(54) Title: PHASE-LOCKED LOOP WITH CONTINUOUSLY ADJUSTABLE BANDWIDTH

**(57) Abstract**

A continuously adjusted bandwidth phase-locked loop is used by a B-CDMA™ receiver to correct for any deviation, or offset, that may exist between the received radio frequency (RF) carrier signal and the frequency of the first stage LO that converts the received RF carrier signal to an intermediate frequency (IF). The PLL in the receiver includes a filter with an adjustable bandwidth. A wider bandwidth is used during initial acquisition of the received signal. After the PLL has acquired the received carrier signal using the wider bandwidth, the bandwidth of the filter is gradually narrowed to provide a low steady-state error.

PHASE-LOCKED LOOP WITH CONTINUOUSLY ADJUSTABLE BANDWIDTH

BACKGROUND OF THE INVENTION

Field of the Invention

This invention is generally directed to wireless digital communication systems. More particularly, the invention is directed to a code division multiple access (CDMA) receiver having a continuously adjustable bandwidth phase-locked loop for accurately determining the carrier frequency of a received signal.

Description of Related Art

Over the last decade consumers have become accustomed to the convenience of wireless communication systems. This has resulted in a tremendous increase in the demand for wireless telephones, wireless data transmission and wireless access to the World Wide Web. Since the amount of available RF spectrum is fixed, the need to utilize the RF spectrum more efficiently has become paramount. CDMA communication systems have shown promise in the effort to provide more efficient utilization of the RF spectrum, particularly Broadband Code Division Multiple Access™ or (B-CDMA™) communication systems. B-CDMA™ communication systems permit many communications to be transmitted over the same bandwidth, thereby greatly increasing the capacity of the RF spectrum. In a B-CDMA™ communication system, an information signal at the transmitter is mixed with a pseudorandom "spreading code" which spreads the information signal across the entire communicating bandwidth. The spread signal is upconverted to an RF signal for transmission. A receiver, having the same pseudorandom

-2-

spreading code, receives the transmitted RF signal and mixes the received signal with an RF sinusoidal signal generated at the receiver by a first-stage local oscillator (LO) to downconvert the spread spectrum signal. The spreaded
5 information signal is subsequently mixed with the pseudorandom spreading code, which has also been locally generated, to obtain the original information signal.

In order to detect the information embedded in a received signal, a receiver must know the exact pseudorandom spreading
10 code that was used to spread the signal. All signals which are not encoded with the pseudorandom code of the receiver appear as background noise to the receiver. Accordingly, as the number of users that are communicating within the operating range of a particular base station increases, the
15 amount of background noise also increases, making it difficult for receivers to properly detect and receive signals. The transmitter may increase the power of the transmitted signal, but this will increase the noise as seen by other receivers. Therefore, increasing the signal-to-noise ratio of a received
20 signal without requiring a corresponding increase in the transmission power of the signal is desirable.

One way to increase the signal-to-noise ratio of a received signal is to ensure that the first stage local oscillator (LO) at the receiver is at the same frequency as
25 the received RF carrier signal. If there is a slight frequency offset, the offset will manifest itself in the baseband section of the receiver as a phase error on the

-3-

decoded QPSK symbol, resulting in a degradation of the quality of the communication.

Accordingly, it is critical to properly detect the frequency of the received RF carrier signal in order to optimize the quality of the received signal.

SUMMARY OF THE INVENTION

The continuously adjusted-bandwidth phase-locked loop (PLL) of the present invention is used by a B-CDMA™ receiver to correct for any deviation, or offset, that may exist between the received radio frequency (RF) carrier signal and the frequency of the first stage LO that converts the received RF carrier signal to an intermediate frequency (IF). The PLL in the receiver includes a filter with an adjustable bandwidth. A wider bandwidth is used during initial acquisition of the received signal. After the PLL has acquired the received carrier signal using the wider bandwidth, the bandwidth of the filter is gradually narrowed to provide a low steady-state error. Accordingly, it is an object of the invention to provide an improved CDMA receiver which corrects for any offset that may exist between the received RF carrier signal and the frequency of the first stage LO.

Other objects and advantages will become apparent to those skilled in the art after reading the detailed description of a presently preferred embodiment.

10 **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT**

The preferred embodiment will be described with reference to the drawing figures wherein like numerals represent like elements throughout.

15 A communication network **2** embodying the present invention is shown in **Figure 1**. The communication network **2** generally comprises one or more base stations **4**, each of which is in wireless communication with a plurality of subscriber units **6**, which may be fixed or mobile. Each subscriber unit **6** communicates with either the closest base station **4** or the
20 base station **4** which provides the strongest communication signal. The base stations **4** also communicate with a base station controller **8**, which coordinates communications among base stations **4**. The communication network **2** may also be
25 connected to a public switched telephone network (PSTN) **9**, wherein the base station controller **8** also coordinates communications between the base stations **4** and the PSTN **9**. Preferably, each base station **4** communicates with the base station controller **10** over a wireless link, although a land

-6-

line may also be provided. A land line is particularly applicable when a base station 4 is in close proximity to the base station controller 8.

The base station controller 8 performs several functions. Primarily, the base station controller 8 provides all of the operations, administrative and maintenance (OA&M) signaling associated with establishing and maintaining all of the wireless communications between the subscriber units 6, the base stations 4, and the base station controller 8. The base station controller 8 also provides an interface between the wireless communication system 2 and the PSTN 9. This interface includes multiplexing and demultiplexing of the communication signals that enter and leave the system 2 via the base station controller 8. Although the wireless communication system 2 is shown employing antennas to transmit RF signals, one skilled in the art should recognize that communications may be accomplished via microwave or satellite uplinks. Additionally, the functions of the base station controller 8 may be combined with a base station 4 to form a "master base station".

Referring to **Figure 2**, the propagation of signals between a base station 4 and a plurality of subscriber units 6 is shown. A two-way communication channel 11 comprises a signal transmitted 13 (Tx) from the base station 4 to the subscriber unit 6 and a signal received 15 (Rx) by the base station 4 from the subscriber unit 6. The signaling between the base station 4 and the subscriber units 6 includes the transmission of a pilot signal 17. The pilot signal 17 is a spreading code

-7-

which carries no data bits. The pilot signal 17 is used for subscriber unit 6 acquisition and synchronization, as well as for determining the parameters of the adaptive matched filter used in the data receiver.

5 The subscriber unit 6 must acquire the pilot signal 17 transmitted by the base station 4 before it can receive or transmit any data. Acquisition is the process whereby the subscriber unit 6 aligns its locally generated spreading code with the received pilot signal 17. The subscriber unit 6
10 searches through all of the possible phases of the received pilot signal 17 until it detects the correct phase, (the beginning of the pilot signal 17).

 The PLL 10 in accordance with the present invention acts upon the transmitted pilot signal 17, which is an auxiliary
15 signal transmitted from the base station 4 to all subscriber units 6 and from subscriber units 6 to the base station 4 which is not used as a traffic channel to transmit any voice or data information. With respect to the subscriber units 6, the signal 17 is used: 1) to provide synchronization of the
20 locally generated pseudorandom code with the transmitted pseudorandom code; and 2) as a transmission power reference during initial power ramp-up of the subscriber unit 6. With respect to the base station 4, the pilot signal 17 is utilized to provide synchronization of the locally generated
25 pseudorandom code with the transmitted pseudorandom code. In accordance with the present invention, the pilot signal 17 is additionally used in both the base station 4 and the subscriber unit 6 to determine the difference between the

-8-

frequency of the received RF carrier signal and the first stage LO that downconverts the received RF carrier signal to IF.

5 The CDMA pilot signal 17 is a sequence of pseudorandom complex numbers which are modulated by a constant complex pilot value having a magnitude of one and phase of zero. The advantage of using the pilot signal 17 is that the transmitted despread value is known to the subscriber unit 6. This can be used by the PLL 10 in the subscriber unit 6 to estimate and
10 correct for phase error due to RF carrier signal offset.

The difference in the frequency of the received RF carrier signal and the first stage LO can be generally attributed to two sources: 1) component mismatches; and 2) RF distortion. Component mismatches between the transmitter
15 oscillator 4 and the receiver oscillator 6 may cause slightly different oscillator outputs. These component mismatches can be further exacerbated by local environmental conditions, such as the heating or cooling of electronic components, which may cause performance changes in the components. With respect to
20 RF distortion, doppler effects caused by the motion of the subscriber unit 6, the base station 4 or a multipath reflector may cause the RF carrier to become distorted during transmission. This may result in a RF carrier offset.

Referring to **Figure 3**, the PLL 10 is implemented in a
25 programmable digital signal processor within the digital receiver section 20 to provide flexibility in system architecture. The pilot signal 17 is received via the antenna 60 and is processed by the analog receiver section 61, which

-9-

includes an RF downconverter 63 and an analog-to-digital section 65. The downconverted and digitized pilot signal 17 is then processed by the digital receiver section 20 which includes a pilot rake receiver 40, the PLL 10, and a data receiver 42. The pilot signal 17 enters the rake receiver 40 for despreading. The PLL monitors the output from the pilot rake receiver 40, which comprises the despread pilot signal 30, to estimate and correct for a phase error due to RF carrier offset, thereby providing acceptable speech quality. The pilot rake receiver 40 operates on the pilot signal 17 to build a receiver filter. The receiver filter compensates for channel distortion due to multipath effects. The filter parameters 45 are forwarded from the pilot rake receiver 40 to the data receiver 42 which constructs the receiver filter in accordance with those parameters 45. Accordingly, when a data signal enters the data receiver 42, the data receiver 42 is able to compensate for channel distortion due to multipath effects and output a more accurate information signal 44.

The rake receiver 40 is shown in greater detail in **Figure 4**. The rake receiver 40 provides an estimate of the complex impulse response, having real and imaginary components, of the channel over which the pilot signal 17 is transmitted. The rake receiver 40 has a plurality of independent rake elements 80.1, 80.2, 80.i, wherein the input to each rake element 80.1, 80.2, 80.i is a delayed and despread replica 100 of the received pilot signal 17. The amount of delay 84 between adjacent rake elements 80.1, 80.2, 80.i is one chip. The delayed replicas 100 of the pilot signal 17 are created

-10-

without delay lines by using a mixer 88, 90, 92 to correlate the received pilot signal 17 with the locally generated pilot pseudonoise code 86, offset by the appropriate amount of chips 84.

5 Each rake element 80.1, 80.2, 80.i performs an open loop estimation of the value of the impulse response of the RF channel, which can be represented as $h(t)$, at the point $t = T \cdot i$, where T is the length of a chip. Thus, the rake receiver 40 produces N noisy estimates of the sampled impulse response
10 of the channel of the received pilot signal 17, at evenly spaced intervals, where N is the number of rake elements 80.1, 80.2, 80.i. The low pass filter on each rake element 80.1, 80.2, 80.i smooths each corresponding sample impulse response estimate. The complex conjugates of each smoothed sampled
15 impulse response estimate are used as the weights on the channel-matching filter. This serves to remove the signal distortion from the received pilot signal 17 and data signals 46 that occur due to multipath effects in the channel.

20 The pilot rake receiver 40 and the PLL 10 operate in conjunction with one another in the receiver section 20. In order for the PLL 10 to perform optimally, it requires a despread pilot signal 30 with the distortion effects due to multipath removed. This is accomplished by the adaptive matched filter obtained from using the channel-impulse-
25 response estimate provided by the pilot rake receiver 40. The pilot rake receiver 40 and the data receiver 42 cannot operate effectively unless the received pilot signal 17 and the data signals 16 have been corrected for phase error due to RF

-11-

carrier signal offset. The phase error correction signal 50 is provided by the PLL 10 to the pilot rake receiver 40 and data receiver 42. Optimal performance of the receiver 20 will not occur until the pilot rake receiver 40 and the PLL 10 have reached a mutually satisfactory equilibrium point. The operation of the data receiver 42 is well known to those of skill in the art.

Referring to **Figure 5**, the continuously adjusted-bandwidth PLL 10 in accordance with the present invention is shown. The PLL 10 comprises a mixer 110, a normalizing unit 112, an arctangent analyzer 114, a PLL filter 116, a voltage controlled oscillator (VCO) 118, and a bandwidth control section 120. The mixer 110 receives its input from the pilot rake receiver 40. The signal output from the rake receiver 40 is the despread pilot signal 30 which has been processed to correct channel distortion due to multipath effects. This signal 30 is mixed with a "correction signal" 50 to produce a complex error signal 122. In accordance with the present invention, the bandwidth of the PLL filter 116 is adjusted by the bandwidth control section 120 to provide a revised correction signal 50 to the mixer 110, the rake receiver 40, and the data receiver 42. This process is repeated until the complex error signal 122 output from the mixer 122 is at a minimum. It is desired to have the complex error signal 122 as small as possible; ideally it should be zero.

The despread pilot signal 17 is a known complex number that has zero phase. This complex number can be represented in two forms as shown in **Figure 6**: 1) Cartesian form; and 2)

-12-

polar form. In Cartesian form, the real part is referred to as the in-phase component, (I-component), and the imaginary part is referred to as the quadrature component, (Q-component). The polar form includes a magnitude (m) and a phase angle (ϕ). To convert from Cartesian to polar form, the following equations are used:

$$\phi = \tan^{-1}(Q/I) \quad \text{Equation (1)}$$

$$m = \sqrt{I^2 + Q^2} \quad \text{Equation (2)}$$

Referring back to **Figure 5**, the complex error signal **122** is processed by the normalizing unit **112**, which will be described in greater detail hereinafter. The normalized signal **124** is then input into the arctangent analyzer **114**. The arctangent analyzer **114** analyzes the normalized signal **124**, which is in Cartesian coordinate form, using an 8I-by-8Q arctangent processor to determine the phase ϕ of the complex number. The arctangent analyzer **114** uses the Cartesian I and Q components which are mapped to provide the phase ϕ of the complex number. Although this function may be implemented in real time using a microprocessor with associated memory, it would require a high-speed processor and a large amount of memory to accurately calculate.

Equations 1 and 2 are implemented using a lookup table **150** when finite resolution is acceptable. For example, if the I component is expected to be an integer between -10 and 10, and the Q component is expected to be an integer between -10 and 10, then the lookup table **150** shown in **Figure 7** may be

-13-

implemented. The phase ϕ for any I and Q component pair may be obtained from the lookup table 150. For example, if I=8.8 and Q=10.1, the values would first be quantized into the integers I=9 and Q=10, resulting in a phase value ϕ_{20} from the lookup table 150. The arctangent analyzer 114 is preferably implemented with a lookup table 152 having eight I bins and eight Q bins, covering a range of possible I and Q values between 1.4 and +1.4, as shown in Figure 8. For example, if I=-0.8 and Q=0.9, the lookup table 152 will return a phase value of ϕ_{55} .

The size and complexity of lookup table 152 implemented within the arctangent analyzer 114 grows as the range of the values input into the arctangent analyzer 114 increases. Thus, if a wide range of values is permitted to be input into the arctangent analyzer 114, the arctangent function increases in complexity and the lookup table 152 dramatically increases in size. Accordingly, in order to keep the implementation as simple as possible, the complex error signal 122 is normalized by the normalizing unit 112 prior to being input into the arctangent analyzer 114. The normalizing unit 112 receives the complex error signal 122 from the mixer 110 and performs a "pseudonormalization" by dividing by the complex error signal 122 by the component, (I or Q), having the larger magnitude. Thus, the magnitude of the number output to the arctangent analyzer 114 will be between 1.0 and 1.414.

Alternatively, true normalization is performed, in which the normalizing unit 112 determines the magnitude of the complex error signal 122, then divides the error signal 122

-14-

by the magnitude. The signal **124** output from the normalizing unit **112** would be complex number with a magnitude of 1 and a phase angle which must be determined by the arctangent analyzer **114**. Although pseudonormalizing the complex error signal **122** is not as optimal as normalization, pseudonormalization requires much less processing power and may be preferred in certain implementations where processing power is at a premium.

Since pseudonormalizing results in a complex number having I and Q component values of between 1.0 and 1.414, performing a pseudonormalization on the complex error signal **122** causes the resulting signal **124** to fall within a smaller input range of the domain of the lookup table **152**. Moreover, by quantizing the I and Q components into 8 bins each, the size of the lookup table **152** is limited to 64 bins, with resolution that is sufficient for the desired PLL performance.

The output from the arctangent analyzer **114** is a quantized phase angle of the complex error signal **122**. Since the pilot signal **17** is transmitted with zero phase angle, it is desired to adjust the quantized phase error signal **126** to have an angle of zero degrees, (a phase of zero). The bandwidth control section **120** continually monitors the quantized phase error signal **126** and generates a control signal **130** to control the bandwidth of the PLL filter **116** based on the quantized phase error signal **126**. As will be explained in detail hereinafter, as the quantized phase error signal **126** approaches zero, the bandwidth of the PLL filter **116** decreases.

-15-

Referring back to **Figure 5**, the quantized phase error signal 126 is provided to two sections of the PLL 10: 1) the PLL filter 116; and 2) the bandwidth control section 120. With respect to the PLL filter 116, the bandwidth of the PLL filter 116 is continuously adjustable. The PLL filter 116 has a wider bandwidth when the quantized phase error signal 126 is large, and a narrow bandwidth when the quantized phase error signal 126 is small. The bandwidth of the PLL filter 116 is selectively and continuously controlled by the bandwidth control section 120 to provide a small steady-state PLL error.

As the bandwidth of the PLL filter 116 is narrowed, the high frequency components of the quantized phase error signal 126 are filtered out. Thus, by eliminating high frequency components, rapid variations in the quantized phase error signal 126 are eliminated and the output signal is smoothed. However, since a filter with a small bandwidth does not have the ability to track rapid variations in an input signal, filters with wide bandwidths are generally used for initial tracking and locking onto a signal.

Referring to **Figure 9**, the PLL filter 116 comprises a lag filter 140 and a lead filter 142. The lag filter 140 receives two inputs: 1) the bandwidth control signal 130 from the bandwidth control section 120; and 2) the quantized phase error signal 126 output from the arctangent analyzer 114. The lag filter 140 has a Laplace transformation of

Equation (3)

$$H(s) = a + b/s \quad ,$$

-16-

where s is the complex number that is used as the kernel for the Laplace transform:

$$H(s) = \int_0^{\infty} h(t) e^{-st} dt \quad , \quad \text{Equation (4)}$$

and the coefficients a and b are both functions of the bandwidth (BW) as follows:

$$a = 2\sqrt{2}\pi \cdot BW \quad , \quad \text{Equation (5)}$$

$$b = (2\pi \cdot BW)^2 \quad . \quad \text{Equation (6)}$$

The lag filter 140 interrogates the quantized phase error signal 126 and generates an estimate of the RF carrier offset 144. The RF carrier offset 144 is input into the lead filter 142 which integrates the RF carrier offset 144 to determine an error voltage 128 corresponding to the phase error.

The output of the PLL filter 116, which is input into the VCO 118, is the error voltage 128. In response to the error voltage 128, the VCO 118 outputs a corresponding correction signal 50 to the mixer 110, the pilot rake receiver 40 and the data receiver 42.

The bandwidth control section 120 will be explained in further detail with reference to **Figure 10**. The bandwidth control section 120 estimates the variance of the quantized phase error signal 126 and converts this into a dynamic bandwidth.

-17-

The bandwidth control section 120 comprises four processing units: a squaring unit 160, a (leaky) integrator unit 162, a bandwidth calculation unit 164 and a sample/hold unit 168. The squaring unit 160 squares the quantized phase error signal 126. The integrator 162, which is a first order low-pass filter, then integrates and smooths the squared signal 170. The squaring unit 160 and the integrator 172 act together to estimate the standard deviation (squared), or variance, 172 of the quantized phase error signal 126. This value 172 is then input into the bandwidth calculation unit 164.

The bandwidth calculation unit 164 determines the desired bandwidth of the PLL filter 116 based upon the input value 172. The operation of the bandwidth calculation unit 164 will be explained in detail with reference to **Figure 11**. As shown, the bandwidth calculation unit 164 utilizes a select transfer function 180 to correlate the input signal 172 to a desired output bandwidth 174. The transfer function is defined by four parameters: 1) BW_{HI} - the widest bandwidth value; 2) BW_{LO} - the narrowest bandwidth; 3) γ_{HI} - the highest value of the variance of the quantized phase error; and 4) γ_{LO} - the lowest value of the variance of the quantized phase error. BW_{HI} is selected to produce the shortest initial lock-on time; typically 1000 Hz. The wider the bandwidth, the faster the initial lock-on period. However, if the bandwidth is too high, lock-on will never occur since the filter will attempt to track the noise. BW_{LO} is selected to provide the required PLL steady state error. Typically, 100 Hz provides 5 degree

-18-

steady state error, which is acceptable for the present invention. γ_{HI} and γ_{LO} depend upon the input signal-to-noise ratio and the particular architecture and application. An initial estimate for γ_{LO} typically is obtained by operating the PLL 10 in an "ideal" mode (the PLL produces a perfect correction for each sample). An initial estimate for γ_{HI} is typically obtained by operating the PLL in the "worst case" mode (the PLL produces a random correction for each sample).

Preferably, the transfer function 180 comprises a linear portion 182 which correlates the input value 172 with the desired output bandwidth 174. It is preferable to limit the linear portion 182 of the transfer function 180 to a range of phase error input values 172 and bandwidth output values 174 in order to simplify the operation of the transfer function unit 164. For example, when the phase error input value 172 is A, the transfer function 180 will provide a desired bandwidth output 174 of B. The bandwidth calculation unit 164 may be implemented by a microprocessor which would dynamically calculate the bandwidth. Additionally, the microprocessor may be dynamically updated with different transfer functions depending upon the conditions of the system and the RF channel.

The bandwidth calculation unit 164 outputs the new bandwidth of the PLL filter 116. This bandwidth 174 is input into the sample/hold unit 168, which samples the bandwidth 174 and outputs a sampled bandwidth 130 to the PLL filter 116 every N symbols, where N is a predetermined number. A small value of N will provide better performance at the expense of

-19-

increased processing. In the preferred embodiment, $N = 8$. The sampled bandwidth 130 from the sample/hold unit 168 is input to the PLL filter 116.

As shown in the simulation results in **Figures 12A-D**, the use of a continuously adjustable PLL 10 greatly improves the performance of the receiver 20. All four plots present data from the same simulation run. **Figure 12A** shows the carrier offset frequency estimate (in Hertz) provided by the output of the lag filter 144 as a function of time in seconds. At approximately 0.01 seconds, the average of the frequency estimate quickly reaches the true value of 7000Hz, but since the bandwidth is wide, the estimate is still noisy. As the bandwidth begins to narrow, the frequency estimate becomes less noisy. At 0.02 seconds, the bandwidth has narrowed significantly, and there is very little noise in the frequency estimate.

Figure 12B shows the phase correction (in degrees) provided by the output of the lead filter 142 as a function of time (in seconds). This correction varies widely until initial lock-on of the PLL 10 at 0.01 seconds. Since the bandwidth is still wide at this point, the correction varies. As the bandwidth is narrowed, the variation in the correction is reduced. At 0.02 seconds, the bandwidth has narrowed significantly and the variation is minimized.

Figure 12C shows the bandwidth control signal (in Radians²) as a function of time (in seconds), which is a measure of the variance of the phase error. After initial lock-on of the PLL 10, the variance begins to decrease which,

-20-

in turn, causes the dynamic bandwidth to narrow (see **Figure 12D**). The variance continues to decrease as the PLL 10 improves its ability to estimate phase correction.

Figure 12D shows the dynamic bandwidth (in Hertz) as a function of time (in seconds). The bandwidth is near its maximum of 1000Hz up until initial lock-on of the PLL 10 at around 0.01 seconds. With lock-on, phase error is reduced, causing the bandwidth to begin narrowing. The bandwidth approaches its minimum of 100Hz as the phase error continues to be reduced.

The process for determining the amount of phase error, determining an appropriate PLL 10 bandwidth, adjusting the PLL 10 bandwidth and controlling the VCO 118 to provide an updated correction signal 50 is summarized in **Figure 13**. After the pilot signal 17 has been received (**step 200**) by the pilot rake receiver 40, the pilot signal 17 is despread (**step 200**) and corrected for channel distortion due to multipath reflections (**step 204**). A complex error signal is produced (**step 206**) and the error signal is normalized (**step 208**) prior to quantizing the phase of the error signal (**step 210**). The bandwidth control section 120 estimates the variance of the phase error (**step 214**) and determines the desired PLL bandwidth to produce a correction signal (**step 216**). The PLL filter 116 provides an estimate of the offset of the RF carrier signal and the phase error due to the carrier signal offset (**step 212**) and provides a correction signal (**step 218**) to the pilot rake receiver 40 and the data receiver 42. In this manner, the bandwidth of the PLL filter 116 is continuously adjusted and

-21-

refined as the magnitude of the error signal 126 output from the arctangent analyzer 114 decreases.

Although the invention has been described in part by making detailed reference to certain specific embodiments, such detail is intended to be instructive rather than restrictive. It will be appreciated by those skilled in the art that many variations may be made in the structure and mode of operation without departing from the spirit and scope of the invention as disclosed in the teachings herein. For example, the specific transfer function may be modified depending upon the RF channel to be analyzed and the current conditions of the system. Additionally, analysis of the quantized phase error signal may be performed using a different mathematical analysis while still providing a continuously updated PLL bandwidth signal. The analysis to be performed on the quantized phase error signal is typically a trade off between the amount of processing power required for the computational analysis versus the improvement in performance.

-22-

What is claimed is:

1. A system for receiving CDMA communication signals comprising:

means for receiving a CDMA communication signal transmitted on a selected RF carrier frequency, including
5 means for removing said RF carrier frequency to provide a received information signal;

means for adjusting the phase of said received information signal to correct for phase errors including:

means for generating a correction signal;

10 means for mixing said correction signal with said received information signal to produce a phase corrected information signal;

means for analyzing the phase of the phase corrected information signal and generating a phase error signal based
15 on the deviation of the analyzed phase from a predetermined phase;

means for providing an adjusting signal of a calculated magnitude within a selected range, said providing means being responsive to said phase error signal whereby the
20 phase corrected signal is recursively adjusted by successive analysis of the corrected information signal.

2. The system of claim 1 wherein said phase corrected information signal comprises an in-phase component and a quadrature component and said analyzing means further comprises look-up table means for determining the phase of
5 said phase corrected information signal; wherein said look-up

-23-

table means accepts said phase corrected information signal and outputs said phase error signal.

3. The system of claim 2 wherein said analyzing means further comprises normalizing means which includes:

means for determining the magnitude of the in-phase component and the magnitude of the quadrature-phase component;

5 means for determining the larger of said magnitudes; and

means for dividing both said magnitudes by said larger magnitude to output a pseudonormalized phase corrected information signal.

4. The system of claim 2 wherein said providing means further includes bandwidth calculation means which accepts said phase corrected information signal and outputs a bandwidth signal based upon a preselected transfer function.

5. The system of claim 4 wherein said providing means further includes a filter, having a selectable bandwidth, for maintaining said adjusting signal within said selected range.

6. The system of claim 5 wherein said filter is responsive to said bandwidth signal from said bandwidth calculation means.

7. The system of claim 5 wherein said predetermined phase is zero phase.

-24-

8. The system of claim 3 wherein said providing means further includes bandwidth calculation means which accepts said psuedonormalized phase corrected information signal and outputs a bandwidth signal based upon a preselected transfer function.

9. The system of claim 6 wherein said providing means further includes a voltage controlled oscillator, responsive to said filter means, for generating said adjusting signal.

10. The system of claim 9 wherein said transfer function comprises a continuous linear function.

11. The system of claim 2 wherein said look-up table means comprises a matrix of eight discrete in-phase component values by eight discrete quadrature component values.

12. The system of claim 2 wherein said analyzing means further comprises normalizing means which includes:

means for determining the magnitude of the phase corrected information signal; and

5 means for dividing said phase corrected information signal by said magnitude to output a normalized phase corrected information signal.

13. A method for receiving CDMA communication signals comprising:

-25-

receiving a CDMA communication signal transmitted on a selected RF carrier frequency, including removing said RF carrier frequency to provide a received information signal;

adjusting the phase of said received information signal to correct for phase errors including:

generating a correction signal;

mixing said correction signal with said received information signal to produce a phase corrected information signal;

analyzing the phase of the phase corrected information signal and generating a phase error signal based on the deviation of the analyzed phase from a predetermined phase;

providing an adjusting signal of a calculated magnitude within a selected range, said providing step being responsive to said phase error signal whereby the phase corrected signal is recursively adjusted by successive analysis of the corrected information signal.

14. The method of claim 13 wherein said phase corrected information signal comprises an in-phase component and a quadrature component and said analyzing step further comprises the step of determining the phase of said phase corrected information signal using a look-up table means; wherein said look-up table means accepts said phase corrected information signal and outputs said phase error signal.

-26-

15. The method of claim 14 wherein said analyzing step further comprises a psuedonormalizing step which includes:

determining the magnitude of the in-phase component and the magnitude of the quadrature-phase component;

5 determining the larger of said magnitudes; and

dividing both said magnitudes by said larger magnitude to output a psuedonormalized phase corrected information signal.

16. The method of claim 14 wherein said providing step further includes a bandwidth calculation step for accepting said phase corrected information signal and outputting a bandwidth signal based upon a preselected transfer function.

17. The method of claim 14 wherein said providing step further includes a filtering step, for maintaining said adjusting signal within said selected range, wherein said filtering is performed within a selectable bandwidth.

18. The method of claim 17 wherein said filter step is responsive to said bandwidth calculation step.

19. The method of claim 17 wherein said predetermined phase is zero phase.

20. The method of claim 15 wherein said providing step further includes a bandwidth calculation step for accepting said normalized phase corrected information signal and

-27-

outputting a bandwidth signal based upon a preselected transfer function.

21. The method of claim 14 wherein said analyzing step further comprises a normalizing step which includes:

determining the magnitude of the phase corrected information signal;

5 dividing phase corrected information signal by said magnitude to output a normalized phase corrected information signal.

INTERNATIONAL SEARCH REPORT

Internat Application No

PCT/US 98/04691

A. CLASSIFICATION OF SUBJECT MATTER
IPC 6 H04L27/233 H04B1/707

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

IPC 6 H04L H04B

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practical, search terms used)

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
X	US 4 630 283 A (SCHIFF LEONARD N) 16 December 1986 see abstract see column 3, line 65 - column 4, line 19 see column 8, line 7 - line 30 see column 12, line 31 - column 13, line 54	1, 2, 13, 14

Further documents are listed in the continuation of box C.

Patent family members are listed in annex.

Special categories of cited documents:

- "A" document defining the general state of the art which is not considered to be of particular relevance
- "E" earlier document but published on or after the international filing date
- "L" document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- "O" document referring to an oral disclosure, use, exhibition or other means
- "P" document published prior to the international filing date but later than the priority date claimed

- "T" later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
- "X" document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- "Y" document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.
- "&" document member of the same patent family
