Abstract: The present invention provides methods of treating, preventing or ameliorating the symptoms of Latent Autoimmune Diabetes in Adults (LADA) and adult-onset type 1 diabetes through the use of anti-human CD3 antibodies. In particular, invention provides methods of preventing or delaying insulin requirement in patients diagnosed with LADA. The methods of the invention provide for administration of antibodies that specifically bind the epsilon subunit within the human CD3 complex. Such antibodies modulate the T cell receptor/alloantigen interaction and, thus, regulate the T cell mediated cytotoxicity associated with autoimmune disorders. Additionally, the invention provides for modification of the anti-human CD3 antibodies such that they exhibit reduced or eliminated effector function and T cell activation as compared to non-modified anti-human CD3 antibodies.
METHODS FOR THE TREATMENT OF LADA AND OTHER ADULT-ONSET AUTOIMMUNE DIABETES USING IMMUNOSUPPRESSIVE MONOCLONAL ANTIBODIES WITH REDUCED TOXICITY

CROSS-REFERENCES TO RELATED APPLICATIONS

[0001] This application claims priority to U.S. Provisional Application Serial No. 60/871,364, filed December 21, 2006, the contents of which are incorporated herein by reference in its entirety.

1. INTRODUCTION

[0002] The present invention provides methods of treating, preventing, slowing the progression of, or ameliorating the symptoms of, Latent Autoimmune Diabetes in Adults (LADA) and other adult-onset autoimmune diabetes disorders through the use of anti-human CD3 antibodies. In particular, the invention provides methods of preventing or delaying the need to administer insulin to patients diagnosed with LADA. The methods of the invention provide for administration of antibodies that specifically bind the epsilon subunit within the human CD3 complex. Such antibodies modulate the T cell receptor/alloantigen interaction and, thus, regulate the T cell mediated cytotoxicity associated with autoimmune disorders. Additionally, the methods of the invention provide for use of anti-human CD3 antibodies modified such that they exhibit reduced or eliminated effector function and T cell activation as compared to non-modified anti-human CD3 antibodies.

2. BACKGROUND OF THE INVENTION

2.1 Diabetes

[0003] Diabetes is typically classified as one of two types: type 1 or type 2 diabetes. Type 2 diabetes is a non-autoimmune disease that is typically diagnosed in adults. It is a progressive disease that develops when the body does not produce sufficient insulin or fails to efficiently use the insulin it produces (a phenomenon known as insulin resistance). Patients diagnosed with type 2 diabetes are typically over age 45, overweight (BMI of 25 or higher) or obese (BMI of 30 or higher), physically inactive, have hypertension (blood pressure of 140/90 mm Hg or higher in adults), and have HDL cholesterol of 35 mg/dL or lower and/or triglyceride level of 250 mg/dL.

[0004] Type 1 diabetes, also known as juvenile diabetes or insulin-dependent diabetes mellitus, is an autoimmune disease that is typically diagnosed in children (although Adult-
Onset Type 1 diabetes may be present in adults. Insulin-dependent diabetes mellitus (IDDM) affects 15 million people in the United States with an estimated additional 12 million people who are currently asymptomatic, and, thus, unaware that they have this disease. Risk factors for developing type 1 diabetes include presumptive genetic factors, exposure to childhood viruses or other environmental factors, and/or the presence of other autoimmune disorders. Although the genetic factors associated with type 1 diabetes are not fully understood, risks for the development of the disease have been linked to both family history and ethnicity. For example, a child that has a parent or sibling with type 1 diabetes has a higher risk of developing type 1 diabetes than a child of non-diabetic parents or with non-diabetic siblings. Further, the genetic factors associated with the risk for developing type 1 diabetes appear to be linked to a particular HLA type: HLA-DR3 and DR4 is associated with a higher risk in Caucasians; HLA-DR7 are associated with a higher risk in people of African decent; and HLA-DR9 is associated with a higher risk in people of Japanese descent.

Unknown factors, including childhood viruses or exposure to some other environmental factor (e.g., exposure to certain foods or chemicals), are also theorized to potentiate or activate an inherited genetic factor and cause the onset of type 1 diabetes. Viruses that have been associated with type 1 diabetes include coxsackie B virus, enteroviruses, adenoviruses, rubella, cytomegalovirus, and Epstein-Barr virus. Last, the presence of other autoimmune disorders, such as thyroid disease and celiac disease, raises the risk of developing type 1 diabetes.

Type 1 Diabetes is caused by an autoimmune response in which the insulin producing β-cells of the pancreas (also known as islet cells) are gradually destroyed. The early stage of the disease, termed insulinitis, is characterized by infiltration of leukocytes into the pancreas and is associated with both pancreatic inflammation and the release of anti-β-cell cytotoxic antibodies. As the disease progresses, the injured tissue may also attract lymphocytes, causing yet further damage to the β-cells. Also, subsequent general activation of lymphocytes, for example in response to a viral infection, food allergy, chemical, or stress, may result in yet more islet cells being destroyed. Early stages of the disease are often overlooked or misdiagnosed as clinical symptoms of diabetes typically manifest only after about 80% of the β-cells have been destroyed. Once symptoms occur, the type-1 diabetic is normally insulin dependent for life. The dysregulation of blood-glucose levels associated with diabetes can lead to blindness, kidney failure, nerve damage and is a major contributing factor in the etiology of stroke, coronary heart disease and other blood vessel disorders.
2.2 **LADA**

[0007] A Latent Autoimmune Diabetes in Adults or LADA patients generally present with symptoms of diabetes as an adult. These patients have autoantibodies against Islet Cell antigens but B-cell function decreases slowly. In fact, at diagnosis, patients generally do not require administration of insulin and may not require insulin for at least six months and possibly years after diagnosis. (Palmer et al., 2005, Diabetes 54:S62-S67; Stenstrom et al., 2005, Diabetes 54: S68-S72). Other names for LADA include type 1.5 diabetes, slowly progressive IDDM, latent type 1 diabetes, youth-onset diabetes of maturity, latent-onset type 1 diabetes, and antibody-positive non-insulin-dependent diabetes. Some have suggested distinguishing LADA patients, who are generally non-obese and do not exhibit insulin cell resistance from those adult-onset patients with Islet cell antibodies and insulin resistance, termed type 1.5 diabetes (Palmer et al., 2003, Diabetes Care 26:536-538.) The Immunology of Diabetes Society has proposed the following criteria to standardize those patients referred to as having LADA: being 30 years old or older; positive for at least one antibody commonly present in type 1 diabetic patients, e.g., islet-cell antibodies to GAD65, IA-2, or insulin; and not requiring insulin treatment within the first 6 months after diagnosis (Palmer et al., 2005, Diabetes 54:S62-S67). The slowly progressive β-cell failure and, thus, gradual insulin dependency distinguishes LADA from classic type 1 diabetes occurring in adult patients. LADA patients are typically non-obese, have a family or personal history of autoimmune disease, and present with acute symptoms including polydipsia, polyuria, and weight loss.

2.3 **T cell Functionality in Diabetes and other Autoimmune Disorders**

[0008] Destruction of β-cells in diabetes, is believed largely mediated by cytotoxic T-lymphocytes (CTLs - also known as CD8+ T cells) that specifically recognize antigenic, target cell derived peptides. CTLs, as well as other types of T cells, recognize these antigenic peptides through their specific T cell receptor (TcR). Unlike antibodies which recognize soluble whole foreign proteins as antigen, the TcR instead interacts with small peptidic antigens presented only in complex with major histocompatibility complex (MHC) proteins. [0009] Most cells of the body express MHC molecules of various classes on their surface and, depending on the class of MHC expressed, will present either soluble antigens, those dispersed within the lymph and/or circulatory systems, or fragments of their cytoplasmic proteins. MHC molecules (called human leukocyte antigens or HLA in humans) and TcRs are extremely polymorphic, each clonal variation recognizing and binding to a
single peptidic sequence, or set of similar peptidic analogs. Apart from cells specific to the immune system, *i.e.* B cells and T cells, cells of the body express multiple variants of the MHC molecule, each variant binding to a different peptide sequence. In contrast, during maturation, B and T cells lose the ability to express multiple variants of MHC and TcR, respectively. Mature T cells, therefore, will express only one of the possible variants of the TcR and will thus recognize/bind a single MHC/antigen complex.

**0010** Binding of a TcR to a MHC/antigen complex elicits an intracellular signal cascade within the T cell, termed activation, which results in clonal proliferation of the T cell and class-specific T cell responses. For example, in CTLs the response to activation also includes the release of cytotoxic enzymes that result in apoptosis/ destruction of the target cell.

### 2.4 Modulation of T cell Activation by Monoclonal Antibodies

**0011** The finding that autoimmune diseases are at least partially caused by aberrant T cell action has lead to the investigation of therapies that either eliminate problematic T cell clones (those expressing TcRs against self antigens) or selectively reduce undesired T cell activity/activation. T cell activation due to TcR binding is, however, an unexpectedly complex phenomenon due to the participation of a variety of cell surface molecules expressed on the responding T cell population (Billadeau et al., 2002, J. Clin. Invest. 109:161-168; Weiss, 1990, J. Clin. Invest. 86:1015-1022; Leo et al., 1987, PNAS 84:1374-1378; Weiss et al., 1984, PNAS 81:4169-4173; Hoffman et al., 1985, J. Immunol. 135:5-8).

**0012** Targeted therapies directed against general T cell activation were problematic in that the TcR is composed of a disulfide-linked heterodimer, containing two clonally distributed, integral membrane glycoprotein chains, α and β, or γ and δ. Most of the research in modulation of T cell activation was done in connection with improving immune suppression in organ transplant recipients. One of the first clinically successful methods of selectively reducing T cell activation was the use of monoclonal antibodies. U.S. Pat. No. 4,658,019, describes a novel hybridoma (designated OKT3, ATCC Accession No. CRL-8001) which produces a murine monoclonal antibody against an antigen found on essentially all normal human peripheral T cells. Binding of OKT3 to T cells in vivo produces pronounced, reversible immunosuppression. OKT3 was found to recognize an epitope on the ε-subunit within the human CD3 complex (Salmeron et al., 1991, J. Immunol. 147:3047-3052; Transy et al., 1989, Eur. J. Immunol. 19:947-950; see also, U.S. Pat. No. 4,658,019). The CD3 complex (also known as T3) is comprised of low molecular weight invariant
proteins, which non-covalently associate with the TcR (Samelson et al., 1985, Cell 43:223-231). The CD3 structures are thought to represent accessory molecules that may be the transducing elements of activation signals initiated upon binding of the TcR α-β to its ligand.

**[0014]** The use of therapeutic mAbs, including for example OKT3, is limited by problems of "first dose" side effects, ranging from mild flu-like symptoms to severe toxicity. The first dose side effects are believed to be caused by cytokine production stimulated by T cell activation. It has been shown that the activating properties of Anti CD3 monoclonal antibodies result from TcR cross-linking mediated by the antibodies bound to T cells (via its variable domain) and to FcγR-bearing cells via its Fc domain (Palacios et al., 1985, Eur. J. Immunol. 15:645-651; Ceuppens et al., 1985, J. Immunol. 134:1498-1502; Kan et al., 1986, Cell Immunol. 98:181-185). For example, the use of OKT3 was found to trigger activation of mAb-bound T cells and FcγR-bearing cells prior to achieving immune suppression, resulting in a massive systemic release of cytokines (Abramowicz, 1989, Transplantation 47:P606; Chatenoud, 1989, N. Eng. J. Med. 25:1420-1421). Reported side effects of OKT3 therapy include flu-like symptoms, respiratory distress, neurological symptoms, and acute tubular necrosis that may follow the first and sometimes the second injection of the mAb (Abramowicz, 1989, Transplantation 47:P606; Chatenoud, 1989, N. Eng. J. Med. 25:1420-1421; Toussaint, 1989, Transplantation 48:524; Thistlethwaite, 1988, Am. J. Kid. Dis. 11:112; Goldman, 1990, Transplantation 50:148).

fragments of 145-2Cl 1, a hamster anti-mouse CD3 that shares many properties with OKT3, have suggested that, in the absence of FcγR binding and cellular activation, anti-CD3 mAbs retain at least some immunosuppressive properties in vivo (Hirsch, 1991, Transplant Proc. 23:270; Hirsch, 1991, J. Immunol. 147:2088). In addition, administration of anti-CD3 antibodies with reduced binding to FcγR to human patients resulted in generally only mild side effects not the severe first class effects associated with OKT3 administration (Herald et al., 2005, Diabetes 54:1763).

2.5 Immunosuppressive Monoclonal Antibodies Exhibiting Reduced T cell Activation

[0016] U.S. Pat. No. 6,491,916, U.S. Pat. application Pub. No. 2005/0064514 and U.S. Pat. application Pub. No. 2005/0037000 describe the modification of the Fc regions of immunoglobulins such that the variant molecules exhibit enhanced or reduced binding to various Fc receptors when compared to immunoglobulins with wild type Fc domains. In particular the patents/applications describe modifications to the Fc regions of IgG antibodies such that the affinity for the FcγR is selectively enhanced or reduced. By tailoring the affinity for activating or suppressive Fc receptors, the specific immune response elicited by the therapeutic mAb may be more selectively controlled. For example, mutations in the CH2 portion of a humanized OKT3 IgG4 have been identified (P234A and L235A) that significantly reduced binding of the mAb to human and murine FcγRI and II and lead to a markedly reduced activating phenotype in vitro (Alegre et al., 1992, 8th International Congress of Immunology 23-28; Alegre et al., 1994, Transplantation 57: 1537-1543; Xu et al., 2000, Cell Immunol. 200:16-26). Importantly, this variant mAb retained the capacity to induce TcR modulation and immunosuppression (Xu et al., 2000, Cell Immunol. 200:16-26). Other modifications to the Fc domain of anti-CD3 antibodies, such as mutations to make the antibody aglycosylated or other mutations of the Fc domain residues, to reduce binding to FcγR have been found to reduce toxicity while maintaining immunosuppressive activity (see, e.g., U.S. Patent 6,491,916; U.S. Patent 5,834,597, Keymeulen et al., 2005, N. Eng. J. Med. 325:2598, all of which are incorporated by reference herein in their entireties).

3. SUMMARY OF THE INVENTION

[0017] The present invention provides methods of treating, preventing, slowing the progression of and ameliorating the symptoms of Latent Autoimmune Diabetes in Adults (LADA) and other adult-onset autoimmune diabetes and preventing or delaying exogenous
insulin administration in patients diagnosed with LADA or other such disorders, by
administering to a subject in need thereof a therapeutically or prophylactically effective
amount of an anti-human CD3 antibody. In particular, the methods of the invention provide
for administration of antibodies that specifically bind the epsilon subunit within the human
CD3 complex. For example, such antibodies may be or may be derived from (e.g.,
humanized or chimerized versions of) one of the antibodies Leu-4, 500A2, CLB-T3/3, M291,
YTH 12.5 or BMA030, or compete with one of Leu-4, 500A2, CLB-T3/3, M291, YTH 12.5
or BMA030 for binding. In a preferred embodiment, the antibody has the binding specificity
of the murine monoclonal antibody OKT3 (see, e.g., U.S. Patent Nos. 4,658,019 and
6,113,901, which are incorporated by reference herein in their entireties), e.g., binds to the
same epitope as OKT3 and/or competes for binding (i.e., in an ELISA or
immunoprecipitation assay) with OKT3, such as a humanized version of the antibody OKT3,
such as OKT3-7 (see the antibodies disclosed in U.S. Patent No. 6,491,916, which is
incorporated herein by reference in its entirety). In the most preferred embodiment, the anti-
human CD3 antibody has diminished (such as, but not limited to, less than 50%, less than
40%, less than 30%, less than 20%, less than 10%, less than 5% or less than 1% as compared
to binding by an antibody having a wild-type, glycosylated Fc domain) or, more preferably,
no detectable binding to one of any FcγR (e.g., FcγRI, FcγRII or FcγRIII) as determined by
assays routine in the art. In addition or alternatively, the anti-human CD3 antibody has
diminished (such as, but not limited to, less than 50%, less than 40%, less than 30%, less than
20%, less than 10%, less than 5% or less than 1% as compared to binding by an antibody
having a wild-type, glycosylated Fc domain) or, more preferably, no detectable binding to
any complement receptors, such as, Clq, as determined in routinely used assays. In
particular embodiments, the antibody is aglycosylated. In other embodiments, the antibody
lacks an Fc domain (e.g., is a Fab fragment, F(ab’)_2 or single chain antibody). In other
embodiments, the antibody has an Fc domain having one or more amino acid modifications
that reduce or abolish binding of the Fc domain to any FcγRs. Certain embodiments, the Fc
domain has mutations at one or more of the residues 234, 235, 236, 237. In preferred
embodiments, the Fc domain has an alanine at position 234 of the Fc region (CH2) and or an
alanine at position 235 of the Fc region (CH2), in particular having alanine at 234 and 235,
such as OKT3γl(ala-ala). In other embodiments, the Fc domain has a glutamate at position
235.

[0018] The invention particularly provides methods of treating, preventing, slowing
the progression or ameliorating the symptoms of Latent Autoimmune Diabetes in Adults
(LADA) and other adult-onset autoimmune diabetes disorders by administration of anti-human CD3 antibodies having reduced toxicity; e.g. having reduced binding to FcγRs. In certain embodiments, the methods exclude administration to patients having Adult-Onset Type 1 diabetes. In preferred embodiments, the methods prevent or delay the need to administer exogenous insulin to patients diagnosed with LADA or other adult-onset autoimmune diabetes disorders. Particularly, the methods of the invention are advantageous in subjects that do not yet require exogenous insulin to slow or reduce the damage from the autoimmunity and maintain a high level of function and/or reduce the need for additional therapy, such as administration of exogenous insulin. In addition, the methods of the invention advantageously reduce the incidence of or result in no incidence of cytokine release syndrome previously associated with administration of anti-human CD3 antibodies such as OKT3. Cytokine release syndrome is manifested by, for example, headache, nausea, vomiting, fever, myalgias, arthralgias and shaking and may be caused by increased serum levels of, for example, IL-2, IL-6, IL-10, TNFα, and IFNγ. The methods also reduce the incidence and severity of other adverse effects, such as, but not limited to, EBV activation, immunogenicity (production of anti-idiotypic antibodies, particularly IgE anti-idiotypic antibodies), lymphopenia, thrombocytopenia or neutropenia.

[0019] LADA patients characteristically do not require administration of exogenous insulin for at least six (6) months after diagnosis. Accordingly, the invention provides methods of delaying the need to administer insulin to the patient. In particular embodiments, administration of anti-human CD3 antibodies with reduced toxicity results in delay in the need to administer exogenous insulin to an LADA patient or other patient with adult-onset type 1 diabetes or on average for a group (10; 100; 200; 500; 1,000; 5,000; 10,000 or more) of LADA patients or other patient with adult-onset type 1 diabetes, for at least 7 months, 8 months, 10 months, 12 months, 15 months, 18 months, 21 months, 24 months, 30 months, 36 months, 4 years, 5 years, 6 years, 8 years, 12 years, 15 years, 18 years, 20 years or for the life of the patient.

[0020] In certain embodiments, the methods of the invention involve administration of the anti-human CD3 antibodies with reduced toxicity to subjects diagnosed with autoimmune diabetes, such as LADA, at an age of at least 25 years, 30 years, 35 years or 40 years of age. In certain embodiments, the subjects are not obese (i.e., BMI of less than 30) or, in more specific embodiments, not overweight (i.e., BMI of less than 25). LADA and other adult-onset autoimmune diabetes patients have serum antibodies against certain islet cell antigens. In certain embodiments, they are positive for GAD antibodies, such as GAD 65
and/or GAD 67, IA-2 antibodies and anti-insulin antibodies, or a combination of the foregoing autoantibodies.

[0021] In other embodiments, the invention provides methods of preventing or delaying the onset of LADA or other adult-onset autoimmune diabetes in a subject predisposed to developing LADA or other adult-onset autoimmune diabetes disorders, but who has yet to experience symptoms of or be diagnosed with LADA or other adult-onset autoimmune diabetes disorder (e.g., according to criteria established by the American Diabetes Association). In certain embodiments, the predisposition manifests as an impaired fasting glucose level, i.e., at least one determination of a glucose level of 100-125 mg/dL after fasting (eight hours without food), or is an impaired glucose tolerance in response to a 75 gram oral glucose tolerance test (OGTT), i.e., at least one determination of a 2-hour glucose level of 140-199 mg/dL in response to a 75 OGTT.

[0022] In preferred embodiments of their invention, whether treating, slowing the progression of, delaying the onset of or preventing LADA or other adult-onset autoimmune diabetes disorder, the subject has retained at least 95%, 90%, 80%, 70%, 60%, 50%, 40%, 30% or 20% β-cell function prior to initiation of treatment and, in some embodiments, β-cell function improves over pre-treatment levels by at least 5%, 10%, 20%, 30% or 40%.

[0023] In other embodiments, the predisposition for development of LADA or other adult-onset autoimmune diabetes disorder is having a first or second degree relative who is a diagnosed Type-1 diabetic. In certain embodiments, the predisposition is positive diagnosis in the patient or in a first or second degree relative according to art accepted criteria of at least one other autoimmune disorder including, but not limited to, thyroid disease, type 1 diabetes, rheumatoid arthritis, systemic lupus erythematosus, multiple endocrine adenopathy, and celiac disease. In some embodiments, the autoimmune disorder is a MHC DR3- and/or a DR4- related autoimmune disease.

[0024] In other embodiments, the predisposition for developing LADA or other adult-onset autoimmune diabetes disorder is the identification of islet cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies detectable by radioassay or ELISA in the serum of a subject. In particular embodiments, the predisposition for developing LADA or other adult-onset autoimmune diabetes disorder is the identification of anti-GAD65 or anti-ICA512 in the serum of a subject. The invention also encompasses administration of an antibody of the invention to subjects presenting combinations of any predisposing factors disclosed herein or known in the art.
With respect to treatment of LADA or other adult-onset diabetes disorders in a diagnosed patient, and the prevention/delay of symptoms thereof in a predisposed individual, and the prevention/delay of insulin requirement in patients diagnosed with LADA, the anti-human CD3 antibody with reduced toxicity is administered to achieve, or maintain a level of glycosylated hemoglobin (HAI or HAIc) of less than 8%, less than 7.5%, less than 7%, less than 6.5%, less than 6%, less than 5.5% or 5% or less. At the initiation of treatment, patients may or may not have been diagnosed with LADA or other adult-onset diabetes disorder and, preferably, have a HAI or HAIc level of less than 8%, less than 7.5%, less than 7%, less than 6.5%, less than 6%, or, more preferably, from 4%-6% (preferably, measured in the absence of other treatment for diabetes, such as administration of exogenous insulin).

In certain embodiments, one or more CD3 binding molecules (e.g., one or more anti-human CD3 antibodies) are administered to prevent a reduction of β-cell mass associated with autoimmune diabetes. In some embodiments, after one or more courses of treatment with an anti-human CD3 antibody according to the invention, the level of β-cell mass of the patient decreases by less than 1%, less than 5%, less than 10%, less than 20%, less than 30%, less than 40%, less than 50%, less than 60%, or less than 70% of the pretreatment levels of at least 3 months, at least 6 months, at least 9 months, at least 1 year, at least 18 months, at least 2 years, at least 3 years, at least 5 years, at least 7 years or at least 10 years after initial treatment. In yet another embodiment of the invention, after one or more courses of treatment with an anti-human CD3 antibody according to the invention, the level of β-cell mass of the patient is maintained at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, at least 50%, at least 40%, or at least 30% of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, at least 30 months, at least 3 years, at least 5 years, or at least 10 years after the first round of treatment.

In another embodiment of the invention, after one or more courses of treatment with an anti-human CD3 antibody according to the invention the level of β cell function of the patient is maintained at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, or at least 50% of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the end of treatment or after the first round of treatment and the mean lymphocyte count of the patient is not less than 800 cells/ml, less than 750 cells/ml, less than 700 cells/ml, less than 650 cells/ml, less than 600 cells/ml, less than 550 cells/ml, less than 500 cells/ml, less than 400 cells/ml, less than 300 cells/ml or less than 200 cells/ml at the
same time period. In another embodiment of the invention, after a course of treatment with an anti-human CD3 antibody according to the invention, the level of β-cell function of the patient is maintained at at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, or at least 50% of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the end of treatment and the mean platelet count of the patient is not less than 100,000,000 platelets/ml, less than 75,000,000 platelets/ml, less than 50,000,000 platelets/ml, less than 25,000,000 platelets/ml, less than 1,000,000 platelets/ml, less than 750,000 platelets/ml, less than 500,000 platelets/ml, less than 250,000 platelets/ml, less than 150,000 platelets/ml or less than 100,000 platelets/ml.

[0028] The administration of the anti-human CD3 antibodies prevents damage to islet cells, thereby delaying onset of the disease or, once diagnosable disease occurs, disease progression, reducing and/or delaying the need for insulin administration. In addition, the invention provides methods of treatment such that a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody (preferably, without any intervening treatment with anti-human CD3 antibodies), results in a level of HAI or HAIc that is 7% or less, 6.5% or less, 6% or less, 5.5% or less, or 5% or less 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment. Specifically, in such methods of the invention a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody (preferably, without any intervening treatment with anti-human CD3 antibodies), decreases the average level of HAI or HAIc in the patient by about 5%, about 10%, about 15%, about 20%, about 25%, about 30%, about 35%, about 40%, about 45%, about 50%, about 55%, about 60%, about 65% or about 70% as compared to pre-treatment levels at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or first round of treatment. In addition, after treatment with a CD3 antibody according to the invention in a single round of treatment or a round of treatment repeated every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months (preferably, without any intervening treatment with anti-human CD3 antibodies), the average level of HAI or HAIc in the patient only increases by about 0.5%, about 1%, about 2.5%, about 5%, about 10%, about 15%, about 20%, about 25%, about 30%, about 35%, about 40%, about 45%, or about 50% as compared to pre-treatment levels at 6 months, 9 months,
12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment. In other embodiments, after a single round of treatment or rounds of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the average level of HAI or HAIc in the patient is greater than about 10%, about 20%, about 30%, about 40%, about 50%, about 60%, about 70% or greater than about 100% less than the levels in a patient that initiated conventional treatment with similar clinical parameters and was administered conventional treatment after the same amount of time, which levels were determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment.

[0029] In another embodiment, the anti-human CD3 antibody is administered to achieve, or maintain the C-peptide response in a subject, who has or has not been diagnosed with LADA or other adult-onset autoimmune diabetes disorder as determined by a mixed-meal tolerance test (MMTT), oral glucose tolerance test (OGTT), intravenous tolerance test (IGTT) or two-phase glucose clamp procedure. In preferred embodiments, the patients have a C-peptide response to MMTT, OGTT, IGTT, or two-phase glucose clamp procedure (preferably MMTT) resulting in an area under curve (AUC) of at least 80 pmol/ml/240 min., preferably, at least 90 pmol/ml/240 min., more preferably at least 100 pmol/ml/240 min., or even at least 110 pmol/ml/240 min. In addition, the invention provides methods of treatment such that after a single round of treatment or treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody (preferably, without any intervening treatment with anti-human CD3 antibodies), the level of C-peptide response in the patient is at least 99%, at least 98%, at least 95%, at least 90%, at least 85%, at least 80%, at least 75%, at least 70%, at least 65% or at least 60% of the pre-treatment response as determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment. Specifically, in such methods of the invention, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the average level of C-peptide response to a MMTT, OGTT, IGTT, or two-phase glucose clamp procedure in the patient decreases by less than 1%, less than 5%, less than 10%, less than 20%, less than 30%, less than 40%, less than 50% of the pre-treatment levels as
determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment. In addition, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the average level of C-peptide response to a MMTT, OGTT, IGTT or two-phase glucose clamp procedure in the patient is at least 10%, 20%, 30%, 40%, 50%, 70% or 100% greater than the levels in a patient who initiated conventional diabetes therapy with similar clinical parameters and was administered conventional diabetes therapy over the 6 month, 9 month, 12 month, 15 month or 18 month period or who did not receive any therapy, said peptide response being determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous treatment.

[0030] In specific embodiments, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the patients have a C-peptide response to MMTT, OGTT, IGTT or two-phase glucose clamp procedure (preferably, MMTT) resulting in an AUC of at least 40 pmol/ml/240 min., 50 pmol/ml/240 min, 60 pmol/ml/240 min, 70 pmol/ml/240 min., 80 pmol/ml/240 min., preferably, at least 90 pmol/ml/240 min., more preferably at least 100 pmol/ml/240 min., or even at least 110 pmol/ml/240 min, said response determined 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or after the previous round of treatment.

[0031] The determination of C-peptide response is a measure of β-cell function as is known to one skilled in the art. In other embodiments, β-cell function or residual β-cell function is determined by First-Phase Insulin Release (FPIR). In preferred embodiments, the patients prior to treatment with an anti-human CD3 antibody according to the invention have a FPIR of at least 300 pmol/l, at least 350 pmol/l, at least 400 pmol/l, at least 450 pmol/l, at least 500 pmol/l, preferably, at least 550 pmol/l, more preferably at least 600 pmol/l, or even at least 700 pmol/l. In addition, the invention provides methods of treatment such that after a single round of treatment or a round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the FPIR is at least 99%, at least 98%, at least
95%, at least 90%, at least 85%, at least 80%, at least 75%, at least 70%, at least 65% or at least 60% of the pre-treatment response, said FPIR determined 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous treatment or initial treatment. Specifically, in such methods of the invention, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the average FPIR in the patient decreases by less than 1%, less than 5%, less than 10%, less than 20%, less than 30%, less than 40%, less than 50% of the pre-treatment levels, said FPIR determined 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous treatment. In addition, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the average FPIR in the patient is at least 10%, 20%, 30%, 40%, 50%, 70% or 100% greater than the levels in a patient who initiated conventional diabetes therapy with similar clinical parameters and was administered conventional diabetes therapy over the 6 month, 9 month, 12 month, 15 month or 18 month period, said FPIR determined 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous treatment or initial round of treatment. In specific embodiments, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the patients have a FPIR of at least 300 pmol/l, at least 400 pmol/l, preferably, at least 500 pmol/l, more preferably at least 600 pmol/l, or even at least 700 pmol/l, said FPIR determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or initial round of treatment.

[0032] In other specific embodiments of the invention with respect to the treatment of LADA or other adult-onset autoimmune diabetes disorder, at the initiation of treatment, the subject does not require administration of insulin or requires less than 1 U/kg/day, preferably less than 0.5 U/kg/day, even more preferably less than 0.25 U/kg/day, and even more preferably less than 0.1 U/kg/day. In certain embodiments, a single treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of
the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), prevents the requirement for administration of insulin or delays the need to administer insulin by at least 6 months, at least 1 year, at least 18 months, at least 2 years, at least 30 months, at least 3 years, at least 5 years, at least 7 years or at least 10 years (on average for a population of LADA patients). In other embodiments, a single treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), results in either a decrease (for example, of 10%, 20%, 30%, 40%, or 50%) in the amount of insulin required on average per day, or no change in the average amount of insulin required per day, or an increase of less than 1%, less than 5%, less than 10%, less than 20% or less than 30% of insulin administered, on average, per day as compared to the pre-treatment average dose of insulin per day. In certain embodiments, a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), results in an average daily dose of insulin that is 10%, 20%, 50%, 75%, 90%, 99% less than the average daily dose of insulin required for a patient similarly situated (i.e., similar chemical parameters at the beginning of the month or year period) that had not received the anti-human CD3 antibody treatment.

[0033] In other embodiments, the methods of the invention result in a reduction in hypoglycemic episodes by 1, 2, 3, 4, 5, 6 or more episodes in a one-day, two-day, 5-day, 10-day or 15-day period as compared to similarly situated patients not having been administered the anti-human CD3 antibody according to the invention.

[0034] The invention also provides combination therapy methods. The methods of the invention can be carried out in combination with any standard treatment for the particular indication, such as standard immunosuppressant and/or anti-inflammatory treatments administered for the treatment or amelioration of autoimmune diseases. For example, the anti-human CD3 antibody therapy of the invention may be administered along with other therapies for diabetes, such as, but not limited to, administration of insulin, exenatide, pramlintide or a combination thereof. The CD3 antibodies of the invention may further be administered with other therapies such as anti IL-2 antibodies, cytokine antagonists, and steroidal therapies (for example, but not limited to, glucocorticoids, dexamethasone, cortisone, hydrocortisone, prednisone, prednisolone, triamcinolone, azulfidine, etc.), non-
steroidal antiinflammatories (NSAIDS), such as, but not limited to aspirin, ibuprofen, diclofenac, etodolac, fenoprofen, indomethacin, ketolorac, oxaprozin, nabumetone, sulindac, tolmentin, naproxen, or ketoprofen, immunosuppressants, such as, methotrexate or cyclosporin, and TNF-α inhibitors such as, but not limited to, etanercept and infliximab. In certain embodiments of the invention, subjects which have become refractory to conventional treatments are treated using methods of the invention. In certain embodiments, the anti-human CD3 antibody is administered in combination with one or more islet cell antigens, such as GAD, IA-2 or other antigens which are bound by autoantigens found in patients with Type 1 diabetes.

[0035] According to the invention, the anti-human CD3 antibody is administered so as to reduce adverse effects, such as the cytokine release associated with antibody administration, EBV activation (as evidenced by EBV-induced lymphoproliferative diseases, e.g., mononucleosis) or lymphopenia (defined as <1000 lymphocytes/µL serum), with administration of anti-human CD3 antibodies, and also reduce the number and duration of the administration. As used herein, "course of treatment" or "round of treatment" means administration of anti-human CD3 antibodies every day, every other day or every 3 or 4 days for a period of time, e.g. 1 to 30 days. In particular embodiments, the invention provides a treatment regimen of administration of a dose of the anti-human CD3 antibody for 2 days, 3 days, 4 days, 5 days, 6 days, 7 days, 8 days, 9 days, 10 days, 11 days, 12 days, 13 days or 14 days. In preferred embodiments, the administration is carried out on consecutive days. In certain, embodiments, the dose administered is the same each day of the regimen. However, in preferred embodiments the dose administered escalates over the first few days of the regimen to reduce or eliminate the incidence of cytokine release syndrome.

[0036] In specific embodiments, the dose administered is based on surface area. For example the dose administered is 5 - 1200 µg/m²/day, preferably, 51 - 826 µg/m²/day. In other embodiments, the dose on day 1 of the regimen is 5 - 100 µg/m²/day, preferably 51 µg/m²/day and escalates to the daily dose as recited immediately above by day 3, 4, 5, 6 or 7. For example, on day 1, the subject is administered a dose of approximately 51 µg/m²/day, on day 2 approximately 103 µg/m²/day, on day 3 approximately 207 µg/m²/day, on day 4 approximately 413 µg/m²/day and on subsequent days of the regimen (e.g., days 5-14) 826 µg/m²/day. In another embodiment, on day 1, the subject is administered a dose of approximately 227 µg/m²/day, on day 2 approximately 459 µg/m²/day, on day 3 and subsequent days, approximately 919 µg/m²/day. In another embodiment, on day 1, the
subject is administered a dose of approximately 284 µg/m²/day, on day 2 approximately 574 µg/m²/day, on day 3 and subsequent days, approximately 1148 µg/m²/day.

[0037] In specific embodiments, to reduce the possibility of cytokine release and other adverse effects, the first 1, 2, 3, or 4 doses or all the doses in the regimen are administered more slowly by intravenous administration. For example, a dose of 51 µg/m²/day may be administered over about 5 minutes, about 15 minutes, about 30 minutes, about 45 minutes, about 1 hour, about 2 hours, about 4 hours, about 6 hours, about 8 hours, about 10 hours, about 12 hours, about 14 hours, about 16 hours, about 18 hours, about 20 hours, and about 22 hours. In certain embodiments, the dose is administered by slow infusion over a period of, e.g., 20 to 24 hours. In specific embodiments, the dose is infused in a pump, preferably increasing the concentration of antibody administered as the infusion progresses.

[0038] In other embodiments, a set fraction of the doses for the 51 µg/m²/day to 826 µg/m²/day regimen described above is administered in escalating doses. In certain embodiments, the fraction is 1/10, 1/4, 1/3, 1/2, 1/2 or 1 of the daily doses of the regimens described above. Accordingly, when the fraction is 1/10, the daily doses will be 5.1 µg/m² on day 1, 10.3 µg/m² on day 2, 20.7 µg/m² on day 3, 41.3 µg/m² on day 4 and 82.6 µg/m² on days 5 to 14. When the fraction is 1/3, the doses will be 17 µg/m² on day 1, 34.3 µg/m² on day 2, 69 µg/m² on day 3, 137.6 µg/m² on day 4, and 275.3 µg/m² on days 5 to 14 and similarly for other fractional dose regimes. In other embodiments, the regimen is identical to one of those described above but only over days 1 to 4, days 1 to 5, or days 1 to 6. In other embodiments, doses in the regimen are administered for a certain number of consecutive days, followed by a certain number of days without any doses administered, followed again by doses administered on a certain number of consecutive days and so on until, for example, 14 (but may be 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19 or 20) doses are administered all together. For example, the day 1, day 2, day 3 and day 4 doses of one of the regimens described above may be administered in four consecutive days and then three days without any doses and then the day 5, 6, 7 and 8 doses are administered, followed by another three days without doses, and then the day 9, 10, 11, 12 day doses, with three days off, and finally the day 13 and 14 doses.

[0039] In certain embodiments, the antibody administered according to these regimens is OKT3γl(ala-ala). In other embodiments the antibody is not OKT3γl(ala-ala) and is administered so as to achieve one or more pharmacokinetic parameters achieved by the administration of OKT3γl(ala-ala) such as the serum titer of the antibody administered at 1
day, 2 days, 3 days, 4 days, 5 days, 6 days, 7 days, 2 weeks, 3 weeks or 1 month after the last
day of the dosing regime.

[0040] In certain embodiments, the anti-human CD3 antibody is administered so as to
achieve a certain level of combined coating and modulation T cell receptor complexes on T
cells, as determined by methods well known in the art, see, e.g., Example 11 of U.S. patent
application publication US 2003/0108548, which is hereby incorporated by reference in its
entirety. In specific embodiments, the dosing regimen achieves a combined T cell receptor
coating and modulation of at least 50%, 60%, 70%, 80%, 90%, 95% or of 100% with, in
specific embodiments, little to no free anti-human CD3 antibody detected (for example, less
than 200 ng/mL the drug detected in the blood of the patient.

[0041] In other embodiments, the anti-human CD3 antibody is administered
chronically to treat, prevent, or slow or delay the onset or progression of LADA or other
adult-onset autoimmune diabetes disorder. For example, in certain embodiments, a low dose
of the anti-human CD3 antibody is administered once a month, twice a month, three times per
month, once a week or even more frequently either as an alternative to the 6 to 14 day dosage
regimen discussed above or after administration of such a regimen to enhance or maintain its
therapeutic effect.

[0042] In other embodiments, the subject may be re-dosed at some time subsequent to
administration of the anti-human CD3 antibody dosing regimen, preferably, based upon one
or more physiological parameters. Such redosing may be administered and/or the need for
such redosing evaluated 6 months, 9 months, 1 year, 15 months, 18 months, 2 years, 30
months or 3 years after administration of a dosing regimen.

[0043] In specific embodiments, subjects are administered a subsequent round of anti-
human CD3 antibody treatment based upon one or a combination of the CD4/CD8 cell ratio,
CD8 cell count, CD4/CD3 inversion, CD4/CD25 cell ratio, CD4/FoxP3 cell ratio, CD4/CD40
cell ratio, CD4/IL-10 cell ratio, and/or CD4/TGF-β cell ratio. Other parameters for
determining whether to administer a subsequent round of treatment include an appearance or
an increase in anti-islet cell antibodies, such as GADAs, IA- antibodies or anti-insulin
antibodies or an appearance or increase in the levels of T cells specific for islet cell antigens.
Subsequent doses may be administered if the number of β-cells or β-cell activity or function
decreases by 20%, 30%, 40%, 50%, 60%, 70%, 80% or 90% as compared to the β-cell
number or activity or function during administration of the preceding round of treatment. β-
cell function may be determined by any method know in the art, for example, the C peptide
response to MMTT, OGTT, IGTT, or two-phase glucose clamp, or the First Phase Insulin
Release (FPIR) test, as discussed above. Other parameters that may be used to determine whether to redoes include the HAI or HAIc levels, the need for administration of exogenous insulin or increase in the dosage of exogenous insulin by more than 0.2 U/kg/day, 0.5 U/kg/day, 1 U/kg/day, 2 U/kg/day, 5 U/kg/day, or 10 U/kg/day. In other embodiments, the further doses may be administered based upon appearance of or increase in number (such as an increase by, on average, 1, 2, 3, 4, 5, 8, 10, 15, or 20), duration and/or severity of hypoglycemic episodes or of ketoacidosis episodes on a daily, weekly or monthly basis.

In preferred embodiments, the anti-human CD3 antibodies are administered parenterally, for example, intravenously, intramuscularly or subcutaneously, or, alternatively, are administered orally. The anti-human CD3 antibodies may also be administered as a sustained release formulation.

Additionally, in certain embodiments, the invention provides methods and regimens of administering anti-human CD3 antibodies that reduce the severity and/or incidence of adverse effects such as, but not limited to, cytokine release, apoptosis, activation of EBV, immune reaction against the anti-human CD3 antibody, lymphopenia, anemia, neutropenia, thrombocytopenia or secondary infection.

The invention, in other embodiments, provides methods of producing anti-human CD3 antibodies, particularly OKT3 derived antibodies, such as, but not limited to, humanized OKTγ1 (ala-ala), in CHO cells. In particular embodiments, the invention provides methods of producing anti-human CD3 antibodies comprising (a) culturing CHO cells that have been transfected with the expression vector pMGX1303, or progeny thereof, in media under conditions suitable for expression of said anti-human CD3 antibody; and (b) recovering said anti-human CD3 antibody from said media.

### 3.1 TERMINOLOGY

As used herein, the term "Latent Autoimmune Diabetes in Adults (LADA)" refers to a form of autoimmune diabetes wherein the patients diagnosed with LADA are 25 years old or older, are positive for at least one antibody commonly present in type 1 diabetic patients, e.g., islet-cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies, and are not insulin requiring within the first 6 months after diagnosis. The slowly progressive β-cell failure and, thus, gradual insulin dependency distinguishes LADA from classic type 1 diabetes occurring in adult patients. In LADA patients, β-cell function is usually impaired within 6 years after diagnosis and may take up to 12 years. Other identifying characteristics of LADA may include (but are not necessarily required) non-
obesity, familial or personal history of autoimmune disease, and acute symptoms including polydipsia, polyuria, and weight loss. The term "LADA" can be used interchangeably with type 1.5 diabetes, slowly progressive IDDM, latent type 1 diabetes, youth-onset diabetes of maturity, latent-onset type 1 diabetes, and antibody-positive non-insulin-dependent diabetes. As used herein, the term "Adult-Onset Type 1 diabetes" refers to a form of autoimmune diabetes wherein the patients diagnosed with Adult-Onset Type 1 diabetes are 25 or older, are positive for at least one antibody commonly present in type 1 diabetic patients, e.g., islet-cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies, and are insulin requiring at the time of diagnosis or within the first 6 months after diagnosis.

As used herein, the term "analog" in the context of polypeptides refers to a polypeptide that possesses a similar or identical function as a second polypeptide but does not necessarily comprise a similar or identical amino acid sequence of the second polypeptide, or possess a similar or identical structure of the second polypeptide. A polypeptide that has a similar amino acid sequence refers to a second polypeptide that satisfies at least one of the following: (a) a polypeptide having an amino acid sequence that is at least 30%, at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95% or at least 99% identical to the amino acid sequence of a second polypeptide; (b) a polypeptide encoded by a nucleotide sequence that hybridizes under stringent conditions to a nucleotide sequence encoding a second polypeptide of at least 5 contiguous amino acid residues, at least 10 contiguous amino acid residues, at least 15 contiguous amino acid residues, at least 20 contiguous amino acid residues, at least 25 contiguous amino acid residues, at least 40 contiguous amino acid residues, at least 50 contiguous amino acid residues, at least 60 contiguous amino acid residues, at least 70 contiguous amino acid residues, at least 80 contiguous amino acid residues, at least 90 contiguous amino acid residues, at least 100 contiguous amino acid residues, at least 125 contiguous amino acid residues, or at least 150 contiguous amino acid residues; and (c) a polypeptide encoded by a nucleotide sequence that is at least 30%, at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95% or at least 99% identical to the nucleotide sequence encoding a second polypeptide. A polypeptide with similar structure to a second polypeptide refers to a polypeptide that has a similar secondary, tertiary or quaternary structure to the second polypeptide. The structure of a polypeptide can be determined by methods known to those skilled in the art, including but not limited to, peptide
sequencing, X-ray crystallography, nuclear magnetic resonance, circular dichroism, and crystallographic electron microscopy.

[0050] To determine the percent identity of two amino acid sequences or of two nucleic acid sequences, the sequences are aligned for optimal comparison purposes (e.g., gaps can be introduced in the sequence of a first amino acid or nucleic acid sequence for optimal alignment with a second amino acid or nucleic acid sequence). The amino acid residues or nucleotides at corresponding amino acid positions or nucleotide positions are then compared. When a position in the first sequence is occupied by the same amino acid residue or nucleotide as the corresponding position in the second sequence, then the molecules are identical at that position. The percent identity between the two sequences is a function of the number of identical positions shared by the sequences (i.e., \( \% \) identity = number of identical overlapping positions/total number of positions \( \times 100\% \)). In one embodiment, the two sequences are the same length.

[0051] The determination of percent identity between two sequences can also be accomplished using a mathematical algorithm. A preferred, non-limiting example of a mathematical algorithm utilized for the comparison of two sequences is the algorithm of Karlin and Altschul, 1990, Proc. Natl. Acad. Sci. U.S.A. 87:2264-2268, modified as in Karlin and Altschul, 1993, Proc. Natl. Acad. Sci. U.S.A. 90:5873-5877. Such an algorithm is incorporated into the NBLAST and XBLAST programs of Altschul et al., 1990, J. Mol. Biol. 215:403. BLAST nucleotide searches can be performed with the NBLAST nucleotide program parameters set, e.g., for score=100, wordlength=12 to obtain nucleotide sequences homologous to a nucleic acid molecules of the present invention. BLAST protein searches can be performed with the XBLAST program parameters set, e.g., to score=50, wordlength=3 to obtain amino acid sequences homologous to a protein molecule of the present invention. To obtain gapped alignments for comparison purposes, Gapped BLAST can be utilized as described in Altschul et al., 1997, Nucleic Acids Res. 25:3389-3402. Alternatively, PSI-BLAST can be used to perform an iterated search which detects distant relationships between molecules (Id.). When utilizing BLAST, Gapped BLAST, and PSI-Blast programs, the default parameters of the respective programs (e.g., of XBLAST and NBLAST) can be used (see, e.g., the NCBI website). Another preferred, non-limiting example of a mathematical algorithm utilized for the comparison of sequences is the algorithm of Myers and Miller, 1988, CABIOS 4:1 1-17. Such an algorithm is incorporated in the ALIGN program (version 2.0) which is part of the GCG sequence alignment software package. When
utilizing the ALIGN program for comparing amino acid sequences, a PAM 120 weight residue table, a gap length penalty of 12, and a gap penalty of 4 can be used.

The percent identity between two sequences can be determined using techniques similar to those described above, with or without allowing gaps. In calculating percent identity, typically only exact matches are counted.

As used herein, the term "analog" in the context of a non-proteinaceous analog refers to a second organic or inorganic molecule which possess a similar or identical function as a first organic or inorganic molecule and is structurally similar to the first organic or inorganic molecule.

As used herein, the terms "antagonist" and "antagonists" refer to any protein, polypeptide, peptide, antibody, antibody fragment, large molecule, or small molecule (less than 10 kD) that blocks, inhibits, reduces or neutralizes the function, activity and/or expression of another molecule. In various embodiments, an antagonist reduces the function, activity and/or expression of another molecule by at least 10%, at least 15%, at least 20%, at least 25%, at least 30%, at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95% or at least 99% relative to a control such as phosphate buffered saline (PBS).

As used herein, the terms "antibody" and "antibodies" refer to monoclonal antibodies, multispecific antibodies, human antibodies, humanized antibodies, chimeric antibodies, single-chain Fvs (scFv), single chain antibodies, Fab fragments, F(ab') fragments, disulfide-linked Fvs (sdFv), and anti-idiotypic (anti-Id) antibodies (including, e.g., anti-Id antibodies to antibodies of the invention), and epitope-binding fragments of any of the above. In particular, antibodies include immunoglobulin molecules and immunologically active fragments of immunoglobulin molecules, i.e., molecules that contain an antigen binding site. Immunoglobulin molecules can be of any type (e.g., IgG, IgE, IgM, IgD, IgA and IgY), class (e.g., IgG1, IgG2, IgG3, IgG4, IgA1 and IgA2) or subclass.

As used herein, the term "C-peptide" refers to a 31-amino acid peptide cleaved from proinsulin as it is converted to insulin. Proinsulin consists of an A chain, a connecting peptide (C-peptide), and a B chain. After proinsulin is cleaved, C-peptide remains in the secretory granules of beta cells in the pancreas with insulin and is cosecreted with insulin in response to glucose stimulation. C-peptide is thus released from the pancreas in equi-molar amounts with insulin and may be used as a marker of endogenous insulin production.

As used herein, the term "derivative" in the context of polypeptides refers to a polypeptide that comprises an amino acid sequence which has been altered by the
introduction of amino acid residue substitutions, deletions or additions. The term "derivative" as used herein also refers to a polypeptide that has been modified, i.e., by the covalent attachment of any type of molecule to the polypeptide. For example, but not by way of limitation, an antibody may be modified, e.g., by glycosylation, acetylation, pegylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to a cellular ligand or other protein, etc. A derivative polypeptide may be produced by chemical modifications using techniques known to those of skill in the art, including, but not limited to specific chemical cleavage, acetylation, formylation, metabolic synthesis of tunicamycin, etc. Further, a derivative polypeptide may contain one or more non-classical amino acids. A polypeptide derivative possesses a similar or identical function as the polypeptide from which it was derived.

[0058] As used herein, the terms "disorder" and "disease" are used interchangeably to refer to a condition in a subject. In particular, the term "autoimmune disease" is used interchangeably with the term "autoimmune disorder" to refer to a condition in a subject characterized by cellular, tissue and/or organ injury caused by an immunologic reaction of the subject to its own cells, tissues and/or organs.

[0059] As used herein, the term "epitopes" refers to fragments of a polypeptide or protein having antigenic or immunogenic activity in an animal, preferably in a mammal, and most preferably in a human. An epitope having immunogenic activity is a fragment of a polypeptide or protein that elicits an antibody response in an animal. An epitope having antigenic activity is a fragment of a polypeptide or protein to which an antibody immunospecifically binds as determined by any method well-known to one of skill in the art, for example by immunoassays. Antigenic epitopes need not necessarily be immunogenic.

[0060] As used herein, the term "Fc region" is used to define a C-terminal region of an IgG heavy chain. Although the boundaries may vary slightly, the human IgG heavy chain Fc region is defined to stretch from Cys226 to the carboxy terminus. The Fc region of an IgG comprises two constant domains, CH2 and CH3. The CH2 domain of a human IgG Fc region usually extends from amino acids 231 to amino acid 341. The CH3 domain of a human IgG Fc region usually extends from amino acids 342 to 447. The Fc region of an IgG comprises two constant domains, CH2 and CH3. The CH2 domain of a human IgG Fc region (also referred to as "Cy2" domain) usually extends from amino acid 231-340. The CH2 domain is unique in that it is not closely paired with another domain. Rather, two N-linked branched carbohydrate chains are interposed between the two CH2 domains of an intact native IgG.
Throughout the present specification, the numbering of the residues in an IgG heavy chain is that of the EU index as in Kabat et al., *Sequences of Proteins of Immunological Interest*, 5th Ed. Public Health Service, NIH, MD (1991), expressly incorporated herein by references. The "EU index as in Kabat" refers to the numbering of the human IgG1 EU antibody.

The "hinge region" is generally defined as stretching from Glu216 to Pro230 of human IgG1. Hinge regions of other IgG isotypes may be aligned with the IgG1 sequence by placing the first and last cysteine residues forming inter-heavy chain S-S binds in the same positions.

As used herein, the term "fragment" refers to a peptide or polypeptide comprising an amino acid sequence of at least 5 contiguous amino acid residues, at least 10 contiguous amino acid residues, at least 15 contiguous amino acid residues, at least 20 contiguous amino acid residues, at least 25 contiguous amino acid residues, at least 40 contiguous amino acid residues, at least 50 contiguous amino acid residues, at least 60 contiguous amino acid residues, at least 70 contiguous amino acid residues, at least contiguous 80 amino acid residues, at least contiguous 90 amino acid residues, at least contiguous 100 amino acid residues, at least contiguous 125 amino acid residues, at least contiguous 150 amino acid residues, at least contiguous 175 amino acid residues, at least contiguous 200 amino acid residues, or at least contiguous 250 amino acid residues of the amino acid sequence of another polypeptide. In a specific embodiment, a fragment of a polypeptide retains at least one function of the polypeptide.

As used herein, the term "functional fragment" refers to a peptide or polypeptide comprising an amino acid sequence of at least 5 contiguous amino acid residues, at least 10 contiguous amino acid residues, at least 15 contiguous amino acid residues, at least 20 contiguous amino acid residues, at least 25 contiguous amino acid residues, at least 40 contiguous amino acid residues, at least 50 contiguous amino acid residues, at least 60 contiguous amino acid residues, at least 70 contiguous amino acid residues, at least contiguous 80 amino acid residues, at least contiguous 90 amino acid residues, at least contiguous 100 amino acid residues, at least contiguous 125 amino acid residues, at least contiguous 150 amino acid residues, at least contiguous 175 amino acid residues, at least contiguous 200 amino acid residues, or at least contiguous 250 amino acid residues of the amino acid sequence of second, different polypeptide, wherein said peptide or polypeptide retains at least one function of the second, different polypeptide.
[0065] As used herein, the term "fusion protein" refers to a polypeptide that comprises an amino acid sequence of a first protein or functional fragment, analog or derivative thereof, and an amino acid sequence of a heterologous protein (i.e., a second protein or functional fragment, analog or derivative thereof different than the first protein or functional fragment, analog or derivative thereof). In particular embodiments, a fusion protein comprises a CD3 binding molecule and a heterologous protein, polypeptide, or peptide.

[0066] As used herein, the term "host cell" refers to the particular subject cell transfected with a nucleic acid molecule and the progeny or potential progeny of such a cell. Progeny of such a cell may not be identical to the parent cell transfected with the nucleic acid molecule due to mutations or environmental influences that may occur in succeeding generations or integration of the nucleic acid molecule into the host cell genome.

[0067] As used herein, the term "hybridizes under stringent conditions" describes conditions for hybridization and washing under which nucleotide sequences at least 60% (65%, 70%, preferably 75%, 80% or 85%, and more preferably, 90% or 95%) identical to each other typically remain hybridized to each other. Such stringent conditions are known to those skilled in the art and can be found in Current Protocols in Molecular Biology, John Wiley & Sons, N.Y. (1989), 6.3.1-6.3.6. In one, non-limiting example stringent hybridization conditions are hybridization at 6X sodium chloride/sodium citrate (SSC) at about 45° C, followed by one or more washes in 0.1X SSC, 0.2% SDS at about 68° C. In a preferred, non-limiting example stringent hybridization conditions are hybridization in 6X SSC at about 45° C, followed by one or more washes in 0.2 X SSC, 0.1% SDS at 50-65° C (i.e., one or more washes at 50° C, 55° C, 60° C or 65° C). It is understood that the nucleic acids of the invention do not include nucleic acid molecules that hybridize under these conditions solely to a nucleotide sequence consisting of only A or T nucleotides.

[0068] As used herein, the term "hypoglycemic episode" refers to a blood glucose level in a subject of less than 60 mg/dL that results in typical symptoms of hypoglycemia such as sweatiness, nausea, blurred vision (e.g., seeing spots), shakiness, numb lips and/or tongue, irritability, fainting, clammy skin, confusion, nervousness, weakness, and/or rapid heart beat.

[0069] As used herein, the term "immunomodulatory agent" and variations thereof refer to an agent that modulates a host's immune system. In certain embodiments, an immunomodulatory agent is an immunosuppressant agent. In certain other embodiments, an immunomodulatory agent is an immunostimulatory agent. Immunomodulatory agents
include, but are not limited to, small molecules, peptides, polypeptides, fusion proteins, antibodies, inorganic molecules, mimetic agents, and organic molecules.

[0070] As used herein, the term "immunospecifically binds to an antigen" and analogous terms refer to peptides, polypeptides, fusion proteins and antibodies or fragments thereof that specifically bind to an antigen or a fragment and do not specifically bind to other antigens. A peptide or polypeptide that immunospecifically binds to an antigen may bind to other peptides or polypeptides with lower affinity as determined by, e.g., immunoassays, BIAcore, or other assays known in the art. Antibodies or fragments that immunospecifically bind to an antigen may cross-reactive with related antigens. Preferably, antibodies or fragments that immunospecifically bind to an antigen do not cross-react with other antigens.

[0071] As used herein, the term "immunospecifically binds to a CD3 polypeptide" and analogous terms refer to peptides, polypeptides, fusion proteins and antibodies or fragments thereof that specifically bind to a CD3 polypeptide or a fragment thereof and do not specifically bind to other polypeptides. A peptide or polypeptide that immunospecifically binds to a CD3 polypeptide may bind to other peptides or polypeptides with lower affinity as determined by, e.g., immunoassays, BIAcore, or other assays known in the art. Antibodies or fragments that immunospecifically bind to a CD3 polypeptide may be cross-reactive with related antigens. Preferably, antibodies or fragments that immunospecifically bind to a CD3 polypeptide or fragment thereof do not cross-react with other antigens. Antibodies or fragments that immunospecifically bind to a CD3 polypeptide can be identified, for example, by immunoassays, BIAcore, or other techniques known to those of skill in the art. An antibody or fragment thereof binds specifically to a CD3 polypeptide when it binds to a CD3 polypeptide with higher affinity than to any cross-reactive antigen as determined using experimental techniques, such as radioimmunoassays (RIA) and enzyme-linked immunosorbent assays (ELISAs). See, e.g., Paul, ed., 1989, Fundamental Immunology, Second Edition, Raven Press, New York at pages 332-336 for a discussion regarding antibody specificity.

[0072] As used herein, the term "in combination" refers to the use of more than one prophylactic and/or therapeutic agent. The use of the term "in combination" does not restrict the order in which prophylactic and/or therapeutic agents are administered to a subject with a disease or disorder. A first prophylactic or therapeutic agent can be administered prior to (e.g., 5 minutes, 15 minutes, 30 minutes, 45 minutes, 1 hour, 2 hours, 4 hours, 6 hours, 12 hours, 24 hours, 48 hours, 72 hours, 96 hours, 1 week, 2 weeks, 3 weeks, 4 weeks, 5 weeks, 6 weeks, 8 weeks, or 12 weeks before), concomitantly with, or subsequent to (e.g., 5 minutes,
15 minutes, 30 minutes, 45 minutes, 1 hour, 2 hours, 4 hours, 6 hours, 12 hours, 24 hours, 48 hours, 72 hours, 96 hours, 1 week, 2 weeks, 3 weeks, 4 weeks, 5 weeks, 6 weeks, 8 weeks, or 12 weeks after) the administration of a second prophylactic or therapeutic agent (different from the first prophylactic or therapeutic agent) to a subject with a disease or disorder.

[0073] As used herein, the term "isolated" in the context of a peptide, polypeptide, fusion protein or antibody refers to a peptide, polypeptide, fusion protein or antibody which is substantially free of cellular material or contaminating proteins from the cell or tissue source from which it is derived, or substantially free of chemical precursors or other chemicals when chemically synthesized. The language "substantially free of cellular material" includes preparations of a peptide, polypeptide, fusion protein or antibody in which the peptide, polypeptide, fusion protein or antibody is separated from cellular components of the cells from which it is isolated or recombinantly produced. Thus, a peptide, polypeptide, fusion protein or antibody that is substantially free of cellular material includes preparations of a peptide, polypeptide, fusion protein or antibody having less than about 30%, 20%, 10%, or 5% (by dry weight) of heterologous protein (also referred to herein as a "contaminating protein"). When the peptide, polypeptide, fusion protein or antibody is recombinantly produced, it is also preferably substantially free of culture medium, i.e., culture medium represents less than about 20%, 10%, or 5% of the volume of the protein preparation. When the peptide, polypeptide, fusion protein or antibody is produced by chemical synthesis, it is preferably substantially free of chemical precursors or other chemicals, i.e., it is separated from chemical precursors or other chemicals which are involved in the synthesis of the peptide, polypeptide, fusion protein or antibody. Accordingly such preparations of a peptide, polypeptide, fusion protein or antibody have less than about 30%, 20%, 10%, 5% (by dry weight) of chemical precursors or compounds other than the peptide, polypeptide, fusion protein or antibody of interest. In a preferred embodiment, a CD3 binding molecule is isolated. In another preferred embodiment, an anti-human CD3 antibody is isolated.

[0074] As used herein, the term "isolated" in the context of nucleic acid molecules refers to a nucleic acid molecule which is separated from other nucleic acid molecules which are present in the natural source of the nucleic acid molecule. Moreover, an "isolated" nucleic acid molecule, such as a cDNA molecule, can be substantially free of other cellular material, or culture medium when produced by recombinant techniques, or substantially free of chemical precursors or other chemicals when chemically synthesized and may be free of cDNA or other genomic DNA molecules, e.g., has been isolated from other clones in a nucleic acid library. In a preferred embodiment, a nucleic acid molecule encoding a CD3
binding molecule is isolated. In another preferred embodiment, a nucleic acid molecule encoding an anti-human CD3 antibody is isolated.

[0075] As used herein, the terms "non-responsive" and refractory" describe patients treated with a currently available prophylactic or therapeutic agent for an autoimmune disorder which is not clinically adequate to relieve one or more symptoms associated with the autoimmune disorder. Typically, such patients suffer from severe, persistently active disease and require additional therapy to ameliorate the symptoms associated with their autoimmune disorder.

[0076] As used herein, the term "onset" of disease with reference to Type-1 diabetes refers to a patient meeting the criteria established for diagnosis of Type-1 diabetes by the American Diabetes Association (see, Mayfield et al, 2006, Am. Fam. Physician 58:1355-1362).

[0077] As used herein, the terms "nucleic acids" and "nucleotide sequences" include DNA molecules (e.g., cDNA or genomic DNA), RNA molecules (e.g., mRNA), combinations of DNA and RNA molecules or hybrid DNA/RNA molecules, and analogs of DNA or RNA molecules. Such analogs can be generated using, for example, nucleotide analogs, which include, but are not limited to, inosine or tritylated bases. Such analogs can also comprise DNA or RNA molecules comprising modified backbones that lend beneficial attributes to the molecules such as, for example, nuclease resistance or an increased ability to cross cellular membranes. The nucleic acids or nucleotide sequences can be single-stranded, double-stranded, may contain both single-stranded and double-stranded portions, and may contain triple-stranded portions, but preferably is double-stranded DNA.

[0078] As used herein, the terms "prophylactic agent" and "prophylactic agents" refer to CD3 binding molecules which can be used in the prevention, treatment, management or amelioration of one or more symptoms of an autoimmune disease. In certain embodiments, the term "prophylactic agent" refers to anti-human CD3 antibodies (e.g., OKT3 and variants and derivatives thereof).

[0079] As used herein, the term "prophylactically effective amount" refers to that amount of a CD3 binding molecule sufficient to prevent the development, recurrence or onset of one or more symptoms of a disorder. In certain embodiments, the term "prophylactically effective amount" refers to the amount of an anti-human CD3 antibody sufficient to prevent the development, recurrence or onset of one or more symptoms of a disorder.

[0080] As used herein, the terms "prevent", "preventing" and "prevention" refer to the prevention of the recurrence or onset of one or more symptoms of an autoimmune or
inflammatory disorder in a subject resulting from the administration of a prophylactic or therapeutic agent.

[0081] As used herein, a "protocol" includes dosing schedules and dosing regimens. The protocols herein are methods of use and include prophylactic and therapeutic protocols. A "dosing regimen" or "course of treatment" may include administration of several doses of a therapeutic or prophylactic agent over 1 to 20 days.

[0082] As used herein, the phrase "side effects" encompasses unwanted and adverse effects of a prophylactic or therapeutic agent. Adverse effects are always unwanted, but unwanted effects are not necessarily adverse.

[0083] As used herein, the terms "subject" and "patient" are used interchangeably. As used herein, the terms "subject" and "subjects" refer to an animal, preferably a mammal including a non-primate (e.g., a cow, pig, horse, cat, dog, rat, and mouse) and a primate (e.g., a monkey or a human), and more preferably a human.

[0084] As used herein, the term "synergistic" refers to a combination of prophylactic or therapeutic agents which is more effective than the additive effects of the agents in the combination when administered individually. A synergistic effect of a combination of prophylactic or therapeutic agents may permit the use of lower dosages of one or more of the agents and/or less frequent administration of said agents to a subject with an autoimmune disorder. The ability to utilize lower dosages of prophylactic or therapeutic agents and/or to administer said agents less frequently reduces the toxicity associated with the administration of said agents to a subject without reducing the efficacy of said agents in the prevention or treatment of autoimmune disorders. In addition, a synergistic effect can result in improved efficacy of agents in the prevention or treatment of autoimmune disorders. Finally, synergistic effect of a combination of prophylactic or therapeutic agents may avoid or reduce adverse or unwanted side effects associated single agent therapy.

[0085] As used herein, the terms "therapeutic agent" and "therapeutic agents" refer to CD3 binding molecules which can be used in the prevention, treatment, management or amelioration of one or more symptoms of an autoimmune or inflammatory disease. In certain embodiments, the term "therapeutic agent" refers to anti-human CD3 antibodies (e.g., OKT3 and variants or derivatives thereof).

[0086] As used herein, the term "therapeutically effective amount" refers to that amount of a therapeutic agent sufficient to result in amelioration of one or more symptoms of a disorder. With respect to diabetes, a therapeutically effective amount preferably refers to the amount of therapeutic agent that reduces a subject's average daily insulin requirements by
at least 20%, by at least 25%, by at least 30%, by at least 35%, by at least 40%, by at least 45%, by at least 50%, by at least 55%, by at least 60%, by at least 65%, by at least 70%, by at least 75%, by at least 80%, by at least 85%, by at least 90%, by at least 95%.

[0087] As used herein, the terms "treat", "treatment" and "treating" refer to the amelioration of one or more symptoms associated with an autoimmune or inflammatory disorder that results from the administration of one or more CD3 binding molecules. In particular, such terms refer to the amelioration of one or more symptoms associated with an autoimmune disorders that results from the administration of one or more anti-human CD3 antibodies

4. DESCRIPTION OF THE FIGURES

[0088] FIGS. IA and IB. Sequences of humanized OKT3 variable regions. FIG. IA and FIG. IB show the alignments of the OKT3 light chain (FIG. IA) (SEQ ID NO:1) and the heavy chain (FIG. IB) (SEQ ID NO:5) variable domain amino acid sequence (row 1), the variable domain sequence from the human antibodies chosen as light and heavy chain acceptor framework (row 2) (SEQ ID NOs:2 and 6, respectively), and the humanized OKT3 variable domain sequences (rows 3-5) (SEQ ID NO:3, SEQ ID NO:4, SEQ ID NO:7, SEQ ID NO:8 and SEQ ID NO:9). The CDR choices are singly underlined. Rows 3-5 show only differences from the human acceptor sequence, with the non-CDR differences shown double underlined. Dashes indicate gaps introduced in the sequences to maximize the alignment. Numbering is as in Kabat et al, Sequences of Proteins of Immunological Interest, 5th Ed. Public Health Service, NHI, MD (1991), which is incorporated by reference herein.

[0089] FIGS. 2A-2G. Amino acid sequence and nucleotide sequence of murine OKT3 heavy and light chains (SEQ ID NOs: 10-13).

[0090] FIGS. 3A-3D. FIGS. 3A and 3B, nucleotide and amino acid sequences, respectively, of the light chain of humanized OKT3γ1 (SEQ ID NOs: 14 and 15, respectively). FIGS. 3C and 3D, nucleotide and amino acid sequences, respectively, of the heavy chain of humanized OKT3γ1 (ala-ala) (SEQ ID NOs: 16 and 17, respectively).

[0091] FIG. 4. Schematic representation of mammalian expression vector pMGX1303, containing coding regions for humanized OKT3 and capable of promoting expression of the humanized antibody in CHO cells.
5. **DETAILED DESCRIPTION OF THE INVENTION**

[0092] The present invention provides methods of treating, preventing, slowing the progression of and ameliorating the symptoms of LADA as well as other adult-onset autoimmune diabetes disorders using proteins, particularly, antibodies, directed against the CD3 complex associated with the human T cell receptor or TcR. In particular embodiments, the antibody binds to the epsilon subunit of the CD3 complex. The methods of the invention may be used with any anti-CD3 antibody presented herein or known in the art, e.g., OKT3, ChAglyCD3 (TRX4™), HUM291 (visilizumab; NUVION™), UCHT1, Leu4, 500A2, CLB-T3/3, BMA030 and YTH 12.5, and variations or derivatives thereof. In one embodiment of the invention the antibody is OKT3, preferably humanized versions of OKT3 or an antibody that competes for binding, for example, as determined by immunoprecipitation assay or ELISA, with OKT3. In another embodiment, the antibody is humanized OKT3, which has been modified at one or more amino acid residues to exhibit reduced T cell activation and/or FcR binding when compared to a non-modified humanized OKT3 antibody, such as having an alanine at, e.g., residue number 234 of the Fc domain, and an alanine at, e.g., residue number 235 of the Fc domain.

[0093] Anti-CD3 mAbs are potent immunosuppressive agents directed against an invariant protein complex associated with the human TcR (Van Wauwe, 1980, J. Immunol. 124:2708). The CD3 complexes are believed to be accessory structures that transduce the activation signals initiated upon binding of the TcR to its ligand. Binding of the anti-CD3 antibody OKT3 to the TcR mediates TcR blockade and inhibits alloantigen recognition and cell-mediated cytotoxicity (Landegren et al., 1982, J. Exp. Med. 155:1579; van Seventer et al., 1987, J. Immunol. 139:2545; Weiss et al., 1986, Ann. Rev. Immunol. 4:593). However, the administration of some immune-cell directed antibodies, including OKT3 and other anti-CD3 antibodies, may induce T cell activation, including the systematic release of several cytokines, including IL-2, IL-6, TNF-α and IFN-γ (Abramowicz, 1989, Transplantation, 47:606-608; Chatenoud, 1989, New Eng. J. Med. 320:1420-1421). This production of cytokines has been correlated with the adverse side-effects frequently observed after the first injection of mAbs (Van Wauwe, 1980, J. Immunol. 124:2708; Chatenoud, 1989, New Eng. J. Med. 320:1420-1421; Thistlethwaite, 1988, Am J Kidney Dis., 11:1 12-9), and may augment the production of anti-isotypic and anti-idiotypic antibodies occurring in some patents after one or two weeks of treatment. This immune response can neutralize the specific antibody,
as well as other antibodies of the same class (isotype), and preclude subsequent treatments (Thistlethwaite, 1988, Am J Kidney Dis. 11:1 12-9).

[0094] Several pieces of evidence strongly suggest that these side-effects are a consequence of the cross-linking between T lymphocytes and Fc receptor (FcR)-bearing cells through the Fc portion of antibodies, including for example, OKT3, resulting in activation of both cell types (Debets, 1990, J. Immunol. 144:1304; Krutman, 1990, J. Immunol. 145:1337): 1) anti-CD3 mAbs did not stimulate T cell proliferation in vitro, unless the antibody was immobilized to plastic or bound to FcR+ antigen presenting cells included in the culture (van Lier, 1989, Immunol. 68:45); 2) the cross-linking of OKT3 through FcRs I and II enhanced proliferation in response to IL-2, in vitro (van Lier, 1987, J. Immunol. 139:2873); 3) proliferation of murine T cells induced by 145-2Cl 1, a hamster monoclonal antibody directed against the murine CD3 complex, could be blocked by the anti-FcR antibody, 2.4G2; 4) the injection into mice of F(ab')2 fragments of 145-2Cl 1 induced significant immunosuppression without triggering full T cell activation (Hirsch, 1990, Transplantation, 49:1 117-23) and was less toxic in mice than the whole antibody (Alegre, 1990, Transplant Proc. 22:1920-1); and 5) the administration of an OKT3 IgA switch variant that displayed a reduced FcR-mediated T cell activation as compared with OKT3 IgG2a, resulted in fewer side effects in chimpanzees in vivo (Parleviet, 1990, Brief Communications 50:889-892).

[0095] Administration of certain anti-CD3 antibodies has also been associated with transient retrovirus activation, specifically activation of dormant Epstein-Barr Virus (EBV) infection. Anti-CD3 antibody treatment has also been found to be lytic to activated T cells and apoptotic to some T cell populations. The reasons for these effects are unclear, but they may be dose related and are probably the result of the modulation of the TcR complex resulting in suboptimal signaling.

[0096] Thus improvement of anti-CD3 mAb therapy can be obtained by molecularly modifying the antibody to reduce its affinity for FcRs. The mutated Ab obtained could lead to lower cellular activation and reduced toxicity in vivo, but retain the original immunosuppressive properties of the antibody.

5.1 **Antibodies that Immunospecifically Bind to CD3 Polypeptides**

[0097] It should be recognized that antibodies that immunospecifically bind to a CD3 polypeptide are known in the art. Examples of known antibodies that immunospecifically bind to a CD3 polypeptide include, but are not limited to OKT3, HuM291, ChAglyCD3, UCHT1, Leu4, 500A2, CLB-T3/3, BMA030, YTH 12.5 and rat CD3 antibody (See Herald et
The present invention provides methods of treating, preventing, slowing the progression of and ameliorating the symptoms of LADA as well as other adult-onset autoimmune diabetes disorders using antibodies that immunospecifically bind to a CD3 polypeptide expressed by an immune cell such as a T cell, wherein said antibodies modulate an activity or function of said T cell. In a specific embodiment, antibodies that immunospecifically bind to a CD3 polypeptide directly or indirectly modulate the activity of lymphocytes, preferably peripheral blood T cells. In particular, the present invention provides antibodies that immunospecifically bind to a CD3 polypeptide expressed by a T cell, and said antibodies modulate the activity of peripheral blood T cell.

In a specific embodiment, antibodies that immunospecifically bind to a CD3 polypeptide inhibit T cell activation by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% and inhibit T cell proliferation by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% in an in vivo or in vitro assay described herein or well-known to one of skill in the art. In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide inhibit alloantigen recognition by T cells by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% in an in vivo or in vitro assay described herein or well-known to one of skill in the art. In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide inhibit T cell mediated cytotoxicity by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% in an in vivo or in vitro assay described herein or well-known to one of skill in the art.

In another embodiment, the methods of the invention employ antibodies that immunospecifically bind to a CD3 polypeptide and do not induce or have reduced (as
compared to unmodified antibodies, e.g., the murine OKT3 monoclonal antibody) cytokine expression and/or release in an in vivo or in vitro assay described herein or well-known to one of skill in the art. In a specific embodiment, antibodies that immunospecifically bind to a CD3 polypeptide do not induce an increase in the concentration cytokines such as, e.g., IFN-\(\gamma\), IL-2, IL-4, IL-6, IL-9, IL-12, and IL-15 in the serum of a subject administered such an antibody. In an alternative embodiment, antibodies that immunospecifically bind to a CD3 polypeptide induce cytokine expression and/or release in an in vitro or in vivo assay described herein or well-known to one of skill in the art but at levels less than those induced by unmodified anti-CD3 antibodies, such as, the murine OKT3 monoclonal antibody. Serum concentrations of a cytokine can be measured by any technique well-known to one of skill in the art such as, e.g., ELISA.

[0101] In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide induce T cell anergy in an in vivo or in vitro assay described herein or well-known to one of skill in the art. In an alternative embodiment, antibodies that immunospecifically bind to a CD3 polypeptide do not induce T cell anergy in an in vivo or in vitro assay described herein or well-known to one of skill in the art. In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide elicit a state of antigen-specific unresponsiveness for at least 30 minutes, at least 1 hour, at least 2 hours, at least 6 hours, at least 12 hours, at least 24 hours, at least 2 days, at least 5 days, at least 7 days, at least 10 days or more in an in vitro assay described herein or known to one of skill in the art.

[0102] In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide inhibit T cell activation by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% and inhibit T cell proliferation by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% in an in vivo or in vitro assay described herein or well-known to one of skill in the art.

[0103] In yet another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide achieve T cell coating or modulation by at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 98% and inhibit T cell proliferation by at least 25%, at least 30%, at least 35%, at least 40%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at
least 80%, at least 85%, at least 90%, at least 98%, at least 99%, and preferably by 100% in an in vivo or in vitro assay described herein or well-known to one of skill in the art.

[0104] In another embodiment, the Fc domain of an antibody that immunospecifically binds to a CD3 polypeptide does not detectably bind to one or more of the Fc receptors ("FcR") FcRI, FcRII, and/or FcRIII expressed by an immune cell such as a T cell, monocyte, and macrophage.

[0105] Antibodies that immunospecifically bind to a CD3 polypeptide include, but are not limited to, monoclonal antibodies, multispecific antibodies, human antibodies, humanized antibodies, chimeric antibodies, single-chain Fvs (scFv), single chain antibodies, Fab fragments, F(ab') fragments, F(ab')\textsubscript{2} fragments, disulfide-linked Fvs (sdFv), and anti-idiotypic (anti-Id) antibodies (including, e.g., anti-Id antibodies to antibodies of the invention), and epitope-binding fragments of any of the above. In particular, antibodies that immunospecifically bind to a CD3 polypeptide include immunoglobulin molecules and immunologically active portions of immunoglobulin molecules, i.e., molecules that contain an antigen binding site that immunospecifically binds to a CD3 polypeptide. The immunoglobulin molecules of the invention can be of any type (e.g., IgG, IgE, IgM, IgD, IgA and IgY), class (e.g., IgG\textsubscript{i}, IgG\textsubscript{2}, IgG\textsubscript{3}, IgG\textsubscript{4}, IgAi and IgA\textsubscript{2}) or subclass of immunoglobulin molecule. In a specific embodiment, the antibodies that immunospecifically bind to a CD3 polypeptide and mediate the activity of T cells comprise an Fc domain or a fragment thereof (e.g., the CH2, CH3, and/or hinge regions of an Fc domain). In a preferred embodiment, the antibodies that immunospecifically bind to a CD3 polypeptide and mediate the activity of T cells comprise an Fc domain or fragment thereof that does not detectably bind to an FcR (or one or more of FcRI, FcRII or FcRIII) expressed by an immune cell or has reduced FcR binding as compared to an antibody with a wild type Fc domain.

[0106] The antibodies that immunospecifically bind to a CD3 polypeptide may be from any animal origin including birds and mammals (e.g., human, murine, donkey, sheep, rabbit, goat, guinea pig, camel, horse, or chicken). Preferably, the antibodies of the invention are human, humanized or chimeric monoclonal antibodies. Human antibodies that immunospecifically bind to a CD3 polypeptide include antibodies having the amino acid sequence of a human immunoglobulin and antibodies isolated from human immunoglobulin libraries or from mice that express antibodies from human genes.
[0107] The antibodies that immunospecifically bind to a CD3 polypeptide may be monospecific, bispecific, trispecific or of greater multispecificity. Multispecific antibodies may be specific for different epitopes of a CD3 polypeptide or may be specific for both a CD3 polypeptide as well as for a heterologous epitope, such as a heterologous polypeptide or solid support material. See, e.g., PCT publications WO 93/17715, WO 93/08802, WO 91/00360, and WO 92/05793; Tutt, et al., J. Immunol. 147:60-69 (1991); U.S. Patent Nos. 4,474,893, 4,714,681, 4,925,648, 5,573,920, and 5,601,819; and Kostelny et al., J. Immunol. 148:1547-1553 (1992).

[0108] The present invention provides for antibodies that have a high binding affinity for a CD3 polypeptide. In a specific embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has an association rate constant or $k_{on}$ rate (antibody (Ab) + antigen (Ag)) of at least $10^{5}$ M$^{-1}$s$^{-1}$, at least $5 \times 10^{5}$ M$^{-1}$s$^{-1}$, at least $10^{6}$ M$^{-1}$s$^{-1}$, at least $5 \times 10^{6}$ M$^{-1}$s$^{-1}$, at least $10^{7}$ M$^{-1}$s$^{-1}$, at least $5 \times 10^{7}$ M$^{-1}$s$^{-1}$, or at least $10^{8}$ IVT$^{-1}$S$^{-1}$. In a preferred embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has a $k_{on}$ of at least $2 \times 10^{5}$ IVT$^{-1}$S$^{-1}$, at least $5 \times 10^{5}$ IVT$^{-1}$S$^{-1}$, at least $10^{6}$ IVT$^{-1}$S$^{-1}$, at least $5 \times 10^{6}$ IVT$^{-1}$S$^{-1}$, at least $10^{7}$ IVT$^{-1}$S$^{-1}$, or at least $10^{8}$ IVT$^{-1}$S$^{-1}$.

[0109] In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has a $k_{off}$ rate (antibody (Ab) + antigen (Ag)) of less than $10^{-1}$ s$^{-1}$, less than $5 \times 10^{-1}$ s$^{-1}$, less than $10^{-2}$ s$^{-1}$, less than $5 \times 10^{-2}$ s$^{-1}$, less than $10^{-3}$ s$^{-1}$, less than $5 \times 10^{-3}$ s$^{-1}$, less than $10^{-4}$ s$^{-1}$, less than $5 \times 10^{-4}$ s$^{-1}$, less than $10^{-5}$ s$^{-1}$, less than $5 \times 10^{-5}$ s$^{-1}$, less than $10^{-6}$ s$^{-1}$, less than $5 \times 10^{-6}$ s$^{-1}$, less than $10^{-7}$ s$^{-1}$, less than $5 \times 10^{-7}$ s$^{-1}$, less than $10^{-8}$ s$^{-1}$, less than $5 \times 10^{-8}$ s$^{-1}$, less than $10^{-9}$ s$^{-1}$, less than $5 \times 10^{-9}$ s$^{-1}$, or less than $10^{-10}$ s$^{-1}$. In a preferred embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has a $k_{on}$ of less than $5 \times 10^{-4}$ s$^{-1}$, less than $10^{-5}$ s$^{-1}$, less than $5 \times 10^{-5}$ s$^{-1}$, less than $10^{-6}$ s$^{-1}$, less than $5 \times 10^{-6}$ s$^{-1}$, less than $10^{-7}$ s$^{-1}$, less than $5 \times 10^{-7}$ s$^{-1}$, less than $10^{-8}$ s$^{-1}$, less than $5 \times 10^{-8}$ s$^{-1}$, less than $10^{-9}$ s$^{-1}$, less than $5 \times 10^{-9}$ s$^{-1}$, or less than $10^{-10}$ s$^{-1}$.

[0110] In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has an affinity constant or $K_a$ (k$_{on}$/k$_{off}$) of at least $10^{2}$ M$^{-1}$, at least $5 \times 10^{2}$ M$^{-1}$, at least $10^{3}$ M$^{-1}$, at least $5 \times 10^{3}$ M$^{-1}$, at least $10^{4}$ M$^{-1}$, at least $5 \times 10^{4}$ M$^{-1}$, at least $10^{5}$ M$^{-1}$, at least $5 \times 10^{5}$ M$^{-1}$, at least $10^{6}$ M$^{-1}$, at least $5 \times 10^{6}$ M$^{-1}$, at least $10^{7}$ M$^{-1}$, at least $5 \times 10^{7}$ M$^{-1}$, at least $10^{8}$ M$^{-1}$, at least $5 \times 10^{8}$ M$^{-1}$, at least $10^{9}$ M$^{-1}$, at least $5 \times 10^{9}$ M$^{-1}$, at least $10^{10}$ M$^{-1}$, at least $5 \times 10^{10}$ M$^{-1}$, at least $10^{11}$ M$^{-1}$, at least $5 \times 10^{11}$ M$^{-1}$, at least $10^{12}$ M$^{-1}$, at least $5 \times 10^{12}$ M$^{-1}$.
M⁻¹, at least 10¹³ M⁻¹, at least 5 x 10¹³ M⁻¹, at least 10¹⁴ M⁻¹, at least 5 x 10¹⁴ M⁻¹, at least 10¹⁵ M⁻¹, or at least 5 x 10¹⁵ M⁻¹. In yet another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide has a dissociation constant or IQ (k_{off}/k_{on}) of less than 10⁻² M, less than 5 x 10⁻² M, less than 10⁻³ M, less than 5 x 10⁻³ M, less than 10⁻⁴ M, less than 5 x 10⁻⁴ M, less than 10⁻⁵ M, less than 5 x 10⁻⁵ M, less than 10⁻⁶ M, less than 5 x 10⁻⁶ M, less than 10⁻⁷ M, less than 5 x 10⁻⁷ M, less than 10⁻⁸ M, less than 5 x 10⁻⁸ M, less than 10⁻⁹ M, less than 5 x 10⁻⁹ M, less than 10⁻¹⁰ M, less than 5 x 10⁻¹⁰ M, less than 10⁻¹¹ M, less than 5 x 10⁻¹¹ M, less than 10⁻¹² M, less than 5 x 10⁻¹² M, less than 10⁻¹³ M, less than 5 x 10⁻¹³ M, less than 10⁻¹⁴ M, less than 5 x 10⁻¹⁴ M, less than 10⁻¹⁵ M, or less than 5 x 10⁻¹⁵ M.

[0111] In a specific embodiment, an antibody that immunospecifically binds to a CD3 polypeptide is humanized OKT3 or an antigen-binding fragment thereof, e.g., (one or more complementarity determining regions (CDRs) of humanized OKT3). OKT3 has the amino acid sequence disclosed, e.g., in U.S. Patent Nos. 4,658,019, 6,113,901 and 6,491,916 (each of which is incorporated herein by reference in its entirety), or the amino acid sequence of the monoclonal antibody produced by the cell line deposited with the American Type Culture Collection (ATCC®), 10801 University Boulevard, Manassas, Virginia 2010-2209 on July 28, 1993 as Accession Number CRL-8001 (which is incorporated herein by reference). Several humanized versions of OKT3 are also reported in U.S. Patent No. 6,491,916. In an alternative embodiment, an antibody that immunospecifically binds to a CD3 polypeptide is not OKT3, a derivative of OKT3, e.g., humanized OKT3, an antigen-binding fragment of OKT3, or, more preferably, not a humanized or chimeric version thereof.

[0112] In a specific embodiment, the present invention also provides antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising a variable heavy ("VH") domain having an amino acid sequence of the VH domain of a humanized OKT3 (for example, SEQ ID NO:5, SEQ ID NO:7, SEQ ID NO:8, or SEQ ID NO:9; FIG. IB). In a preferred embodiment, the humanized OKT3 antibody comprises a heavy chain with the amino acid sequence of hOKT3γl(ala-ala) provided in FIG. 3D (SEQ ID NO: 17) or encoded by the nucleotide sequence of hOKT3γl(ala-ala) provided in FIG. 3C (SEQ ID NO: 16).

[0113] In a specific embodiment, the present invention also provides antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising a variable light ("VL") domain having an amino acid sequence of the VL domain for a humanized OKT3 (SEQ ID NO:1, SEQ ID NO:3, or SEQ ID NO:4; FIG IA). In a preferred embodiment, the humanized OKT3 antibody comprises a light chain with the amino acid sequence of
hOKT3γ1 provided in FIG. 3B (SEQ ID NO: 15) or encoded by the nucleotide sequence of hOKT3γ1 provided in FIG. 3A (SEQ ID NO: 14).

[01 14] The present invention also provides antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising a VH domain disclosed herein, or a VH domain of an antibody disclosed herein, combined with a VL domain disclosed herein, or other VL domain. The present invention further provides antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising a VL domain disclosed herein, or a VL domain of an antibody disclosed herein, combined with a VH domain disclosed herein, or other VH domain.

[01 15] In one embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a VH domain having the amino acid sequence of the VH domain of humanized OKT3 (SEQ ID NO:5; FIG. IB).

[01 16] In a preferred embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a heavy chain having the amino acid sequence of the heavy chain of hOKT3γ1 disclosed in FIG. 3D(SEQ ID NO: 17).

[01 17] In one embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a VL domain having the amino acid sequence of the VL domain of a humanized OKT3, for example, SEQ ID NO:3 or 4 (FIG. IA).

[01 18] In a preferred embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a light chain having the amino acid sequence of the light chain of hOKT3γ1 disclosed in FIG. 3B (SEQ ID NO: 15).

[01 19] In another embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a VH domain having the amino acid sequence of the VH domain of a humanized OKT3, for example, SEQ ID NO:7, SEQ ID NO:8, or SEQ ID NO:9 (FIG. IB) and a VL domain having the amino acid sequence of the VL domain of a humanized OKT3, for example, SEQ ID NO: 3 or SEQ ID NO:4 (FIG. IA). In another embodiment, an isolated nucleic acid molecule encodes an antibody that immunospecifically binds to a CD3 polypeptide, said antibody comprising a
heavy chain having the nucleotide or amino acid sequence of the heavy chain of a humanized OKT3, for example the amino acid sequence of hOKT3γ1 disclosed in FIG. 3D (SEQ ID NO: 17), and a light chain having the nucleotide or amino acid sequence of the light chain of a humanized OKT3, for example the nucleotide or amino acid sequence of hOKT3γ-1 disclosed in FIG. 3B (SEQ ID NO: 15).

[0120] In one embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise one or more VH CDRs disclosed in FIG. IB. In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise more than one of the VH CDRs disclosed in FIG. IB.

[0121] In one embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise one or more of the VL CDRs disclosed in FIG. IA. In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise more than one of the VL CDRs disclosed in FIG. IA.

[0122] In another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise one or more VH CDRs disclosed in FIG. IB and one or more VL CDRs disclosed in FIG. IA. In yet another embodiment, antibodies that immunospecifically bind to a CD3 polypeptide comprise more than one of the VH CDRs disclosed in FIG. IB and more than one of the VL CDRs disclosed in FIG. IA.

[0123] The present invention also provides antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising derivatives of the VH domains, VH CDRs, VL domains, or VL CDRs described herein, or available to one of ordinary skill in the art, that immunospecifically bind to a CD3 polypeptide. Standard techniques known to those of skill in the art can be used to introduce mutations in the nucleotide sequence encoding an antibody of the invention, including, for example, site-directed mutagenesis and PCR-mediated mutagenesis which results in amino acid substitutions. Preferably, the derivatives include less than 25 amino acid substitutions, less than 20 amino acid substitutions, less than 15 amino acid substitutions, less than 10 amino acid substitutions, less than 5 amino acid substitutions, less than 4 amino acid substitutions, less than 3 amino acid substitutions, or less than 2 amino acid substitutions relative to the original molecule. In a preferred embodiment, the derivatives have conservative amino acid substitutions are made at one or more predicted non-essential amino acid residues (i.e., amino acid residues which are not critical for the antibody to immunospecifically bind to a CD3 polypeptide). A
"conservative amino acid substitution" is one in which the amino acid residue is replaced with an amino acid residue having a side chain with a similar charge. Families of amino acid residues having side chains with similar charges have been defined in the art. These families include amino acids with basic side chains (e.g., lysine, arginine, histidine), acidic side chains (e.g., aspartic acid, glutamic acid), uncharged polar side chains (e.g., glycine, asparagine, glutamine, serine, threonine, tyrosine, cysteine), nonpolar side chains (e.g., alanine, valine, leucine, isoleucine, proline, phenylalanine, methionine, tryptophan), beta- branched side chains (e.g., threonine, valine, isoleucine) and aromatic side chains (e.g., tyrosine, phenylalanine, tryptophan, histidine). Alternatively, mutations can be introduced randomly along all or part of the coding sequence, such as by saturation mutagenesis, and the resultant mutants can be screened for biological activity to identify mutants that retain activity. Following mutagenesis, the encoded antibody can be expressed and the activity of the antibody can be determined.

[0124] In a specific embodiment, the present invention provides for antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising the amino acid sequence of a humanized OKT3 with one or more amino acid residue substitutions in the variable light (VL) domain and/or variable heavy (VH) domain. The present invention also provides for antibodies that immunospecifically bind to a CD3 polypeptide, said antibodies comprising the amino acid sequence of the heavy and light chains (or heavy and light chain variable domains) of murine OKT3 (SEQ ID NOs: 2 and 4, respectively and provided in FIGS. 2A-2G) with one or more amino acid residue substitutions in one or more VL CDRs and/or one or more VH CDRs. The antibody generated by introducing substitutions in the VH domain, VH CDRs, VL domain and/or VL CDRs of humanized OKT3 can be tested in vitro and in vivo, for example, for its ability to bind to a CD3 polypeptide, or for its ability to inhibit T cell activation, or for its ability to inhibit T cell proliferation, or for its ability to induce T cell lysis, or for its ability to prevent, treat or ameliorate one or more symptoms associated with an autoimmune disorder.

[0125] In a specific embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises a nucleotide sequence that hybridizes to the nucleotide sequence encoding the monoclonal antibody produced by the cell line deposited with the ATCC® as Accession Number CRL-8001 under stringent conditions, e.g., hybridization to filter-bound DNA in 6x sodium chloride/sodium citrate (SSC) at about 45° C followed by one or more washes in 0.2xSSC/0.1% SDS at about 50-65° C, under highly stringent conditions, e.g.,
hybridization to filter-bound nucleic acid in 6xSSC at about 45° C followed by one or more
washes in 0.1xSSC/0.2% SDS at about 68° C, or under other stringent hybridization
conditions which are known to those of skill in the art (see, for example, Ausubel, F.M. et al.,
and John Wiley & Sons, Inc., New York at pages 6.3.1-6.3.6 and 2.10.3).

[0126] In a specific embodiment, an antibody that immunospecifically binds to a CD3
polypeptide comprises a nucleotide sequence that hybridizes to the nucleotide sequence
encoding the humanized OKT3 under stringent conditions, *e.g.*, hybridization to filter-bound
DNA in 6x sodium chloride/sodium citrate (SSC) at about 45° C followed by one or more
washes in 0.2xSSC/0.1% SDS at about 50-65° C, under highly stringent conditions, *e.g.*, 
hybridization to filter-bound nucleic acid in 6xSSC at about 45° C followed by one or more
washes in 0.1xSSC/0.2% SDS at about 68° C, or under other stringent hybridization
conditions which are known to those of skill in the art (see, for example, Ausubel, F.M. et al.,
and John Wiley & Sons, Inc., New York at pages 6.3.1-6.3.6 and 2.10.3).

[0127] In a specific embodiment, an antibody that immunospecifically binds to a CD3
polypeptide comprises an amino acid sequence of a VH domain or an amino acid sequence a
VL domain encoded by a nucleotide sequence that hybridizes to the nucleotide sequence
encoding the VH or VL domains of humanized OKT3 under stringent conditions, *e.g.*, 
hybridization to filter-bound DNA in 6x sodium chloride/sodium citrate (SSC) at about 45° C
followed by one or more washes in 0.2xSSC/0.1% SDS at about 50-65° C, under highly
stringent conditions, *e.g.*, hybridization to filter-bound nucleic acid in 6xSSC at about 45° C
followed by one or more washes in 0.1xSSC/0.2% SDS at about 68° C, or under other
stringent hybridization conditions which are known to those of skill in the art (see, for
Green Publishing Associates, Inc. and John Wiley & Sons, Inc., New York at pages 6.3.1-
6.3.6 and 2.10.3).

[0128] In another embodiment, an antibody that immunospecifically binds to a CD3
polypeptide comprises an amino acid sequence of a VH CDR or an amino acid sequence of a
VL CDR encoded by a nucleotide sequence that hybridizes to the nucleotide sequence
encoding any one of VH CDRs or VL CDRs of the monoclonal antibody produced by the cell
line deposited with the ATCC® as Accession Number CRL-8001 under stringent conditions
*e.g.*, hybridization to filter-bound DNA in 6x sodium chloride/sodium citrate (SSC) at about
45° C followed by one or more washes in 0.2xSSC/0.1% SDS at about 50-65° C, under highly stringent conditions, e.g., hybridization to filter-bound nucleic acid in 6xSSC at about 45° C followed by one or more washes in 0.1xSSC/0.2% SDS at about 68° C, or under other stringent hybridization conditions which are known to those of skill in the art.

[0129] In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises an amino acid sequence of a VH CDR and an amino acid sequence of a VL CDR encoded by nucleotide sequences that hybridizes to the nucleotide sequences encoding the monoclonal antibody produced by the cell line deposited with the ATCC® as Accession Number CRL-8001 under stringent conditions, e.g., hybridization to filter-bound DNA in 6x sodium chloride/sodium citrate (SSC) at about 45° C followed by one or more washes in 0.2xSSC/0.1% SDS at about 50-65° C, under highly stringent conditions, e.g., hybridization to filter-bound nucleic acid in 6xSSC at about 45° C followed by one or more washes in 0.1xSSC/0.2% SDS at about 68° C, or under other stringent hybridization conditions which are known to those of skill in the art.

[0130] In a specific embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises an amino acid sequence that is at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 99% identical to the amino acid sequence of the monoclonal antibody produced by the cell line deposited with the ATCC® as Accession Number CRL-8001. In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises an amino acid sequence that is at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 99% identical to the amino acid sequence of humanized OKT3.

[0131] In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises an amino acid sequence of a VH domain that is at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 99% identical to the VH domain of humanized OKT3.

[0132] In another embodiment, an antibody that immunospecifically binds to a CD3 polypeptide comprises an amino acid sequence of a VL domain that is at least 35%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least
75%, at least 80%, at least 85%, at least 90%, at least 95%, or at least 99% identical to the VL domain of humanized OKT3.

[0133] The present invention encompasses antibodies that compete with an antibody described herein for binding to a CD3 polypeptide. In a specific embodiment, the present invention encompasses antibodies that compete with anti-CD3 antibodies known in the art, derivatives thereof or antigen binding fragments thereof. For example, antibodies provided by the invention compete with OKT3 or a derivative thereof, e.g. humanized OKT3, or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with ChAglyCD3 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with HuM291 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with UCHT1 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with Leu4 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with YTH 12.5 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with 500A2 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with CLB-T3/3 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide. In another specific embodiment, the present invention encompasses antibodies that compete with BMA030 or a derivative thereof or an antigen-binding fragment thereof for binding to the CD3 polypeptide.

[0134] The present invention also encompasses VH domains that compete with the VH domain of the antibodies disclosed herein, or with the VH domains of other anti-human CD3 antibodies known in the art, or derivatives or variants thereof for binding to a CD3 polypeptide. In a specific embodiment, the present invention encompasses VH domains that compete with the VH domain of OKT3 or a derivative thereof, e.g. humanized OKT3, for binding to a CD3 polypeptide. The present invention also encompasses VL domains that compete with the VL domain of the antibodies disclosed herein, or with the VL domains of
other anti-human CD3 antibodies known in the art, or derivatives or variants thereof for
binding to a CD3 polypeptide. In a specific embodiment, the present invention encompasses
VL domains that compete with a VL domain of OKT3 or a derivative thereof, e.g. humanized
OKT3, for binding to a CD3 polypeptide.

[0135] The antibodies that immunospecifically bind to a CD3 polypeptide include
derivatives that are modified, i.e., by the covalent attachment of any type of molecule to the
antibody such that covalent attachment. For example, but not by way of limitation, the
antibody derivatives include antibodies that have been modified, e.g., by glycosylation,
acetylation, pegylation, phosphorylation, amidation, derivatization by known
protecting/blocking groups, proteolytic cleavage, linkage to a cellular ligand or other protein,
etc. Any of numerous chemical modifications may be carried out by known techniques,
including, but not limited to, specific chemical cleavage, acetylation, formylation, metabolic
synthesis of tunicamycin, etc. Additionally, the derivative may contain one or more non-
classical amino acids.

[0136] The present invention also provides antibodies that immunospecifically bind
to a CD3 polypeptide, said antibodies comprising a framework region known to those of skill
in the art. Preferably, the fragment region of an antibody of the invention is human.

[0137] The present invention also encompasses methods using antibodies that
immunospecifically bind to a CD3 polypeptide, said antibodies comprising the amino acid
sequence of OKT3 or a derivative thereof, e.g. humanized OKT3, with mutations (e.g., one or
more amino acid substitutions) in the framework regions. In certain embodiments, antibodies
which immunospecifically bind to a CD3 polypeptide comprise the amino acid sequence of
OKT3 or a derivative thereof, e.g. humanized OKT3, with one or more amino acid residue
substitutions in the framework regions of the VH and/or VL domains.

[0138] The present invention also encompasses antibodies which immunospecifically
bind to a CD3 polypeptide, said antibodies comprising the amino acid sequence of OKT3 or a
derivative thereof, e.g. humanized OKT3, with mutations (e.g., one or more amino acid
residue substitutions) in the variable and framework regions.

[0139] The present invention also provides for fusion proteins comprising an antibody
that immunospecifically binds to a CD3 polypeptide and a heterologous polypeptide.
Preferably, the heterologous polypeptide that the antibody is fused to is useful for targeting
the antibody to T cells.
The antibodies of the invention include derivatives that are otherwise modified, *i.e.*, by the covalent attachment of any type of molecule to the antibody such that covalent attachment does not prevent the antibody from binding antigen and/or generating an anti-idiotypic response. For example, but not by way of limitation, the antibody derivatives include antibodies that have been modified, *e.g.*, by glycosylation, acetylation, pegylation, phosphorylation, amidation, derivatization by known protecting/blocking groups, proteolytic cleavage, linkage to a cellular ligand or other protein, etc. Any of numerous chemical modifications may be carried out by known techniques, including, but not limited to, specific chemical cleavage, acetylation, formylation, metabolic synthesis of tunicamycin, etc. Additionally, the derivative may contain one or more non-classical amino acids.

5.1.1 **Polypeptides and Antibodies with variant Fc Regions**

The use of therapeutic monoclonal antibodies is limited by problems of "first dose" side effects. First dose side effects, range from mild flu-like symptoms to severe toxicity, can be mild to severe, and include symptoms, such as, high fever, chills/rigors, headache, tremor, nausea/vomiting, diarrhea, abdominal pain, malaise, muscle/joint aches and pains, and generalized weakness. The first dose side effects are believed to be caused by lymphokine production and cytokine release stimulated by the Fc region of an antibody binding to and activating an FcγR on an FcγR-containing cell.

The invention thus encompasses CD3 binding molecules that reduce or eliminate at least one symptom associated with first dose side effects by reducing or eliminating binding of the Fc to one or more FcγRs. Such CD3 binding proteins comprise a variant Fc region having one or more amino acid modifications, relative to a wild type Fc region. The modification decreases or eliminates binding of the Fc to one or more FcγRs,
relative to a comparable wild type Fc region. The modification is typically an amino acid substitution. However, the modification can be an amino acid insertion and/or deletion. Typically, the modification occurs in the CH2 and/or hinge region. Alternatively, binding of Fc to one or more FcγRs can be reduced or eliminated by altering or eliminating one or more glycosyl groups on the Fc domain. Fc glycosylation can be altered or eliminated by methods well known in the art. For example, Fc glycosylation can be altered by producing the Fc in a cell that is deficient in fucosylation (e.g., fuc6 null cells), or eliminated by deglycosylation enzymes or an amino acid modification that alters or eliminates a glycosylation site (e.g., the N-X-S/T glycosylation site at positions 297-299 in the CH2 domain). FcγR binding can be measured using standard methods known in the art and exemplified herein. The antibodies of the invention are thus particularly useful because they have reduced or no in vivo toxicity caused by lymphokine production or cytokine release. The affinities and binding properties of the molecules of the invention for an FcR are initially determined using in vitro assays (biochemical or immunological based assays) known in the art for determining Fc-FcR interactions, i.e., specific binding of an Fc region to an FcR including but not limited to ELISA assay, surface plasmon resonance assay, immunoprecipitation assays (See Section 5.4). Preferably, the binding properties of the molecules of the invention are also characterized by in vitro functional assays for determining one or more FcγR mediator effector cell functions (See Section 5.4). In most preferred embodiments, the molecules of the invention have similar binding properties in in vivo models (such as those described and disclosed herein) as those in in vitro based assays. However, the present invention does not exclude molecules of the invention that do not exhibit the desired phenotype in in vitro based assays but do exhibit the desired phenotype in vivo.

[0144] FcγReceptors

[0145] Each member of this family is an integral membrane glycoprotein, possessing extracellular domains related to a C2-set of immunoglobulin-related domains, a single membrane spanning domain and an intracytoplasmic domain of variable length. There are three known FcγRs, designated FcγRI(CD64), FcγRII(CD32), and FcγRIII(CD16), which exhibit extensive homology but are encoded by distinct genes. Both activating and inhibitory signals are transduced through the FcγRs following ligation. These diametrically opposing functions result from structural differences among the different receptor isoforms. In general, the binding of a complimentary Fc domain to FcγRI, FcγRIIA and FcγRIIIA results in activation of downstream substrates (e.g., PI3K) and leading to the release of
proinflammatory mediators. In contrast, the binding of a complimentary Fc domain to FcγRIIB results in phosphorylation of FcγRIIB and association with the SH2 domain of the inosital polyphosphate 5'-phosphatase (SHIP). SHIP hydrolyzes phosphoinositol messengers released as a consequence of FcγRI mediated tyrosine kinase activation, consequently preventing the influx of intracellular Ca⁺. Thus crosslinking of FcγRIIB dampens the activating response to FcγR ligation and inhibits cellular responsiveness.

[0146] Methods of measuring lymphokine production and cytokine release are known and routine in the art and encompassed herein. For example, cytokine release may be measured by measuring secretion of cytokines including but not limited to TNF-α, GM-CSF, IFN-γ. See, e.g., U.S. Patent No. 6,491,916; Isaacs et al., 2001, Rheumatology, 40: 724-738; each of which is incorporated herein by reference in its entirety. Lymphokine production may be measured by measuring secretion of lymphokines including but not limited to Interleukin -2 (IL-2), Interleukin-4 (IL-4), Interleukin-6 (IL-6), Interleukin-12 (IL-12), Interleukin-16 (IL-16), PDGF, TGF-α, TGF-β, TNF-α, TNF-β, GCSF, GM-CSF, MCSF, IFN-α, IFN-β, TFN-γ, IGF-I, IGF-II. For example, see, Isaacs et al., 2001, Rheumatology, 40: 724-738; Soubrane et al., 1993, Blood, 81(1): 15-19; each of which is incorporated herein by reference in its entirety.

[0147] As used herein, the term "Fc region" is used to define a C-terminal region of an IgG heavy chain. Although the boundaries may vary slightly, the human IgG heavy chain Fc region is defined to stretch from Cys226 to the carboxy terminus. The Fc region of an IgG comprises two constant domains, CH2 and CH3. The CH2 domain of a human IgG Fc region usually extends from amino acids 231 to amino acid 341. The CH3 domain of a human IgG Fc region usually extends from amino acids 342 to 447. The CH2 domain of a human IgG Fc region (also referred to as "Cy2" domain) usually extends from amino acid 231-340. The CH2 domain is unique in that it is not closely paired with another domain. Rather, two N-linked branched carbohydrate chains are interposed between the two CH2 domains of an intact native IgG.

[0148] In preferred embodiments, the invention encompasses molecules comprising a variant Fc region, wherein said variant Fc region comprises at least one amino acid modification relative to a wild-type Fc region, which variant Fc region does not bind any FcγR, as determined by standard assays known in the art and disclosed herein, relative to a comparable molecule comprising the wild type Fc region. In a specific embodiment, the one
or more amino acid modifications which abolish binding to all FcγRs generate Fc regions which have a phenylalanine at position 233; or an arginine at position 238; or an alanine at position 265; or a glutamic acid at position 265; or an alanine at position 270; or an asparagine at position 270; or an alanine at position 297; or a glutamine at position 297; or a phenylalanine at position 298; or an asparagine at position 298; or a any amino acid at position 299 other than serine or threonine; or an alanine at position 265 and at position 297; or an alanine at position 265 and a glutamine at position 297; or a glutamic acid at position 265 and an alanine at position 297; or a glutamic acid at position 265 and a glutamine at position 297; or an alanine at position 234 and an alanine at position 235. In another embodiment, the one or more amino acid modifications which abolish binding to all FcγRs comprise combinations of the modifications listed herein or combinations of the modifications listed herein with any that may confer null binding to FcγRIIIA, FcγRIIIB, and FcγRIIIA as determined by the methods disclosed herein or known to one skilled in the art.

[0149] The invention encompasses methods for reducing or eliminating at least one symptom associated with first dose side effect in a patient comprising administering an effective amount of one or more antibodies of the invention. The methods of the invention reduce at least one symptom associated with cytokine release syndrome including but not limited to high fever, chills/rigors, headache, tremor, nausea/vomiting, diarrhea, abdominal pain, malaise, muscle/joint aches and pains, and generalized weakness.

[0150] The present invention provides for antibodies that immunospecifically bind to a CD3 polypeptide which have a extended half-life in vivo. In particular, the present invention provides antibodies that immunospecifically bind to a CD3 polypeptide which have a half-life in an animal, preferably a mammal and most preferably a human, of greater than 3 days, greater than 7 days, greater than 10 days, preferably greater than 15 days, greater than 25 days, greater than 30 days, greater than 35 days, greater than 40 days, greater than 45 days, greater than 2 months, greater than 3 months, greater than 4 months, or greater than 5 months.

[0151] To prolong the serum circulation of antibodies (e.g., monoclonal antibodies, single chain antibodies and Fab fragments) in vivo, for example, inert polymer molecules such as high molecular weight polyethylene glycol (PEG) can be attached to the antibodies with or without a multifunctional linker either through site-specific conjugation of the PEG to the N-terminus or C-terminus of the antibodies or via epsilon-amino groups present on lysine residues. Linear or branched polymer derivatization that results in minimal loss of biological
activity will be used. The degree of conjugation can be closely monitored by SDS-PAGE and mass spectrometry to ensure proper conjugation of PEG molecules to the antibodies. Unreacted PEG can be separated from antibody-PEG conjugates by size-exclusion or by ion-exchange chromatography. PEG-derivatized antibodies can be tested for binding activity as well as for *in vivo* efficacy using methods well-known to those of skill in the art, for example, by immunoassays described herein.

**[0152]** Antibodies having an increased half-life *in vivo* can also be generated introducing one or more amino acid modifications (*i.e.*, substitutions, insertions or deletions) into an IgG constant domain, or FcRn binding fragment thereof (preferably a Fc or hinge-Fc domain fragment). See, *e.g.*, International Publication No. WO 98/23289; International Publication No. WO 97/34631; and U.S. Patent No. 6,277,375, each of which is incorporated herein by reference in its entirety.

### 5.1.2 Antibody Conjugates

**[0153]** The present invention encompasses antibodies or antigen-binding fragments thereof that immunospecifically bind to a CD3 polypeptide recombinantly fused or chemically conjugated (including both covalently and non-covalently conjugations) to a heterologous polypeptide (or a fragment thereof, preferably at least 5, at least 10, at least 20, at least 30, at least 40, at least 50, at least 60, at least 70, at least 80, at least 90 or at least 100 contiguous amino acids of the polypeptide) to generate fusion proteins. The fusion does not necessarily need to be direct, but may occur through linker sequences. For example, antibodies may be used to target heterologous polypeptides to particular cell types (*e.g.*, T cells), either *in vitro* or *in vivo*, by fusing or conjugating the antibodies to antibodies specific for particular cell surface receptors such as, *e.g.*, CD4 and CD8.

**[0154]** The present invention also encompasses antibodies or antigen-binding fragments thereof that immunospecifically bind to a CD3 polypeptide fused to marker sequences, such as a peptide to facilitate purification. In preferred embodiments, the marker amino acid sequence is a hexa-histidine peptide, such as the tag provided in a pQE vector (QIAGEN, Inc., 9259 Eton Avenue, Chatsworth, CA, 91311), among others, many of which are commercially available. As described in Gentz et al., 1989, Proc. Natl. Acad. Sci. USA 86:821-824, for instance, hexa-histidine provides for convenient purification of the fusion protein. Other peptide tags useful for purification include, but are not limited to, the hemagglutinin" HA" tag, which corresponds to an epitope derived from the influenza hemagglutinin protein (Wilson et al., 1984, Cell 37:767) and the "flag" tag.
The present invention further encompasses antibodies or antigen-binding fragments thereof that immunospecifically bind to a CD3 polypeptide conjugated to an agent which has a potential therapeutic benefit. An antibody or an antigen-binding fragment thereof that immunospecifically binds to a CD3 polypeptide may be conjugated to a therapeutic moiety such as a cytotoxin, e.g., a cytostatic or cytotoxic agent, an agent which has a potential therapeutic benefit, or a radioactive metal ion, e.g., alpha-emitters. A cytotoxin or cytotoxic agent includes any agent that is detrimental to cells. Examples of a cytotoxin or cytotoxic agent include, but are not limited to, paclitaxel, cytchalasin B, methotrexate, ethidium bromide, emetine, mitomycin, etoposide, tenoposide, vincristine, vinblastine, colchicin, doxorubicin, daunorubicin, dihydroxy anthracin dione, mitoxantrone, mithramycin, actinomycin D, 1-dehydrotestosterone, glucocorticoids, procaine, tetracaine, lidocaine, propranolol, and puromycin and analogs or homologs thereof. Agents which have a potential therapeutic benefit include, but are not limited to, antimetabolites (e.g., methotrexate, 6-mercaptopurine, 6-thioguanine, cytarabine, 5-fluorouracil decarbazine), alkylating agents (e.g., mechlorethamine, thioepa chlorambucil, melphalan, carbustine (BSNU) and lomustine (CCNU), cyclophosphamide, busulfan, dibromomannitol, streptozotocin, mitomycin C, and cisplatin (DDP) cisplatin), anthracyclines (e.g., daunorubicin (formerly daunomycin) and doxorubicin), antibiotics (e.g., dactinomycin (formerly actinomycin), bleomycin, mithramycin, and anthramycin (AMC)), and anti-mitotic agents (e.g., vincristine and vinblastine).

Further, an antibody or an antigen-binding fragment thereof that immunospecifically binds to a CD3 polypeptide may be conjugated to a therapeutic agent or drug moiety that modifies a given biological response. Agents which have a potential therapeutic benefit or drug moieties are not to be construed as limited to classical chemical therapeutic agents. For example, the drug moiety may be a protein or polypeptide possessing a desired biological activity. Such proteins may include, for example, a toxin such as abrin, ricin A, pseudomonas exotoxin, or diphtheria toxin; a protein such as tumor necrosis factor, interferon-α("IFN-α"), interferon-β("IFN-β"), nerve growth factor("NGF"), platelet derived growth factor("PDGF"), tissue plasminogen activator("TPA"), an apoptotic agent, e.g., TNF-α, TNF-β, AIM I (see, International Publication No. WO 97/33899), AIM II (see, International Publication No. WO 97/3491 1), Fas Ligand (Takahashi et al, 1994, J. Immunol, 6:1567-1574), and VEGF (see, International Publication No. WO 99/23105), a thrombotic agent or an anti-angiogenic agent, e.g., angiostatin or endostatin; or, a biological
response modifier such as, for example, a lymphokine (e.g., interleukin-1 ("IL-1"), IL-2, IL-6, IL-10, granulocyte macrophage colony stimulating factor ("GM-CSF"), and granulocyte colony stimulating factor ("G-CSF")), or a growth factor (e.g., growth hormone ("GH")).

Techniques for conjugating such therapeutic moieties to antibodies are well known, see, e.g., Arnon et al., "Monoclonal Antibodies For Immunotargeting Of Drugs In Cancer Therapy", in Monoclonal Antibodies And Cancer Therapy, Reisfeld et al. (eds.), pp. 243-56 (Alan R. Liss, Inc. 1985); Hellstrom et al., "Antibodies For Drug Delivery", in Controlled Drug Delivery (2nd Ed.), Robinson et al. (eds.), pp. 623-53 (Marcel Dekker, Inc. 1987); Thorpe, "Antibody Carriers Of Cytotoxic Agents In Cancer Therapy: A Review", in Monoclonal Antibodies '84: Biological And Clinical Applications, Pinchera et al. (eds.), pp. 475-506 (1985); "Analysis, Results, And Future Prospective Of The Therapeutic Use Of Radiolabeled Antibody In Cancer Therapy", in Monoclonal Antibodies For Cancer Detection And Therapy, Baldwin et al. (eds.), pp. 303-16 (Academic Press 1985); and Thorpe et al., 1982, Immunol. Rev. 62:1 19-58.

An antibody or an antigen-binding fragment thereof that immunospecifically binds to a CD3 polypeptide can be conjugated to a second antibody to form an antibody heteroconjugate as described by Segal in U.S. Patent No. 4,676,980, which is incorporated herein by reference in its entirety.

Antibodies or antigen-binding fragments thereof that immunospecifically bind to a CD3 polypeptide may be attached to solid supports, which are particularly useful for the purification of CD3+ immune cells such as T cells. Such solid supports include, but are not limited to, glass, cellulose, polyacrylamide, nylon, polystyrene, polyvinyl chloride or polypropylene.

5.2 Prophylactic and Therapeutic Methods

The present invention is directed to therapies which involve administering CD3 binding molecules, particularly anti-human CD3 antibodies, to a subject, preferably a human subject, for preventing, treating, delaying the onset of, slowing the progression of or ameliorating one or more symptoms of LADA or another adult-onset autoimmune diabetes disorder. In particular, the present invention is directed to therapies which involve administering CD3 binding molecules, particularly anti-human CD3 antibodies, more particularly human or humanized forms of anti-human CD3 antibodies, such as OKT3, that have Fc domains that do not bind or have significantly reduced binding to Fc receptors, to a
subject, preferably a human subject, for preventing, treating, delaying the onset of, slowing the progression of or ameliorating one or more symptoms of LADA.

5.2.1 LADA

[0161] Immune-mediated diabetes mellitus or Type 1 diabetes is caused by an autoimmune response in which the insulin producing β-cells of the pancreas are gradually destroyed. Destruction of the β-cells is believed largely mediated by CTLs (CD8+ T cells). The early stage of the disease, termed insulinitis, is characterized by infiltration of leukocytes into the pancreas and is associated with both pancreatic inflammation and the release of anti-β-cell cytotoxic antibodies. Early stages of the disease are often overlooked or misdiagnosed as clinical symptoms of diabetes typically manifest only after about 80% of the β-cells have been destroyed. Even with immunosuppressive therapy, β-cell populations do not recover to a significant extent; therefore, once clinical symptoms occur, the type-1 diabetic is normally insulin dependent for life. Insulin is currently the only standard therapy for treating symptoms of type 1 diabetes. Although immunosuppressive drugs such as methotrexate and cyclosporin showed early clinical promise in the treatment of type 1 diabetes, e.g., maintenance of β-cell function, as with all general immunosuppressants, their prolonged use was associated with a number of severe side effects. Use of the invention in the context of diabetes therefore encompasses methods to sustain/protect the levels and functionality of β-cells which exist at the time of treatment.

[0162] LADA refers to a form of immune-mediated diabetes mellitus wherein the patients diagnosed with LADA are 25 years old or older, are positive for at least one antibody commonly present in type 1 diabetic patients, e.g., islet-cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies, and are not insulin requiring within the first 6 months after diagnosis. The slowly progressive β-cell failure and thus gradual insulin dependency distinguishes LADA from classic type 1 diabetes occurring in adult patients. In LADA patients, β-cell function is usually impaired within 6 years after diagnosis and may take up to 12 years. The term "LADA" can be used interchangeably with type 1.5 diabetes, slowly progressive IDDM, latent diabetes, youth-onset diabetes of maturity, latent-onset type 1 diabetes, and antibody-positive non-insulin-dependent diabetes.

[0163] In certain embodiments, patients are not insulin dependent for at least 6 months, 1 year, 2 years, 3 years, 4 years, 5 years, 6 years, 7 years, 8 years, 9 years, 10 years, 11 years, 12 months after diagnosis of LADA or Type-2 diabetes. In other embodiments, patients develop insulin dependency more than 6 months, 1 year, 2 years, 3 years, 4 years, 5
years, 6 years, 7 years, 8 years, 9 years, 10 years, 11 years, 12 years after diagnosis of LADA or Type-2 diabetes. In other embodiments, there is an initial diagnosis of Type-2 diabetes and the development of insulin dependency more than 6 months, 1 year, 2 years, 3 years, 4 years, 5 years, 6 years, 7 years, 8 years, 9 years, 10 years, 11 years, 12 years after diagnosis. The invention also encompasses administration of an antibody of the invention to subjects presenting combinations of any predisposing factors disclosed herein or known in the art.

[0164] Adult-Onset Type 1 diabetes refers to a form of immune-mediated diabetes mellitus wherein the patients diagnosed with Adult-Onset Type 1 diabetes are 25 years old or older, are positive for at least one antibody commonly present in type 1 diabetic patients, e.g., islet-cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies, and are insulin requiring at the time of diagnosis or within the first 6 months after diagnosis.

[0165] In a specific embodiment, anti-human CD3 antibody therapy is not used for the treatment of LADA or Adult-Onset Type 1 diabetes but rather to prevent progression of the disease. In a specific embodiment, anti-human CD3 therapy is used only in patients that have residual β-cell function as determined by methods described herein or known to one of ordinary skill in the art.

[0166] In alternate embodiments, the invention encompasses administration of anti-human CD3 antibodies to individuals predisposed to develop LADA or Adult-Onset Type 1 diabetes, but do not meet the criteria for diagnosis of either disorder as established by the American Diabetes Association or the Immunology of Diabetes Society to prevent or delay the onset of LADA or other adult-onset type 1 diabetes and/or to prevent or delay the need for administration of insulin to such patients. In certain embodiments, high-risk factors for identification of predisposed subjects 25 years or older in accordance with this embodiment are having first or second degree relatives with diagnosed type-1 diabetes, an impaired fasting glucose level (i.e., at least one determination of a glucose level of 100-125 mg/dl after fasting (8 hour with no food)), an impaired glucose tolerance in response to a 75g OGTT (i.e., at least one determination of a 2-hr glucose level of 140-199 mg/dl in response to a 75g OGTT), an HLA type of DR7 in a Caucasian, an HLA type of DR4 in a person of African descent, an HLA type of DR9 in a person of Japanese descent, exposure to childhood viruses (e.g., coxsackie B virus, enteroviruses, adenoviruses, rubella, cytomegalovirus, Epstein-Barr virus), a positive diagnosis according to art accepted criteria of at least one other autoimmune disorder (e.g., thyroid disease, celiac disease), and/or the detection of autoantibodies, particularly ICAs, in the serum or other tissues. In certain embodiments, the subject
identified as predisposed to developing LADA or Adult-Onset Type 1 diabetes according the
methods of the invention has at least one of the risk factors described herein and/or as known in
the art. The invention also encompasses identification of subjects predisposed to
development of LADA or Adult-Onset Type 1 diabetes, wherein said subject presents a
combination of two or more, three or more, four or more, or more than five of the risk factors
disclosed herein or known in the art.

[0167] Serum autoantibodies associated with LADA or Adult-Onset Type 1 diabetes
or with a predisposition for the development of LADA or Adult-Onset Type 1 diabetes are
islet-cell autoantibodies (e.g., anti-ICA512 autoantibodies), glutamic acid decarboxylase
autoantibodies (e.g., anti-GAD65 autoantibodies), and/or anti-insulin autoantibodies.
Accordingly, in a specific example in accordance with this embodiment, the invention
encompasses the treatment of an individual with detectable autoantibodies associated with a
predisposition to the development of LADA or Adult-Onset Type 1 diabetes or associated
with early stage LADA or Adult-Onset Type 1 diabetes (e.g., anti-ICA512, anti-GAD65 or
anti-insulin autoantibodies), wherein said individual has not been diagnosed with LADA or
Adult-Onset Type 1 diabetes and/or is a first or second degree relative of a type-1 diabetic.
In certain embodiments, the presence of the autoantibodies is detected by ELISA, radioassay
(see, e.g., Yu et al., 1996, J. Clin. Endocrinol. Metab. 81:4264-4267), or by any other method
for immunospecific detection of antibodies described herein or as known to one of ordinary
skill in the art.

[0168] β-cell function prior to, during, and after therapy may be assessed by methods
described herein or by any method known to one of ordinary skill in the art. For example, the
Diabetes Control and Complications Trial (DCCT) research group has established the
monitoring of percentage glycosylated hemoglobin (HAI and HAIc) as the standard for
Alternatively, characterization of daily insulin needs, C-peptide levels/response,
hypoglycemic episodes, and/or FPIR may be used as markers of β-cell function or to
establish a therapeutic index (See Keymeulen et al., 2005, N. Engl. J. Med. 352:2598-2608;
Herold et al., 2005, Diabetes 54:1763-1769; U.S. Pat. Appl. Pub. No. 2004/0038867 Al; and
Greenbaum et al., 2001, Diabetes 50:470-476, respectively). For example, FPIR is calculated
as the sum of insulin values at 1 and 3 minutes post IGTT, which are performed according to
Islet Cell Antibody Register Users Study protocols (see, e.g., Bingley et al., 1996, Diabetes
Patients with autoimmune diabetes generally have an increasing frequency of CTL that recognize autoantigens. In the context of tissue transplantation, the patients will exhibit an increasing frequency of CTL that recognize donor-specific antigens. Such autoreactive or donor-reactive CTL may be detected in peripheral blood or target tissues. For example, in the diabetic patient, autoreactive CTL may be detected in pancreatic islet cell tissues. Since the generation of autoreactive or donor-reactive CTL is thought to precede the development of auto/donor antibodies and other indicia of the clinical symptoms of immune disorders, detection of specific CTL may in some cases enable more sensitive and specific diagnosis of the disorder.

The assays can also be used to quantify both the absolute number and the proportion of autoreactive CTL present in a sample, such as a peripheral blood sample, in both pre-clinical subjects and patients that have received therapy. In some embodiments, both the severity and course of the autoimmune diabetes may be predicted and followed using such assays. For example, the human MHC class I molecule HLA-A 0201 can be used in combination with the a diabetic autoantigen, for example IA-2, to detect autoreactive CTL present in a peripheral blood sample of a pre-diabetic subject or diabetic patient currently undergoing therapy using the methods of the invention.

Antigen-specific CTLs can be detected using a wide variety of assays, including immunospot (e.g., ELISPOT) assays, MHC class I tetramer assays, or other assays, as described herein or as known to a person skilled in the art.

5.2.2 Therapeutic and Prophylactic Methods

The invention provides methods of treating, preventing, managing or ameliorating the symptoms of LADA or, in alternative embodiments, of another adult-onset type 1 diabetes disorder. As LADA characteristically progresses slowly, the goal of the methods of the invention is to maintain high level functioning and prevent, slow or reduce additional tissue damage, for example, to delay or even avoid the need to administer exogenous insulin or other therapies.

In the methods of the invention, pharmaceutical compositions comprising one or more CD3 binding molecules (e.g., one or more anti-human CD3 antibodies) are administered one or more times, preferably in a dosing regimen administered in multiple doses over a period of 2 to 20 days, to prevent or slow the decrease in β-cell function associated with LADA or other adult-onset autoimmune diabetes disorders or to delay or
prevent the onset of LADA or other adult-onset autoimmune diabetes disorder in a subject
with a predisposition for development of Type-1 diabetes as described in section 5.2.1. In
accordance with these embodiments, changes in a subject's β-cell function may be assessed
by characterization of daily insulin requirements, HAIc levels, C-peptide function/levels,
frequency of hypoglycemic episodes or FPIR as known in the art, e.g., as discussed in
Section 5.2.1.

[0174] In a specific embodiment, anti-human CD3 therapy is used in LADA or other
adult-onset type 1 diabetes patients that have at least 99%, at least 95%, at least 90%, at least
85%, at least 80%, at least 75%, at least 70%, at least 75%, at least 60%, at least 50% residual
β-cell function as compared to an individual with no indicators of LADA or predisposition to
diabetes in the same population (i.e. age, sex, race, and general health) and determined by
methods described herein or known to one of ordinary skill in the art. In another
embodiment, after a course of treatment with an anti-human CD3 antibody according to the
invention, the level of β-cell function of the patient decreases by less than 1%, less than 5%,
less than 10%, less than 20%, less than 30%, less than 40% or less than 50% of the
pretreatment levels. In yet another embodiment of the invention, after a course of treatment
with an anti-human CD3 antibody according to the invention, the level of β-cell function of
the patient is maintained at at least 99%, at least 95%, at least 90%, at least 80%, at least
70%, at least 60%, or at least 50% of pretreatment levels for at least 4 months, at least 6
months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at
least 30 months after the end of treatment. In another embodiment of the invention, after a
course of treatment with an anti-human CD3 antibody according to the invention, the level of
β-cell function of the patient is maintained at at least 99%, at least 95%, at least 90%, at least
80%, at least 70%, at least 60%, or at least 50% of pretreatment levels for at least 4 months,
at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months,
or at least 30 months after the end of treatment and the mean lymphocyte count of the patient
is not less than 800 cells/ml, less than 750 cells/ml, less than 700 cells/ml, less than 650
cells/ml, less than 600 cells/ml, less than 550 cells/ml, less than 500 cells/ml, less than 400
cells/ml, less than 300 cells/ml or less than 200 cells/ml at the same time period. In another
embodiment of the invention, after a course of treatment with an anti-human CD3 antibody
according to the invention, the level of β-cell function of the patient is maintained at at least
99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, or at least 50% of
pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12
months, at least 18 months, at least 24 months, or at least 30 months after the end of
treatment and the patient's mean platelet count is not less than 100,000,000 platelets/ml, less
than 75,000,000 platelets/ml, less than 50,000,000 platelets/ml, less than 25,000,000
platelets/ml, less than 1,000,000 platelets/ml, less than 750,000 platelets/ml, less than
500,000 platelets/ml, less than 250,000 platelets/ml, less than 150,000 platelets/ml or less
than 100,000 platelets/ml.

[0175] In certain embodiments, one or more pharmaceutical compositions comprising
one or more CD3 binding molecules (e.g., one or more anti-human CD3 antibodies) are
administered to a subject having LADA or, in other embodiments, another adult-onset type 1
diabetes disorder, to prevent or slow the reduction β-cell mass associated with autoimmune
diabetes. In some embodiments, after a course of treatment with an anti-human CD3
antibody according to the invention, the level of β-cell mass of the patient decreases by less
than 1%, less than 5%, less than 10%, less than 20%, less than 30%, less than 40%, less than
50%, less than 60%, or less than 70% of the pretreatment levels. In yet another embodiment
of the invention, after a course of treatment with an anti-human CD3 antibody according to
the invention, the level of β-cell function of the patient is maintained at least 99%, at least
95%, at least 90%, at least 80%, at least 70%, at least 60%, at least 50%, at least 40%, or at
least 30% of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at
least 12 months, at least 18 months, at least 24 months, or at least 30 months after the end of
treatment. In another embodiment of the invention, after a course of treatment with an anti-
human CD3 antibody according to the invention, the level of β-cell function of the patient is
maintained at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least
60%, or at least 50% of pretreatment levels for at least 4 months, at least 6 months, at least 9
months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after
the end of treatment and the mean lymphocyte count of the patient is not less than 800
cells/ml, less than 750 cells/ml, less than 700 cells/ml, less than 650 cells/ml, less than 600
cells/ml, less than 550 cells/ml, less than 500 cells/ml, less than 400 cells/ml, less than 300
cells/ml or less than 200 cells/ml over the same time period. In another embodiment of the
invention, after a course of treatment with an anti-human CD3 antibody according to the
invention the level of β-cell function of the patient is maintained at least 99%, at least 95%, at
least 90%, at least 80%, at least 70%, at least 60%, or at least 50% of pretreatment levels for
at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months,
at least 24 months, or at least 30 months after the end of treatment and the mean platelet
count of the patient is not less than 100,000,000 platelets/ml, less than 75,000,000 platelets/ml, less than 50,000,000 platelets/ml, less than 25,000,000 platelets/ml, less than 1,000,000 platelets/ml, less than 750,000 platelets/ml, less than 500,000 platelets/ml, less than 250,000 platelets/ml, less than 150,000 platelets/ml or less than 100,000 platelets/ml.

[0176] LADA patients, characteristically, are not insulin requiring upon diagnosis. Accordingly, in the methods of the invention, the anti-human CD3 therapy is administered in patients that do not require daily insulin, or that have average insulin requirements of less than 0.05 U/kg/day, less than 0.1 U/kg/day, less than 0.2 U/kg/day, less than 0.4 U/kg/day, less than 0.6 U/kg/day, less than 0.8 U/kg/day, less than 1 U/kg/day, less than 2 U/kg/day or 5 U/kg/day or more. In another embodiment, human patient with LADA or other adult-onset autoimmune diabetes disorder is administered a regimen of doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies to avoid or delay the need to administer insulin for more than 6 months, 1 year, 18 months, 24 months, 30 months, 36 months, 5 years, 7 years or 10 years after diagnosis of LADA or other adult-onset type 1 diabetes. In other embodiments in patients who do require exogenous insulin, methods of the invention achieve a reduction in daily insulin requirement by at least 10%, at least 15%, at least 20%, at least 25%, at least 30%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, or at least 90% of pretreatment levels. In yet another embodiment of the invention in patients who require exogenous insulin, after a course of treatment with an anti-human CD3 antibody according to the invention, the reduction of a patient's daily insulin requirements by at least 10%, at least 15%, at least 20%, at least 25%, at least 30%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, at least 85%, or at least 90% of pretreatment levels is maintained for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the course of treatment. In yet another embodiment of the invention, after a course of treatment with an anti-human CD3 antibody according to the invention, the reduction of a patient's daily insulin requirements by at least 10%, at least 15%, at least 20%, at least 25%, at least 30%, at least 40%, at least 45%, at least 50%, at least 55%, at least 60%, at least 65%, at least 70%, at least 75%, at least 80%, or at least 85% of pretreatment levels is maintained for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the course of treatment and the mean lymphocyte count of the patient is not less than 800 cells/ml, less than 750 cells/ml, less
than 700 cells/ml, less than 650 cells/ml, less than 600 cells/ml, less than 550 cells/ml, less than 500 cells/ml, less than 400 cells/ml, less than 300 cells/ml or less than 200 cells/ml over the same time period.

In yet another embodiment, a human subject having LADA or Adult-Onset Type 1 diabetes, or a human identified as having a predisposition to developing LADA and Adult-Onset Type 1 diabetes is administered a course of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies to preserve the subject's C-peptide response or FPIR to MMTT, OGTT, IGTT or two phase glucose clamp procedure over about 2 weeks, about 1 month, about 2 months, about 4 months, about 5 months, about 6 months, about 7 months, about 8 months, about 9 months, about 10 months, about 11 months, about 12 months, about 15 months, about 18 months, about 21 months or about 24 months after treatment. In preferred embodiments, the patients initially have a C-peptide response to MMTT, OGTT, IGTT, or two-phase glucose clamp procedure (preferably MMTT) resulting in an area under curve (AUC) of at least 80 pmol/ml/240 min., preferably, at least 90 pmol/ml/240 min., more preferably at least 100 pmol/ml/240 min., or even at least 110 pmol/ml/240 min. In preferred embodiments, the patients prior to treatment with an anti-human CD3 antibody according to the invention have a FPIR of at least 300 pmol/l, at least 350 pmol/l, at least 400 pmol/l, at least 450 pmol/l, at least 500 pmol/l, preferably, at least 550 pmol/l, more preferably at least 600 pmol/l, or even at least 700 pmol/l. In another embodiment of the invention, after a course of treatment with an anti-human CD3 antibody according to the invention, the C-peptide response or FPIR of the patient to MMTT, OGTT, IGTT, or two-phase glucose clamp procedure decreases by less than 1%, less than 5%, less than 10%, less than 20%, less than 30%, less than 40% or less than 50% of the pretreatment levels. In yet another embodiment of the invention, after a course of treatment with an anti-human CD3 antibody according to the invention, the C-peptide response or FPIR of the patient to MMTT, OGTT, IGTT or two phase glucose clamp procedure is maintained at at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, or at least 50% of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the course of treatment. In another embodiment of the invention, after a course of treatment with an anti-human CD3 antibody according to the invention, the C-peptide response or FPIR of the patient to MMTT, OGTT, IGTT or two phase glucose clamp procedure is maintained at at least 99%, at least 95%, at least 90%, at least 80%, at least 70%, at least 60%, or at least 50%
of pretreatment levels for at least 4 months, at least 6 months, at least 9 months, at least 12 months, at least 18 months, at least 24 months, or at least 30 months after the end of treatment and the mean lymphocyte count of the patient is not less than 800 cells/ml, less than 750 cells/ml, less than 700 cells/ml, less than 650 cells/ml, less than 600 cells/ml, less than 550 cells/ml, less than 500 cells/ml, less than 400 cells/ml, less than 300 cells/ml or less than 200 cells/ml over the same time period.

[0178] In particular embodiments, the invention provides methods of treatment such that a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody (preferably, without any intervening treatment with anti-human CD3 antibodies), results in a level of HAI or HAIc that is 7% or less, 6.5% or less, 6% or less, 5.5% or less, or 5% or less 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or the first round of treatment. In specific embodiments, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the patients have a C-peptide response to MMTT, OGTT, IGTT or two-phase glucose clamp procedure (preferably, MMTT) resulting in an AUC of at least 40 pmol/ml/240 min., 50 pmol/ml/240 min, 60 pmol/ml/240 min, 70 pmol/ml/240 min., 80 pmol/ml/240 min., preferably, at least 90 pmol/ml/240 min., more preferably at least 100 pmol/ml/240 min., or even at least 110 pmol/ml/240 min, said response determined 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or after the previous round of treatment. In specific embodiments, after a single round of treatment or round of treatment every 6 months, every 9 months, every 12 months, every 15 months, every 18 months, or every 24 months with an anti-human CD3 antibody according to the methods of the invention (preferably, without any intervening treatment with anti-human CD3 antibodies), the patients have a FPIR of at least 300 pmol/1, at least 400 pmol/1, preferably, at least 500 pmol/1, more preferably at least 600 pmol/1, or even at least 700 pmol/1, said FPIR determined at 6 months, 9 months, 12 months, 15 months, 18 months, or 24 months after the previous round of treatment or initial round of treatment.

[0179] In another embodiment, a subject is administered one or more unit doses of approximately 0.5-50 µg/kg, approximately 0.5-40 µg/kg, approximately 0.5-30 µg/kg,
approximately 0.5-20 µg/kg, approximately 0.5-15 µg/kg, approximately 0.5-10 µg/kg, approximately 0.5-5 µg/kg, approximately 20-40 µg/kg, approximately 20-30 µg/kg, approximately 22-28 µg/kg or approximately 25-26 µg/kg of one or more anti-human CD3 antibody to prevent, treat, delay the onset of, slow the progression of or ameliorate one or more symptoms of LADA or another adult-onset type 1 diabetes disorder. In another embodiment, a subject is administered one or more doses of about 5 - 1200 µg/m², preferably, 51 - 826 µg/m². In another embodiment, a subject is administered one or more unit doses of 1200 µg/m², 1150 µg/m², 1100 µg/m², 1050 µg/m², 1000 µg/m², 950 µg/m², 900 µg/m², 850 µg/m², 800 µg/m², 750 µg/m², 700 µg/m², 650 µg/m², 600 µg/m², 550 µg/m², 500 µg/m², 450 µg/m², 400 µg/m², 350 µg/m², 300 µg/m², 250 µg/m², 200 µg/m², 150 µg/m², 100 µg/m², 50 µg/m², 40 µg/m², 30 µg/m², 20 µg/m², 15 µg/m², 10 µg/m², or 5 µg/m² of one or more anti-human CD3 antibodies to prevent, treat, slow the progression of, delay the onset of or ameliorate one or more symptoms of LADA or Adult-Onset Type 1 diabetes.

[0180] In another embodiment, the subject is administered a treatment regimen comprising one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies, wherein the course of treatment is administered over 2 days, 3 days, 4 days, 5 days, 6 days, 7 days, 8 days, 9 days, 10 days, 11 days, 12 days, 13 days or 14 days. In one embodiment, the treatment regimen comprises administering doses of the prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies every day, every 2nd day, every 3rd day or every 4th day. In certain embodiments, the treatment regimen comprises administering doses of the prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies on Monday, Tuesday, Wednesday, Thursday of a given week and not administering doses of the prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies on Friday, Saturday, and Sunday of the same week until 14 doses, 13 doses, 12 doses, 11 doses, 10 doses, 9 doses, or 8 doses have been administered. In certain embodiments the dose administered is the same each day of the regimen. In certain embodiments, a subject is administered a treatment regimen comprising one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies, wherein the prophylactically or therapeutically effective amount is 1200 µg/m²/day, 1150 µg/m²/day, 1100 µg/m²/day, 1050 µg/m²/day, 1000 µg/m²/day, 950 µg/m²/day, 900 µg/m²/day, 850 µg/m²/day, 800 µg/m²/day, 750 µg/m²/day, 700 µg/m²/day,
650 µg/m²/day, 600 µg/m²/day, 550 µg/m²/day, 500 µg/m²/day, 450 µg/m²/day, 400 µg/m²/day, 350 µg/m²/day, 300 µg/m²/day, 250 µg/m²/day, 200 µg/m²/day, 150 µg/m²/day, 100 µg/m²/day, 50 µg/m²/day, 40 µg/m²/day, 30 µg/m²/day, 20 µg/m²/day, 15 µg/m²/day, 10 µg/m²/day, or 5 µg/m²/day.

In another embodiment, the intravenous dose of 1200 µg/m² or less, 1150 µg/m² or less, 1100 µg/m² or less, 1050 µg/m² or less, 1000 µg/m² or less, 950 µg/m² or less, 900 µg/m² or less, 850 µg/m² or less, 800 µg/m² or less, 750 µg/m² or less, 700 µg/m² or less, 650 µg/m² or less, 600 µg/m² or less, 550 µg/m² or less, 500 µg/m² or less, 450 µg/m² or less, 400 µg/m² or less, 350 µg/m² or less, 300 µg/m² or less, 250 µg/m² or less, 200 µg/m² or less, 150 µg/m² or less, 100 µg/m² or less, 50 µg/m² or less, 40 µg/m² or less, 30 µg/m² or less, 20 µg/m² or less, 15 µg/m² or less, 10 µg/m² or less, or 5 µg/m² or less of one or more anti CD3 antibodies is administered over about 24 hours, about 22 hours, about 20 hours, about 18 hours, about 16 hours, about 14 hours, about 12 hours, about 10 hours, about 8 hours, about 6 hours, about 4 hours, about 2 hours, about 1.5 hours, about 1 hour, about 50 minutes, about 40 minutes, about 30 minutes, about 20 minutes, about 10 minutes, about 5 minutes, about 2 minutes, about 1 minute, about 30 seconds or about 10 seconds to prevent, treat or ameliorate one or more symptoms of LADA or Adult-Onset Type 1 diabetes.

[0181] In preferred embodiments, the dose escalates over the first fourth, first half or first 2/3 of the doses (e.g., over the first 2, 3, 4, 5, or 6 days of a 10, 12, 14, 16, 18 or 20 day regimen of one dose per day) of the treatment regimen until the daily prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies is achieved. In certain embodiments, a subject is administered a treatment regimen comprising one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies, wherein the prophylactically or therapeutically effective amount is increased by, e.g., 1 µg/m², 5 µg/m², 10 µg/m², 15 µg/m², 20 µg/m², 30 µg/m², 40 µg/m², 50 µg/m², 60 µg/m², 70 µg/m², 80 µg/m², 90 µg/m², 100 µg/m², 150 µg/m², 200 µg/m², 250 µg/m², 300 µg/m², 350 µg/m², 400 µg/m², 450 µg/m², 500 µg/m², 550 µg/m², 600 µg/m², or 650 µg/m², as treatment progresses. In certain embodiments, a subject is administered a treatment regimen comprising one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies, wherein the prophylactically or therapeutically effective amount is increased by a factor of 1.25, a factor of 1.5, a factor of 2, a factor of 2.25, a factor of 2.5, or a factor of 5 until the daily prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies is achieved.
In specific embodiments in which escalating doses are administered for the first days of the dosing regimen, the dose on day 1 of the regimen is 5 - 100 µg/m²/day, preferably 51 µg/m²/day and escalates to the daily dose as recited immediately above by day 3, 4, 5, 6 or 7. For example, on day 1, the subject is administered a dose of approximately 51 µg/m²/day, on day 2 approximately 103 µg/m²/day, on day 3 approximately 207 µg/m²/day, on day 4 approximately 413 µg/m²/day and on subsequent days of the regimen (e.g., days 5-14) 826 µg/m²/day. In another embodiment, on day 1, the subject is administered a dose of approximately 227 µg/m²/day, on day 2 approximately 459 µg/m²/day, on day 3 and subsequent days, approximately 919 µg/m²/day. In another embodiment, on day 1, the subject is administered a dose of approximately 284 µg/m²/day, on day 2 approximately 574 µg/m²/day, on day 3 and subsequent days, approximately 1148 µg/m²/day.

In specific embodiments, to reduce the possibility of cytokine release and other adverse effects, the first 1, 2, 3, or 4 doses or all the doses in the regimen are administered more slowly by intravenous administration. For example, a dose of 51 µg/m²/day may be administered over about 5 minutes, about 15 minutes, about 30 minutes, about 45 minutes, about 1 hour, about 2 hours, about 4 hours, about 6 hours, about 8 hours, about 10 hours, about 12 hours, about 14 hours, about 16 hours, about 18 hours, about 20 hours, and about 22 hours. In certain embodiments, the dose is administered by slow infusion over a period of, e.g., 20 to 24 hours. In specific embodiments, the dose is infused in a pump, preferably increasing the concentration of antibody administered as the infusion progresses.

In other embodiments, a set fraction of the doses for the 51 µg/m²/day to 826 µg/m²/day regimen described above is administered in escalating doses. In certain embodiments, the fraction is 1/10, 1/5, 1/3, 2/5 or 3/5 of the daily doses of the regimens described above. Accordingly, when the fraction is 1/10, the daily doses will be 5.1 µg/m² on day 1, 10.3 µg/m² on day 2, 20.7 µg/m² on day 3, 41.3 µg/m² on day 4 and 82.6 µg/m² on days 5 to 14. When the fraction is 1/3, the doses will be 17 µg/m² on day 1, 34.3 µg/m² on day 2, 69 µg/m² on day 3, 137.6 µg/m² on day 4, and 275.3 µg/m² on days 5 to 14 and similarly for other fractional dose regimes. In other embodiments, the regimen is identical to one of those described above but only over days 1 to 4, days 1 to 5, or days 1 to 6. In other embodiments, doses in the regimen are administered for a certain number of consecutive days, followed by a certain number of days without any doses administered, followed again by doses administered on a certain number of consecutive days and so on until, for example, 14 (but may be 6, 7, 8, 9, 10, 11, 12, 13, 15, 16, 17, 18, 19 or 20) doses are administered all together.
For example, the day 1, day 2, day 3 and day 4 doses of one of the regimens described above may be administered in four consecutive days and then three days without any doses and then the day 5, 6, 7 and 8 doses are administered, followed by another three days without doses, and then the day 9, 10, 11, 12 day doses, with three days off, and finally the day 13 and 14 doses.

[0185] In certain embodiments, the antibody administered according to these regimens is OKT3γl(ala-ala). In other embodiments the antibody is not OKT3γl(ala-ala) and is administered so as to achieve one or more pharmacokinetic parameters achieved by the administration of OKT3γl(ala-ala) such as the serum titer of the antibody administered at 1 day, 2 days, 3 days, 4 days, 5 days, 6 days, 7 days, 2 weeks, 3 weeks or 1 month after the last day of the dosing regime.

[0186] In certain embodiments, the anti-human CD3 antibody is administered so as to achieve a certain level of combined coating and modulation T cell receptor complexes on T cells, as determined by methods well known in the art, see, e.g., Example 11 of U.S. patent application publication US 2003/0108548, which is hereby incorporated by reference in its entirety. In specific embodiments, the dosing regimen achieves a combined T cell receptor coating and modulation of at least 50%, 60%, 70%, 80%, 90%, 95% or of 100% with, in specific embodiments, little to no free anti-human CD3 antibody detected (for example, less than 200 ng/mL of the drug is detected in the blood of the patient).

[0187] In other embodiments, the anti-human CD3 antibody is administered chronically to treat, prevent, or slow or delay the onset or progression of LADA or other adult-onset autoimmune diabetes disorder. For example, in certain embodiments, a low dose of the anti-human CD3 antibody is administered once a month, twice a month, three times per month, once a week or even more frequently either as an alternative to the 6 to 14 day dosage regimen discussed above or after administration of such a regimen to enhance or maintain its therapeutic effect.

[0188] In other embodiments, the subject may be re-dosed at some time subsequent to administration of the anti-human CD3 antibody dosing regimen, preferably, based upon one or more physiological parameters or may be done as a matter of course. Such redosing may be administered and/or the need for such redosing evaluated 2 months, 4 months, 6 months, 8 months, 9 months, 1 year, 15 months, 18 months, 2 years, 30 months or 3 years after administration of a dosing regimen.
In specific embodiments, subjects are administered a subsequent round of anti-human CD3 antibody treatment based upon measurements of one or a combination of the following: the CD4/CD8 cell ratio, CD8 cell count, CD4/CD3 inversion, CD4/CD25 cell ratio, CD4/FoxP3 cell ratio, CD4/CD40 cell ratio, CD4/IL-10 cell ratio, and/or a CD4/TGF-β cell ratio. Other parameters for determining whether to administer a subsequent round of treatment include an appearance or an increase in anti-islet cell antibodies, such as GADAs, IA-2 antibodies or anti-insulin antibodies or an appearance or increase in the levels of T cells specific for islet cell antigens. Subsequent doses may be administered if the number of β-cells or β-cell activity or function decreases by 20%, 30%, 40%, 50%, 60%, 70%, 80% or 90% as compared to the β-cell number or activity or function during administration of the preceding round of treatment. β-cell function may be determined by any method known in the art, for example, the C-peptide response to MMTT, OGTT, IGTT, or two-phase glucose clamp, or the First Phase Insulin Release (FPIR) test, as discussed above. Other parameters that may be used to determine whether to redose include the HAI or HAIc levels, the need for administration of exogenous insulin or increase in the dosage of exogenous insulin by more than 0.1 U/kg/day, 0.2 U/kg/day, 0.5 U/kg/day, 0.6 U/kg/day, 1 U/kg/day, or 2 U/kg/day. For example, a subject may be administered a subsequent round of treatment when the C-peptide response or FPIR of the patient to MMTT, OGTT, IGTT or two phase glucose clamp procedure decreases by more than 1%, more than 5%, more than 10%, more than 20%, more than 30%, more than 40% or more than 50% of pretreatment levels. In particular embodiments, subjects are redosed if they have a C-peptide response to MMTT, OGTT, IGTT or two-phase glucose clamp procedure (preferably, MMTT) resulting in an AUC of less than 40 pmol/ml/240 min., less than 50 pmol/ml/240 min, less than 60 pmol/ml/240 min, less than 70 pmol/ml/240 min., less than 80 pmol/ml/240 min., or less than at least 90 pmol/ml/240 min. In specific embodiments, subjects may be redosed they have a FPIR of less than 300 pmol/1, less than 400 pmol/1, less than 500 pmol/1, less than 600 pmol/1, or less than 700 pmol/1. Also for example, a subject may be redosed when the subject’s HAI or HAIc levels increase by at least 5%, at least 10%, at least 20%, at least 30%, at least 40%, at least 50%, at least 60%, at least 70%, at least 80% or at least 90% compared to pre-treatment levels or the absolute levels are greater than 8%, greater than 7.5%, or greater than 7%. In other embodiments, the further doses may be administered based upon appearance of or increase in number (such as an increase by, on average, 1, 2, 3, 4, 5, 8, 10 15, or 20), duration and/or severity of hypoglycemic episodes or of ketoacidosis episodes on a daily, weekly or monthly basis.
In preferred embodiments, the anti-human CD3 antibodies are administered parenterally, for example, intravenously, intramuscularly or subcutaneously, or, alternatively, are administered orally. The anti-human CD3 antibodies may also be administered as a sustained release formulation.

In a specific embodiment, the mean absolute lymphocyte count in a subject with LADA or other adult-onset type 1 diabetes disorder is assessed before and/or after the administration of one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies to determine whether one or more subsequent doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies should be administered to said subject. In another embodiment, the mean absolute lymphocyte count in a subject with LADA or Adult-Onset Type 1 diabetes is assessed before and/or after the administration of one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies to determine whether one or more subsequent doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies should be administered to said subject. Preferably, a subsequent dose of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies is not administered to said subject if the lymphocyte count is less than 800 cells/mm$^3$, less than 750 cells/mm$^3$, less than 700 cells/mm$^3$, less than 650 cells/mm$^3$, less than 600 cells/mm$^3$, less than 500 cells/mm$^3$, less than 400 cells/mm$^3$ or less than 300 cells/mm$^3$.

In another embodiment, the mean absolute lymphocyte count in a subject with LADA or an adult-onset type 1 diabetes disorder is determined prior to the administration of a first dose of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies and the mean absolute lymphocyte count is monitored prior to the administration of one or more subsequent doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies. Preferably, the mean absolute lymphocyte count in the subject is at least 900 cells/mm$^3$, preferably at least 950 cells/mm$^3$, at least 1000 cells/mm$^3$, at least 1050 cells/mm$^3$, at least 1100 cells/mm$^3$, at least 1200 cells/mm$^3$, or at least 1250 cells/mm$^3$ prior to the administration of a first dose of one or more anti-human CD3 antibodies.

In another embodiment, a mean absolute lymphocyte count of approximately 700 cells/ml to approximately 1200 cells/ml, approximately 700 cells/ml to approximately 1100 cells/ml, approximately 700 cells/ml to approximately 1000 cells/ml, approximately 700
to approximately 900 cells/ml, approximately 750 cells/ml to approximately 1200 cells/ml, approximately 750 cells/ml to approximately 1100 cells/ml, approximately 750 cells/ml to approximately 1000 cells/ml, approximately 800 cells/ml to approximately 1200 cells/ml, approximately 800 cells/ml to approximately 1100 cells/ml, approximately 800 cells/ml to approximately 1000 cells/ml, approximately 900 cells/ml to approximately 1200 cells/ml, approximately 900 cells/ml to approximately 1100 cells/ml, approximately 900 cells/ml to approximately 1000 cells/ml, or approximately 1000 cells to approximately 1200 cells/ml is maintained in a subject having LADA or an adult-onset type 1 diabetes disorder by administering one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies. In another embodiment, a mean absolute lymphocyte count of approximately 700 cells/ml to below 1000 cells/ml is maintained in a subject having LADA or an adult-onset type 1 diabetes disorder by administering one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies.

[0194] In a specific embodiment, the administration of one or more doses or a dosage regimen of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies does not induce or reduces relative to other immunosuppressive agents one or more of the following unwanted or adverse effects: vital sign abnormalities (fever, tachycardia, bardycardia, hypertension, hypotension), hematological events (anemia, lymphopenia, leukopenia, thrombocytopenia), headache, chills, dizziness, nausea, asthenia, back pain, chest pain (chest pressure), diarrhea, myalgia, pain, pruritus, psoriasis, rhinitis, sweating, injection site reaction, vasodilatation, an increased risk of opportunistic infection, activation of Epstein Barr Virus, apoptosis of T cells and an increased risk of developing certain types of cancer. In another specific embodiment, the administration of one or more doses of a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies does not induce or reduces relative to other immunosuppressive agents one or more of the following unwanted or adverse effects: vital sign abnormalities (fever, tachycardia, bardycardia, hypertension, hypotension), hematological events (anemia, lymphopenia, leukopenia, thrombocytopenia), headache, chills, dizziness, nausea, asthenia, back pain, chest pain (chest pressure), diarrhea, myalgia, pain, pruritus, psoriasis, rhinitis, sweating, injection site reaction, vasodilatation, an increased risk of opportunistic infection, Epstein Barr Virus activation, apoptosis of T cells, and an increased risk of developing certain types of cancer.
5.2.3 **Combinatorial Therapy**

[0195] The present invention provides compositions comprising one or more anti-human CD3 antibody and one or more prophylactic or therapeutic agents other than anti-human CD3 antibodies, and methods for preventing, treating, delaying the onset of, slowing the progression of or ameliorating one or more symptoms associated with LADA or another adult-onset type 1 diabetes disorder in a subject in need thereof comprising administering to said subject one or more of said compositions. Therapeutic or prophylactic agents include, but are not limited to, peptides, polypeptides, fusion proteins, nucleic acid molecules, small molecules, mimetic agents, synthetic drugs, inorganic molecules, and organic molecules. Any agent which is known to be useful, or which has been used or is currently being used for the prevention, treatment or amelioration of one or more symptoms associated with an autoimmune disorder, particularly type 1 diabetes can be used in combination with an anti-human CD3 antibody in accordance with the invention described herein. Examples of such agents include, but are not limited to antibody fragments, GLP-1 analogs or derivatives, GLP-1 agonists (*e.g.* exendin-4; exentatide), amylin analogs or derivatives, insulin, and immunomodulatory agents (*e.g.*, small organic molecules, a T cell receptor modulators, cytokine receptor modulators, T cell depleting agents, cytokine antagonists, monokine antagonists, lymphocyte inhibitors, or anti-cancer agents). Any immunomodulatory agent well-known to one of skill in the art may also be used in the methods and compositions of the invention. Immunomodulatory agents can affect one or more or all aspects of the immune response in a subject. Aspects of the immune response include, but are not limited to, the inflammatory response, the complement cascade, leukocyte and lymphocyte differentiation, proliferation, and/or effector function, monocyte and/or basophil counts, and the cellular communication among cells of the immune system. In certain embodiments of the invention, an immunomodulatory agent modulates one aspect of the immune response. In other embodiments, an immunomodulatory agent modulates more than one aspect of the immune response. In a preferred embodiment of the invention, the administration of an immunomodulatory agent to a subject inhibits or reduces one or more aspects of the subject's immune response capabilities. In a specific embodiment of the invention, the immunomodulatory agent inhibits or suppresses the immune response in a subject. In accordance with the invention, an immunomodulatory agent is not an anti-human CD3 antibody. In certain embodiments, an immunomodulatory agent is not an anti-inflammatory agent. In other embodiments, an immunomodulatory agent is not a CD3 binding molecule. In yet other embodiments, an immunomodulatory agent is not OKT3 or a derivative thereof.
[0196] An immunomodulatory agent may be selected to interfere with the interactions between the T helper subsets (TH1 or TH2) and B cells to inhibit neutralizing antibody formation. An immunomodulatory agent may be selected to inhibit the interaction between TH1 cells and CTLs to reduce the occurrence of CTL-mediated killing. An immunomodulatory agent may be selected to alter (e.g., inhibit or suppress) the proliferation, differentiation, activity and/or function of the CD4+ and/or CD8+ T cells. For example, antibodies specific for T cells can be used as immunomodulatory agents to deplete, or alter the proliferation, differentiation, activity and/or function of CD4+ and/or CD8+ T cells.

[0197] In specific embodiments, the anti-human CD3 binding molecule is co-administered with a cytokine antagonist. In other embodiments, the anti-human CD3 binding molecule is co-administered with an anti-IL-2 antibody, such as, for example, daclizumab, basiliximab or MT204 (Micromet) or other IL-2 inhibitor, such as but not limited to rapamycin, cyclosporine, or tacrolimus.

[0198] In other embodiments, the anti-human CD3 binding molecule is administered in conjunction with an antigen targeted by anti-islet cell antibodies such as, but not limited to GAD (such as GAD 65), insulin, IA-2, ICA512 or other antigen against which autoantibodies are found in type 1 diabetes patients. Such co-administration may lead to tolerance to the islet cell antigens.

[0199] In accordance with the invention, one or more prophylactic, therapeutic or immunomodulatory agents are administered to a subject with LADA or other adult-onset type 1 diabetes, or a predisposition thereto, prior to, subsequent to, or concomitantly with the therapeutic and/or prophylactic agents of the invention. Such methods may be employed to treat, prevent, delay the onset of, slow the progression of or ameliorate one or more symptoms of LADA or another adult-onset type 1 diabetes disorder.

[0200] In specific embodiments, the present invention provides a method for preventing, treating, managing, delaying the onset of, slowing the progression of, or ameliorating one or more symptoms of LADA or another adult-onset type 1 diabetes, said method comprising administering to said subject a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies and a prophylactically or therapeutically effective amount of insulin. In one embodiment, the present invention provides a method for preventing, treating, managing, delaying the onset of, slowing the progression of, or ameliorating one or more symptoms of LADA or another adult-onset type
1 diabetes, said method comprising administering to said subject a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies and a prophylactically or therapeutically effective amount of GLPl or GLPl analog. In one embodiment, the present invention provides a method for preventing, treating, managing, delaying the onset of, slowing the progression of, or ameliorating one or more symptoms of LADA or another adult-onset type 1 diabetes, said method comprising administering to said subject a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies and a prophylactically or therapeutically effective amount of amylin or an analog thereof. In one embodiment, the present invention provides a method for preventing, treating, managing, delaying the onset of, slowing the progression of, or ameliorating one or more symptoms of LADA or another adult-onset type 1 diabetes, said method comprising administering to said subject a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies and a prophylactically or therapeutically effective amount of amylin or an analog thereof. In another embodiment, the present invention provides a method for preventing, treating, managing, delaying the onset of, slowing the progression of, or ameliorating one or more symptoms of LADA or another adult-onset type 1 diabetes, said method comprising administering to said subject a prophylactically or therapeutically effective amount of the humanized anti-human CD3 antibody OKT3 and a prophylactically or therapeutically effective amount of insulin.

[0201] Nucleic acid molecules encoding proteins, polypeptides, or peptides with prophylactic, therapeutic or immunomodulatory activity or proteins, polypeptides, or peptides with prophylactic, therapeutic or immunomodulatory activity can be administered to a subject with LADA or another adult-onset type 1 diabetes disease in accordance with the methods of the invention. Further, nucleic acid molecules encoding derivatives, analogs, fragments or variants of proteins, polypeptides, or peptides with prophylactic, therapeutic or immunomodulatory activity, or derivatives, analogs, fragments or variants of proteins, polypeptides, or peptides with prophylactic, therapeutic or immunomodulatory activity can be administered to a subject in accordance with the methods of the invention. Preferably, such derivatives, analogs, variants and fragments retain the prophylactic, therapeutic or immunomodulatory activity of the full-length wild-type protein, polypeptide, or peptide.

[0202] Proteins, polypeptides, or peptides that can be used as prophylactic, therapeutic or immunomodulatory agents can be produced by any technique well-known in the art or described herein. See, e.g., Chapter 16 Ausubel et al. (eds.), 1999, Short Protocols
in Molecular Biology, Fourth Edition, John Wiley & Sons, NY, which describes methods of producing proteins, polypeptides, or peptides, and which is incorporated herein by reference in its entirety. Antibodies which can be used as prophylactic, therapeutic or immunomodulatory agents can be produced by, e.g., methods described in U.S. Patent No. 6,245,527 and in Harlow and Lane Antibodies: A Laboratory Manual, Cold Spring Harbor Laboratory Press, Cold Spring Harbor, NY, 1988, which are incorporated herein by reference in their entirety. Preferably, agents that are commercially available and known to function as prophylactic, therapeutic or immunomodulatory agents are used in the compositions and methods of the invention. The prophylactic, therapeutic or immunomodulatory activity of an agent can be determined in vitro and/or in vivo by any technique well-known to one skilled in the art, including, e.g., by CTL assays, proliferation assays, and immunoassays (e.g. ELISAs) for the expression of particular proteins such as co-stimulatory molecules and cytokines.

[0203] The combination of one or more anti-human CD3 antibodies and one or more prophylactic or therapeutic agents other than anti-human CD3 antibodies produces a better prophylactic or therapeutic effect in a subject than either treatment alone. In certain embodiments, the combination of an anti-human CD3 antibody and a prophylactic or therapeutic agent other than an anti-human CD3 antibody achieves a 20%, 25%, 30%, 35%, 40%, 45%, 50%, 55%, 60%, 65%, 70%, 75%, 80%, 85%, 90%, 95% or 98% better prophylactic or therapeutic effect in a subject with LADA or another adult-onset type 1 diabetes disorder, or predisposition thereto, than either treatment alone.

[0204] The combination therapies of the invention enable lower dosages of anti-human CD3 antibodies and/or less frequent administration of anti-human CD3 antibodies to a subject with LADA or other adult-onset type 1 diabetes disorder to achieve a prophylactic or therapeutic effect. The combination therapies of the invention enable lower dosages of the prophylactic or therapeutic agents utilized in conjunction with anti-human CD3 antibodies and/or less frequent administration of such prophylactic or therapeutic agents to achieve a prophylactic or therapeutic effect.

[0205] The prophylactic or therapeutic agents of the combination therapies of the present invention can be administered concomitantly, concurrently or sequentially. The prophylactic or therapeutic agents of the combination therapies of the present invention can also be cyclically administered. Cycling therapy involves the administration of a first prophylactic or therapeutic agent for a period of time, followed by the administration of a second prophylactic or therapeutic agent for a period of time and repeating this sequential
administration, i.e., the cycle, in order to reduce the development of resistance to one of the agents, to avoid or reduce the side effects of one of the agents, and/or to improve the efficacy of the treatment.

5.3 **Pharmaceutical Compositions**

[0206] The present invention provides compositions for the treatment, prophylaxis, and amelioration of one or more symptoms associated with LADA or an adult-onset type 1 diabetes disorder. In a specific embodiment, a composition comprises one or more anti-human CD3 antibodies. In another embodiment, a composition comprises one or more nucleic acid molecules encoding the heavy and light chains of one or more anti-human CD3 antibodies.

[0207] In a specific embodiment, a composition comprises an anti-human CD3 antibody, wherein said anti-human CD3 antibody is a human or humanized monoclonal antibody, preferably modified to reduce binding of the Fc domain to Fc receptors and, thereby, reduce toxicity of the antibody. In yet another preferred embodiment, a composition comprises humanized OKT3, a analog, derivative, fragment thereof that immunospecifically binds to CD3 polypeptides, preferably OKT3γl(ala-ala).

[0208] In a preferred embodiment, a composition of the invention is a pharmaceutical composition. Such compositions comprise a prophylactically or therapeutically effective amount of one or more anti-human CD3 antibodies, and a pharmaceutically acceptable carrier. In a specific embodiment, the term "pharmaceutically acceptable" means approved by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopeia or other generally recognized pharmacopeia for use in animals, and more particularly in humans. The term "carrier" refers to a diluent, adjuvant (e.g., Freund's adjuvant (complete and incomplete)), excipient, or vehicle with which the therapeutic is administered. Such pharmaceutical carriers can be sterile liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. Water is a preferred carrier when the pharmaceutical composition is administered intravenously. Saline solutions and aqueous dextrose and glycerol solutions can also be employed as liquid carriers, particularly for injectable solutions. Suitable pharmaceutical excipients include starch, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, sodium stearate, glycerol monostearate, talc, sodium chloride, dried skim milk, glycerol, propylene, glycol, water, ethanol and the like. (See, for example, Handbook of Pharmaceutical Excipients, Arthur H. Kibbe (ed.), 2000,
which is incorporated by reference herein in its entirety), Am. Pharmaceutical Association, Washington, DC. The composition, if desired, can also contain minor amounts of wetting or emulsifying agents, or pH buffer. These compositions can take the form of solutions, suspensions, emulsion, tablets, pills, capsules, powders, sustained release formulations and the like. Oral formulation can include standard carriers such as pharmaceutical grades of mannitol, lactose, starch, magnesium stearate, sodium saccharine, cellulose, magnesium carbonate, etc. Examples of suitable pharmaceutical carriers are described in "Remington's Pharmaceutical Sciences" by E.W. Martin. Such compositions will contain a prophylactically or therapeutically effective amount of a prophylactic or therapeutic agent preferably in purified form, together with a suitable amount of carrier so as to provide the form for proper administration to the patient. The formulation should suit the mode of administration. In a preferred embodiment, the pharmaceutical compositions are sterile and in suitable form for administration to a subject, preferably an animal subject, more preferably a mammalian subject, and most preferably a human subject.

[0209] In a specific embodiment, it may be desirable to administer the pharmaceutical compositions of the invention locally to the area in need of treatment; this may be achieved by, for example, and not by way of limitation, local infusion, by injection, or by means of an implant, said implant being of a porous, non-porous, or gelatinous material, including membranes, such as sialastic membranes, or fibers. Preferably, when administering an anti-human CD3 antibody, care must be taken to use materials to which the anti-human CD3 antibody does not absorb.

[0210] In another embodiment, the composition can be delivered in a vesicle, in particular a liposome (see Langer, Science 249:1527-1533 (1990); Treat et al., in Liposomes in the Therapy of Infectious Disease and Cancer, Lopez-Berestein and Fidler (eds.), Liss, New York, pp. 353-365 (1989); Lopez-Berestein, ibid., pp. 3 17-327; see generally ibid.).

[0211] In yet another embodiment, the composition can be delivered in a controlled release or sustained release system. In one embodiment, a pump may be used to achieve controlled or sustained release (see Langer, supra; Sefton, 1987, CRC Crit. Ref. Biomed. Eng. 14:20; Buchwald et al., 1980, Surgery 88:507; Saudek et al., 1989, N. Engl. J. Med. 321:574). In another embodiment, polymeric materials can be used to achieve controlled or sustained release of the antibodies of the invention or fragments thereof (see e.g., Medical Applications of Controlled Release, Langer and Wise (eds.), CRC Pres., Boca Raton, Florida (1974); Controlled Drug Bioavailability, Drug Product Design and Performance, Smolen and

Examples of polymers used in sustained release formulations include, but are not limited to, poly(2-hydroxy ethyl methacrylate), poly(methyl methacrylate), poly(acrylic acid), poly(ethylene-co-vinyl acetate), poly(methacrylic acid), polyglycolides (PLG), polyanhydrides, poly(N-vinyl pyrrolidone), poly(vinyl alcohol), polyacrylamide, poly(ethylene glycol), polylactides (PLA), poly(lactide-co-glycolides) (PLGA), and polyorthoesters. In a preferred embodiment, the polymer used in a sustained release formulation is inert, free of leachable impurities, stable on storage, sterile, and biodegradable.

In yet another embodiment, a controlled or sustained release system can be placed in proximity of the therapeutic target, i.e., the lungs, thus requiring only a fraction of the systemic dose (see, e.g., Goodson, in Medical Applications of Controlled Release, supra, vol. 2, pp. 115-138 (1984)).

[0213] A pharmaceutical composition of the invention is formulated to be compatible with its intended route of administration. Examples of routes of administration include, but are not limited to, parenteral, e.g., intravenous, intradermal, subcutaneous, oral (e.g., inhalation), intranasal, transdermal (topical), transmucosal, and rectal administration. In a specific embodiment, the composition is formulated in accordance with routine procedures as a pharmaceutical composition adapted for intravenous, subcutaneous, intramuscular, oral, intranasal or topical administration to human beings. In a preferred embodiment, a pharmaceutical composition is formulated in accordance with routine procedures for
subcutaneous administration to human beings. Typically, compositions for intravenous administration are solutions in sterile isotonic aqueous buffer. Where necessary, the composition may also include a solubilizing agent and a local anesthetic such as lignocamne to ease pain at the site of the injection.

[0214] If the compositions of the invention are to be administered topically, the compositions can be formulated in the form of, e.g., an ointment, cream, transdermal patch, lotion, gel, shampoo, spray, aerosol, solution, emulsion, or other form well-known to one of skill in the art. See, e.g., Remington's Pharmaceutical Sciences and Introduction to Pharmaceutical Dosage Forms, 4th ed., Lea & Febiger, Philadelphia, PA (1985). For non-sprayable topical dosage forms, viscous to semi-solid or solid forms comprising a carrier or one or more excipients compatible with topical application and having a dynamic viscosity preferably greater than water are typically employed. Suitable formulations include, without limitation, solutions, suspensions, emulsions, creams, ointments, powders, liniments, salves, and the like, which are, if desired, sterilized or mixed with auxiliary agents (e.g., preservatives, stabilizers, wetting agents, buffers, or salts) for influencing various properties, such as, for example, osmotic pressure. Other suitable topical dosage forms include sprayable aerosol preparations wherein the active ingredient, preferably in combination with a solid or liquid inert carrier, is packaged in a mixture with a pressurized volatile (e.g., a gaseous propellant, such as freon), or in a squeeze bottle. Moisturizers or humectants can also be added to pharmaceutical compositions and dosage forms if desired. Examples of such additional ingredients are well-known in the art.

[0215] If the compositions of the invention are to be administered intranasally, the compositions can be formulated in an aerosol form, spray, mist or in the form of drops. In particular, prophylactic or therapeutic agents for use according to the present invention can be conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebuliser, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of, e.g., gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

[0216] If the compositions of the invention are to be administered orally, the compositions can be formulated orally in the form of, e.g., tablets, capsules, cachets, gelcaps,
solutions, suspensions and the like. Tablets or capsules can be prepared by conventional means with pharmaceutically acceptable excipients such as binding agents (e.g., pregelatinised maize starch, polyvinylpyrrolidone or hydroxypropyl methylcellulose); fillers (e.g., lactose, microcrystalline cellulose or calcium hydrogen phosphate); lubricants (e.g., magnesium stearate, talc or silica); disintegrants (e.g., potato starch or sodium starch glycolate); or wetting agents (e.g., sodium lauryl sulphate). The tablets may be coated by methods well-known in the art. Liquid preparations for oral administration may take the form of, for example, solutions, syrups or suspensions, or they may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may be prepared by conventional means with pharmaceutically acceptable additives such as suspending agents (e.g., sorbitol syrup, cellulose derivatives or hydrogenated edible fats); emulsifying agents (e.g., lecithin or acacia); non-aqueous vehicles (e.g., almond oil, oily esters, ethyl alcohol or fractionated vegetable oils); and preservatives (e.g., methyl or propyl-p-hydroxybenzoates or sorbic acid). The preparations may also contain buffer salts, flavoring, coloring and sweetening agents as appropriate. Preparations for oral administration may be suitably formulated for slow release, controlled release or sustained release of a prophylactic or therapeutic agent(s).

[0217] The compositions of the invention may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulatory agents such as suspending, stabilizing and/or dispersing agents. Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, e.g., sterile pyrogen-free water, before use.

[0218] The compositions of the invention may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

[0219] In addition to the formulations described previously, the compositions of the invention may also be formulated as a depot preparation. Such long acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the compositions may be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable
oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

[0220] The compositions of the invention can be formulated as neutral or salt forms. Pharmaceutically acceptable salts include those formed with anions such as those derived from hydrochloric, phosphoric, acetic, oxalic, tartaric acids, etc., and those formed with cations such as those derived from sodium, potassium, ammonium, calcium, ferric hydroxides, isopropylamine, triethylamine, 2-ethylamino ethanol, histidine, procaine, etc.

[0221] Generally, the ingredients of compositions of the invention are supplied either separately or mixed together in unit dosage form, for example, as a dry lyophilized powder or water free concentrate in a hermetically sealed container such as an ampoule or sachette indicating the quantity of active agent. Where the composition is to be administered by infusion, it can be dispensed with an infusion bottle containing sterile pharmaceutical grade water or saline. Where the composition is administered by injection, an ampoule of sterile water for injection or saline can be provided so that the ingredients may be mixed prior to administration.

[0222] In particular, the invention provides that one or more anti-human CD3 antibodies, or pharmaceutical compositions of the invention is packaged in a hermetically sealed container such as an ampoule or sachette indicating the quantity of the agent. In one embodiment, one or more of the anti-human CD3 antibodies, or pharmaceutical compositions of the invention is supplied as a dry sterilized lyophilized powder or water free concentrate in a hermetically sealed container and can be reconstituted, e.g., with water or saline to the appropriate concentration for administration to a subject. Preferably, one or more of the anti-human CD3 antibodies, or pharmaceutical compositions of the invention is supplied as a dry sterile lyophilized powder in a hermetically sealed container at a unit dosage of at least 5 mg, more preferably at least 10 mg, at least 15 mg, at least 25 mg, at least 35 mg, at least 45 mg, at least 50 mg, at least 75 mg, or at least 100 mg. The lyophilized prophylactic or therapeutic agents, or pharmaceutical compositions of the invention should be stored at between 2 and 8°C in its original container and the prophylactic or therapeutic agents, or pharmaceutical compositions of the invention should be administered within 1 week, preferably within 5 days, within 72 hours, within 48 hours, within 24 hours, within 12 hours, within 6 hours, within 5 hours, within 3 hours, or within 1 hour after being reconstituted. In an alternative embodiment, one or more of the anti-human CD3 antibodies, or pharmaceutical compositions of the invention is supplied in liquid form in a hermetically sealed container indicating the
quantity and concentration of the agent. Preferably, the liquid form of the administered composition is supplied in a hermetically sealed container at least 0.25 mg/ml, more preferably at least 0.5 mg/ml, at least 1 mg/ml, at least 2.5 mg/ml, at least 5 mg/ml, at least 8 mg/ml, at least 10 mg/ml, at least 15 mg/kg, at least 25 mg/ml, at least 50 mg/ml, at least 75 mg/ml or at least 100 mg/ml. The liquid form should be stored at between 2°C and 8°C in its original container.

[0223] In a preferred embodiment, the invention provides that the composition of the invention is packaged in a hermetically sealed container such as an ampoule or sachette indicating the quantity of anti-human CD3 antibody.

[0224] The compositions may, if desired, be presented in a pack or dispenser device that may contain one or more unit dosage forms containing the active ingredient. The pack may for example comprise metal or plastic foil, such as a blister pack.

[0225] Generally, the ingredients of the compositions of the invention are derived from a subject that is the same species origin or species reactivity as recipient of such compositions. Thus, in a preferred embodiment, human or humanized antibodies are administered to a human patient for therapy or prophylaxis.

[0226] The amount of the composition of the invention which will be effective in the treatment, prevention or amelioration of one or more symptoms associated with an inflammatory disease or autoimmune disorder can be determined by standard clinical techniques. The precise dose to be employed in the formulation will also depend on the route of administration, and the seriousness of the condition, and should be decided according to the judgment of the practitioner and each patient's circumstances. Effective doses may be extrapolated from dose-response curves derived from in vitro or animal model test systems.

5.4 Characterization of Anti-CD3 Therapeutic or Prophylactic Utility

and Felici, 1991, J. Mol. Biol. 222:301-310) (each of these references is incorporated herein in its entirety by reference). CD3 binding molecules that have been identified to immunospecifically bind to a CD3 polypeptide can then be assayed for their specificity and affinity for a CD3 polypeptide.

CD3 binding molecules may be assayed for immunospecific binding to a CD3 polypeptide and cross-reactivity with other polypeptides by any method known in the art. Immunoassays which can be used to analyze immunospecific binding and cross-reactivity include, but are not limited to, competitive and non-competitive assay systems using techniques such as western blots, radioimmunoassays, ELISA (enzyme linked immunosorbent assay), "sandwich" immunoassays, immunoprecipitation assays, precipitin reactions, gel diffusion precipitin reactions, immunodiffusion assays, agglutination assays, complement-fixation assays, immunoradiometric assays, fluorescent immunoassays, protein A immunoassays, to name but a few. Such assays are routine and well known in the art (see, e.g., Ausubel et al, eds, 1994, Current Protocols in Molecular Biology, Vol. 1, John Wiley & Sons, Inc., New York, which is incorporated by reference herein in its entirety). Exemplary immunoassays are described briefly below (but are not intended by way of limitation).

Immuno precipitation protocols generally comprise lysing a population of cells in a lysis buffer such as RIPA buffer (1% NP-40 or Triton X-100, 1% sodium deoxycholate, 0.1% SDS, 0.15 M NaCl, 0.01 M sodium phosphate at pH 7.2, 1% Trasylol) supplemented with protein phosphatase and/or protease inhibitors (e.g., EDTA, PMSF, aprotinin, sodium vanadate), adding the CD3 binding molecule of interest to the cell lysate, incubating for a period of time (e.g., 1 to 4 hours) at 40°C, adding protein A and/or protein G sepharose beads to the cell lysate, incubating for about an hour or more at 40°C, washing the beads in lysis buffer and resuspending the beads in SDS/sample buffer. The ability of the CD3 binding molecule of interest to immunoprecipitate a particular antigen can be assessed by, e.g., western blot analysis. One of skill in the art would be knowledgeable as to the parameters that can be modified to increase the binding of the CD3 binding molecule to a CD3 polypeptide and decrease the background (e.g., pre-clearing the cell lysate with sepharose beads). For further discussion regarding immunoprecipitation protocols see, e.g., Ausubel et al, eds, 1994, Current Protocols in Molecular Biology, Vol. 1, John Wiley & Sons, Inc., New York at 10.16.1.

Western blot analysis generally comprises preparing protein samples, electrophoresis of the protein samples in a polyacrylamide gel (e.g., 8%-20% SDS-PAGE
depending on the molecular weight of the antigen), transferring the protein sample from the polyacrylamide gel to a membrane such as nitrocellulose, PVDF or nylon, blocking the membrane in blocking solution (e.g., PBS with 3% BSA or non-fat milk), washing the membrane in washing buffer (e.g., PBS-Tween 20), blocking the membrane with CD3 binding molecule of interest (e.g., an antibody of interest) diluted in blocking buffer, washing the membrane in washing buffer, blocking the membrane with an antibody (which recognizes the CD3 binding molecule) conjugated to an enzymatic substrate (e.g., horseradish peroxidase or alkaline phosphatase) or radioactive molecule (e.g., $^{32}$P or $^{125}$I) diluted in blocking buffer, washing the membrane in wash buffer, and detecting the presence of the CD3 polypeptide. One of skill in the art would be knowledgeable as to the parameters that can be modified to increase the signal detected and to reduce the background noise. For further discussion regarding western blot protocols see, e.g., Ausubel et al, eds, 1994, Current Protocols in Molecular Biology, Vol. 1. John Wiley & Sons, Inc., New York at 10.8.1.

[0231] ELISAs comprise preparing CD3 polypeptide, coating the well of a 96 well microtiter plate with the CD3 polypeptide, adding the CD3 binding molecule of interest conjugated to a detectable compound such as an enzymatic substrate (e.g., horseradish peroxidase or alkaline phosphatase) to the well and incubating for a period of time, and detecting the presence of the CD3 polypeptide. In ELISAs the CD3 binding molecule of interest does not have to be conjugated to a detectable compound; instead, an antibody (which recognizes the CD3 binding molecule of interest) conjugated to a detectable compound may be added to the well. Further, instead of coating the well with the CD3 polypeptide, the CD3 binding molecule may be coated to the well. In this case, an antibody conjugated to a detectable compound may be added following the addition of the CD3 polypeptide to the coated well. One of skill in the art would be knowledgeable as to the parameters that can be modified to increase the signal detected as well as other variations of ELISAs known in the art. For further discussion regarding ELISAs see, e.g., Ausubel et al, eds, 1994, Current Protocols in Molecular Biology, Vol. 1. John Wiley & Sons, Inc., New York at 11.2.1.

[0232] The binding affinity of a CD3 binding molecule to a CD3 polypeptide and the off-rate of an CD3 binding molecule-CD3 polypeptide interaction can be determined by competitive binding assays. One example of a competitive binding assay is a radioimmunoassay comprising the incubation of labeled CD3 polypeptide (e.g., $^{3}$H or $^{125}$I) with the CD3 binding molecule of interest in the presence of increasing amounts of unlabeled
CD3 polypeptide, and the detection of the CD3 binding molecule bound to the labeled CD3 polypeptide. The affinity of a CD3 binding molecule for a CD3 polypeptide and the binding off-rates can be determined from the data by scatchard plot analysis. Competition with a second CD3 binding molecule can also be determined using radioimmunoassays. In this case, a CD3 polypeptide is incubated with a CD3 binding molecule conjugated to a labeled compound (e.g., $^3$H or $^{125}$I) in the presence of increasing amounts of a second unlabeled CD3 binding molecule.

[0233] In a preferred embodiment, BIAcore kinetic analysis is used to determine the binding on and off rates of CD3 binding molecules to a CD3 polypeptide. BIAcore kinetic analysis comprises analyzing the binding and dissociation of a CD3 polypeptide from chips with immobilized CD3 binding molecules on their surface.

[0234] The CD3 binding molecules, in particular anti-human CD3 antibodies, and compositions of the invention can also be assayed for their ability to modulate T cell activation. T cell activation can be determined by measuring, e.g., changes in the level of expression of cytokines and/or T cell activation markers. Techniques known to those of skill in the art, including, but not limited to, immunoprecipitation followed by western blot analysis, ELISAs, flow cytometry, Northern blot analysis, and RT-PCR can be used to measure the expression cytokines and T cell activation markers. In a preferred embodiment, a CD3 binding molecule or composition of the invention is tested for its ability to induce the expression of IFN-γ and/or IL-2.

[0235] The anti-human CD3 antibodies, and compositions of the invention can also be assayed for their ability to induce T cell signaling. The ability of an anti-human CD3 antibody or a composition of the invention induce T cell signaling can be assayed, e.g., by kinase assays and electrophoretic shift assays (EMSAs).

[0236] The anti-human CD3 antibodies, and compositions of the invention can be tested in vitro or in vivo for their ability to modulate T cell proliferation. For example, the ability of an anti-human CD3 antibody or a composition of the invention to modulate T cell proliferation can be assessed by, e.g., $^3$H-thymidine incorporation, trypan blue cell counts, and fluorescence activated cell sorting (FACS).

[0237] The anti-human CD3 antibodies, and compositions of the invention can be tested in vitro or in vivo for their ability to induce cytolysis. For example, the ability of an
anti-human CD3 antibody or a composition of the invention to induce cytolysis can be
essessed by, e.g., $^{51}$Cr-release assays.

[0238] The anti-CD3 antibodies, and compositions of the invention can be tested in
vitro or in vivo for their ability to mediate the depletion of peripheral blood T cells. For
example, the ability of an anti-CD3 antibody or a composition of the invention to mediate
the depletion of peripheral blood T cells can be assessed by, e.g., measuring T cell counts using
flow cytometry analysis.

[0239] The anti-CD3 antibodies, and compositions of the invention can be tested in vivo for
their ability to mediate peripheral blood lymphocyte counts. For example, the ability
of an anti-CD3 antibody or a composition of the invention to mediate peripheral blood
lymphocyte counts can be assessed by, e.g., obtaining a sample of peripheral blood from a
subject, separating the lymphocytes from other components of peripheral blood such as
plasma using, e.g., a Ficoll gradient, and counting the lymphocytes using trypan blue.

5.4.1 Characterization of Immunoglobulin Molecules with
Variant Fc Regions

[0240] In preferred embodiments, characterization of molecules comprising variant
Fc regions with altered FcγR affinities (e.g., null FcγR binding) are done with one or more
biochemical based assays, preferably in a high throughput manner. The one or more
biochemical assays can be any assay known in the art for identifying Fc-FcγR interaction,
_i.e._, specific binding of an Fc region to an FcγR, including, but not limited to, an ELISA
assay, surface plasmon resonance assays, immunoprecipitation assay, affinity
chromatography, and equilibrium dialysis. The functional based assays can be any assay
known in the art for characterizing one or more FcγR mediated effector cell functions.
Comparison of antibodies with altered Fc regions of the invention to control antibodies
provides a measure of the extent of decrease or elimination of Fc-FcγR interaction. Non-
limiting examples of effector cell functions that can be used in accordance with the methods
of the invention, include but are not limited to, antibody-dependent cell mediated cytotoxicity
(ADCC), antibody-dependent phagocytosis, phagocytosis, opsonization, opsonophagocytosis,
cell binding, rosetting, Clq binding, and complement dependent cell mediated cytotoxicity.
In preferred embodiments, characterization of molecules comprising variant Fc regions with
altered FcγR affinities (e.g., null FcR binding) are done with one or more biochemical based
assays in combination or in parallel with one or more functional based assays, preferably in a
high throughput manner.
In some embodiments, characterization of molecules comprising variant Fc regions with altered FcγRI affinities (e.g., null FcγRI binding) comprise: characterizing the binding of the molecule comprising the variant Fc region to a FcγRI (one or more), using a biochemical assay for determining Fc-FcγRI interaction, preferably, an ELISA based assay followed by comparison of the results to the results of the same assay obtained with a control, i.e. non-modified, antibody. Once the molecule comprising a variant Fc region has been characterized for its interaction with one or more FcγRs and determined to have null binding to one or more FcγRs, by at least one biochemical based assay, e.g., an ELISA assay, the molecule maybe engineered into a complete immunoglobulin, using standard recombinant DNA technology methods known in the art, and the immunoglobulin comprising the variant Fc region expressed in mammalian cells for further biochemical characterization. The immunoglobulin into which a variant Fc region of the invention is introduced (e.g., replacing the Fc region of the immunoglobulin) can be any immunoglobulin including, but not limited to, polyclonal antibodies, monoclonal antibodies, bispecific antibodies, multi-specific antibodies, humanized antibodies, and chimeric antibodies. In preferred embodiments, a variant Fc region is introduced into an immunoglobulin specific for the CD3 complex associated with the human TCR.

The variant Fc regions, preferably in the context of an immunoglobulin, can be further characterized using one or more biochemical assays and/or one or more functional assays, preferably in a high throughput manner. In some alternate embodiments, the variant Fc regions are not introduced into an immunoglobulin and are further characterized using one or more biochemical based assays and/or one or more functional assays, preferably in a high throughput manner. The one or more biochemical assays can be any assay known in the art for identifying Fc-FcγRI interactions, including, but not limited to, an ELISA assay, and surface plasmon resonance-based assay for determining the kinetic parameters of Fc-FcγRI interaction, e.g., BIAcore assay. The one or more functional assays can be any assay known in the art for characterizing one or more FcγRI mediated effector cell function as known to one skilled in the art or described herein. In specific embodiments, the immunoglobulins comprising the variant Fc regions are assayed in an ELISA assay for binding to one or more FcγRs, e.g., FcγRIIIA, FcγRIIA, FcγRIIA; followed by one or more ADCC assays. In some embodiments, the immunoglobulins comprising the variant Fc regions are assayed further using a surface plasmon resonance-based assay, e.g., BIAcore. For further a detailed

[0243] The immunoglobulin comprising the variant Fc regions may be analyzed at any point using a surface plasmon based resonance based assay, e.g., BIAcore, for defining the kinetic parameters of the Fc-FcγR interaction, using methods known to those of skill in the art.

[0244] In most preferred embodiments, the immunoglobulin comprising the variant Fc regions is further characterized in an animal model for interaction with an FcγR. Preferred animal models for use in the methods of the invention are, for example, transgenic mice expressing human FcγRs, e.g., any mouse model described in U.S. Patent No. 5,877,397, which is incorporated herein by reference in its entirety. Transgenic mice for use in the methods of the invention include, but are not limited to, nude knockout FcγRIIIA mice carrying human FcγRIIIA; nude knockout FcγRIIIA mice carrying human FcγRIIA; nude knockout FcγRIIIAmice carrying human FcγRIIB and human FcγRIIA; nude knockout FcγRIIIA mice carrying human FcγRIIB and human FcγRIIA.

5.4.2 In Vitro and In Vivo Characterization

[0245] Several aspects of the pharmaceutical compositions or the anti-human CD3 antibodies of the invention are preferably tested in vitro, in a cell culture system, and in an animal model organism, such as a rodent animal model system, for the desired therapeutic activity prior to use in humans.

[0246] In accordance with the invention, clinical trials with human subjects need not be performed in order to demonstrate the prophylactic and/or therapeutic efficacy of anti-CD3 antibodies. In vitro and animal model studies using anti-CD3 antibodies can be extrapolated to humans and are sufficient for demonstrating the prophylactic and/or therapeutic utility of said anti-CD3 antibodies.

[0247] Anti-CD3 antibodies can be tested in suitable animal model systems prior to use in humans. Such animal model systems include, but are not limited to, rats, mice, chicken, cows, monkeys, pigs, dogs, rabbits, etc. Any animal system well-known in the art may be used. In a specific embodiment of the invention, CD3 binding molecules are tested in a mouse model system. Such model systems are widely used and well-known to the skilled artisan. CD3 binding molecules can be administered repeatedly. Several aspects of the
procedure may vary. Said aspects include the temporal regime of administering CD3 binding molecules, and whether such agents are administered separately or as an admixture.

[0248] The toxicity and/or efficacy of anti-CD3 antibodies or pharmaceutical compositions of invention can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for determining the LD50 (the dose lethal to 50% of the population) and the ED50 (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD50/ED50. Anti-CD3 antibodies that exhibit large therapeutic indices are preferred. While anti-CD3 antibodies that exhibit toxic side effects may be used, care should be taken to design a delivery system that targets such agents to the site of affected tissue in order to minimize potential damage to uninfected cells and, thereby, reduce side effects.

[0249] The data obtained from the cell culture assays and animal studies can be used in formulating a range of dosage of anti-human CD3 antibodies for use in humans. The dosage of such agents lies preferably within a range of circulating concentrations that include the ED50 with little or no toxicity. The dosage may vary within this range depending upon the dosage form employed and the route of administration utilized. For any agent used in the method of the invention, the therapeutically effective dose can be estimated initially from cell culture assays. A dose may be formulated in animal models to achieve a circulating plasma concentration range that includes the IC50 (i.e., the concentration of the test compound that achieves a half-maximal inhibition of symptoms) as determined in cell culture. Such information can be used to more accurately determine useful doses in humans. Levels in plasma may be measured, for example, by high performance liquid chromatography.

[0250] Efficacy in treating LADA or other adult-onset type 1 diabetes may be demonstrated, e.g. by detecting the ability of an anti-human CD3 antibodies or composition of the invention to reduce one or more symptoms of diabetes, to preserve the C-peptide response to MMTT, to reduce the level HAI or HAIc, to reduce the daily requirement for insulin, or to decrease T cell activation in pancreatic islet tissue.

5.5 Methods of Monitoring Lymphocyte Counts and Percent Binding

[0251] The effect of one or more doses of one or more anti-CD3 antibodies or composition on peripheral blood lymphocyte counts can be monitored/assessed using standard techniques known to one of skill in the art. Peripheral blood lymphocytes counts in
a mammal can be determined by, *e.g.*, obtaining a sample of peripheral blood from said mammal, separating the lymphocytes from other components of peripheral blood such as plasma using, *e.g.*, Ficoll-Hypaque (Pharmacia) gradient centrifugation, and counting the lymphocytes using trypan blue. Peripheral blood T cell counts in mammal can be determined by, *e.g.*, separating the lymphocytes from other components of peripheral blood such as plasma using, *e.g.*, a use of Ficoll-Hypaque (Pharmacia) gradient centrifugation, labeling the T cells with an antibody directed to a T cell antigen such as CD2, CD3, CD4, and CD8 which is conjugated to FITC or phycoerythrin, and measuring the number of T cells by FACS. Further, the effect on a particular subset of T cells (*e.g.*, CD2+, CD4+, CD8+, CD4+R0+, CD8+R0+, CD4+RA+, or CD8+RA+) cells can be determined using standard techniques known to one of skill in the art such as FACS.

[0252] The percentage of CD3 polypeptides expressed by peripheral blood lymphocytes bound by anti-CD3 antibodies prior or after, or both prior to and after the administration of one or more doses of anti-CD3 antibodies can be assessed using standard techniques known to one of skill in the art. The percentage of CD3 polypeptides expressed by peripheral blood T cells bound by anti-CD3 antibodies can be determined by, *e.g.*, obtaining a sample of peripheral blood from a mammal, separating the lymphocytes from other components of peripheral blood such as plasma using, *e.g.*, Ficoll-Hypaque (Pharmacia) gradient centrifugation, and labeling the T cells with an anti-CD3 binding molecule antibody other than that of the invention conjugated to FITC and an antibody directed to a T cell antigen such as CD3, CD4 or CD8 which is conjugated to phycoerythrin, and determining the number of T cells labeled with anti-CD3 binding molecule antibody relative to the number of T cells labeled with an antibody directed to a T cell antigen using FACS.

5.6 Methods of Producing Antibodies

[0253] Antibodies that immunospecifically bind to an CD3 polypeptide can be produced by any method known in the art for the synthesis of antibodies, in particular, by chemical synthesis or preferably, by recombinant expression techniques.

[0254] Polyclonal antibodies that immunospecifically bind to an antigen can be produced by various procedures well-known in the art. For example, a human antigen can be administered to various host animals including, but not limited to, rabbits, mice, rats, etc. to induce the production of sera containing polyclonal antibodies specific for the human antigen. Various adjuvants may be used to increase the immunological response, depending on the host species, and include but are not limited to, Freund's (complete and incomplete),
mineral gels such as aluminum hydroxide, surface active substances such as lysolecithin, pluronic polyols, polyanions, peptides, oil emulsions, keyhole limpet hemocyanins, dinitrophenol, and potentially useful human adjuvants such as BCG (bacille Calmette-Guerin) and corynebacterium parvum. Such adjuvants are also well known in the art.

Monoclonal antibodies can be prepared using a wide variety of techniques known in the art including the use of hybridoma, recombinant, and phage display technologies, or a combination thereof. For example, monoclonal antibodies can be produced using hybridoma techniques including those known in the art and taught, for example, in Harlow et al., Antibodies: A Laboratory Manual, (Cold Spring Harbor Laboratory Press, 2nd ed. 1988); Hammerling, et al., in: Monoclonal Antibodies and T cell Hybridomas 563 681 (Elsevier, N.Y., 1981) (said references incorporated by reference in their entireties). The term "monoclonal antibody" as used herein is not limited to antibodies produced through hybridoma technology. The term "monoclonal antibody" refers to an antibody that is derived from a single clone, including any eukaryotic, prokaryotic, or phage clone, and not the method by which it is produced.

Methods for producing and screening for specific antibodies using hybridoma technology are routine and well known in the art. Briefly, mice can be immunized with a CD3 antigen and once an immune response is detected, e.g., antibodies specific for a CD3 antigen (preferably, CD3 ε antigen) are detected in the mouse serum, the mouse spleen is harvested and splenocytes isolated. The splenocytes are then fused by well known techniques to any suitable myeloma cells, for example cells from cell line SP20 available from the ATCC. Hybridomas are selected and cloned by limited dilution. The hybridoma clones are then assayed by methods known in the art for cells that secrete antibodies capable of binding a polypeptide of the invention. Ascites fluid, which generally contains high levels of antibodies, can be generated by immunizing mice with positive hybridoma clones.

Accordingly, the present invention provides methods of generating antibodies by culturing a hybridoma cell secreting an antibody of the invention wherein, preferably, the hybridoma is generated by fusing splenocytes isolated from a mouse immunized with a CD3 antigen with myeloma cells and then screening the hybridomas resulting from the fusion for hybridoma clones that secrete an antibody able to bind to a CD3 antigen (preferably, CD3 ε antigen).
Antibody fragments which recognize specific CD3 antigens (preferably, CD3 ε antigen) may be generated by any technique known to those of skill in the art. For example, Fab and F(ab’)2 fragments of the invention may be produced by proteolytic cleavage of immunoglobulin molecules, using enzymes such as papain (to produce Fab fragments) or pepsin (to produce F(ab’)2 fragments). F(ab’)2 fragments contain the variable region, the light chain constant region and the CHI domain of the heavy chain. Further, the antibodies of the present invention can also be generated using various phage display methods known in the art.

In phage display methods, functional antibody domains are displayed on the surface of phage particles which carry the polynucleotide sequences encoding them. In particular, DNA sequences encoding VH and VL domains are amplified from animal cDNA libraries (e.g., human or murine cDNA libraries of affected tissues). The DNA encoding the VH and VL domains are recombined together with an scFv linker by PCR and cloned into a phagemid vector. The vector is electroporated in E. coli and the E. coli is infected with helper phage. Phage used in these methods are typically filamentous phage including fd and M13 and the VH and VL domains are usually recombinantly fused to either the phage gene III or gene VIII. Phage expressing an antigen binding domain that binds to a particular antigen can be selected or identified with antigen, e.g., using labeled antigen or antigen bound or captured to a solid surface or bead. Examples of phage display methods that can be used to make the antibodies of the present invention include those disclosed in Brinkman et al., 1995, J. Immunol. Methods 182:41-50; Ames et al., 1995, J. Immunol. Methods 184:177-186; Kettleborough et al., 1994, Eur. J. Immunol. 24:952-958; Persic et al., 1997, Gene 187:9-18; Burton et al., 1994, Advances in Immunology 57:191-280; PCT Application No. PCT/GB91/01 134; International Publication Nos. WO 90/02809, WO 91/10737, WO 92/01047, WO 92/18619, WO 93/1 1236, WO 95/15982, WO 95/20401, and WO97/13844; and U.S. Patent Nos. 5,698,426, 5,223,409, 5,403,484, 5,580,717, 5,427,908, 5,750,753, 5,821,047, 5,571,698, 5,427,908, 5,516,637, 5,780,225, 5,658,727, 5,733,743 and 5,969,108; each of which is incorporated herein by reference in its entirety.

As described in the above references, after phage selection, the antibody coding regions from the phage can be isolated and used to generate whole antibodies, including human antibodies, or any other desired antigen binding fragment, and expressed in any desired host, including mammalian cells, insect cells, plant cells, yeast, and bacteria, e.g., as described below. Techniques to recombinantly produce Fab, Fab’ and F(ab’)2 fragments
can also be employed using methods known in the art such as those disclosed in PCT publication No. WO 92/22324; Mullinax et al, 1992, BioTechniques 12(6):864-869; Sawai et al, 1995, AJRI 34:26-34; and Better et al., 1988, Science 240:1041-1043 (said references incorporated by reference in their entireties).

[0261] To generate whole antibodies, PCR primers including VH or VL nucleotide sequences, a restriction site, and a flanking sequence to protect the restriction site can be used to amplify the VH or VL sequences in scFv clones. Utilizing cloning techniques known to those of skill in the art, the PCR amplified VH domains can be cloned into vectors expressing a VH constant region, e.g., the human gamma 4 constant region, and the PCR amplified VL domains can be cloned into vectors expressing a VL constant region, e.g., human kappa or lambda constant regions. Preferably, the vectors for expressing the VH or VL domains comprise an EF-1α promoter, a secretion signal, a cloning site for the variable domain, constant domains, and a selection marker such as neomycin. The VH and VL domains may also cloned into one vector expressing the necessary constant regions. The heavy chain conversion vectors and light chain conversion vectors are then co-transfected into cell lines to generate stable or transient cell lines that express full-length antibodies, e.g., IgG, using techniques known to those of skill in the art.

[0262] For some uses, including in vivo use of antibodies in humans and in vitro detection assays, it may be preferable to use human or chimeric antibodies. Completely human antibodies are particularly desirable for therapeutic treatment of human subjects. Human antibodies can be made by a variety of methods known in the art including phage display methods described above using antibody libraries derived from human immunoglobulin sequences. See also U.S. Patent Nos. 4,444,887 and 4,716,111; and International Publication Nos. WO 98/46645, WO 98/50433, WO 98/24893, WO98/16654, WO 96/34096, WO 96/33735, and WO 91/10741; each of which is incorporated herein by reference in its entirety.

[0263] Human antibodies can also be produced using transgenic mice which are incapable of expressing functional endogenous immunoglobulins, but which can express human immunoglobulin genes. For example, the human heavy and light chain immunoglobulin gene complexes may be introduced randomly or by homologous recombination into mouse embryonic stem cells. Alternatively, the human variable region, constant region, and diversity region may be introduced into mouse embryonic stem cells in addition to the human heavy and light chain genes. The mouse heavy and light chain
immunoglobulin genes may be rendered non functional separately or simultaneously with the introduction of human immunoglobulin loci by homologous recombination. In particular, homozygous deletion of the J_{H} region prevents endogenous antibody production. The modified embryonic stem cells are expanded and microinjected into blastocysts to produce chimeric mice. The chimeric mice are then be bred to produce homozygous offspring which express human antibodies. The transgenic mice are immunized in the normal fashion with a selected antigen, e.g., all or a portion of a polypeptide of the invention. Monoclonal antibodies directed against the antigen can be obtained from the immunized, transgenic mice using conventional hybridoma technology. The human immunoglobulin transgenes harbored by the transgenic mice rearrange during B cell differentiation, and subsequently undergo class switching and somatic mutation. Thus, using such a technique, it is possible to produce therapeutically useful IgG, IgA, IgM and IgE antibodies. For an overview of this technology for producing human antibodies, see Lonberg and Huszar (1995, Int. Rev. Immunol. 13:65-93). For a detailed discussion of this technology for producing human antibodies and human monoclonal antibodies and protocols for producing such antibodies, see, e.g., PCT publication Nos. WO 98/24893, WO 96/34096, and WO 96/33735; and U.S. Patent Nos. 5,413,923, 5,625,126, 5,633,425, 5,569,825, 5,661,016, 5,545,806, 5,814,318, and 5,939,598, which are incorporated by reference herein in their entirety. In addition, companies such as Abgenix, Inc. (Freemont, CA) and Genpharm (San Jose, CA) can be engaged to provide human antibodies directed against a selected antigen using technology similar to that described above.

[0264] A chimeric antibody is a molecule in which different portions of the antibody are derived from different immunoglobulin molecules. Methods for producing chimeric antibodies are known in the art. See e.g., Morrison, 1985, Science 229:1202; Oi et al., 1986, BioTechniques 4:214; Gillies et al., 1989, J. Immunol. Methods 125:191-202; and U.S. Patent Nos. 5,807,715, 4,816,567, 4,816,397, and 6,331,415, which are incorporated herein by reference in their entirety.

[0265] A humanized antibody is an antibody or its variant or fragment thereof which is capable of binding to a predetermined antigen and which comprises a framework region having substantially the amino acid sequence of a human immunoglobulin and a CDR having substantially the amino acid sequence of a non-human immunoglobulin. A humanized antibody comprises substantially all of at least one, and typically two, variable domains (Fab, Fab’, F(ab’)_{2}, Fabc, Fv) in which all or substantially all of the CDR regions correspond to
those of a non human immunoglobulin (i.e., donor antibody) and all or substantially all of the
framework regions are those of a human immunoglobulin consensus sequence. Preferably, a
humanized antibody also comprises at least a portion of an immunoglobulin constant region
(Fc), typically that of a human immunoglobulin. Ordinarily, the antibody will contain both
the light chain as well as at least the variable domain of a heavy chain. The antibody also
may include the CH1, hinge, CH2, CH3, and CH4 regions of the heavy chain. The
humanized antibody can be selected from any class of immunoglobulins, including IgM, IgG,
IgD, IgA and IgE, and any isotype, including IgGl, IgG2, IgG3 and IgG4. Usually the
constant domain is a complement fixing constant domain where it is desired that the
humanized antibody exhibit cytotoxic activity, and the class is typically IgGl. Where such
cytotoxic activity is not desirable, the constant domain may be of the IgG2 class. Examples of
VL and VH constant domains that can be used in certain embodiments of the invention
include, but are not limited to, C-kappa and C-gamma-1 (nGlml) described in Johnson et al.
humanized antibody may comprise sequences from more than one class or isotype, and
selecting particular constant domains to optimize desired effector functions is within the
ordinary skill in the art. The framework and CDR regions of a humanized antibody need not
 correspond precisely to the parental sequences, e.g., the donor CDR or the consensus
framework may be mutagenized by substitution, insertion or deletion of at least one residue
so that the CDR or framework residue at that site does not correspond to either the consensus
or the import antibody. Such mutations, however, will not be extensive. Usually, at least
75% of the humanized antibody residues will correspond to those of the parental FR and
CDR sequences, more often 90%, and most preferably greater than 95%. Humanized
antibody can be produced using variety of techniques known in the art, including but not
limited to, CDR-grafting (European Patent No. EP 239,400; International publication No.
WO 91/09967; and U.S. Patent Nos. 5,225,539, 5,530,101, and 5,585,089), veneering or
Immunology 28(4/5):489-498; Studnicka et al., 1994, Protein Engineering 7(6):805-814; and
Roguska et al., 1994, PNAS 91:969-973), chain shuffling (U.S. Patent No. 5,565,332), and
techniques disclosed in, e.g., U.S. Pat. No. 6,407,213, U.S. Pat. No. 5,766,886, WO 9317105,
(1997), Roguska et al., Protein Eng. 9(10):895 904 (1996), Couto et al., Cancer Res. 55 (23
Gene 150(2):409-10 (1994), and Pedersen et al, J. MoL Biol. 235(3):959-73 (1994). See also U.S. Patent Pub. No. US 2005/0042664 A1 (Feb. 24, 2005), which is incorporated by reference herein in its entirety. Often, framework residues in the framework regions will be substituted with the corresponding residue from the CDR donor antibody to alter, preferably improve, antigen binding. These framework substitutions are identified by methods well known in the art, e.g., by modeling of the interactions of the CDR and framework residues to identify framework residues important for antigen binding and sequence comparison to identify unusual framework residues at particular positions. (See, e.g., Queen et al., U.S. Patent No. 5,585,089; and Riechmann et al., 1988, Nature 332:323, which are incorporated herein by reference in their entireties.)

5.7 Polynucleotides Encoding Antibodies

[0267] The invention provides polynucleotides comprising a nucleotide sequence encoding an antibody that immunospecifically binds to a CD3 polypeptide. The invention also encompasses polynucleotides that hybridize under high stringency, intermediate or lower stringency hybridization conditions, e.g., as defined supra, to polynucleotides that encode an antibody of the invention.

[0268] The polynucleotides may be obtained, and the nucleotide sequence of the polynucleotides determined, by any method known in the art. The nucleotide sequence of antibodies immunospecific for a CD3 polypeptide can be obtained, e.g., from the literature or a database such as GenBank. Since the amino acid sequences of, e.g., humanized OKT3 is known, nucleotide sequences encoding these antibodies can be determined using methods well known in the art, i.e., nucleotide codons known to encode particular amino acids are assembled in such a way to generate a nucleic acid that encodes the antibody. Such a polynucleotide encoding the antibody may be assembled from chemically synthesized oligonucleotides (e.g., as described in Kutmeier et al., 1994, BioTechniques 17:242), which, briefly, involves the synthesis of overlapping oligonucleotides containing portions of the
sequence encoding the antibody, annealing and ligating of those oligonucleotides, and then amplification of the ligated oligonucleotides by PCR.

[0269] Alternatively, a polynucleotide encoding an antibody may be generated from nucleic acid from a suitable source. If a clone containing a nucleic acid encoding a particular antibody is not available, but the sequence of the antibody molecule is known, a nucleic acid encoding the immunoglobulin may be chemically synthesized or obtained from a suitable source (e.g., an antibody cDNA library, or a cDNA library generated from, or nucleic acid, preferably poly A+ RNA, isolated from, any tissue or cells expressing the antibody, such as hybridoma cells selected to express an antibody of the invention) by PCR amplification using synthetic primers hybridizable to the 3' and 5' ends of the sequence or by cloning using an oligonucleotide probe specific for the particular gene sequence to identify, e.g., a cDNA clone from a cDNA library that encodes the antibody. Amplified nucleic acids generated by PCR may then be cloned into replicable cloning vectors using any method well known in the art.

[0270] Once the nucleotide sequence of the antibody is determined, the nucleotide sequence of the antibody may be manipulated using methods well known in the art for the manipulation of nucleotide sequences, e.g., recombinant DNA techniques, site directed mutagenesis, PCR, etc. (see, for example, the techniques described in Sambrook et al, 1990, Molecular Cloning, A Laboratory Manual, 2d Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, NY and Ausubel et al, eds., 1998, Current Protocols in Molecular Biology, John Wiley & Sons, NY, which are both incorporated by reference herein in their entireties), to generate antibodies having a different amino acid sequence, for example to create amino acid substitutions, deletions, and/or insertions.

[0271] In a specific embodiment, one or more of the CDRs is inserted within framework regions using routine recombinant DNA techniques. The framework regions may be naturally occurring or consensus framework regions, and preferably human framework regions (see, e.g., Chothia et al., 1998, J. Mol. Biol. 278: 457-479 for a listing of human framework regions). Preferably, the polynucleotide generated by the combination of the framework regions and CDRs encodes an antibody that specifically binds to a CD3 polypeptide. Preferably, as discussed supra, one or more amino acid substitutions may be made within the framework regions, and, preferably, the amino acid substitutions improve binding of the antibody to its antigen. Additionally, such methods may be used to make amino acid substitutions or deletions of one or more variable region cysteine residues
participating in an intrachain disulfide bond to generate antibody molecules lacking one or more intrachain disulfide bonds. Other alterations to the polynucleotide are encompassed by the present invention and within the skill of the art.

5.8 RECOMBINANT EXPRESSION OF MOLECULES OF THE INVENTION

[0272] Once a nucleic acid sequence encoding molecules of the invention (i.e., antibodies) has been obtained, the vector for the production of the molecules may be produced by recombinant DNA technology using techniques well known in the art. Methods which are well known to those skilled in the art can be used to construct expression vectors containing the coding sequences for the molecules of the invention and appropriate transcriptional and translational control signals. These methods include, for example, in vitro recombinant DNA techniques, synthetic techniques, and in vivo genetic recombination. (See, for example, the techniques described in Sambrook et al., 1990, Molecular Cloning, A Laboratory Manual, 2d Ed., Cold Spring Harbor Laboratory, Cold Spring Harbor, NY and Ausubel et al. eds., 1998, Current Protocols in Molecular Biology, John Wiley & Sons, NY).

[0273] An expression vector comprising the nucleotide sequence of a molecule identified by the methods of the invention (i.e., an antibody) can be transferred to a host cell by conventional techniques (e.g., electroporation, liposomal transfection, and calcium phosphate precipitation) and the transfected cells are then cultured by conventional techniques to produce the molecules of the invention. In specific embodiments, the expression of the molecules of the invention is regulated by a constitutive, an inducible or a tissue, specific promoter. In specific embodiments the expression vector is pMGX1303 (FIG. 4).

[0274] The host cells used to express the molecules identified by the methods of the invention may be either bacterial cells such as Escherichia coli, or, preferably, eukaryotic cells, especially for the expression of whole recombinant immunoglobulin molecule. In particular, mammalian cells such as Chinese hamster ovary cells (CHO), in conjunction with a vector such as the major intermediate early gene promoter element from human cytomegalovirus is an effective expression system for immunoglobulins (Foecking et al., 1998, Gene 45:101; Cockett et al., 1990, Bio/Technology 8:2).

[0275] A variety of host-expression vector systems may be utilized to express the molecules identified by the methods of the invention. Such host-expression systems represent vehicles by which the coding sequences of the molecules of the invention may be
produced and subsequently purified, but also represent cells which may, when transformed or transfected with the appropriate nucleotide coding sequences, express the molecules of the invention in situ. These include, but are not limited to, microorganisms such as bacteria (e.g., E. coli and B. subtilis) transformed with recombinant bacteriophage DNA, plasmid DNA or cosmid DNA expression vectors containing coding sequences for the molecules identified by the methods of the invention; yeast (e.g., Saccharomyces Pichia) transformed with recombinant yeast expression vectors containing sequences encoding the molecules identified by the methods of the invention; insect cell systems infected with recombinant virus expression vectors (e.g., baculovirus) containing the sequences encoding the molecules identified by the methods of the invention; plant cell systems infected with recombinant virus expression vectors (e.g., cauliflower mosaic virus (CaMV) and tobacco mosaic virus (TMV) or transformed with recombinant plasmid expression vectors (e.g., Ti plasmid) containing sequences encoding the molecules identified by the methods of the invention; or mammalian cell systems (e.g., COS, CHO, BHK, 293, 293T, 3T3 cells, lymphotic cells (see U.S. 5,807,715), Per C.6 cells (human retinal cells developed by Crucell) harboring recombinant expression constructs containing promoters derived from the genome of mammalian cells (e.g., metallothionein promoter) or from mammalian viruses (e.g., the adenovirus late promoter; the vaccinia virus 7.5K promoter).

[0276] In bacterial systems, a number of expression vectors may be advantageously selected depending upon the use intended for the molecule being expressed. For example, when a large quantity of such a protein is to be produced, for the generation of pharmaceutical compositions of an antibody, vectors which direct the expression of high levels of fusion protein products that are readily purified may be desirable. Such vectors include, but are not limited to, the E. coli expression vector pUR278 (Ruther et al, 1983, EMBOJ. 2:1791), in which the antibody coding sequence may be ligated individually into the vector in frame with the lac Z coding region so that a fusion protein is produced; pIN vectors (Inouye & Inouye, 1985, Nucleic Acids Res. 13:3101-3109; Van Heeke & Schuster, 1989, J. Biol. Chem. 24:5503-5509); and the like. pGEX vectors may also be used to express foreign polypeptides as fusion proteins with glutathione S-transferase (GST). In general, such fusion proteins are soluble and can easily be purified from lysed cells by adsorption and binding to a matrix glutathione-agarose beads followed by elution in the presence of free gluta-thione. The pGEX vectors are designed to include thrombin or factor Xa protease cleavage sites so that the cloned target gene product can be released from the GST moiety.
In an insect system, Autographa californica nuclear polyhedrosis virus (AcNPV) is used as a vector to express foreign genes. The virus grows in Spodoptera frugiperda cells. The antibody coding sequence may be cloned individually into non-essential regions (e.g., the polyhedrin gene) of the virus and placed under control of an AcNPV promoter (e.g., the polyhedrin promoter).

In mammalian host cells, a number of viral-based expression systems may be utilized. In cases where an adenovirus is used as an expression vector, the antibody coding sequence of interest may be ligated to an adenovirus transcription/translation control complex, e.g., the late promoter and tripartite leader sequence. This chimeric gene may then be inserted in the adenovirus genome by in vitro or in vivo recombination. Insertion in a non-essential region of the viral genome (e.g., region E1 or E3) will result in a recombinant virus that is viable and capable of expressing the immunoglobulin molecule in infected hosts (e.g., see Logan & Shenk, 1984, Proc. Natl. Acad. Sci. USA 81:355-359). Specific initiation signals may also be required for efficient translation of inserted antibody coding sequences. These signals include the ATG initiation codon and adjacent sequences. Furthermore, the initiation codon must be in phase with the reading frame of the desired coding sequence to ensure translation of the entire insert. These exogenous translational control signals and initiation codons can be of a variety of origins, both natural and synthetic. The efficiency of expression may be enhanced by the inclusion of appropriate transcription enhancer elements, transcription terminators, etc. (see Bittner et al., 1987, Methods in Enzymol. 153:51-544).

In addition, a host cell strain may be chosen which modulates the expression of the inserted sequences, or modifies and processes the gene product in the specific fashion desired. Such modifications (e.g., glycosylation) and processing (e.g., cleavage) of protein products may be important for the function of the protein. Different host cells have characteristic and specific mechanisms for the post-translational processing and modification of proteins and gene products. Appropriate cell lines or host systems can be chosen to ensure the correct modification and processing of the foreign protein expressed. To this end, eukaryotic host cells which possess the cellular machinery for proper processing of the primary transcript, glycosylation, and phosphorylation of the gene product may be used. Such mammalian host cells include but are not limited to CHO, VERY, BHK, HeLa, COS, MDCK, 293, 293T, 3T3, WI38, BT483, Hs578T, HTB2, BT20 and T47D, CRL7030 and Hs578Bst.
[0280] For long-term, high-yield production of recombinant proteins, stable expression is preferred. For example, cell lines which stably express an antibody of the invention may be engineered. Rather than using expression vectors which contain viral origins of replication, host cells can be transformed with DNA controlled by appropriate expression control elements (e.g., promoter, enhancer, sequences, transcription terminators, polyadenylation sites, etc.), and a selectable marker. Following the introduction of the foreign DNA, engineered cells may be allowed to grow for 1-2 days in an enriched media, and then are switched to a selective media. The selectable marker in the recombinant plasmid confers resistance to the selection and allows cells to stably integrate the plasmid into their chromosomes and grow to form foci which in turn can be cloned and expanded into cell lines. This method may advantageously be used to engineer cell lines which express the antibodies of the invention. Such engineered cell lines may be particularly useful in screening and evaluation of compounds that interact directly or indirectly with the antibodies of the invention.

[0282] The expression levels of an antibody of the invention can be increased by vector amplification (for a review, see Bebbington and Hentschel, *The use of vectors based on gene amplification for the expression of cloned genes in mammalian cells in DNA cloning*, Vol. 3 (Academic Press, New York, 1987). When a marker in the vector system expressing an antibody is amplifiable, increase in the level of inhibitor present in culture of host cell will increase the number of copies of the marker gene. Since the amplified region is associated with the nucleotide sequence of the antibody, production of the antibody will also increase (Crouse et al., 1983, *Mol. Cell. Biol.* 3:257).

[0283] The host cell may be co-transfected with two expression vectors of the invention, the first vector encoding a heavy chain derived polypeptide and the second vector encoding a light chain derived polypeptide. The two vectors may contain identical selectable markers which enable equal expression of heavy and light chain polypeptides. Alternatively, a single vector may be used which encodes both heavy and light chain polypeptides. In such situations, the light chain should be placed before the heavy chain to avoid an excess of toxic free heavy chain (Proudfoot, 1986, *Nature* 322:52; Kohler, 1980, *Proc. Natl. Acad. Sci. USA* 77:2197). The coding sequences for the heavy and light chains may comprise cDNA or genomic DNA.

[0284] Once a molecule of the invention (*i.e.*, antibodies) has been recombinantly expressed, it may be purified by any method known in the art for purification of polypeptides or antibodies, for example, by chromatography (*e.g.*, ion exchange, affinity, particularly by affinity for the specific antigen after Protein A, and sizing column chromatography), centrifugation, differential solubility, or by any other standard technique for the purification of polypeptides or antibodies.

6. **EXAMPLES**

6.1 **Anti-CD3 Monoclonal Antibody Therapy for LADA Patients**

[0285] Patients: Forty patients with LADA are recruited for participation according to the following criteria: between 25 and 65 years of age, within 6 weeks of diagnosis of LADA, confirmation of the presence of anti-GAD, anti-ICA, and/or anti-insulin autoantibodies and determination of no insulin requirement. The patients remain under the care of their personal physicians during the course of the study.

[0286] Eligible patients are randomly assigned to a control group and a anti-human CD3 antibody treatment group. After randomization, blood samples are drawn to establish
baseline HAIC levels, a pretreatment C-peptide response to a MMTT is established and a pretreatment FPIR to IGTT is performed. Patients in both groups are hospitalized to receive either a 14-day course treatment of the anti-human CD3 monoclonal antibody hOKT3γl(ala-ala) or placebo. The antibody is administered intravenously in the following dosage: 51 µg/m²/day on day 1; 103 µg/m²/day on day 2; 207 µg/m²/day on day 3; 413 µg/m²/day on day 4; and 826 µg/m²/day on days 5 through 14. During initial studies the antibody dosage on the first three days of treatment is administered via slow infusion IV over 20 hours to monitor for adverse reactions. Subsequent studies will decrease the time of administration and/or split the dosage into 2 to 4 equal parts to be administered as bolus injections evenly distributed over the course of 12 hours. Patients in the control group undergo metabolic and immunologic tests but do not receive monoclonal antibodies and are not hospitalized. Patients are monitored throughout the study for immunosuppressive effects of the anti-human CD3 monoclonal antibody hOKT3γl(ala-ala).

Patients are monitored for 18 months after the treatment. β-cell function is determined every 6 months in the case of impaired glucose tolerance and every 12 months in case of normal glucose tolerance. Patients are allowed to have a normal diet, and remain under the care of their personal physician throughout the duration of the study. Immunological assays are repeated in intervals of 6 months. Insulin therapy will be given to the patients as directed by their personal physician.

β-cell function will be analyzed according to the changes of the C-peptide levels as measured by radioimmunoassay. After drawing samples for baseline C-peptide and glucose, the patients are given a mixed meal. The C-peptide levels are measured in samples drawn after 15, 30, 60, 90, 120, 150, 180, 210, and 240 min. The C-peptide response to the mixed-meal tolerance test (MMTT) is expressed as the total area under the response curve (AUC). A change in the response is considered to have occurred if the response differs by more than 7.5 percent from the response at study entry. The patients’ C-peptide responses to MMTT are continuously monitored 6 months, 9 months, 12 months, 15 months and 18 months after the treatment. Alternatively, the β-cell function is assessed by FPIR to IGTT. Serum insulin levels are measured by a modification of a double-antibody radioimmunoassay method using monoiodinated tyrosine A14-labeled insulin (Amersham Pharmacia). FPIR is calculated as the sum of insulin levels at 1 and 3 minutes after a glucose load (0.5 g/kg). Glycosylated hemoglobin levels are measured by latex-agglutination inhibition test.
Immunological Monitoring: The level of autoantibodies against GAD65, IA2/ICA512, and insulin are measured with radiobinding assays as known in the art (e.g., Woo et al, 2000, J. Immunol Methods 244:91-103). HLA-DQA and HLA-DQB genotyping are performed by direct sequencing of exon 2 polymorphisms after PCR amplification. The level of cytokines in serum after the administration of the monoclonal antibody is measured by enzyme-linked immunosorbent assay (ELISA). Production of anti-idotype antibodies is monitored by ELISA assay using a plate bound hOKT3γl(ala-ala) or by flow cytometry to measure blockade of binding of hOKT3γl(ala-ala)-FITC to CD3.

Statistical Analysis: Data analysis will be conducted on residual beta-cell function, autoantibody level, cytokine level, and glycosylated hemoglobin level. A χ² analysis will be performed to test the effect of drug treatment before and after drug administration. Comparison between the control group and the treatment group will be made with the Mann-Whitney U test.

6.2 Anti-CD3 Monoclonal Antibody Therapy in Recent Adult-Onset Type 1 Diabetes

Patients: Forty patients with Adult-Onset Type 1 diabetes of recent onset are recruited for participation according to the following criteria: between 35 and 65 years of age, within 6 weeks of hospital discharge or diagnosis of type-1 diabetes according to American Diabetes Association criteria (see, e.g., Mayfield et al., 2006, Am. Fam. Physician 58:1355-1362), confirmation of the presence of anti-GAD, anti-ICA, and/or anti-insulin autoantibodies. The patients remain under the care of their personal physicians during the course of the study. Accordingly, patients may have received insulin treatment before the beginning of study and will the physician recommended insulin therapy during the course of this study.

Eligible patients are randomly assigned to a control group and a monoclonal-antibody treatment group. After randomization, blood samples are drawn to establish baseline HAIc levels, a pretreatment C-peptide response to a MMTT is established and a pretreatment FPIR to IGTT is performed. Patients in both groups are hospitalized to receive either a 14-day course treatment of the anti-human CD3 monoclonal antibody hOKT3γl(ala-ala) or placebo. The antibody is administered intravenously in the following dosage: 51 µg/m²/day on day 1; 103 µg/m²/day on day 2; 207 µg/m²/day on day 3; 413 µg/m²/day on day 4; and 826 µg/m²/day on days 5 through 14. During initial studies the antibody dosage on the first three days of treatment is administered via slow infusion IV over 20 hours to monitor for adverse
reactions. Subsequent studies will decrease the time of administration and/or split the dosage into 2 to 4 equal parts to be administered as bolus injections evenly distributed over the course of 12 hours. Patients in the control group undergo metabolic and immunologic tests but do not receive monoclonal antibodies and are not hospitalized. Patients are monitored throughout the study for immunosuppressive effects of the anti-human CD3 monoclonal antibody hOKT3γl(ala-ala).

[0293] Residual β-cell function will be analyzed according to the changes of the C-peptide levels as measured by radioimmunoassay. After drawing samples for baseline C-peptide and glucose, the patients are given a mixed meal. The C-peptide levels are measured in samples drawn after 15, 30, 60, 90, 120, 150, 180, 210, and 240 min. The C-peptide response to the mixed-meal tolerance test (MMTT) is expressed as the total area under the response curve (AUC). A change in the response is considered to have occurred if the response differs by more than 7.5 percent from the response at study entry. The patients' C-peptide responses to MMTT are continuously monitored 6 months, 9 months, 12 months, 15 months and 18 months after the treatment. Alternatively, the β-cell function is assessed by FPIR to IGTT. Serum insulin levels are measured by a modification of a double-antibody radioimmunoassay method using moniodinated tyrosine A14-labeled insulin (Amersham Pharmacia). FPIR is calculated as the sum of insulin levels at 1 and 3 minutes after a glucose load (0.5 g/kg). Glycosylated hemoglobin levels are measured by latex-agglutination inhibition test.

[0294] Immunological Monitoring: The level of autoantibodies against GAD65, IA2/ICA512, and insulin are measured with radiobinding assays as known in the art (e.g., Woo et al, 2000, J. Immunol Methods 244:91-103). HLA-DQA and HLA-DQB genotyping are performed by direct sequencing of exon 2 polymorphisms after PCR amplification. The level of cytokines in serum after the administration of the monoclonal antibody is measured by enzyme-linked immunosorbent assay (ELISA). Production of anti-idotype antibodies is monitored by ELISA assay using a plate bound hOKT3γl(ala-ala) or by flow cytometry to measure blockade of binding of hOKT3γl(ala-ala)-FITC to CD3.

[0295] Statistical Analysis: Data analysis will be conducted on residual beta-cell function, autoantibody level, cytokine level, and glycosylated hemoglobin level. A χ² analysis will be performed to test the effect of drug treatment before and after drug administration. Comparison between the control group and the treatment group will be made with the Mann-Whitney U test.
6.3 **Anti-CD3 Monoclonal Antibody Therapy in Subjects Predisposed to LADA**

**[0296]** Patients: Screening for subjects with predisposition for developing LADA is based on first or second degree relationship with a diagnosed Type-1 diabetic; an impaired fasting glucose level; an impaired glucose response to OGTT; the presence of serum autoantibodies against GAD65, against IA2/ICA512, and/or against insulin; or impaired insulin production after MMTT, OGTT, IGTT or two phase glucose clamp procedure as determined by C-peptide response or FPIR. Patients who have been diagnosed with type 1 diabetes according to the criteria established by the American Diabetes Association by a physician, or who otherwise meet said criteria, are excluded from this study.

**[0297]** Patients selected for the study are randomly placed into two equal-sized groups. Treatment protocols and clinical monitoring are as described in section 6.1. Patients are monitored for 18 months after the treatment. β-cell function is determined every 6 months in the case of impaired glucose tolerance and every 12 months in case of normal glucose tolerance. Patients are allowed to have a normal diet, and remain under the care of their personal physician throughout the duration of the study. Immunological assays are repeated in intervals of 6 months. Insulin therapy will be given to the patients as directed by their personal physician.

7. **EQUIVALENTS**

**[0298]** Those skilled in the art will recognize, or be able to ascertain using no more than routine experimentation, many equivalents to the specific embodiments of the invention described herein. Such equivalents are intended to be encompassed by the following claims.

**[0299]** All publications, patents and patent applications mentioned in this specification are herein incorporated by reference into the specification to the same extent as if each individual publication, patent or patent application was specifically and individually indicated to be incorporated herein by reference.
WHAT IS CLAIMED:

1. A method of preventing or delaying the onset of Latent Autoimmune Diabetes in Adults (LADA) in a patient predisposed to developing an autoimmune disorder, said method comprising administering to said patient a therapeutically effective amount of an anti-human CD3 antibody.

2. A method of preventing the progression of Latent Autoimmune Diabetes in Adults (LADA) in a patient diagnosed with LADA, said method comprising administering to said patient a therapeutically effective amount of an anti-human CD3 antibody.

3. A method of treating Latent Autoimmune Diabetes in Adults (LADA) or ameliorating the symptoms thereof in a patient suffering therefrom, said method comprising administering to said patient a therapeutically effective amount of an anti-human CD3 antibody.

4. A method of preventing or delaying insulin requirement in a patient diagnosed with Latent Autoimmune Diabetes in Adults (LADA), said method comprising administering to said patient a therapeutically effective amount of an anti-human CD3 antibody.

5. A method of treating or preventing Adult Onset Type 1 Diabetes or ameliorating the symptoms thereof in a patient suffering therefrom, said method comprising administering to said patient a therapeutically effective amount of an anti-human CD3 antibody.

6. The method of claim 1, wherein said patient has a first or second degree relative who is diagnosed with an autoimmune disorder.

7. The method of claim 1, wherein said patient has an autoimmune disorder other than LADA.

8. The method of claim 6 or 7, wherein the autoimmune disorder is selected from the group consisting of thyroid disease, type 1 diabetes, rheumatoid arthritis, systemic lupus, erythematous, multiple endocrine adenopathy, and celiac disease.

9. The method of claim 6 or 7, wherein the autoimmune disorder is a DR3- and/or DR4- related autoimmune disease.

10. The method of claim 2, 3, 4, or 5 wherein Islet Cell antibodies (ICAs), GAD antibodies (GADA), IA-2 antibodies, or insulin antibodies are detectable by radioassay or ELISA in the serum of said patient.

11. The method of claim 2, 3, 4, or 5, wherein the patient has one or more acute symptoms selected from the group consisting of polydipsia, polyuria, and weight loss.
12. The method of claim 2, 3, or 4, wherein the patient is not insulin dependent for at least 6 months after diagnosis of diabetes.
13. The method of claim 2, 3, or 4, wherein the patient is not insulin dependent for at least 2 years after diagnosis of diabetes.
14. The method of claim 2 or 3, wherein the patient is initially diagnosed as having type 2 diabetes and develops insulin dependency more than 6 months after diagnosis.
15. The method of claim 2 or 3, wherein the patient is initially diagnosed as having type 2 diabetes and develops insulin dependency more than 2 years after diagnosis.
16. The method of claim 2, 3, 4, or 5 wherein the patient is predisposed to developing an autoimmune disorder.
17. The method of claim 16, wherein said patient has a first or second degree relative who is diagnosed with an autoimmune disorder.
18. The method of claim 16, wherein said patient has an autoimmune disorder other than LADA.
19. The method of claim 17 or 18, wherein the autoimmune disorder is selected from the group consisting of thyroid disease, type 1 diabetes, rheumatoid arthritis, systemic lupus, erythematous, multiple endocrine adenopathy, and celiac disease.
20. The method of claim 17 or 18, wherein the autoimmune disorder is a DR3- and/or DR4-related autoimmune disease.
21. The method of claim 1, 2, 3, 4, or 5 wherein the patient is not obese.
22. The method of claim 1, 2, 3, 4, or 5 wherein the patient is 25 years old or older.
23. The method of claim 3, wherein the patient is in early stages of LADA.
24. The method of claim 1, 2, 3, 4, or 5, wherein the anti-human CD3 antibody has at least 50% reduced binding to each FcγR than an antibody with a wild type Fc domain.
25. The method of claim 24, wherein said method results in a reduction of cytokine release compared to administration of OKT3.
26. The method of claim 1, 2, 3, 4, or 5 wherein said antibody does not detectably bind to any FcγR.
27. The method of claim 1, 2, 3, 4, or 5, wherein said antibody has at least 50% reduced binding to CIq.
28. The method of claim 1, 2, 3, 4, or 5, wherein said antibody does not detectably bind to any complement related receptors.
29. The method of claim 1, 2, 3, 4, or 5, wherein said antibody does not detectably bind to CIq.
30. The method of claim 1, 2, 3, 4, or 5, wherein six months after said administration, said patient requires no increase in adjunctive therapy to manage the LADA.

31. The method of claim 1, 2, 3, 4, or 5, wherein said anti-human CD3 antibody is chimeric or humanized.

32. The method of claim 1, 2, 3, 4, or 5, wherein said antibody is a humanized or chimerized version of OKT3, Leu-4, 500A2, CLB-T3/3, M291, YTH 12.5 or BMA030.

33. The method claim 1, 2, 3, 4, or 5, wherein said antibody is aglycosylated.

34. The method claim 1, 2, 3, 4, or 5, wherein said antibody has an Fc domain having an amino acid modification, wherein said modified Fc domain does not bind any FcγR.

35. The method of claim 32, wherein said antibody is humanized OKT3γ1 ala-ala.

36. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in less than 10% reduction of β-cell mass six months after said treatment.

37. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in less than 25% reduction of β-cell mass six months after said treatment.

38. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in less than 50% reduction of β-cell mass six months after said treatment.

39. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in less than 75% reduction of β-cell mass six months after said treatment.

40. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in an increase in the average daily dose of insulin of no more than 1 U/kg/day six months after said treatment.

41. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in an increase in the average daily dose of insulin of no more than 0.5 U/kg/day six months after said treatment.

42. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in no increase in the average daily dose of insulin six months after said treatment.

43. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in an average daily dose of insulin of no more than 0.5 U/kg/day six months after said treatment.

44. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in an average daily dose of insulin of no more than 0.2 U/kg/day six months after said treatment.

45. The method of claim 1, 2, 3, 4, or 5, wherein said patient does not require administration of insulin at least 1 year after said treatment.

46. The method of claim 1, 2, 3, 4, or 5, wherein said patient does not require administration of insulin at least 2 years after said treatment.
47. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in a HAIc of less than 7.5% one year after said treatment.

48. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in a HAIc of less than 7.5% two years after said treatment.

49. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in a HAIc of less than 6.8% one year after said treatment.

50. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results in a HAIc of less than 6.8% two years after said treatment.

51. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results a C-peptide response to MMTT twelve months after said treatment that is at least 90% of the C-peptide response to MMTT in said patient before said treatment.

52. The method of claim 1, 2, 3, 4, or 5, wherein said treatment results a C-peptide response to MMTT twelve months after said treatment that is at least 95% of the C-peptide response to MMTT in said patient before said treatment.

53. The method of claim 45, wherein said treatment results in a HAIc of less than 7.5% one year after said treatment.

54. The method of claim 45, wherein said treatment results in a HAIc of less than 7.5% two years after said treatment.

55. The method of claim 45, wherein said treatment results in a HAIc of less than 7.5% one year after said treatment.

56. The method of claim 45, wherein said treatment results in a HAIc of less than 7.5% two years after said treatment.

57. The method of claim 45, wherein said treatment results a C-peptide response to MMTT twelve months after said treatment that is at least 90% of the C-peptide response to MMTT in said patient before said treatment.

58. The method of claim 45, wherein said treatment results a C-peptide response to MMTT twelve months after said treatment that is at least 95% of the C-peptide response to MMTT in said patient before said treatment.

59. The method of claim 1, 2, 3, 4, or 5, wherein said treatment comprises administration of doses of said antibody on at least 4 consecutive days.

60. The method of claim 1, 2, 3, 4, or 5, wherein said treatment comprises administration of doses of said antibody on at least 6 consecutive days.

61. The method of claim 1, 2, 3, 4, or 5, wherein said treatment comprises administration of doses of said antibody on no more than 21 consecutive days.
62. The method of claim 1, 2, 3, 4, or 5, wherein said treatment comprises administration of doses of said antibody on no more than 14 consecutive days.
63. The method of claim 1, 2, 3, 4, or 5, wherein said treatment comprises administration of doses of said antibody on no more than 8 consecutive days.
64. The method of claim 1, 2, 3, 4, or 5, wherein said antibody is administered intramuscularly or subcutaneously.
65. The method of claim 64, wherein said dosage regimen is 8 days or less.
66. The method of claim 64, wherein said dosage regimen is 10 days or less.
67. The method of claim 64, wherein said dosage regimen is 12 days or less.
68. The method of claim 64, wherein said dosage regimen is 14 days or less.
69. The method of claim 64, wherein said dosage regimen is 18 days or less.
70. The method of claim 64, wherein said dosage regimen is 21 days or less.
71. The method of claim 64, wherein the dose on day 1 is approximately 51 µg/m², the dose on day 2 is approximately 103 µg/m², the dose on day 3 is approximately 207 µg/m², the dose on day 4 is approximately 413 µg/m², and the dose on subsequent days is approximately 826 µg/m².
72. The method of claim 71, wherein said dosage regimen is 8 days or less.
73. The method of claim 71, wherein said dosage regimen is 10 days or less.
74. The method of claim 71, wherein said dosage regimen is 12 days or less.
75. The method of claim 71, wherein said dosage regimen is 14 days or less.
76. The method of claim 71, wherein said dosage regimen is 18 days or less.
77. The method of claim 71, wherein said dosage regimen is 21 days or less.
78. The method of claim 64, wherein the dose on day 1 is approximately 17 µg/m², the dose on day 2 is approximately 34.3 µg/m², the dose on day 3 is approximately 69 µg/m², the dose on day 4 is approximately 137 µg/m², and the dose on subsequent days is approximately 275 µg/m².
79. The method of claim 1, 2, 3, 4, or 5, wherein said antibody is administered intravenously.
80. The method of claim 79, wherein said antibody is administered over a period of at least 30 minutes.
81. The method of claim 1, 2, 3, 4, or 5, wherein said antibody is administered intramuscularly or subcutaneously.
82. The method of claim 1, 2, 3, 4, or 5, in which said administration is in combination with administration of insulin.

83. The method of claim 1, 2, 3, 4, or 5, in which said administration is in combination with administration of an immunosuppressant.

84. The method of claim 1, 2, 3, 4, or 5, in which said administration is in combination with administration with exenatide.

85. The method of claim 1, 2, 3, 4, or 5, in which said administration is in combination with administration with pramlintide.

86. The method of claim 1, 2, 3, 4, or 5, in which said administration does not result in EBV-induced lymphoproliferative diseases or lymphocyte counts less than 1000 lymphocytes/µl serum.
