Abstract

The present invention provides a method and apparatus for managing updates to a catalog based on a reference electronic catalog. The reference catalog has a reference format and a plurality of items, each with associated characteristics and the second catalog has a second format and a plurality of items, each with associated characteristics. The reference catalog is maintained with updates and revisions to the items and associated characteristics and the second catalog is maintained by repeating the mapping of at least a portion of the reference catalog into the second catalog after maintaining the reference catalog. Preferably, the maintenance times for both catalogs are recorded and the second catalog is maintained by comparing the recorded times and mapping only portions of the reference catalog that have been maintained into the second catalog.

METHOD AND APPARATUS FOR MANAGING UPDATES TO A CATALOG

FIELD OF THE INVENTION

[0001] This invention relates to electronic databases in general, and more specifically to a method and apparatus for managing updates to an electronic catalog in which a first catalog serves as a reference to the catalog or catalogs that is or are updated.

BACKGROUND OF THE INVENTION

[0002] Searchable electronic catalogs are commonly used in support of electronic commerce and purchasing functions. These electronic catalogs typically are rendered into databases, HTML page collections and other electronic means. Individual purchaser or marketplace system installations benefit by maintaining a single catalog rather than several different catalogs from several different sources. With multiple catalogs, for example, an office supply procurement system may contain office supply catalogs from several different office supply vendors or manufacturers. Some of the catalogs may describe identical items such as a blue pen while each catalog will likely describe similar but different items, such as different makes of blue pens. By combining the catalogs into a single catalog, desired items can be found and compared more quickly and easily than with multiple catalogs.

[0003] Unfortunately, different purchaser and marketplace installations have different specifications for a combined electronic catalog. These specifications arise from differences in languages and measuring, from regional legal requirements, from needs in the particular industry or marketplace or from preferences of the catalog user. Different preferences in categorizing items also create different requirements. In order to satisfy the differing needs of purchasers, marketplaces and suppliers different catalogs in different formats must be provided. The proliferation of different catalogs requires that each different catalog be separately maintained with revisions, updates, new items and restructuring. The present invention allows a single reference catalog to be used to maintain many different catalogs in many different formats. The reference catalog simplifies updates and revisions since all maintenance can be performed on a single catalog. It is consistently updated and maintained and these updates and revisions are then applied to each of the different purchaser, marketplace and supplier catalogs. The updates can include both changes in the structure and organization of the catalog as well as product and service information.

SUMMARY OF THE INVENTION

[0004] In a preferred embodiment, the present invention includes a method and apparatus for managing updates to a catalog based on a reference electronic catalog. The reference catalog has a reference format and a plurality of items, each with associated characteristics and the second catalog has a second format and a plurality of items, each with associated characteristics. The method comprises, maintaining the reference catalog with updates and revisions to the items and associated characteristics, establishing a second catalog format for a second catalog, mapping at least a portion of the reference catalog into the second format to create the second catalog, and maintaining the second catalog by repeating the mapping of at least a portion of the reference catalog into the second catalog after maintaining the reference catalog.

[0005] In a preferred embodiment, the method includes mapping only portions of the reference catalog that have been maintained into the second catalog. In a further preferred embodiment, the method further includes recording the time of each maintenance of the reference catalog and recording the time of each maintenance of the second catalog and maintaining the second catalog includes comparing the recorded times and mapping only portions of the reference catalog that have been maintained into the second catalog. In a further preferred embodiment, the method further includes associating a record with each item of the reference catalog and second catalog, respectively, and maintaining the second catalog includes comparing the recorded times for each item in the second catalog to the recorded times for each corresponding item in the reference catalog and mapping any changes in the reference catalog that occur after the last change in the second catalog to the second catalog.

[0006] Alternatively, in a further preferred embodiment, the invention includes compiling a record of operations performed on the reference catalog and the time that each operation was performed, compiling a record of operations performed on the second catalog and the time that each operation was performed, performing the operations on the second catalog that are performed on the reference catalog and that also have a later time than the last operation performed on the second catalog. An operation preferably includes at least one of updating, revising and reformatting characteristics of an item and adding new items. The catalog characteristics preferably include attributes and categories.

BRIEF DESCRIPTION OF THE DRAWINGS

[0007] The appended claims set forth the features of the invention with particularity. The invention, together with its advantages, may be best understood from the following detailed description taken in conjunction with the accompanying drawings of which:

[0008] FIG. 1 is a block diagram showing components that may be used to implement one embodiment of the present invention;

[0009] FIG. 2 is a flow diagram showing one embodiment of the present invention;

[0010] FIG. 3 is a flow diagram showing a further detail for mapping values of one catalog into another; and

[0011] FIG. 4 is an example of a typical computer system upon which one embodiment of the present invention may be implemented.

DETAILED DESCRIPTION

[0012] The present invention is directed toward maintaining an electronic catalog of items with associated characteristics using a reference electronic catalog in a different format. The catalog constitutes a list of items and an associated description of each item. The catalog can be in the format of a database or any other electronic format, such as a spreadsheet or text. The catalog is created, expanded, updated or maintained based on any such electronic format. The software that operates on the catalog can be written to handle a variety of different formats. The present application will describe the invention in terms of a database catalog.

[0013] In the context of the present invention, the terms catalog and database should not be construed as limited to any particular type of structure but rather in a broader sense as a list or a sequence in which items are accompanied by descrip-
tions. Such a catalog or database can be viewed, for example, as a collection of two-dimensional tables in which each row represents a different item or record and each column represents a different attribute, category or field. In the case of a catalog of office supplies, a record provides the catalog information for a particular office supply item such as a particular pen. Different pens each have a different record. For each record, there are several fields. Each field describes an attribute of the item such as price, color, weight, size, etc. Other fields describe categories for the item such as dry goods, office supplies, writing implements. The present invention analyzes the values that are entered into the fields of the database, whether they are attributes or categories or any other characteristic of an item.

[0014] Table 1 below shows an example of a portion of a table of catalog information for three items in a magazine rack category. In Table 1, each item occupies a different column. The attributes are identified on the left and the attribute values for each item are provided in the respective column.

</table>

[0015] FIG. 1 shows a general structure for implementing the present invention. In a preferred embodiment, a reference catalog is created and maintained which forms the basis for specialized catalogs for many different purchasers, suppliers and marketplaces. The reference catalog is referred to as the Unified Catalog 30 and it contains several tables. The tables include a table of items with associated attributes 32, a table of items with associated categories 34 and a table of changes with associated times 36. While the reference catalog is shown as the Unified Catalog, any catalog may be used as a reference catalog. The Unified Catalog contains a variety of items sufficient to support many different catalogs. For example, the items preferably include office supplies, electronic components, industrial fasteners, and electrical motor system parts, among many others. The attributes for each item describe the item in order to support finding, identifying and purchasing an item and include characteristics such as SKU (stock keeping unit), UPC (universal product code), supplier, part number, price, size, weight, color, material, country of origin and so on. In addition, each part is associated with at least one category. Ballpoint pens would be in a category of Pens, or of office supplies, or of writing instruments or all three, for example. The specific structure of the reference catalog in terms of categories and attributes is not essential to the present invention and many variations on any format is possible.

[0016] In addition, the reference catalog has a specified style set forth in a style guide. The style guide requires, for example that the color black is always spelled out in full and capitalized (“Black”) when used to describe a particular characteristic of an item. A particular purchaser catalog, on the other hand may specify that Black be rendered by “bk.” The particular style selected is not important. It is preferred, however, that a style be specified in order to ease the use of both the reference catalog and the purchaser, supplier or marketplace catalog. The use of different styles in different catalogs complicates maintenance, however, as will be discussed below.

[0017] The reference catalog is maintained almost continuously, with new items, revisions to old items and restructuring. The revisions are required when any characteristic of an item in the catalog changes, such as price or color. New items are added to expand the reference catalog and also to accommodate changes in supply offerings. The restructurings can happen for many reasons. Typically this is required when a group of items in one category are to be moved to another category, but it can also happen when new attributes are to be added to a group of items in exchange for old attributes or when there is a change in the style or format of the reference catalog. All of these changes in the catalog are tracked in the changes table 36. This table preferably has a description of the change and a time and date stamp associated with each item that experienced a change. The description of the change can simply be what was changed, the name of the operation, the former value for the characteristic or item, the affected item and the time of the operation. For example, to record that an item was moved from the “pens” category to the “roller ball” category, the record contains “category, rename, pens, item 1234, 14 23:48, 04:17:2001.” This particular format is presently preferred, however, the records may be kept in a variety of different ways. For this format, to determine what the category was changed to one must refer to the particular item in the category table.

[0018] FIG. 1 also shows a buyer catalog 38 which also includes a table of items with associated attributes 40, a table of items with associated categories 42 and a table of changes with associated times 44. While the second catalog is shown as a buyer catalog, the second catalog may be a supplier catalog, a marketplace catalog, a general purchasing catalog or any other catalog. The attribute and categories tables are similar to the ones described above with respect to the reference catalog except that the attributes and categories may be described differently, and more or fewer attributes and categories may be associated with each item. For example, a purchaser may desire that its catalog include separate internal reference numbers or department numbers for different items. These separate numbers are maintained by the purchaser and not using the reference catalog since the numbers do not occur in the reference catalog. The categories may have different names or may be built into a different hierarchical system, for example, paper may be in an “office supply” category or a “stationery” category or in a “paper goods” category and these categories may be sub-categories or super-categories to other categories, all of which may be different between the reference catalog and the secondary buyer catalog. In addition, the style of the buyer catalog may be different from that
of the reference catalog, so for example, as mentioned above, the color black is always shown as “bk.”

[0019] The changes table 44 of the second catalog is preferably configured in the same way as the changes table 36 of the reference catalog for ease of use but shows only changes to items in the buyer catalog. A comparison between the two changes tables can then quickly determine the operations that were performed in the reference catalog and not in the buyer catalog.

[0020] To accomplish this comparison, FIG. 1 shows an extractor 46. The extractor is coupled to the reference catalog and the buyer catalog and accesses the changes tables as well as the other table. It is preferred that the accessing and location of information in both databases is performed using the invention described in U.S. Pat. No. 6,032,145, issued Feb. 29, 2000, entitled Method and System for Database Manipulation and assigned to the assignee herein, the disclosure of which is hereby incorporated fully by reference herein. The extractor looks at the list of operations performed on the reference catalog and on the buyer catalog and compiles a list of operations that have been performed on the reference catalog, apply to items in the buyer catalog and have not been performed on the buyer catalog. This is the changes list 48.

[0021] The list of changes can be compiled by looking at every operation in the two changes tables and comparing, however, it is preferred that the time information associated with each operation be used. In this way, the extractor looks only at operations performed on the reference catalog only after the last operation that was performed on the buyer catalog. These reference catalog operations are then limited to those that apply to items in the buyer catalog. Typically, the buyer catalog will contain fewer items than the reference catalog, however, a buyer may add items to its catalog which are not present in the reference catalog. In addition, it may be preferred, rather than establishing a single reference catalog, that several smaller catalogs be created so that the buyer catalog contains more items than any one reference catalog. The reference catalogs may also be distributed to different locations, systems or responsible maintenance organizations so that each reference catalog is separately maintained at different times and in different formats. In all of these instances, the present invention can be used to compare the changes table in any one reference catalog and extract the needed changes for items in the buyer catalog.

[0022] The changes list 48 is applied to a loader 50. The loader converts the list data into an electronic format that can be loaded easily and directly into the buyer catalog 38. Presently XML is preferred so that the loader takes the extracted information in the changes list and creates a series of XML statements that can be applied directly to the buyer catalog to update the buyer catalog. The example above was a changes table entry of “category, rename, pens, item 1234, 14:23:48, 04:17:2001.” Thus on Apr. 17, 2001 at the time 14:23:48, for item 1234, the category value was changed from “pens.” The extractor on seeing this entry refers to the changes table for the buyer catalog and sees that there is no entry for item 1234 after the category rename. The extractor then goes to the category table in the reference catalog to determine that the category value for item 1234 is “roller ball.” The extractor adds a mapping rule to the changes list, map the category value in item 1234 to “roller ball.” This mapping rule is converted in the loader into an XML sequence for application to the buyer catalog.

[0023] When the mapping rule is loaded, into the buyer catalog, the category value for item 1234 will be changed to “roller ball” and an entry will be made in the changes table that will match the corresponding entry in the reference catalog but with the time stamp that applies to the change in the buyer catalog. In this way, the entire catalog can be updated to reflect updates to the reference catalog. In addition the records made in the reference catalog and in the buyer catalog make it simple to ensure that all of the updates, revisions, and restructurings have been applied.

[0024] The combination of the XML actions with the ability to track changes in the catalog allows catalogs to be kept in-sync with one another by creating delta difference changes and applying the changes with the XML actions. For large catalogs, it is cumbersome to transport an entire catalog to support replication. Catalogs can communicate changes with each other via a delta difference process; in which only information that has changed since the last update is sent.

[0025] FIG. 2 is a flow diagram which shows the process that has just been described. First, maintenance records are retrieved from the buyer catalog by accessing the changes table 52. Next, the maintenance records in the changes table of the reference catalog are retrieved 54. The maintenance records are compared to each other 56 so as to extract all of the operations that are to be performed on the buyer catalog 58. Preferably, times associated with each record are used to select the operations that have not yet been performed and the item numbers are compared to select only the operations that apply to items that are in or should be in the buyer catalog. The operations are compiled 60, preferably into XML statements and then applied to the buyer catalog 62. As a part of the application of the operations, a record is made 64 in the buyer catalog changes table for each operation that is performed.

[0026] Alternatively, the extraction can be performed by extracting the product categories or items that appear in the buyer catalog and also in the reference catalog and then providing replacement listings for all of the relevant items. This type of extraction can be done without referring to the changes tables. In the example above, instead of changing “pens” to “roller balls,” the process would instead replace the entire record for item 1234. As mentioned above, however, a buyer catalog may have characteristics of items that are maintained by the buyer or that have been added by the buyer. In addition, the buyer catalog may be in a different format than the reference catalog. In accordance with the present invention, the entire record for item 1234 is not simply written into the corresponding record in the buyer catalog, it is mapped into the appropriate categories and attributes as defined by the mapping rules between the reference catalog and the buyer catalog. Mapping values from one catalog into another catalog is defined in more detail in co-pending patent application Ser. No. _______ filed concurrently herewith, entitled Method and Apparatus for Mapping One Catalog into Another Catalog and assigned to the assignee herein, the disclosure of which is hereby incorporated fully by reference herein.

[0027] The mapping is presented briefly in FIG. 3 which shows a generalized flow diagram for mapping values from the reference catalog to the buyer catalog. The process is also used to create a new electronic catalog from an existing electronic catalog. This is important when the buyer catalog presents information about items in a different way either to meet certain business requirements or to satisfy unique tastes. For example, a building supply wholesaler and an aircraft manufacturer may purchase the same fasteners from the same
supplier but have different requirements for finding and ordering the fasteners. Similarly, an aircraft manufacturer in Norway and an aircraft manufacturer in the United States may have different requirements for ordering the same fastener. The mapping process is also useful when reconfiguring an existing catalog to accommodate changes in industry or the marketplace. For example, a product may appear to fit within an existing category but later become such a large group of products that it requires its own category. These kinds of changes are among the changes that would be extracted from the changes table in the reference catalog, however, they can also be applied to the buyer catalog only.

[0028] In FIG. 3, initially items are selected for conversion 70. The selection of the items is preferably made on the basis of the extraction described above. For example, if the purpose of conversion is to accommodate a reclassification of items, then only the reclassified items will be selected. Next, the values for the selected items are retrieved from the catalog 72. Each selected item is then checked against a table that contains the conversion information to go from the first catalog format to the second catalog format 74. It is presently preferred that the conversion be performed on each item, one item at a time, however, the conversion can be performed on attributes or categories and the list organized by attribute or category. The conversion can alternatively be performed on all items with each step being performed for each item before moving on to the next item.

[0029] The table will not only specify the conversion rule but will also specify whether there are any special cases to apply. If there is a special case to apply then it is fetched from the table referred to in the conversion table 78. It is preferred that this table contain a listing of the items to which a special case applies together with the specific unique conversion as will be better understood in the context of the description below. If there is no special case, or if the special case does not apply to the item in question, then the default conversion is performed 76.

[0030] The default conversion can take many forms, differing in complexity. A straightforward conversion is to change the value for an attribute or category for a particular item to a different value for the same attribute or category for the item. For example, the first catalog may have a category called “Writing Instruments” and the second catalog may use “Pens” instead. This is a matter of user preference and the present invention, through the mapping tables, can accommodate many different style preferences. The rule, then maps all the category values that are “Writing Instruments” into “Pens.” The same principle applies when converting the catalog into a different language. Each value will be mapped directly into a selected corresponding expression in the language of the second catalog. For example, the color attribute value “Black” maps to “Swart” and the color attribute “Brown” maps to “Brun.” The table will provide mapping rules for all of the conversions for all anticipated values of the relevant attribute. The same principle also applies to the use of abbreviations and the use of case. The table for the item may require that “cc.” be mapped to “CC,” that “ea.” be mapped to “each,” or that “Lbs.” be mapped to “Pds.” or “Net Pounds.”

[0031] The same principle also applies to changes in category or attributes. The first catalog may provide a single category “Ballpoint Pens;” while the second catalog includes “Ballpoint Pens” as a subcategory to “Pens” which is a subcategory to “Office Supplies.” In this case, there is a one-to-one mapping for the items with the category value “Ballpoint Pens” into all three of the tiered categories in the second catalog. Accordingly, based on the category value “Ballpoint Pens,” the table will specify a mapping of the value “Ballpoint Pens” into the first tier category, “Pens” into the second tier category and “Office Supplies” into the third tier category. In another example, the first table may provide for an attribute of “Description” while the second table may provide for an attribute of “ink Color.” In order to make the conversion, the ink color values in the description attribute must be mapped to the “ink Color” attribute. This mapping will work well for pens and pencils but for erasers, a different mapping will be required. The mapping for erasers can be identified as a special case.

[0032] It is preferred that the table provide a default rule and if there is a special case for particular items, that the special case be treated in another table. For the examples above, there may be some items in the “Writing Instruments” category that are not to be mapped to “Pens,” for example. The special mapping table will identify these items by item number, supplier and supplier part number, or some other unique identifier, and instead map them to a different category such as “Markers.” The default table accommodates the greatest number of items in the simplest way and permits the complicated cases to be handled separately. In another example, it may be preferred for some applications that “cc.” be mapped to “CC” only for some items but for other items that “cc.” be mapped to “ML.” due to the particular market or industry served by the catalog. Again, in such a case the default mapping is to “CC” and the special case is to “ML.”

[0033] The simplest case above, mapping items in the “Writing Instruments” category to the “Pens” category can be called a one-to-one mapping. For a one-to-one mapping, when a value for a particular attribute or category is to be mapped into a different attribute or category, the default mapping table just described is used. When there is a special case, this is a conditional mapping, for example the “cc.” to either “CC” or “ML.” For a conditional mapping, when the same value for different items is to be mapped into a different value depending upon the item, then a special case is used to distinguish which mapping is to be applied to which item. For a many-to-one mapping, when several different values are to be mapped to the same value, again the default rule for each value is used. This would be the case if “Ballpoint Pens” were to be mapped to “Pens” and “Roller Ball Pens” were also to be mapped to “Pens.” As can be understood from the examples above, using this basic structure of tables with defaults and special cases, any type of mapping can be accommodated, one-to-one, one-to-many, many-to-one, many-to-many, etc.

[0034] Additional operations can be added to the mapping table to accommodate more sophisticated changes. For example, if a first catalog requires different units of measure from a second catalog, e.g., inches and centimeters, then it is not enough to change the designation of the unit of measure, the numerical value must be converted, e.g. the value in inches must be multiplied by 2.54. Accordingly, the table sets forth not only the mapping of the units designator (in.) to another designator (cm.) but also the conversion rule for converting the numerical value to the new units of measure. Another example is if the second catalog requires a different grammatical structure, e.g. “Blue Pen,” not “Pen, Blue.” Again the table must specify that the words are to be reversed in order and the comma deleted.

[0035] Another level of complexity is required for some types of mapping such as when multiple attributes or catalogs
are collapsed into a single attribute or category in the second catalog. For example, the first catalog may have a attributes of "Width," "Height," and "Depth," while the second catalog has "Size." In such a case the table sets forth that the values for the three attributes are assembled together with the desired syntax, e.g. "x" between each number, and mapped into the "Size" attribute. Similarly the table will accommodate a change in the opposite direction by specifying that the value is to be disassembled and the values each mapped into the one of the three respective attributes.

[0036] According to FIG. 3, the default conversion is applied to the item, if the default conversion is specified 76. Alternatively, if a special mapping is specified, then the table for the special case is retrieved 78 and the conversion for the special case, as outlined above, is applied 80. This process is repeated until all of the selected items are converted 82. In a preferred embodiment, the process is performed item-by-item and every attribute and category for the item to which a conversion applies is converted before moving on to the next item. As mentioned above, the conversion can be performed in any other order. Similarly the conversion can be based on attributes, categories or any other characteristic of items in the catalog. For example, all attribute values for a particular attribute can be converted for every item before moving to the next item. If conversion is only required for some of the characteristics of the items, this approach may be preferred. Finally, the converted values are recompiled into the buyer catalog 44.

[0037] Tables 2 and 3 below show, as an example, a result of mapping one of the magazine racks from the first catalog shown in Table 1 into a second catalog. Table 2 shows the partial table from the first catalog for a magazine rack shown in Table 1. Table 3 shows a hypothetical example of how the magazine rack can be mapped into a second catalog applying the principles of the present invention. All of the information in the second catalog (Table 3) is derived from information in the first or source catalog (Table 2). The category has been renamed, several of the attributes have been renamed, the values for UOM, price and description have been modified. Price has been converted from dollars to pounds and the units designator "C" has been inserted. Finally, Mfg Part Num has been deleted. These changes all represent examples of the types of changes that can be performed on a single item applying the present invention. By applying the present invention to build an entire catalog, the second catalog can become very different from the source catalog.

[0038] The present invention is preferably implemented in Java software instructions using XML (Extensible Mark-up Language) although any other computer programming language can be used. The Java code can be run on a wide variety of computer systems. The preferred XML implementation is designed to allow maximum flexibility by specifying as little as possible in the XML document type definition (DTD). Preferably, a language is specified to support the modification of the existing structure of items within a catalog. To implement the mapping, each affected schema or data element has an XML attribute that specifies the action to perform and sub-elements that specify the data upon which the action is performed. The available options for the action attribute are ADD, UPDATE, DELETE, MOVE, COPY. This allows catalogs to communicate changes to one another. A catalog can communicate deletes, updates to content, and reclassifications of items using the MOVE action. The reclassifications support mapping of category specific attributes so that data is not lost during a reclassification. The XML statements easily permit the mappings to be specified by user, category, attribute or the nature of a value in the catalog.

[0039] The following example XML statement shows how a move action can be used to map all items in the “Pens” category of the source catalog to a “Fine Writing Instruments” category in a second catalog. In addition, values for attributes of “Color” and “Point” are mapped to the corresponding attributes in the second catalog that are labeled “Ink Color” and “Point Style.”

```
<ITEM action="MOVE">
  <OWNER><NAME>Pens</NAME></OWNER>
  <UPDATE>
    <OWNER><KEY>Color</KEY><VALUE>Tropic Sand</VALUE></OWNER>
    <OWNER><KEY>Point Style</KEY><VALUE>Tropic Sand</VALUE></OWNER>
  </UPDATE>
</ITEM>
```

[0040] The following XML statement provides an example of how to convert from units of measurement using an "ADD" action. First the statement creates a new attribute “Product Shipping Weight” to a category of items “Pen Gift Set.” The statement takes the weight for the existing items, converts it to grams and adds the designation “gram to the value for the “Product Shipping Weight” attribute.

```
<ITEM action="ADD">
  <OWNER><NAME>Pen Gift Set</NAME></OWNER>
  <UPDATE>
    <OWNER><KEY>Product Shipping Weight</KEY><VALUE>
      <VALUEc-Color-AVALUEc <AKEYVALUEc <KEYVALUE <KEY>Point Style{/KEY> <VALUE-Point-FVALUEc <AKEYVALUEc </UPDATE>
  </UPDATE>
</ITEM>
```
As mentioned above, it is preferred that a single catalog be maintained with full updates to all items so that partial and reconfigured catalogs may be provided at any time using the present invention. In this way, it is no longer necessary to separately maintain each of the catalogs.

The present invention is preferably implemented in Java software instructions although any other computer programming language can be used. The Java code can be run on a wide variety of computer systems. An example of such a computer system upon which the present invention may be implemented will now be described with reference to FIG. 4. The computer system comprises a bus or other communication means 1 for communicating information, and a processing means such as a processor 2 coupled with the bus 1 for processing information. The computer system further comprises a random access memory (RAM) or other dynamic storage device 4 (referred to as main memory), coupled to the bus 1 for storing information and instructions to be executed by the processor 2. The main memory 4 also may be used for storing temporary variables or other intermediate information during execution of instructions by the processor 2. The computer system may also include a read only memory (ROM) or other static storage device 6 coupled to the bus 1 for storing static information and instructions for the processor 2.

A data storage device 7 such as a magnetic disk or optical disc and its corresponding drive may also be coupled to the computer system for storing information and instructions. The computer system can also be coupled via the bus 1 to a display device 21, such as a cathode ray tube (CRT) or Liquid Crystal Display (LCD), for displaying information to an end user. For example, graphical and textual indications of installation status, time remaining in the trial period, and other information may be presented to the prospective purchaser on the display device 21. Typically, an alphanumeric input device 22, including alphanumeric and other keys, may be coupled to the bus 1 for communicating information and command selections to the processor 2. Another type of user input device is a cursor control 23, such as a mouse, a trackball, or cursor direction keys for communicating direction information and command selections to the processor 2 and for controlling cursor movement on the display 21.
computer program product, wherein the program may be transferred from a remote computer to a requesting computer by way of data signals embodied in a carrier wave or other propagation medium via a communication link (e.g., a modem or network connection).

[0050] Importantly, while embodiments of the present invention are described with reference to maintaining an electronic catalog using a reference catalog, the method and apparatus described herein are equally applicable to the maintenance of any sort of database based on a reference database. For example, the techniques described herein are thought to be useful in connection with databases for client or customer management, for inventory management and for transportation management and scheduling.

[0051] While this invention has been particularly shown and described with reference to a preferred embodiment thereof, it will be understood by those skilled in the art that variations, adaptations and modifications may be made therein without departing from the spirit and scope of the invention as defined by the following claims.

1. A method of maintaining a catalog based on a reference electronic catalog, the reference catalog having a reference format and a plurality of items, each with associated characteristics, the method comprising:
   - maintaining the reference catalog with updates and revisions to the items and associated characteristics;
   - establishing a second catalog format for a second catalog;
   - mapping at least a portion of the reference catalog into the second format to create the second catalog;
   - maintaining the second catalog by repeating the mapping of at least a portion of the reference catalog into the second catalog after maintaining the reference catalog.
