous forms, such as for instance to the rifaximin obtained by means of a milling process.

The preparation of the tablets according to the present invention is carried

out by means of a process comprising the steps of:

- a) dry granulation of rifaximin obtained by a spray drying process, optionally mixed with rifaximin in crystalline form or in a mixture with other hydrate, solvate or amorphous form of rifaximin and/or in the presence of pharmaceutically acceptable excipients;
- b) lubrication of the obtained granulate ;
- c) tableting the granulate of step b) with pharmaceutically acceptable excipients;
- d) optionally, preparation of coating varnish and coating of cores.

Example 3 describes a non limiting preparation of tablets comprising rifaximin obtained by a spray drying process.

The rifaximin powder obtained by spray drying is in form of granules. The granules are compressed in a Kilian machine, or an equivalent thereof, equipped with concave punches having different diameters according to the desired shape of the tablet with extra granule acceptable excipients.

The term “pharmaceutically acceptable excipients” includes, for instance, disgregants, lubricants, glidants, diluents, buffering agents, opacizer, plasticizer colouring flavouring.

The solid composition can comprise bioadhesive compounds providing bioadhesive properties.

Disgregants are selected among, for instance, cellulose derivatives such as sodium carboxymethylcellulose also called carmelose, cross-linked sodium carboxymethylcellulose also called croscarmellose, hydroxyl propyl methyl cellulose, hydroxyl propyl ethyl cellulose, hydroxyl propyl cellulose phthalate, polyvinyl acetate phthalate, povidone (polymer of polyvinylpyrrolidone), copovidone (copolymer of polyvinylpyrrolidone), acrylic polymer and copolymer,

polyvinyl acetate phthalate, poly vinyl acetate phthalate, or sodium starch glycolate and lubricants, such as for instance magnesium or calcium stearate, sodium stearyl fumarate, vegetable hydrogenated oils, mineral oils, polyethylene glycols, sodium lauryl sulfate, glycerides, sodium benzoate or their mixture.

5 Diluents are selected among cellulose, microcrystalline cellulose, calcium phosphate, starch, kaolin, hydrated calcium sulfate, calcium carbonate, lactose, sucrose, mannitol, glucose, glucans, xyloglucans, starches, such as corn starch and potato starch, powdered tragacanth, malt, gelatin.

 The tablets can comprise glidants such as talc, cellulose microcrystalline or
10 magnesium carbonate and lubricant such as magnesium or calcium stearate, glycerol distearate, glycerol dibenate.

 The tablets can also comprise excipients, such as and natural oil, glycols, such as propylene glycol, polyols, such as glycerin, sorbitol, mannitol and polyethylene glycol, esters, such as ethyl oleate and ethyl laurate, buffering agents,
15 such as magnesium hydroxide and aluminum hydroxide, alginic acid, pyrogen-free water; isotonic saline, ethyl alcohol, phosphate buffer solutions, and other non-toxic compatible substances employed in pharmaceutical formulations.

 The tablets also can contain sweetening agents such as sucrose, sorbitol, mannitol, saccharine, acesulfame and neosperidin.

20 Colouring agents, release agents, coating agents, sweetening, flavouring and perfuming agents, preservatives and antioxidants can also be present in the compositions.

 Preservative and antioxidants also can be included, such as ascorbic acid, cysteine hydrochloride, sodium bisulfate, sodium metabisulfite, sodium sulfite and
25 metal chelating agents, such as citric acid, ethylenediamine tetraacetic acid (EDTA), sorbitol, tartaric acid, phosphoric acid.

Other excipients are polysaccharides such as starch, kitosan, chondroitin sulphate, dextran, guar gum, xyloglucan, xantanes or inulin and pectin, plasticizers such as, e.g. adipates, azelates, benzoates, citrates, phthalates, stearates and glycols, cellulose acetate, cellulose acetate butyrate, cellulose acetate propionate, ethyl cellulose, fat acids and their esters, waxes and zeins.

Optionally, hydrophilic polymers such as hydroxy ethyl and hydroxy propyl cellulose can be included.

The tablets can be coated with a film coating formed by filmogen agent such as microcrystalline cellulose, hydroxy methyl cellulose or hydroxy propyl cellulose, opacizer such as titanium dioxide, plasticizer such as propylene glycol or ethylene glycol and optionally colouring or flavouring substances.

To prolong the rifaximin residence time in the small intestine a dissolution profile comprised between 5% and 90% is considered appropriate. In order to achieve this objective a special granulation technology was used. In pharmaceutical technology the method most frequently used by the persons skilled in the art is the wet granulation method, which is adopted when the intent is to favour the dissolution of poorly soluble compounds.

The use of the of the known techniques would have produced the transformation of the amorphous form to other forms with the risk to have a complete dissolution or dissolution at concentrations lower than 5% (Cryst. Eng. Comm., 2008, 10, 1074-1081).

On the contrary, by adopting a dry granulation technique it was possible to prevent such transformation and to obtain tablets characterized by a dissolution corresponding to a value comprised between 5% and 90% of the rifaximin contained in the composition, according to the requirements described in European Pharmacopoeia Ed. 6.0 pp. 266-275.

In a particular aspect, pharmaceutical compositions in tablets comprising rifaximin in solid form obtained by spray drying process, comprise one or more disgregant, one or more glidants, one or more diluents wherein rifaximin can range between 10-90% by weight of the solid composition.

5 The preferred composition comprise rifaximin in an amount between 30 to 70% by weight, lubricant between 2 to 5% by weight; disgregant between 3 to 8% by weight; diluent between 5 to 65% by weight; glidants between 0.1 to 2% by weight to the finished composition and optionally flavouring and colouring agent.

10 In the preferred composition of the invention the disgregant are selected among sodium carboxymethylcellulose, cross-linked carboxymethylcellulose, copovidone, sodium starch glycolate.

Diluents are selected among microcrystalline cellulose, lactose, cellulose and mannitol.

The lubricant is selected between glycerol distearate and glycerol dibenate.

15 The glidants is selected among talc, silica and colloidal anhydrous silica.

Tablets can be coated with a film coating comprising opacizers, colouring agents, plasticizers and flavouring agents.

20 Table 7 reports the dissolution profile of the tablets of the present invention, comprising rifaximin prepared by spray drying in comparison with commercial rifaximin tablets, named a Normix® tablet. The new solid composition resulting from the combination of the amorphous form of rifaximin, the morphology of the powder obtained by the spray drying method of preparation, and the solid pharmaceutical composition in form of tablets, shows the unexpected result of obtaining a pharmaceutical composition able to provide prolonged release of the
25 rifaximin active ingredient. The pharmaceutical composition in form of tablets comprising 200 mg of rifaximin, as in Example 3, is able to allow a longer time of

residence of rifaximin in human organs, where it carries on its pharmacological action longer, if compared with the commercially available preparations of rifaximin, without remarkably increasing the levels of plasmatic absorption, which is a relevant aspect for limiting the side effects and/or adverse events.

5 The PK profile indicates that this new formulation, by providing effective concentrations of rifaximin in-vivo, is able to guarantee a better therapeutic action in case of oral administration of a 200 mg tablet three times a day.

 This evidence is shown in Example 4, which reports a pharmacokinetic study using tablets prepared according to Example 3, containing rifaximin obtained
10 by spray drying as described in Example 1. The study has been carried out in comparison with the commercial formulation Normix® containing a crystalline rifaximin like the polymorph of rifaximin- α . A group of 24 healthy volunteers, whose demographic data are reported in Table 8 and Table 9, received one or two 200 mg tablets of rifaximin prepared as described in Example 3 in comparison
15 with an equivalent number of 200 mg tablets of Normix®.

 Table 10 reports the plasma concentrations of rifaximin expressed in nanograms per blood milliliter, measured over time in humans after the oral administration of a 200 mg tablet of rifaximin prepared as in Example 4. Table 11, on the other hand, reports the corresponding values obtained when a 200 mg tablet
20 of commercially available rifaximin, namely Normix®, was administered.

 The comparison of the data shows that the 200 mg tablets of rifaximin prepared according to Example 3, lengthen the time interval wherein rifaximin is detectable in the plasma if compared with the commercially available tablets. Example 4 reports PK comparative data in subjects who received a single oral 200
25 mg dose, or two 200 mg doses of composition comprising rifaximin from spray drying of Example 3, in respect to a single oral 200 mg dose or two 200 mg doses

of commercial tablets. The results demonstrate that commercial preparation rifaximin is no longer detectable in the plasma 4 hours after the administration in most subjects, and is no longer detectable in the plasma 6 hours after the administration in all subjects (Table 11), while composition comprising rifaximin from spray drying according to the present invention is detected in the plasma in
5 nearly all subjects 4 hours after the administration (10/12), in most subjects (7/12) even 8 hours after the administration, and in some subjects even up to 16 hours after the administration.

In the case of an administration of two 200 mg tablets of rifaximin with the
10 preparation of Example 3, most subjects (10/12) show remarkable amounts of rifaximin 12 hours, and some subjects even up to 24 hours, after the administration.

These results are associated to the fact that the absolute plasma concentration does not exceed about 15 ng/ml with the administration of one 200
15 mg tablet, and 100 ng/ml with the administration of two 200 mg tablets.

By administering the same amount of Normix®, a few subjects show detectable plasma concentrations of rifaximin just 6 hours after the administration, and no subject shows them 12 hours after the administration.

Under these conditions, the most suitable dosage for the tablets comprising
20 rifaximin prepared by spray drying is three 200 mg tablets of rifaximin three times a day, as e.g. prescribed in the treatment of the travellers' diarrhoea. In fact, this posology guarantees a better antibiotic effect of rifaximin for the subject. To this regard and for exemplificative purposes only, Figure 1 and Figure 2 show the calculated PK profiles in the hypothesis of repeated doses of three 200 mg tablets
25 of rifaximin three times a day, for the subjects V7 and V11, on the basis of the values obtained in Table 10 and Table 11.

Solid preparation in the form of tablets of Example 3 comprising rifaximin obtained by spray drying, guarantee a more constant presence of rifaximin, though maintaining limited maximum concentrations in the plasma and producing a limited drug accumulation during the therapy.

5 The effect of limitation of maximum concentration of rifaximin in the plasma is the result of the tablet composition, of the adopted pharmaceutical form and of the preparation method of the pharmaceutical form. In fact, Table 16 of Example 5 reports the PK parameters obtained in dogs when only the rifaximin prepared according to Example 1, without any additional excipient, is administered
10 to the animal. In order to compare these data with the values obtained after the administration to humans, reported in Table 14 of the Example 3, the different species, human and canine, and the different dosages must be taken in account.

 With regard to the species, it is known that it is possible to compare bioavailability data in human and canine species, as described by Dressmann J.B.
15 in Pharm. Res. 4, 123-31, 1986, since the physiology of the stomach in the two species is quite similar. However, humans and dogs show a different pH in the small intestine, which in humans is about 5, whereas in dogs is about 7. This difference could affect the bioavailability if it were relevant for the solubility of the compound.

20 In the case of rifaximin, however, this difference is not relevant since a pH variation between 5 and 7 does not affect the solubility of rifaximin, as shown in Example 6.

 Another observed difference between human and canine species is the shorter intestinal transit time in dogs, which could conceivably result in a lower
25 fraction adsorbed for drugs.

 The different bioavailability factors in human and canine species have been

taken in account by adopting the conversion factor from dog doses to human equivalent doses (HED) of 0.54, as reported in the FDA Guidance-for-Industry. In Example 5, having the dogs received a dose of 100 mg/kg, it corresponds to 54 mg/kg HED.

- 5 The human subjects of the patients studied who had received a 200 mg tablet of rifaximin, had a mean body weight of 67.67 kg, as shown in Table 8, therefore they received an average of 2.9 mg/kg of rifaximin, namely a 18.6-folds lower amount of rifaximin than the HED administered to the dogs. The PK parameters, therefore, could be expected to be proportionally reduced by about the
- 10 same factor, as shown in Table 1.

TABLE 1

Comparison of PK values dog-man receiving rifaximin - Mean values \pm standard error			
	C_{\max} (ng/ml)	T_{\max} (h)	AUC_{0-24h} (ng.h/ml)
Values observed in dogs after administration of 100 mg/kg (Table 14) corresponding to a HED of 54.4 mg/kg	1044.1 ± 588.46	2	2854.31 ± 1489.87
Values calculated in humans proportionally reduced to the dosage 2.9 mg/kg	56.1 ± 31.63	ND	143.4 ± 80.10
Values observed in humans after administration of 200 mg tablets corresponding to 2.9 mg/kg	3.70 ± 0.55	1.04	11.47 ± 2.35

By comparing the values of PK parameters calculated at 2.9 mg/kg HED obtained on the basis of the experiment on dogs with those observed on humans,

when the rifaximin of Example 1 is comprised in the pharmaceutical preparation of Example 3, it results that the new composition, by combining the effect of the form of rifaximin and pharmaceutical composition, as described in Example 3, reduces the bioavailability levels of rifaximin in blood if compared to a direct
5 administration of the rifaximin prepared by the spray-drying method, as described in Example 1.

The pharmaceutical composition in tablets obtained according to Example 3 shows indeed the unexpected result derived from the combination of parameters working in opposite ways: the rifaximin produced by the spray drying process
10 leads to more soluble rifaximin with a possible increase of bioavailability, whereas the composition and the pharmaceutical form in tablets and the production method limits the absorption level, giving as a result a controlled release.

The evidence of the property of the formulation is shown in figures 1 and 2, reporting the values of plasma concentrations in two different volunteers,
15 calculated after repeated administrations of formulations in tablets containing the rifaximin prepared according to Example 3 if compared with the commercial product Normix®.

The comparison of the two profiles in the two healthy volunteers treated with the formulation of the present invention demonstrates that no time interval
20 over the whole therapy shows any rifaximin detectable in the plasma, whereas the patients treated with the commercially available tablets containing rifaximin (Normix®) show non -analytically detectable plasma concentrations of rifaximin.

Therefore an aspect of the invention is a composition able to release rifaximin at predictable and controlled release. Such composition comprises a
25 rifaximin powder having the morphological feature described above, which are obtained by a spray drying process.

Another aspect of the present invention is represented by pharmaceutical formulations containing rifaximin in solid form in an amount comprised between 10 and 800 mg in a solid preparation with acceptable excipients.

Another aspect of the invention is a rifaximin powder having the morphological features described above, prepared by spray drying, and associated
5 with acceptable excipients known to the skilled in the art, for use as topical administration such as ointment, cream lavage, foam.

Another aspect of the invention is rifaximin powder having the morphological features described above, prepared by spray drying, and associated
10 with acceptable excipients known to the skilled in the art, for use as oral administration as suspension, syrup or mounth wash.

A further aspect of the present invention are pharmaceutical compositions able to produce plasma concentrations of rifaximin higher than 0.5 ng/ml in the blood of humans 4-12 hours after the administration of an amount of rifaximin not
15 lower than 200 mg in the form of tablets.

A further aspect of the present invention is a pharmaceutical composition containing rifaximin obtained by spray drying, able to produce plasma concentrations of rifaximin higher than 0.5 ng/ml in the blood of humans 6-24 hours after the administration of an amount of rifaximin not lower than 400 mg in
20 the form of tablets.

A further aspect of the present invention is a formulation of rifaximin that, with an administration of 200 mg of rifaximin, produces a maximum concentration of rifaximin in the blood lower than about 15 ng/ml.

A further aspect of the present invention is a pharmaceutical composition
25 comprising rifaximin that, with an administration of 200 mg, produces a maximum concentration of rifaximin in the blood lower than about 100 ng/ml.

A further aspect of the present invention is the use of the formulation in the treatment of bacterial bowel infections.

A further aspect of the present invention is a packaged composition comprising a therapeutically effective amount of rifaximin having the morphological features described above, prepared by spray draying, and a pharmaceutically acceptable carrier or diluent, wherein the composition is formulated for treating a subject suffering from or susceptible to a bowel disorder, and packaged with instructions to treat a subject suffering from or susceptible to a bowel disorder.

Kits are also provided herein, for example, kits for treating a bowel disorder in a subject. The kits may contain, for example, one or more of the solid dispersion forms of rifaximin having the morphological features described above, prepared by spray draying, and instructions for use. The instructions for use may contain proscribing information, dosage information, storage information, and the like.

Rifaximin can be administered at dosage higher than 2500 mg/day without any side effect and the rifaximin composition can be administered at a concentration of about 1 mg to about 200 mg per kilogram of body weight.

The pharmaceutical composition can be administered in combination with other therapy treatment.

The following non-limiting examples of the invention are provided.

Example 1

Method of preparation of a rifaximin powder by spray drying

In a fluid bed equipment Glatt GPCG 60, provided with an 18-inch Wurster system and a 1.8 mm spraying nozzle, 40 kg of rifaximin- α are charged and then added with 457.2 litres of 96% ethanol (v/v). The suspension so formed is kept under stirring till complete dissolution of rifaximin.

The ethanol solution is sprayed inside the fluid bed under a pressure comprised between 1.0 and 1.5 bar through the 1.8 mm nozzle under a previously heated flow of heated air. At the end of the spraying phase the solid rifaximin powder is further dried to remove the excess solvent.

5 The conditions adopted for the spraying process are described in detail in Table 2.

TABLE 2

Process parameters	Preheating	Spraying	Drying
Inlet air volume	$800 \pm 200 \text{ m}^3/\text{h}$	$800 \pm 200 \text{ m}^3/\text{h}$	$800 \pm 200 \text{ m}^3/\text{h}$
Inlet air temperature	$90 \pm 10^\circ\text{C}$	$90 \pm 10^\circ\text{C}$	$60 \pm 5^\circ\text{C}$
Spray pressure		$0.7 \pm 0.2 \text{ Bar}$	
Spray rate		50 - 380 g/min	
Product temperature		$55 - 70^\circ\text{C}$	$50 \pm 2^\circ\text{C}$

The obtained rifaximin powder is analyzed by X-ray spectroscopy, ^{13}C -NMR spectrometry and IR spectroscopy and is stable at a temperature of $40^\circ\text{C}+2$
 10 with a relative humidity of 75% up to three months.

X-ray diffraction spectrum is reported in Figure 3 who shows halo-peaks having maximum at $7.75^\circ \pm 0.2$, $14.54^\circ \pm 0.2$ and $18.33^\circ \pm 0.2$, 2θ .

X-ray diffraction spectrum are obtained by the Bragg-Brentano geometry under the following conditions: X-ray pipe: copper; radiation: $\text{K}(\alpha_1)$, $\text{K}(\alpha_2)$;
 15 generator current tension: KV 40, mA 40; monochromator: graphite; step size: 0.02; step time: 1.25 seconds; initial and final angular value of 2θ : 3.0° - $30^\circ \pm 0.2$ d.

Figure 4 shows the ^{13}C -NMR spectrum obtained by the Varian 400 instrument at 100.56 MHz, by melting the sample in chloroform having a purity higher than 99.8% and containing tetramethylsilane as internal standard.

20 Figure 5 reports the IR spectrum obtained with the Spectrum One equipment, Perkin Elmer, by using a 0.5% dispersion of rifaximin in potassium

bromide and the spectrum is recorded at frequencies of 4000 to 450 cm^{-1} .

The so obtained rifaximin is stable, as shown in Table 3.

5 Example 2

Comparative analysis between rifaximin obtained by spray drying and by a milling process

a) X-ray Analysis

The X-ray diffraction spectrum are obtained by the Bragg-Brentano
10 geometry under the following conditions: X-ray pipe: copper; radiation: $\text{K}(\alpha_1)$,
 $\text{K}(\alpha_2)$; generator current tension: KV 40, mA 40; monochromator: graphite; step
size: 0.02; step time: 1.25 seconds; initial and final angular value of 2θ : 3.0° -

30°±0.2 .

Figure 3 and Figure 6 report respectively X-ray spectrum of rifaximin obtained by spray drying and by milling.

X-ray diffraction spectrum of rifaximin obtained by spray drying process is characterized by halo-peaks having maximum at $7.75^{\circ} \pm 0.2$, $14.54^{\circ} \pm 0.2$ and $18.33^{\circ} \pm 0.2$, 2θ .

X-ray diffraction spectrum of rifaximin obtained by milling process is characterized by halo-peaks having maximum at $7.44 \pm 2\theta$, $14.40 \pm 2\theta$; $17.19 \pm 2\theta$.

b) Particle Size Dimension (PSD)

The particle size analysis were performed using Beckman – Coulter LS100 Q particle size analyzer equipped with a micro-volume cell. The solvent used is White Spirit (WS).

In Table 4 are reported the average size of the particles obtained with spray drying and milling processes.

A percentage corresponding to 10% (d10) of the total particles has an average size of 4.56 μm for spray drying and 1.84 for milling; a percentage corresponding to 50% (d50) of the total particles has an average size of 19.60 μm for spray drying and 8.17 for milling; a percentage corresponding to 90% (d90) of the total particles has an average size of 62.21 μm for spray drying and 12.92 for milling;

TABLE 4

	Diameter Particle (μm) Spray Drying Process	Diameter Particle (μm) Milling Process
d ₁₀	4.56	1.84
d ₅₀	19.60	8.17
d ₉₀	62.21	12.92

Figure 7 and Figure 8, show the particle size profile of rifaximin obtained by spray drying process and milling process respectively.

c) SEM microscopy

The samples were analyzed by SEM and the results are reported in Figure 9 and in Figure 10, respectively, for rifaximin amorphous forms obtained by spray drying and milling.

Rifaximin prepared by spray drying shows aggregates having dimension between 10 and 40 μm and the powder presents porous characteristics and a defined profile; solid rifaximin by milling shows aggregates having dimension between 3 and 15 μm and the powder presents porous characteristics and a spherical profile.

d) Bulk density

Three measures with three different samples were done for rifaximin by spray drying and for rifaximin by milling and the density calculated in grams per milliliter using a 10 ml volumetric flask.

The density of rifaximin by spray drying is 0.257 g/ml and the density of rifaximin by milling is 0.327 g/ml.

e) Specific surface area (BET)

For the determination of low surface areas a flowing gas technique was used. The analysis were performed using nitrogen gas on 300 mg of sample dried under vacuum, increasing the temperature from 25°C to 100°C with a heating rate of 10°C/min. The specific surface area of rifaximin by spray drying is between 0.01 and 5 m²/g and the specific surface area of rifaximin by milling is between 6 and 12 m²/g.

f) Solubility

500 Mg of each preparation of rifaximin reported in Example 1 and

rifaximin by milling, respectively, were separately suspended in 750 ml of an aqueous buffer solution of phosphates, pH 6.8, temperature $30 \pm 0.5^{\circ}\text{C}$.

The solutions containing suspended rifaximin are stirred by means of a sweep stirrer for 150 minutes at the stirring rate of 250 rpm. Samples taken at 5-
5 minute intervals during the first hour and at 15-minute intervals in the remaining time, are analysed in HPLC after filtration. The results are reported in Table 5.

TABLE 5

Solubility over time of rifaximin preparation		
	Concentration (mg/l)	
Time (min)	Spray drying	Milling
5	14.4	10.8

135	9.0	8.3
150	8.8	7.9

Example 3**Preparation of rifaximin in tablets**

5 The preparation of the tablets containing 200 mg of rifaximin comprises the following steps:

- a. Preparation of rifaximin powder by spray drying as described in Examples 1;

-38-

- b. Dry granulation by compaction;
- c. Lubrication of granulate;
- d. Tableting;
- e. Preparation of coating varnish;
- 5 f. Coating of cores.

A tablet contains the amounts reported in Table 6.

TABLE 6

Composition of a 200 mg tablet		
Drug Substance	Amount (mg)	% (w/w)
Powder Rifaximin	200.00	55.97
Sodium starch glycolate	15.00	4.20
Glycerol distearate	18.00	5.04
Colloidal anhydrous silica	1.00	0.28
Talc	1.00	0.28
Microcrystalline cellulose	115.00	32.18
Hydroxy propyl methyl cellulose	5.15	1.44
Titanium dioxide	1.50	0.42
Disodium edetate	0.02	5.60×10^{-3}
Propylene glycol	0.50	0.14
Iron oxide E172	0.15	0.04

Sodium starch glycolate, glycerol distearate, talc and microcrystalline cellulose are weighted in the respective amounts reported in Table 6 and passed
 10 through a 0.8 mm sieve. They are then put in a V-type powder mixer and the

mixture is stirred for at least 30 minutes.

The powder mixture is put with the respective amount of rifaximin, into a hopper of the continuous compacting-granulating machine, which produces a granulate of the desired calibration.

5 The granulate is then added with glycerol distearate, talc, microcrystalline cellulose, colloidal anhydrous silica, all being previously passed through a 0.5 mm sieve. Colloidal anhydrous silica and microcrystalline cellulose are premixed before sieving. The mixture is then put back in the mixer and mixed for 7 minutes. The granulate is compressed by means of a rotative tableting machine Kilian or
10 equivalent equipped with concave punches with a 10 mm diameter to obtain the tablets. The coating procedure is performed in an appropriate room under microclimatic control.

Tablets are heated at range 41°C - 43°C by warm air, and the film coating is sprayed on the tablets. At the end of coating phase tablets are dried at range 41°C -
15 43°C by warm air for 30 min.

The disintegration time of the tablets coming from the above mentioned manufacturing process was of 5 minutes by performing the test in accordance with Ph. Eur. conditions, Ed. 6.3, no. 20901 pp. 3943-3945.

The measured dissolution rate of the tablets, evaluated by performing a
20 dissolution test in accordance with Ph. Eur. conditions, Ed. 6.0, no. 20903, pp. 266-275, by introducing a tablet in 1000 ml phosphate buffer 0.1 M at pH 7.4 at a temperature of $37 \pm 0.5^\circ\text{C}$, rotation speed 100 rpm, is shown in Table 7.

The rifaximin released by the thus prepared tablets was analysed and compared with the commercially available Normix® tablets containing rifaximin-
25 α . The amount of rifaximin released in the phosphate buffer was determined by wavelength spectrophotometry corresponding to 293 ± 2 nm in comparison with a

reference solution of rifaximin. The amounts of rifaximin released up to 180 minutes are reported in Table 7.

TABLE 7

Dissolution profile of the tablets		
Time (min)	200 mg rifaximin as described in Example 3	200 mg commercial rifaximin (Normix®) containing rifaximin- α
0	0.0	0.0
15	4.1	2.5
30	9.3	2.8
45	12.5	2.8
60	17.0	3.1
90	19.4	3.2
120	23.0	3.1
180	27.2	2.7

Example 4

- 5 **Randomized crossover study for the evaluation of safety and of PK profile of a single oral 200 mg dose or two 200 mg doses of rifaximin tablets as obtained in Example 3 in comparison with a single oral 200 mg dose of Normix® or two 200 mg doses in healthy human volunteers**

10 In the fasted state, 12 healthy volunteers whose demographic data are reported in Table 7, received in crossover a tablet containing 200 mg of rifaximin described in Example 3 or a 200 mg tablet of Normix®, and 12 healthy volunteers, whose demographic data are reported in Table 9, received two 200 mg tablets of rifaximin described in Example 3 or two 200 mg tablets of Normix®.

15 Each subject received each of the two rifaximin preparations separated by an interval of one week.

TABLE 8

Demographic parameters of the subjects who have received one 200 mg tablet of rifaximin of Example 3				
	Age (years)	Height (cm)	Weight (kg)	BMI
Mean	36.67	169.25	67.67	23.50
SD	8.53	9.35	11.65	2.71
CV%	23.27	5.53	17.22	11.55
Min	27.00	153.00	52.00	19.00
Max	51.00	180.00	86.00	27.00

TABLE 9

Demographic parameters of the subjects, who have received two 200 mg tablets of rifaximin of Example 3				
	Age (years)	Height (cm)	Weight (kg)	BMI
Mean	37.67	169.83	72.75	25.08
SD	8.30	7.41	11.23	2.91
CV%	22.05	4.36	15.44	11.59
Min	21.00	158.00	50.00	20.00
Max	51.00	186.00	90.00	30.00

The study determined the bioavailability of the two rifaximin preparations by measuring the plasma concentration of rifaximin over time after oral administration.

The blood samples, respectively taken 0; 0.5; 1; 1.5; 2; 3; 4; 6; 8; 10; 12; 16; 24 hours after the administrations, were analysed by a LC-MS/MS method having a limit of quantization of 0.5 ng/ml and the results are shown in Table 10

and in Table 11 for the administration of a 200 mg tablet of rifaximin of Example 3 and of Normix®, respectively. In Table 12 and in Table 13 the values corresponding to the administration of two 200 mg tablets of rifaximin of Example 3 and Normix® are reported.

The following bioavailability parameters are calculated for comparing the two rifaximin preparations: maximum observed plasma concentration (C_{\max}); time from administration to obtain C_{\max} (T_{\max}); area under concentration-time curve from time 0h (first experimental point) up to last sampling (24 h after administration) $AUC_{(0-24\text{ h})}$. The results are shown in Table 14 and Table 15, in the case of the administration of two 200 mg tablets of rifaximin as described in Example 3 and of two 200 mg tablets of Normix®.

TABLE 14

Example 5**PK study on dogs of rifaximin prepared by spray drying**

Four female beagles received as a single oral administration the rifaximin prepared according to Example 1 at the dosage of 100 mg per kg of body weight of the animal.

Capsules of hard gelatin containing only rifaximin were administered, and the pre- and post-dose observations, the body weight and the physical examination were evaluated.

Blood samples were collected from all animals on each day of dosing at: 0 (pre-dose), 1, 2, 4, 6, 8 and 24 hours after each dosing.

The concentration-time curve determines the PK parameters of AUC_{0-24h} , C_{max} and T_{max} reported in Table 16.

TABLE 16

Mean values of PK parameters of the animals receiving 100 mg/kg of rifaximin			
Mean values (\pm standard error)			
Rifaximin preparation according to Example 1	C_{max} (ng/ml)	T_{max} (h)	AUC_{0-24h} (ng·h /ml)
Dose of 100 mg/kg	1044.1 \pm 588.46	2	2854.31 \pm 1489.87

Example 6**Rifaximin solubility at different pH**

The study was conducted in accordance with accepted principles in order to meet the requirements of the Annex to European Commission Directive 92/69/EEC and the OECD Guidelines for Testing of Chemicals (EEC Method A6, OECD Method 105).

Water solubility was determined in purified water and buffer solutions at pH

4 and 7, by the shake flask method at 20°C.

Aliquots of the saturated solutions of rifaximin- α were adequately diluted, then analyzed by a high performance liquid chromatography (HPLC) method. The solubility of rifaximin was determined versus calibration solutions of rifaximin.

5 The obtained results are reported in Table 17.

TABLE 17

Rifaximin solubility at different pH	
Solvent system	Solubility (mg/l)
Purified water	3.63
pH 4 buffer solution	4.12
pH 7 buffer solution	3.22
pH 10 buffer solution	299

CLAIMS

1. Rifaximin powder having X-Ray diffraction spectrum showing an amorphous form, characterized by a particle size comprised (d_{90}) between 40 and
5 120 micrometers.
2. Rifaximin according to claim 1 characterized by, a bulk density between 0.1 and 0.50 g/ml.
3. Rifaximin according to claims 1 and 2 characterized a surface area of between 0.01 and 5 m²/g.
- 10 4. Rifaximin according to claim 1, characterized in that said rifaximin is soluble in a solubilisation test at a pH of 6.8 and a temperature of 30°C in an amount between 5% and 90% with respect to the total rifaximin comprised.
5. Rifaximin powder according to claim 1, characterized by the fact that it is obtained by spray drying of a solution of rifaximin.
- 15 6. Pharmaceutical composition according to claim 1 comprising rifaximin powder in an amount between 10 and 800 mg.
7. The pharmaceutical composition according to claim 6, comprising rifaximin powder in an amount comprised between 200 to 400 mg.
8. Pharmaceutical composition characterised by comprising rifaximin
20 according to claim 1 and one or more pharmaceutically acceptable excipients, said composition being in form of tablets and said excipients comprising one or more of disgregants, diluents, sweeteners, plasticizers, anti-agglomeration agents, anti-sticking agents, glidants, ligant, and optionally colouring, buffering, flavouring and sweetening agents.
- 25 9. Pharmaceutical composition according to claim 8 in the form of tablets having the following composition:

-50-

- Rifaximin 10-800.0 mg
- Sodium starch glycolate 5.0-30.0 mg
- Glycerol distearate 4.0-400.0 mg
- Colloidal anhydrous silica 0.2-10.0 mg

- 5 - Talc 0.2-10.0 mg
- Microcrystalline cellulose 10.0-500.0 mg

and optionally coated with coating film comprising opacizer, plasticizer colouring agent.

- 10.** A process for the preparation of the pharmaceutical composition according to claim 6 or 7, characterized by the following steps:

- Preparation of a powder form of rifaximin by solubilisation of crystalline or amorphous rifaximin, or their mixtures, in organic solvents or their mixtures, or in mixtures with water, spraying of said solution, evaporation and drying;
- 15 — Collection of rifaximin solid form from said spray drying process ;
- Compaction of the granules of rifaximin, tablets formation with or without acceptable excipients ;
- Optionally, coating of the tablets with a film coating.

- 11.** Pharmaceutical composition according to claim 6 or 7 for use as
- 20 medicament.

12. Pharmaceutical composition according to claim 11 for the treatment of bacterial bowel infections, wherein said treatment is characterized in that detectable plasma concentrations of rifaximin are maintained over a period of time comprised between 4 and 24 hours after the administration.

- 25 **13.** Composition according to claim 11, wherein the treatment foresees two or three daily administrations.

- 14.** Composition according to claim 11, wherein the plasma concentrations of rifaximin are detectable over the whole treatment period.
- 15.** Composition according to claim 14, wherein the plasma concentrations of rifaximin are not higher than 100 µg/ml.
