AUTOMATIC TELEPHONE SYSTEM

Harry G. Evers, Chicago, Ill., assignor to Associated Electric Laboratories, Inc., Chicago, Ill., a corporation of Delaware

Application May 7, 1934, Serial No. 724,274

20 Claims. (Cl. 179-17)

This invention relates in general to automatic telephone systems, but more in particular to small systems suited for installation in towns or villages. An automatic telephone system of this type is generally known as a community automatic exchange or C. A. X., and may have a capacity of fifty lines, more or less. Usually the lines are party lines having either bridged or grounded ringing circuits over which the subscribers are signalled by means of code ringing. Provision is also made for trunking calls to and from distant exchanges.

The object of the present invention is to provide a novel and improved all relay community automatic exchange of the foregoing character.

One of the features of the invention relates to the novel circuit arrangement in the all-relay finder connector link for interconnecting the various lines in this system.

Another feature of invention relates to an im-20 proved talking arrangement for receiving the impulses transmitted from a calling line and for repeating the impulses.

Another feature of the invention relates to the circuit arrangement for selecting and connecting various code rings to called subscribers lines.

These and other features of the invention will be apparent from the following detailed description of the invention.

Referring now to the drawings, comprising Figs. 30 1 to 6, inclusive, there is shown by means of the usual circuit diagram one of the all-relay finder connector links, the different line circuits and substation circuits by means of which the invention may be described and understood.

Fig. 1 shows a party line, in this case line 17 and its associated line circuit. The line conductors 14 and 15 and the incoming test conductor 16 of this line, shown bracketed, extend to the connecting end of the finder connector link in 40 Fig. 4 where the conductors connect with correspondingly numbered conductors. The remainder of Fig. 1 shows the finding end of the finder connector link comprising a set of finder group relays FGR and finder units relays FUR. Each 45 group of lines, such as the ten group, has two finder group relays, such as relay 110 for connecting only the line conductors of line group 10 to the link, and relay III which connects only the test conductors of line group 10 to the link. It is assumed in this case that there are eight groups of lines, each comprising seven lines each. In order to simplify the drawings, only three groups of lines, namely the 10-group, 20-group, and 80-group have been shown. Each of the lines 55 are connected to a line circuit in the same manner

as illustrated for line 17. The finder unit relays FUR correspond in number to the number of lines in each group, in this case, since there are seven lines in each group there are seven finder unit relays. Only three of the finder unit relays, 5 however, have been shown in order to simplify the drawings.

Figs. 2 and 3 show the control relays of this finder connector link.

Fig. 4 shows the connecting end of this finder 10 connector link and two line circuits. In the same manner as described for the finder group relays the connecting end of the link includes two relays for each group of lines. The connector group relay 410 for the first or tens group connects only 15 the line conductors of the lines in the 10-group to the link while the relay 411 connects only the test conductors of the line in the 10-group to the link. Since there are eight groups of lines then there are eight sets of connector group relays 20 provided, but only four of such sets have been shown. The connector unit relays comprise a group of seven relays, one relay for each corresponding line in a group. In this case only four of the connector unit relays are shown in order 25 to reduce the drawings. Each odd connector unit relay prepares a circuit for the succeeding even connector unit relay, and each even connector unit relay prepares a circuit for the succeeding odd connector unit relay, as diagrammatically 30 illustrated by the dotted lines. In a similar manner each odd connector group test relay, such as relay 411, prepares a circuit for the succeeding even connector group test relay, such as relay 421. In a similar manner each even connector 35 group test relay such as relay 421 prepares a circuit for the succeeding odd connector group test relay, such as relay 431, not shown. In the upper right-hand corner is shown the line circuit for party line 71. The subscriber's ringers on 40 this line are connected to both the negative and positive line conductors to provide the so-called divided ringing. In the lower right-hand corner of Fig. 4 is shown the line circuit of a grounded twenty-party line.

Fig. 5 in its upper portion diagrammatically illustrates the chain circuit arrangement between the various finder connector links in this system while relays 500 to 570, inclusive, comprise the allotting and alarm relays. TS diagrammati-50 cally-illustrates a time switch which is started in response to the operation of start reay 510 to close springs 502 and 503 at predetermined time intervals. Relays 580 and 590 and interrupter 593 comprise a timing device for freeing a finder 55

2,022,503 2

connector link in case the same is held by a permanent line.

Fig. 6 shows the code selecting relays CSR which are controlled by the impulse repeating relay in the link to selectively connect one of the code ringing conductors extending to a ringing interrupter, not shown. The ringing machine, not shown, is started in operation in response to the operation of a switching relay in 10 any link circuit and periodically grounds the code ring conductors shown to produce codes indicated by the numerals associated with such conductors.

Briefly, the operation of this system is as follows: When a calling subscriber initiates a call the test conductor of the calling line is marked with calling potential and the calling group is marked in all the finder group relays in all of the links. The start conductor is grounded and 20 the finder group relays in the first idle link operate in sequence to find the calling group. When the calling group is found the last operated finder group relay connects the test conductor of all the lines in the calling group to the finder 25 unit relay, which now operates in sequence until the marked calling line is found.

When the calling line is found the transfer relay in the link is operated to prepare another idle link for use and the calling line is connected 30 to the control circuit of the link in use. The first digit transmitted by the calling subscriber operates an impulse repeating relay to successively operate the connector group relays. Only the last operated connector group relay is main-35 tained energized to connect the test conductor of the called group to the connector units relays of the link. The second digit reoperates the impulse repeating relay to successively operate the corresponding connector unit relays. Only the last operated connector unit relay is maintained energized to connect the test conductor of the called line to the link control circuit. The third digit reoperates the impulse repeating relay to select the ringing code. If the called line is 45 idle the ringing interrupter, not shown, grounds the selected code ringing conductor to cause the bells on the called line to be rung in accordance with the code selected.

In outgoing trunk calls the calling line is found 50 in the same manner as just described and in response to dialling the two digits designating a trunk call the corresponding connector group and unit relays operate as before to connect with the trunk line. In this case the code selecting digit 55 is not dialled as none is needed.

Local calls

It will now be assumed that subscriber S in 60 Fig. 1 desires to call a subscriber S4 shown in When subscriber S removes his receiver a circuit is completed for energizing line relay over the following circuit: from ground by way of armature 19 and resting contact, lower wind-65 ing of line relay 1, line conductor 15, through the substation loop over line conductor 14, armature 8 and through the upper winding of relay I to battery; at armature 5, relay I connects calling potential to the test conductor by way of 70 armature 11 and the winding of cut-off relay 2; at armature 6 and resting contact disconnects the cut-off relay. 2 from the incoming test conductor 15 and at its make contact grounds the test conductor 16 to make this line busy to other 75 subscribers attempting to call the same. At

armature 7 relay I grounds the start lead 61 common to the 10-line group to complete a circuit for energizing the common start relay 510 as follows: from ground by way of armature 7, armature 12 and resting contact, common start lead 5 61, resistance 61' and through the winding of start relay 510 to battery. At armature 511 relay 510 completes a circuit for energizing line relay 207; at armature 512 prepares the locking circuit for relays 540, 550 and 560; at armature 10 513 completes the circuit for energizing relay 520, and at armature 514 prepares a circuit for shunting relay 520 and for energizing relay 530. The circuit for energizing relay 520 extends from ground through winding of relay 520, armatures 15 513, 533, and 544, resistance 546 to battery. Relay 520, upon energizing, at armatures 521 prepares a circuit for energizing relay 530 and at armature 523 connects the winding of relay 560 to the time switch TS. Relay 530 is not energized at 20 this time because this relay is shunted over the following circuit: from battery through the resistance 546, armatures 544, 533, 513, and 521 to the winding of relay 530 and battery.

Line relay 207 energizes over the following cir- 25 cuit: ground by way of armature 501, armature 511, resistance 515, armature 531 and resting contact, in start lead 281, armature 215 and resting contact, conductor 150, armature 246 and resting contact, upper left-hand winding of re- 30 peating coil RC, normally closed spring controlled by armature 233 and through the winding of line relay 207 to battery. At armature 230 relay 207 completes the circuit for energizing impulse repeating relay 303, and at armature 35 231 prepares the circuit for energizing relay 301. The circuit for energizing impulse repeating relay 303 may be traced as follows: from ground by way of armature 249 and resting contact, conductor 262, armature 320 and resting contact, 40 conductor 261, armature 230, conductor 260, and through the winding of impulse repeating relay 303 to battery. At armature 324 and working contact relay 303 completes a holding circuit for itself by way of resistance 329 and conduc- 45 tor 261; at armature 325 completes an obvious circuit for energizing relay 301 and grounds conductor 264; at armature 326 opens a point in the circuit to relays 306, 307 and 309, and at armature 327 shunts armature 238. At armature 316 50 relay 301 prepares a high resistance circuit for line relay 207, at armature 317 prepares a circuit for switch-through relay 213, and at armature 318 grounds conductor 271 to complete a circuit for energizing slow to release relay 302 as 55follows: from ground by way of armature 318, conductor 271, through armatures 239 and 226 in multiple to conductor 272 and through the winding of relay 302 to battery.

At armature 320 and resting contact relay 302 60 opens the original energizing circuit of relay 303 which is now held energized over its locking circuit from ground at armature 324. At armature 320 and working contact relay 302 grounds conductor 263 and closes a multiple ground circuit 65 to relay 301 by way of armature 231 and working contact and conductor 264. At armature 321 relay 302 grounds conductor 265 to prepare a circuit for the disconnect relay 206, at armature 322 connects grounded conductor 275 to finder 70 lock conductor 153 and completes a circuit for energizing the first finder group relay III, and at armature 323 grounds the connector lock conductor 278 as well as lock conductor 279 by way of armature 241.

The circuit for energizing the first finder group relay III extends from grounded conductor 153. armature 223 and resting contact, armature 220 and resting contact, conductor 156, resistance 190, armature 187 and resting contact, through the armatures and resting contacts of the finder group relays, not shown, to armature 127, resting contact of armature 127, armature 117 and resting contact, through the winding of relay 10 III to battery. At armature 116, relay III completes its own locking circuit through the resting contacts of armatures such as armatures 125 and 185, on the finder group relays to grounded conductor 153; at armature 118 prepares the 15 circuit for relay 110; at armature 119 connects the grounded start lead 6! to the group test relay 203 by way of conductor 159 and armature 244; at armature 117 and resting contact opens its original energizing circuit and at its working 20 contact closes the circuit for the second finder group relay 121. Relays such as relays 111, 121 and 181 are slightly slow to operate on account of their slugs and the resistance 190. At the upper armatures of relay !!! the test conductors of the 10 line group are connected to the test armatures of the finder units relays.

In order to describe the operation of the finder group relays it will be assumed for the time being that the calling line is not in the first or 30 the 10 line group. In this case, after an interval relay 121 energized over the following circuit: from grounded lock conductor 153, by way of armatures 223 and 220 and their resting contacts, conductor 156, resistance 190, armatures 35 and resting contacts of the finder group relays to armature 117 and its working contact and through the winding of relay 121 to battery. In a manner similar to that described for relay !!! relay 121 energizes and at armature 126 locks 40 itself to grounded conductor 153. At armature 125 relay 121 opens the locking circuit of relay III whereupon the latter relay deenergizes after an interval, and at armature 127 opens a point in its original energizing circuit and at the 45 working contact of armature 127 completes the circuit for the succeeding finder group relay associated with the 30-line group, not shown. At armature 128 relay 121 prepares the circuit for relay 120, at armature 129 connects the start 50 lead 62 of the 20-line group to the group test relay 203, and at its upper armatures connects the test conductors of the 20-line group to the finder units relay. Relay !!!, upon deenergizing, at its upper armatures disconnects the test 55 conductors of the 10-line group, at armature 118 opens the prepared circuit to relay 110 and at armature 119 disconnects the start lead 61 from the group test relay 203. Finder group relays 131 to 171, inclusive, not shown, and relay 181 op-60 erate in the manner just described, each succeeding relay opening the locking circuit to the preceding relay to deenergize the same, connecting the corresponding group start lead to the group test relay 203, preparing a circuit to its associated line connecting relay, completing its own locking circuit, and connecting the test conductors of its associated group to the finder units relay.

When the finder group relay corresponding to the group in which the calling line is located is operated ground on the start lead completes the circuit for energizing the group test relay 203. For example, relay !!! at armature !!! completes the circuit for energizing group test relay 75 203 in case a line in the !0-line group is calling

as follows: from grounded start lead 61, armature 119, conductor 159, armature 224 and through the lower winding of group test relay 203 to battery. At armature 218 relay 203 completes a short circuit around its upper winding 5 to make this relay slow to release, at armature 219 opens a point in the circuit to relay 202, at armature 220 disconnects grounded conductor 153 from conductor 156 to open the circuit to the succeeding finder group relay before the same 10 can energize and close its locking circuit, and at armature 220 and working contact connects the grounded conductor 153 to conductor 155 for energizing the first finder unit relay 101 as follows: from grounded conductor 153, armature 15 223 and resting contact, armature 220 and working contact, conductor 155, armature 142 and resting contact, armature 145 and resting contact, through similar armatures on the finder unit relays (not shown) to armature 148 and 20 resting contact and through the winding of relay 101 to battery. At armature 141 relay 101 completes a locking circuit for itself by way of armatures 143 and 146 and the corresponding armatures on the other finder unit relays (not 25 shown) to grounded conductor 153. At armature 142 relay 101 opens its original energizing circuit and completes the circuit for relay 102 and at its upper armatures connects the link line conductors 150 and 151 to contacts on the finder 30 group relay and at armature 160 connects the test lead 152 to the test lead 19 of line 11 to prepare a circuit for the line test relay 204.

The finder unit relays, due to the copper slug on their upper ends, are fairly slow to operate, 35 and therefore the second finder unit relay only operates after a time sufficient to permit the energization of the line test relay 204 in case a calling line is connected with. In case line !! is not a calling line, then the relay 102 energizes 40 after an interval by way of grounded conductor 155, armature 142 and working contact. At armature 143 relay 142 opens the locking circuit of relay 101 which accordingly deenergizes after an interval, at armature 144 completes a locking 45 circuit for itself from grounded conductor 153, at armature 145 and working contact prepares the circuit for the third finder unit relay (not shown) and at its upper armatures connects the line conductors 150 and 151 to the line finder group 50 contacts and at armature 124 connects the test conductor of line 12, since relay 111 associated with the 10-line group is energized, to the test conductor [52]

Relay 101, upon deenergizing, at its upper ar- 55 matures disconnects the test and line conductors, at armature 141 opens a point in its own locking circuit, at armatures 142 and working contact opens the original energizing circuit of relay 102. and at the testing contact of armature 142 con-60 nects the third finder unit relay (not shown) to grounded conductor 155, by way of armature 145 and its working contact. Finder unit relays 103 to 186, inclusive (not shown), and relay 107 operate in the manner just described, each relay 65 at its upper armature connecting the test conductor of its corresponding line to line test relay 204, opening the locking circuit of the preceding operated relay, closing its own locking circuit, and preparing the energizing circuit to the suc- 70ceeding relay which is completed when the preceding relay deenergizes.

In this case, since line !7 is calling, then when the finder unit relay !07 energizes this relay at armature !74 completes the circuit for energiz- 75

ing the line test relay 204 in series with the cutoff relay 2 as follows: from ground at armature 318, conductor 271, upper winding of line test relay 204, conductor 152, armature 174, armature 114, armature 5, armature 11 and through the winding of cut-off relay 2 to battery. At armature 221 relay 204, upon energizing, completes a circuit for energizing relay 312 and for grounding conductor 259, at armature 222 short 10 circuits its upper winding to render the relay slow to release and to connect direct ground to the test conductor, at armature 223 disconnects grounded conductor 153 from conductor 155 to open the circuit to the succeeding finder unit 15 relay before the same can fully energize, at armature 223 and working contact completes a locking circuit to its lower winding and a circuit for energizing relay 110, and at armature 224 opens the circuit to group test relay 203 to cause this 20 relay to deenergize.

Cut-off relay 2, upon energizing, at armatures 8 and 10 opens the circuit of line relay 1, at armature 9 completes a locking circuit for itself to grounded test conductor 152, and at armature 25 10 and its working contact completes the circuit for energizing lock-out relay 3. Relay 110 is energized over the following circuit: from grounded conductor 153 by way of armature 223 and working contact, armature 225, conductor 157, armature 118 and through the winding of relay 110 to battery. At its upper armatures relay 110 connects the line conductors of the lines in the 10line group to the contacts of the finder unit relays and in the case of armatures 112 and 113 35 connects the calling line, or line 17, to conductors 150 and 151 by way of armatures 172 and 173, thereby completing a new energizing circuit for line relay 207 and for connecting dial tone to the calling subscriber's line to notify such sub-40 scriber that he may now dial the called subscriber's number. Lock-out relay 3, upon energizing, at armature 11 opens the original energizing circircuit of cut-off relay 2, at armature 12 and resting contact, disconnects ground from the start 45 conductor 6! to deenergize start relay 510 if no other line is calling, and at armature 12 and its working contact completes a locking circuit for itself from grounded armature 7. Line relay I, upon deenergizing, at armature 6 disconnects 50 direct ground from incoming test conductor 16 at its working contact and at its resting contact connects ground by way of armature 318, conductor 211, armature 222, conductor 152, armatures 174 and 114, and armature 9 to the incoming test conductor 16 to maintain this line busy at the called end of the link. At armature 7 relay I opens the locking circuit of lock-out relay 3.

Group test relay 203, upon deenergizing when its circuit is opened at armature 224, at armature 60 219 completes a circuit for energizing relay 202 through its upper winding by way of working contact of armature 223 and grounded conductor 153. At armature 217 relay 202 completes an obvious circuit for the transfer relay 201. At 65 armature 214 relay 201 prepares a locking circuit for itself, at armature 215 opens the original energizing circuit of line relay 207 now held energized over the calling subscriber's loop, and at the working contacts of armature 215 con-70 nects the in start conductor 281 with the out conductor 282 so that a succeeding call may seize the next idle finder connector link. At armature 216 relay 201 completes one point in the all link busy chain by connecting conductor 280 to 75 conductor 283.

The circuit for energizing relay 312 may be traced as follows: from grounded armature 249 and resting contact, conductor 262, armature 221, conductor 259, armature 330 and resting contact and through the winding of relay 312 to battery. 5 At armature 362 relay 312 prepares a locking circuit for itself, at armature 363 prepares a circuit through the lower winding of relay 311, which relay does not energize at this time because the lower winding is short circuited by way of 10 armature 363, armature 320 and resting contact, and the normally closed springs closed by armature 337. At armatures 364 to 367, inclusive, relay 312 prepares the pulsing circuit to the connector group relay.

Relay 510 deenergizes in case no other line is calling at this time, and at armature 511 disconnects ground from the start in lead 281. At armature 513 relay 510 opens the shunt circuit of relay 530 which relay now energizes in series 20 with relay 520 by way of armature 521. Relay 530, upon energizing, at armatures 531 transfers the start circuit from the beginning of the chain to the middle of the chain; at armature 532 prepares a short circuit for relay 520 and a circuit 25 for relay 530, at armature 533 opens a point in the low resistance shunt of relay 530, and at armature 534 disconnects the time switch from relay 560 before the time switch has had sufficient time to energize relay 560.

At this point it may be advisable to consider the operation of the allotter relays in response to a second call when relay 530 is energized. In this case start relay 510 is energized over the common start lead as before, and at armature 35 511 completes the start circuit and grounds the in start lead 28!' as follows: ground by way of armature 501, armature 511, resistance 515, armature 53! and working contact to in start lead 281', extending to the finder connector link near 40 the middle of the chain. At armature 514 relay 510 connects grounded armature 543 by way of armature 532 to the winding of relays 520 and 530 with the result that relay 520 is short circuited and deenergizes, while relay 530 is maintained 45 energized over this circuit. Relay 520, upon deenergizing, at armature 522 connects springs 503 of the time switch TS to the winding of relay 560. Relay 510 is deenergized and ground is removed from the in start lead 231' at armature 511. At 50 armature 514 relay 510 opens the circuit of relay 530 which accordingly deenergizes. At armature 531 relay 530 transfers the start circuit back to the beginning of the chain and at armature 543 disconnects the time switch TS from the winding 55 of relay 560.

A circuit for maintaining line relay 207 energized over the calling subscriber's loop may be traced as follows: from ground by way of armature 236, resting contact and armature 247, con- 60 ductor 151, armatures 173 and 113, positive line conductor 15 through the substation loop to negative line conductor 14, armatures 112 and 172, conductor 150, armature 246 and resting contact, upper left-hand winding of repeating 65 coil RC, normally closed springs controlled by armature 233, and through the winding of line relay 207 to battery. Dial tone is also connected to the calling line at this time over the following circuit: from dial tone in Fig. 3, resting contact 70 and armature 328, tone condenser TC, conductor 254, resting contact and armature 246, thence over the calling loop circuit just traced. The calling subscriber, after listening to the dial tone, dials the group and line digits followed by the 75

code selecting digit. Line relay ${f 207}$ deenergizes in response to each impulse. In response to the first pulse relay 207 at armature 230 opens the circuit of impulse repeating relay 303 which accordingly deenergizes. At armature 231 and its resting contact relay 207 closes a high resistance priming circuit for itself which may be traced as follows: from grounded conductor 262, armature 329 and working contact, conductor 10 263, armature 231 and resting contact, conductor 257, armature 316, resistance 319, conductor 254, upper left-hand winding of repeating coil RC, normally closed switch springs controlled by armature 233, and through the winding of line relay 207 to battery. This priming circuit while insufficient to energize line relay 207 due to resistance 319 greatly assists the energization of line relay 207 when the same is connected to a "leaky" calling line. At armature 23! and its 20 make contact one of the multiple ground connections to relay 301 is opened but this relay due to its slow releasing characteristics remains energizing during the impulsing period.

Impulse repeating relay 303, upon deenergiz-25 ing, at armature 324 opens a point in its own holding circuit, at armature 325 opens a further circuit to slow to release relay 301, and at armature 326 completes a circuit for energizing relays 306, 307 and 309. The circuit for energizing re-30 lay 306 and relay 307 extends from grounded conductor 262, armature 320 and working contact, normally closed spring controlled by armature 326, armature 333 and resting contact, and through the upper winding of relay 306 and the winding of 307 to battery. A branch of this circuit extends by way of armature 348 and resting contact, through the upper winding of relay 309 for energizing the latter relay. At armature 336 relay 306 short circuits the upper left-hand winding of repeating coil RC in order to improve the impulsing circuit, at armature 337 completes a holding circuit for relay 312 by way of grounded conductor 259 and armatures 357 and 362, at armature 338 prepares an energizing circuit for 45 relay 304 and the holding circuit extending to the lower windings of relays 308 and 309, at armature 339 prepares a point in the circuit for the busy relay 305, and at armature 340 disconnects grounded conductor 259 from conductors 269 50 and 394.

Slow to release relay 397, upon energizing, at armature 342 prepares a holding circuit for relay 309, at armature 343 completes a locking circuit from grounded armature 376 through the lower winding of relay 309, and at armature 345 prepares a point in the circuit for the first connector group relay 411. Relay 307, due to its slow release characteristics, is maintained energized during the impulsing period and therefore deepergizes shortly after each series of impulses.

Impulse repeating relay 309, upon energizing, at armature 349 prepares a point in the energizing circuit of relay 308 and in the holding circuit of relay 309, at armature 350 prepares a new energizing circuit for impulse repeating relay 303 and the circuit through the lower winding of relays 308 and 309, at armature 351 prepares a holding circuit for the lower windings of relays 308 and 309, at armature 352 disconnects ground at armature 376 from the even pulse conductor 386 and connects ground to the odd pulse conductor 384, and at armature 353 completes a circuit for energizing connector group relay 411 as follows: from grounded lock conductor 278, through armatures 442, 452 and 465 of the connector group re-

lays to conductor 389, working contact and armature 366, resting contact and armature 360, armatures 345 and 353, armature 361 and resting contact, armature 367 and working contact, conductor 391, and through the winding of relay 5411 to battery. Relay 411 at its upper armatures connects the test conductors of the lines in the 10-group to the connector unit relays; at armature 490 completes a locking circuit for itself to grounded lock conductor 278 by way of armatures 10 465, 452 and 442; and at armature 492 prepares the circuit for relay 410.

At the termination of the first impulse line relay 207 again energizes over the subscriber's loop to complete a circuit at armature 230 for energiz- 15 ing impulse repeating relay 303 and a circuit through the lower winding of relays 309 and 308. At armature 231 relay 207 opens its priming circuit and recloses the circuit for slow to release relay 301 to maintain the same in energized posi- 20 tion. The circuit for energizing relay 303 may be traced as follows: from ground at armature 350 on the energized repeating relay 309, resting contact and armature 347, conductor 261, armature 230, conductor 260, and through the wind- 25 ing of relay 303 to battery. A branch of this circuit extends by way of conductor 260, armatures 342, 346 and 349, through the lower windings of relays 308 and 309 and by way of armature 351 to relay 304. At armature 324 relay 303 again 30 completes its holding circuit, at armature 325 again closes a multiple circuit for relay 301, and at the normally closed spring controlled by armature 326 opens the original energizing circuit of relays 306, 307 and 309, while at armature 326 35 and its working contact completes a circuit from grounded conductor 263 by way of armatures 338 for energizing relay 304 and for completing a circuit by way of armature 351 through the lower windings of relays 308 and 309. Relay 309 is 40 maintained energized over this circuit while relay 308 is energized. At armature 346 relay 308 opens a point in one of its energizing circuits, at armature 347 opens the original energizing circuit of relay 303 which is now maintained energized 45 over its own locking circuit, at armature 348 and resting contact opens the original energizing circuit of relay 309 and at its working contact prepares a locking circuit for itself. Relays 308 and 309 at this time are maintained energized from 50 ground by way of conductor 263, working contact and armature 326, armature 338, armature 351 and through the lower windings of relays 308 and 309 to battery. Relay 304, upon energizing, at armature 328 disconnects dial tone and prepares a 55 circuit for connecting ring back tone to the calling subscriber, at armature 330 and its resting contact opens the original energizing circuit of relay 312 and its working contact closes a locking circuit for itself from grounded conductor 259 60 as well as opening its original energizing circuit. At this time relay 312 is maintained energized over the following circuit: from grounded conductor 259, working contact and armature 337, armature 357 and resting contact, armature 362 65 and the winding of relay 312 to battery.

In response to the second pulse of the first series, line relay 207 again deenergizes and at armature 230 opens the circuit to the impulse repeating relay 303, while at armature 231 the 70 multiple circuit to slow to release relay 301 is opened and the priming circuit for the line relay is again closed. Relay 303, upon deenergizing, at armature 324 again opens its own holding circuit, at armature 325 again opens the circuit to slow 75

to release relay 301, at armature 326 recloses the circuit to slow to release relay 307 before such relay deenergizes, at armature 326 opens the holding circuit extending through the lower windings of relays 308 and 309, and at the normally closed springs controlled by armature 326 completes a locking circuit through the upper winding of relay 308 by way of armatures 333 and 348. Relay 309, upon deenergizing, at armature 10 350 prepares a circuit for reenergizing relay 303, at armature 351 opens a further point in the holding circuit through the lower windings of relays 308 and 309, at armature 352 connects ground at armature 375 to the even conductor 386 to complete an energizing circuit for the next connector group relay, in this case relay 421, and at armature 353 opens the original energizing circuit of relay 411. The circuit for energizing relay 421 may be traced as follows: from grounded 20 armature 376 and resting contact, armature 343, armature 352 and resting contact, armature 359 and resting contact, armature 365 and working contact, conductor 386, armature 491, and through the winding of relay 421 to battery. Re-25 lay 421, upon energizing, at its upper armatures connects the test conductors of the lines in the 20-group to the connector unit relays, at armature 465 opens the locking circuit of relay 411 which accordingly deenergizes, at armature 466 30 completes a locking circuit for itself from grounded lock conductor 278 by way of armatures, such as armatures 442 and 452, at armature 467 prepares a circuit for relay 420, at armature 468 connects the succeeding connector group re-35 lay 431 (not shown) to the odd pulse conductor 384, and at armature 469 prepares a point in the circuit for code switching relay 600. Relay 411, upon deenergizing, at its upper armatures opens the circuit to the test conductors of the line in 40 the 10-group, at armature 490 opens its own locking circuit, at armature 491 opens the circuit to relay 421 now locked energized, and at armature 492 opens the prepared circuit to relay 410.

Line relay 207 reenergizes over the calling sub-45 scriber's loop at the end of the second pulse, and at armature 230 closes a circuit for energizing relay 303 by way of resting contact of armature 350 and working contact of armature 347, while at armature 231 the circuit to slow release relay 301 50 is again reclosed. Relay 303, upon energizing, at armature 324 again closes its locking circuit, at armature 325 again closes the circuit for relay 301, and at armature 326 opens the holding circuit through the upper winding of relay 308 which accordingly deenergizes. Relay 308, upon deenergizing, at armature 346 prepares a point in the original energizing circuit of relay 308, at armature 347 opens the energizing circuit of relay 303 which is now held energized over its locking cir-60 cuit, and at armature 348 opens a point in its own locking circuit and prepares a circuit for relay 309. From the foregoing it will be seen that relay 303 follows the pulses of line 201; that relays 308 and 309 are energized on the first pulse, 65 and for each odd pulse; that relays 309 and 308 are deenergized on the second pulse or on each even pulse; that relay 309 grounds the odd pulse conductor 384 on energization and grounds the even pulse conductor 386 on deenergization to suc-70 cessively operate the connector group relay such as relays 411, 421, etc. The circuit for reoperating impulse repeating relay 303 is taken through armatures 347 and 350 so that the circuit to relay 303 cannot be closed until relays 308 and 309 75 have operated or released.

As is well known the line relay, such as relay 207, may be sluggish in its deenergization due to the leaky or heavily loaded condition of the line connected with. In order to insure correct pulsing a so-called lock-pulse arrangement is pro- 5 vided. In this arrangement the armatures or springs operated by line relay 207 have a strong adjustment or tension and the springs or armatures operated by pulse repeating relay 303 also have a very stiff adjustment so that this relay 100 will very quickly fall back when its circuit is momentarily opened by line relay 207 at armature 230. When relay 303 is deenergized such relay cannot again energize until the repeating relays 308 or 309 have operated or released to close the 155 circuit for relay 303, even though the line relay is immediately reoperated. Relays 308 and 309 need not necessarily be fast operating relays in order to repeat the impulses received. In addition a primary circuit or artificial leak is pro- 200 vided through resting contacts on the line relay 207 for facilitating its reoperation over long, clear lines. This impulsing circuit in combination with the odd and even pulsing circuits has proven to be a very satisfactory circuit arrangement on lines 25 of varying electrical characteristics which heretofore have prevented automatic working.

In response to the third pulse relays 207 and 303 deenergize and relay 303 causes the energization of relay 309 as previously described for the 300 When relay 309 grounds the odd conductor 384 the third connector group relay 431 (not shown) is energized over the odd pulse conductor 384 at armature 468. In the same manner as described for relay 421, relay 431 (not shown) 255 closes its upper armatures to connect the test leads of the 30-line group; opens the locking circuit of relay 421 which deenergizes; closes its own locking circuit; prepares the circuit through its associated line connecting relay (not shown) sim- 400 ilar to relay 423; and connects the connector group test relay of the 49-line group (not shown) to the even conductor 386. At the end of the third pulse relays 207, 303 and 308 energize as previously described for the end of the first pulse. (5

In response to the fourth impulse relays 201, 303 and 309 deenergize as described for the second impulse. When relay 309 grounds the even conductor 386 the connector group test relay (not shown) for the 40-line group is energized in a 50 manner similar to that previously described. This connector group relay closes the test leads of the 40-line group; opens the locking circuit of the connector group relay of the 30-line group which deenergizes; closes its own locking circuit; prepares a circuit through its own associated line connecting relay (not shown), and connects the connector group test relay of the fifth line group (not shown) to the odd conductor 384.

In the same manner as just described each odd 👀 pulse grounds the odd conductor 384 to energize the corresponding connector group relay, and each even pulse grounds the even conductor 395 to energize the corresponding connector group test relay. The connector group test relays 431 and 65 461 and the associated connector group line connecting relays 430 to 450 are not shown because their circuit operations are identical with the connector group relays shown. In response to the seventh pulse odd conductor 384 is grounded by 70 relay 309 to energize the connector group test relay 471 of the 70-line group by way of armature 456 on the connector group test relay of the 60line group. Relay 471 at its upper armatures connects the test leads of the lines in the 70-group 75 opens the locking circuit of the last operated connector group test relay, at armature 453 closes its own locking circuit, at armature 454 connects the connector group test relay 481 of the 80-line group to even conductor 386, at armature 455 prepares the circuit to line connecting relay 470 of the 70-line group and at armature 456 prepares a circuit for the ring reversing relay 314.

Relays 201 and 303 remain energized after the last impulse of the series and after an interval slow to release relay 307 deenergizes. At armature 343 relay 307 opens a point in the pulsing circuit as well as the holding circuit of relay 306 which accordingly deenergizes, and at armature 345 opens a point in the original energizing circuit of relay 411. Relay 306, upon deenergizing, at armature 335 removes the short circuit from the repeating coil RC, at armature 337 opens 20 the locking circuit of relay 3!2 and substitutes the circuit through the lower winding of relay 311 in series with the winding of relay 312, whereby relay 312 is maintained energized and relay 311 is energized over the circuit from grounded conductor 259 in series with the winding of relay 312. At armature 338 relay 306 opens the circuit to relays 308 and 309 to deenergize the same if they should be energized at this time, at armature 339 opens a point in the circuit to the busy relay 305, and at armature 340 reconnects grounded conductor 259 to conductors 269 and 394. Relay 311, upon energizing, in series with relay 312, at armature 357 prepares a locking circuit for itself, at armatures 358 and 359 prepares the pulsing circuit over the odd and even conductor 383 and 385 to the connector unit relays and at armatures 360 and 361 prepares a circuit for connecting the grounded lock conductor 278 to conductor 390.

The calling subscriber may now dial the second digit of the desired called subscriber's number. In the same manner as previously described, the line relay 207 and repeating relay 303 deenergize for each impulse and in response to the 45 first impulse completes the circuit for energizing relays 306, 307 and 309. Relay 306, upon energizing, at armature 337 opens the holding circuit of relay 312 to cause this relay to deenergize and likewise completes a locking circuit through the upper winding of relay 311 for maintaining this relay in energized position. In response to the energization of relays 307 and 309 a circuit is completed for energizing the first connector unit relay 401. Relay 312, upon de-55 energizing, at armatures 364 to 367 prepares the pulsing circuit for the code selecting relay CSR.

Relay 40! energizes over the following circuit: from grounded lock conductor 278, armatures 412, 415, 432, and similar armatures on the con-60 nector unit relays (not shown), conductor 387, working contact and armature 360, armatures 345 and 353, armature 361 and working contact, conductor 390, and through the winding of relay 491 to battery. At armatures 492 and 493 relay 65 401 connects the talking conductors 252 and 255 of the link to the connector group relays, at armature 494 connects the test conductor 382 to the test conductor 34 of line 11; at armature 435 completes a locking circuit for itself from grounded lock conductor 278 through the armatures of the unoperated connector unit relays, at armature 436 prepares a circuit to the succeeding even connector unit relay 402, at armature 437 prepares a point in the circuit for the trunk switch 75 through relay 213, and at armature 438 grounds

conductor 392. Line relay 201 energizes at the end of each pulse and again completes the circuit for energizing repeating relay 303 in case relays 308 or 309 have operated or released, as previously described.

In order to describe the operation of the connector unit relays it will be assumed that the second digit being dialled is more than the digit 1. Relays 207, 303 and 309 deenergize in the same manner as previously described for the 10 second pulse. At armature 353 relay 309 opens the circuit to connector unit relay 401, now held over its locking circuit, and at armature 352 disconnects ground from the odd pulse conductor 383 and connects ground to the even 15 pulse conductor 385 to energize the second connector unit relay 492. This circuit may be traced as follows: ground by way of armature 476 and resting contact, armature 343, armature 352 and resting contact, armature 359 and working contact, even pulse conductor 385, armature 436 and through the winding of relay 402 to battery. At its two uppermost armatures relay 402 connects the link line conductors 252 and 255 to the contacts of the connector group relays, at the 25 third uppermost contact connects the link test conductor 382 to the test conductor of line 72 by way of the operated contacts on connector group relay 471. At armature 433 relay 492 completes a locking circuit for itself from grounded 30 locking conductor 278 by way of armatures 412 and 416 and similar armatures on other connector units relays (not shown); at armature 432 opens the locking circuit of relay 401 which now deenergizes and at armature 434 connects 5 the third connector relay 403 (not shown) to the odd pulse conductor 383. At the end of the second pulse relays 207 and 303 reenergize and relay 308 deenergizes, as previously described.

In response to the third pulse relays 207 and 40 303 deenergize and relay 309 reenergizes to ground the odd pulse conductor 383, as previously described. The third connector unit relay 403 (not shown) is energized to connect up the test conductor of line 13; to unlock the second connector 45 relay 402 which accordingly deenergizes; to lock itself to lock conductor 218; and to connect the fourth connector unit relay (not shown) to the even pulse conductor 335. Relays 201, 303 and 308 energize at the end of the third pulse, as 50 previously described.

In response to the fourth pulse relays 207, 303 and 309 deenergize, as previously described. At armature 352 relay 309 grounds the even pulse conductor 385 to energize the fourth connector 55 unit relay. The fourth connector unit relay connects up the test conductor of line 74; unlocks the third connector unit relay which deenergizes; locks itself to lock conductor 278; and connects the fifth connector unit relay (shown dotted) 69 with the odd conductor 383. In the same manner as just described the remaining connector unit relays are energized and deenergized in response to succeeding pulses to connect the test conductors of the succeeding lines in the group 65 to the link test conductor 382. Since, in this case subscriber S4 on line 71 is being called, the second digit therefore comprises only one pulse and therefore the first connector unit relay 401 is energized to connect the test conductor 34 of 70 line 71 to the link test conductor.

After the last impulse of the second digit relays 201 and 303 remain energized and relay 307 falls back after an interval. At armature 343 relay 307 opens the locking circuit of relay 306 which there-

upon deenergizes. Relay 306, upon deenergizing, at armature 337 opens the locking circuit of relay 311 which likewise deenergizes; at armature 338 opens the circuit extending through the lower windings of relays 308 and 309 to deenergize the same if they are energized; and at armature 340 grounds conductors 269 and 394. Relay 311, upon deenergizing, at armature 357 opens a point in its own locking circuit, and at armatures 358, 359, 360 and 361 prepares the impulsing circuit to the code selecting relays CSR shown in Fig. 6.

The calling subscriber now dials the third or code selecting digit of the desired called subscriber's line. Line relay 207 follows the impulses 15 transmitted by the calling subscriber again causing relay 303 to deenergize for each pulse. Relay 306, 307 and 309 energize in the same manner as previously described. At armature 339 relay 306 prepares the circuit for busy relay 305. At 20 armature 343 relay 307 completes the locking circuit for relay 306, and at armature 345 prepares the circuit for relay 610. At armature 352 relay 309 grounds the odd pulse conductor 398 in response to the first pulse and at armature 353 completes an energizing circuit for relay 610. This circuit may be traced as follows: from grounded armature 323, conductor 278, armature 241, conductor 279, armatures 652, 642, 632 and 622, conductor 395, resting contact and armatures 367 and 361, armatures 353 and 345, armatures 369 and 365 and their resting contacts, conductor 396, and through the winding of relay 610 to battery.

The first code selecting relay 610 energizes over the above traced circuit, and at armature 611 closes the circuit for energizing the busy test relay 305 in its first step in series with test relay 315 in case the called line is busy. At armature 613 relay 610 completes a locking circuit for itself through the armatures 622, 632, 642 and 652 to the grounded lock conductor 219, at armature 614 connects the second code selecting relay 620 to the even pulse conductor 397, and at armatures 615 and 616 prepares points in the code ringing circuit. At the end of the first pulse relays 207, 303 and 398 energize as before.

In response to the second pulse relays 207, 303 and 309 deenergize, as previously described. At armature 353 relay 309 opens the original energizing circuit of relay 610, which is now held en-50 ergized over its locking circuit and at armature 352 grounds the even pulse conductor 397 to energize relay 620. This circuit may be traced as follows: from ground by way of armature 376 and resting contact, armature 343, armature 352 and 55 resting contact, armatures 359 and 365 and their resting contacts, conductor 397, armature 614, and through the winding of relay 620 to battery. At armature 621 relay 620 connects the test relay 315 in series with the busy relay 305 to test the idle or busy condition of the called line, at armature 622 opens the locking circuit of relay 610 which now deenergizes, at armature 623 closes its own locking circuit to grounded lock conductor 279, at armature 624 connects the third code selecting 65 relay 630 to the odd pulse conductor 398, and at armatures 625 and 626 prepares points in the code ringing circuit.

Code selecting relays 630, 640 and 650 energize in response to the third, fourth and fifth pulses 70 as a result of relay 309 alternately grounding the odd and even pulse conductors 398 and 397. Each subsequently operated code selecting relay opens the locking circuit to the previously operated code selecting relay to cause its deenergization. In re-

the even pulse conductor 397. At armature 661 relay 660 again completes the busy test circuit, at armature 663 locks itself to grounded lock conductor 279, at armature 664 opens its original energizing circuit after completion of its locking cir- 5 cuit, at armature 665 switches from one set of code ringing contacts to the other set, and at armature 666 completes the circuit for energizing the ring reversing relay 314. This circuit may be traced as follows: from ground by way of arma- 10tures 456 and 438, conductor 392, armature 666. conductor 379, and through the winding of relay 314 to battery. At armatures 371 and 372 relay 314 reverses the ringing connection so that generator will now be connected with the positive line 15 conductor instead of the negative line conductor.

In response to the seventh pulse relay 309 at armature 353 completes an energizing circuit for relay 610 as follows: from grounded lock conductor 279; armature 663, armature 664, and working 20 contact, armatures 642, 632 and 622, conductor 395, resting contacts of armatures 367 and 361, armatures 353-345, armatures 360 and 366 and their resting contacts, conductor 396 and through the winding of relay 610 to battery. Relay 610 25 operates its armature for the purpose previously stated and in addition at armature 612 opens the locking circuit of code selecting relay 650 to cause its deenergization. In response to the eighth, ninth, and tenth pulse code selecting relays 620, 30 630 and 640, respectively, energize and lock, and deenergize the previously energized code selecting relay in the same manner as previously described. From the foregoing it will be seen that the code selecting relays 610, 620, 630, 640 and 650 are 35 energized in response to the first five impulses in the code selecting digit, that relays 650 and 660 are energized for the sixth pulse, that relays 610 and 660, relays 620 and 660, relays 630 and 660. and relays 640 and 660 are energized for the sev- 40enth, eighth, ninth and tenth pulses.

In case the called line is busy a circuit is completed for energizing the busy test relay 305 in its first step in series with the marginal test relay 315 as follows: from ground on the test con- 45 ductor 34 of the called line, armatures 474 and 494, conductor 382, through the upper winding of marginal test relay 315, conductor 381. through the operated one of the multiple contacts 611 to 661, inclusive, conductor 394, resistance 50 341, armature 339 and through the winding of busy test relay 305 to battery. Busy test relay 305, due to resistance 341 closes only its "X" contact at armature 334 to prepare a circuit for fully energizing itself when relay 305 later on deener- 55 gizes. After the last pulse of the code selecting digit relays 207 and 303 again energize, and relays 306, 307, 308 and 309 deenergize, as previously described. Relay 306, upon deenergizing, at armature 339 completes the circuit for fully en- 60 ergizing the busy test relay 305 as follows: from grounded conductor 259, armature 334 and working contact, normally closed springs controlled by armature 339 and through the winding of busy relay 305 to battery.

Assuming, however, that the called line is idle, then busy relay 305 is not energized because no ground is connected to the test conductor 34 of the called line. Now, when relay 306 deenergizes after the code selecting digit a circuit is completed for energizing the test relay 315 in series with the cut-off relay 22 of the called line as follows: from grounded conductor 259, armature 334 and resting contact, on the unoperated busy relay 305, armature 340, conductor 394, through 75

the operated one of the armature 611 to 661, inclusive, conductor 381, through the upper winding of test relay 315, conductor 382, armatures 494 and 474, conductor 34, armature 25 and resting contact, and through the winding of cut-off relay 22 to battery. At armature 377 relay 315 completes its own locking circuit before operating its remaining armatures as follows: from ground at the normally closed springs controlled by 10 armature 228, conductor 275, armature 322, conductor 153, armature 377 and through the lower winding of test relay 315 to battery. At armature 373 relay 315 prepares a circuit for connecting ground to the negative link conductor 252 since 15 ring reversing relay 314 is energized, at armature 374 prepares the circuit for connecting generator to the positive link conductor 255, at armature 375 connects direct ground to conductor 382 to maintain the called line busy; at armature 376 20 grounds conductor 268 to energize the prepared connector group relay, in this case relay 470, and at armature 373 prepares the circuit for energizing the pick-up relay 670.

The circuit for energizing connector group re-25 lay 470 may be traced as follows: from grounded armature 376, and working contact, conductor 258, armature 455 on the operated connector group relay 471, and through the winding of relay 470 to battery. At armatures 472 and 473 relay 470 connects the line conductors 32 and 33 of the called line to the link conductors 252 and 255. When cut-off relay 22 energizes in series with relay 315 that relay at armatures 27 and 29 disconnects the line relay 21 from the line conductor 35 32 and ground, at armature 28 connects the grounded test conductor 34 to the finder test conductor 35 to mark this line as busy in the finder end of the link circuit, and at armature 29 completes an obvious circuit for energizing the lock-40 out relay 23. Relay 23, at armature 31 opens a point in the start circuit to start conductor 67.

At the beginning of each code ringing cycle generated by the ringing machine (not shown) the ringing machine grounds the pick-up lead 45 and completes the circuit for energizing relay 670 as follows: from grounded pick-up lead extending from the ringing machine, normally closed springs controlled by armature 612, conductor 330, armature 378, conductor 276, armature 240, conductor 277, and through the winding of pick-up relay \$10 to battery. At armature 671 relay 670 prepares a circuit for ringing relay 313, at armature 672 opens its original energizing circuit and completes its locking circuit 55 to lock conductor 279, and at armatures 673 and 674 prepares further points in the circuit to ringing relay 313.

The ringing machine is arranged to ground the code ring conductors at certain predetermined times during its cycles of operations, as indicated at the lower left-hand corner of Fig. 6. For example, 4-4 indicates that this conductor is grounded at predetermined periods in each cycle to operate the ringing relay 313 to generate four short rings, then a pause, followed by four more short rings. In this case, assuming that the code ring conductor 2-2 has been selected, then ringing relay 313 is energized over the following circuit: from ground at the ringing machine over 70 the conductor marked 2-2, resting contact and armature 691, armatures 645 and 673, working contact and armature 665, conductor 680, armature 671, conductor 399, and through the winding of ringing relay 313 to battery. The code ring 75 conductor 2-2 was selected because in this case it is assumed that the code selecting digit dialled was the digit 0, in which case code selecting relays 640 and 660 have been operated and locked in operated position. Each time ringing relay 313 is energized from the ringing machine said relay at armature 368 connects ground by way of armatures 371 and 373 to the negative link conductor 252 since relay 314 is energized, at armature 369 connects generator to the positive link conductor 255 by way of armatures 372 and 374 10 to code ring the called subscriber, and at armature 370 completes an obvious circuit for energizing condenser discharging relay 310. Relay 310 follows the impulses transmitted by ringing relay 343, but due to its slow release characteris- 15 tics this relay lags behind ringing relay 313 and at armature 354 connects battery through resistance 355 to the negative link conductor 352 momentarily after each application of generator in order to discharge the condensers associated with 20 the ringers on the called line. At armature 359 relay 310 completes a circuit for transmitting ring back tone to the calling subscriber as follows: from generator through working contact and armature 356, working contact and armature 328, 25 the tone condenser TC to conductor 254 and thence over the calling subscriber's loop, as previously described.

Ringing current to the called subscriber may now be traced as follows: from generator, working contact and armature 372, working contact and armature 369, armature 374, positive link conductor 255, armatures 493 and 473, conductor 33, through the ringers connected to the positive line conductor of this line to ground. In case the ringers of this line should be bridged instead of grounded, then the ground return circuit extends back by way of negative line conductor 32, armatures 472 and 492, conductor 252, armatures 373, 368, and 371 to ground.

When subscriber S4 answers his code ring during the silent period or when ringing relay 313 is in deenergized position back bridge relays 211 and 212 energize in case the called line is a metallic line, or in case the called line is a grounded 45 line then relay 211 alone is energized. The circuit for energizing back bridge relays 211 and 212 in case of a metallic line may be traced as follows: from ground through the winding of relay 212, lower right-hand winding of repeating coil RC, 50 conductor 256, resting contact and armature 369, armature 374, over the circuit to the called subscriber's loop previously traced for ringing current, back to conductor 252, armatures 373 and 368, conductor 253, through the upper right-hand 55 winding of repeating coil RC over armatures 238 and 327 in multiple, through the winding of relay 211 to battery. In case the called line is a grounded line relay 212 is short circuited over the following path: from the grounded positive line 60 conductor of the called line over armatures 473 and 493, conductor 255, armatures 374 and 369, conductor 256, through right-hand winding of repeating coil RC, and through the winding of relay 212 to ground.

Relay 211, upon energizing, at armature 242 and resting contact opens a point in the circuit to disconnect relay 206 and at its working contact completes a circuit for energizing relay 210. At armature 243 relay 211 completes a circuit for 70 energizing the battery reversing relay 209 in case the calling line is such as to require reverse battery supervision. The circuit for energizing relay 210 may be traced as follows: from ground at armature 321, conductor 265, armature 242 and 75

working contact, normally closed springs controlled by armature 237, and through the winding of relay 210 to battery. At armature 237 relay 210 completes its own locking circuit to grounded con-5 ductor 259 and opens its original energizing circuit, at armature 238 completes the talking circuit, at armature 236 removes the short circuit from around relay 208 to permit its energization in case the calling line is a metallic line, at 10 armature 239 opens one of the multiple circuits to relay 302, at armature 240 opens the circuit to pick-up relay 670 which accordingly de-energizes and at armature 241 disconnects ground from lock conductor 279 to cause the deenergization of 15 the operated code selecting relays. Relay 208 now operates in series with the calling subscriber's loop and relay 207 in case the calling line is a metallic line as follows: from ground through the winding of relay 208, normally 20 closed springs controlled by armature 234, lower left-hand winding of repeating coil RC, resting contact and armature 247, conductor 151, armatures 173 and 113, positive line conductor 15 of line 17 and thence through the calling subscriber's 25 loop and over the previously traced circuit through the winding of line relay 207 to battery. In case the calling line is a grounded line then the positive line conductor such as conductor 15 will be grounded and relay 208 is prevented from 30 operating. Relay 208, upon energizing if the calling line is a metallic line, at armature 232 completes a circuit for energizing battery reversing relay 209 in case the calling line is in a group requiring reverse battery supervision, in which 35 case conductor 158 is connected to contacts, such as contacts 118, to conductor 157 which is grounded thereby completing the circuit by way of armature 243 for energizing the battery reversing relay 209

All the code selecting relays in Fig. 6 now restore and relay 660 at armature 666 opens the circuit to ring reversing relay 314 and relay 670 at armature 671 opens the circuit to ringing relay 313. Relay 209, upon energizing, at armatures 45 233 and 234 reverse battery to the calling line, and at armature 235 completes a locking circuit for itself independent of armature 232.

When the calling line is a metallic line, talking battery is supplied from the windings of relays 50 207 and 208 through the left-hand windings of the repeating coil RC over the resting contacts and armatures 246 and 247 to conductors 150 and 151, and thence over the calling loop. In case the calling line is a grounded line, then talking 55 battery is supplied through the winding of line relay 207 and from the grounded positive line conductor of the calling line. When the called line is a metallic line talking battery is supplied through the windings of relays 211 and 212 over 60 the previously traced circuit to the called subscriber's loop and in this case if relay 210 is operated the circuit for relay 211 extends from the winding of repeating coil through armature 327 and conductor 266. In case the called line is a grounded line then the battery is supplied through the winding of relay 211 and from ground on the grounded positive line conductor of the called line.

After conversation and responsive to the called party replacing his receiver relays 211 and 212 70 deenergize. At armature 243 relay 211 opens the circuit of relay 209 in case it is energized, and at armature 242 prepares the circuit for the disconnect relay 206 so that this link will be automatically released after a predetermined interval 75 if the calling subscriber fails to replace his receiver. Battery reversing relay 209, if energized, now deenergizes and reverses battery to the calling line for supervisory purposes. In response to the calling subscriber replacing his receiver line relay 207 deenergizes and likewise relay 208, if energized. At armature 230 line relay 207 opens the circuit of relay 303 which deenergizes and at armature 231 opens one of the multiple ground circuits to slow to release relay 301. Relay 303, upon deenergizing, at armature 325 opens the 10 circuit of slow to release relay 301, at armature 327 disconnects relay 211 from conductor 253, and at armature 326 closes the circuit for relays 306, 307 and 309. Relay 301, upon deenergizing, at armature 318 opens the circuit-of relay 302 15 and disconnects ground from test conductor 152 to open the circuit of the cut-off relay 2. Cut-off relay 2, upon deenergizing, at armature 10 opens the circuit of lock-out relay 3, and at armatures 8 and 9 operatively connects line relay 1 to the 20 line. After an interval lock-out relay 3 deenergizes and at armature 12 prepares the circuit for start lead 61.

Slow to release relay 302, upon deenergizing, at armature 320 disconnects ground from re-25 lays 306, 307 and 309 to cause their deenergization, at armature 32! disconnects ground from conductor 265 to open a point in the circuit of the disconnect relay 206, at armature 322 opens the locking circuit of relay 315 and disconnects 30 ground from conductors 153 and 157 to unlock the operated finder group relays 110 and 111, the operated finder unit relay 107, and relays 204 and 202. At armature 323 relay 302 disconnects ground from the lock conductor 278 to unlock the 35 operated connector unit relay 49! and connector group relay 471. Relay 401, upon deenergizing, at armatures 492, 493 and 494, disconnects the conductors of line 71 from the control relays in the link. Relay 471, upon deenergizing, at arma-40 ture 474 disconnects the test lead 34 from the link circuit thereby opening the circuit to cut-off relay 22. At armature 455 relay 471 opens the circuit to relay 470 which accordingly deenergizes and disconnects the line conductors 32 and 33 45 from the link. Relay 315, upon deenergizing, at armature 375 disconnects ground from test conductor 382, at armature 376 disconnects ground from conductor 268 to open the circuit of relay 470, and at armatures 373 and 374 opens a point 50in the talking circuit. Relay 204, upon deenergizing, at armature 221 opens the locking circuit from relays 210 and 304 to cause the latter relays to deenergize.

Relay 110, upon deenergizing, at armatures 55 112 and 113 disconnects the line conductors 14 and 15 from the repeating coil RC. Relay !!!, upon deenergizing, at armature 114 disconnects the test lead of the line from test conductor 152. Relay 107, upon deenergizing, at armatures 172, 60 173 and 174, disconnects the control relays of the link from the calling line. Relay 202, upon de-energizing, at armature 217 transfers the transfer relay 201 from direct ground to the in lead 281 of the start chain so that if the in lead 281 65 is grounded at this time the transfer relay 201 will not restore and interfere with the operation of a succeeding link. In case the in lead 281 is not grounded 201 deenergizes and at armature 216 opens a point in the all link busy chain. At 70 armature 215 relay 20! disconnects the out lead 282 and connects up the in lead 281 to line relay 207. Relay 210, upon deenergizing, at armature 236 short circuits relay 203 and grounds conductor 151, at armature 237 opens a point in its 75 own locking circuit as well as preparing its own original energizing circuit, and at armature 238 separates the right-hand windings of repeating coil RC. Relay 394, upon deenergizing, at armature 328 restores the circuit for connecting dial tone to a calling line, and at armature 330 prepares a point in the circuit to relay 312 as well as a point in its own original energizing circuit. Cut-off relay 22, upon deenergizing at armatures 27 and 29 prepares the circuit for line relay 21 and at armature 29 opens the circuit to lock-out relay 23. Lock-out relay 23 restores and at armature 31 prepares the circuit to start lead 67. All relays are now in their normal position and the link circuit may be used in a subsequent call.

Assuming now that the called line was busy instead of idle, and returning to the operation at a time when busy relay 205 was fully energized after the code selecting digit was dialled, busy 20 relay 305, upon energizing, at armature 331 connects the busy tone to the calling line as follows: from busy tone by way of armature 331, resting contact and armature 356, working contact and armature 328, tone condenser TC, conductor 254, 25 resting contact and armature 246, and thence over the calling subscriber's loop, as previously described. At armature 332 relay 305 prepares a circuit for grounding test lead 382, and at armature 333 opens the circuit to relays 396, 307 and 30 309 and likewise prepares a circuit for reoperating relay 303 in case relay 207 is again operated. At armature 335 relay 305 prepares a point in the circuit to reverting call relay 205 and at armature 334 completes a locking circuit for itself as follows: from grounded conductor 259, armature 334 and working contact, normally closed springs controlled by armature 339, and through the winding of busy relay 305 to battery. After receipt of busy tone the calling subscriber re-40 places his receiver, thereby opening the circuit to line relay 207, which accordingly deenergizes and causes the release of the operated relays in the manner as described for the release from an idle line. In this case, since busy relay 305 is en-45 ergized, the deenergization of relay 204 at armature 221 opens the circuit of busy relay 305 to cause its deenergization.

The foregoing circuit descriptions are the circuit operations for ringing the subscribers, such as subscribers S4 and S6, which have their ringers connected to the positive line conductor. As diagrammatically illustrated in Fig. 4 line 11 has ten substations connected thereto, five of such substations having their ringers connected to the negative line conductor and the remaining lines having their ringers connected to the positive line conductor. In order to ring the subscribers having their ringers connected to the positive line conductor, the code ringing digit dialled is six or more so that the code selecting relay 660 will be energized to cause the energization of ring reversing relay 314, as previously described. In order to ring the subscribers having their ringers connected to the negative line conductor the code ringing digit dialled is less than six, and therefore relays 660 and 314 are not energized. In this case the operation of ringing relay 313 connects generator to the negative line conductor to operate the 70 ringers thereon. This arrangement is known as ten party divided ringing.

Some of the party lines have as many as twenty subscribers on a line, for example, the line Nos. 26 and 27 shown in Fig. 4, illustrate a grounded line having twenty subscribers there-

on. As will be noticed armatures 424 and 430 on connector group relay 421 are tied together and connected to the test conductor 44 of this Armatures 422 and 427 and armatures 423 and 428 are tied together and connected respectively to the negative and positive line conductors 42 and 43. From the foregoing description it will therefore be understood that this line may be connected with in response to dialling the digits 2-6 or 2-7. The first ten sub- 10 scribers on this line are signalled by dialling digits 2 and 6 and then a code selecting digit 1 to 0. In response to the calling subscriber dialling the digits 2 and 6 the control relays operate in the same manner as previously described 15 to cause the energization of the connector unit and connector group relays 421 and 406. In response to dialling the code selecting digit the code selecting relays CSR are energized as previously described to select the desired code. 20 Since in this case ring reversing relay 314 is not energized, ringing relay 3/3 always connects the generator to the negative line and since relay 600 is not energized, the code selected by the code digit dialled is determined by the con- 25 ductor selected over the resting contacts of the armatures of relay 600. The second ten subscribers on this line are signalled by dialling the digits 2 and 7 and then a code selecting digit 1 to 0. In response to the calling subscriber 30 dialling the digits 2 and 7 the control relays operate as previously described to cause the energization of the connector unit and connector group relays 421 and 401. When relay 401 operates its armature 414 a circuit is completed 35 for energizing the code switching relay 600, as follows: from grounded conductor 279, armatures 469 and 414, conductor 393, and through the winding of code switching relay 600 to battery. Relay 600 at its resting contact discon- 40 nects the first ten code ring conductors and at the working contact of these armatures connects the second ten code ring conductors. In response to dialling the code selecting digit the code selecting relays are operated as before to 45 select the desired code ring conductor in the second set. Now when the ringing relay 313 is energized over the selected code ring conductor, generator is connected to the negative line conductor in accordance with the selected code ring 50 conductor. The following chart shows the digits dialled and the code ring conductors selected in accordance therewith:

20-party code ring

| $\begin{array}{cccccccccccccccccccccccccccccccccccc$ | | · | | |
|---|--|---|--|--|
| $\begin{array}{c ccccccccccccccccccccccccccccccccccc$ | Digits | Ring cond. | Digits | Ring cond. |
| | 26-2 26-3 26-4 26-5 26-6 26-7 26-8 26-8 | 3 4 1-1 1-2 1-3 1-4 2-1 | 27-2 27-3 27-4 27-5 27-6 27-7 27-8 27-9 | 2-4 3-1 3-2 3-3 3-4 4-1 4-2 4-3 |

A modification in Fig. 4 shows how the first or group selecting digit dialled by the calling subscriber will determine which group of code ring 70 conductors are to be used in signalling the subscribers on a twenty-subscriber party line. For example, if dotted conductor 415 shown in Fig. 4 should be arranged to permanently shunt armature 414 then whenever the group selecting 75

55

digit 2 is dialled the circuit for code switching relay 600 in Fig. 6 is completed over conductor 393. Relay 600, it will be remembered, switches from one set of code ring conductors to the other set whenever the same is energized. Therefore, in response to dialling group selecting digit 2 one group of the ten subscribers may be signalled. In order to code ring the other ten subscribers on the line some other group select-10 ing digit will be dialled to cause corresponding connector relays to operate and extend the connection to this line. In this case the connector relay operated does not complete a circuit for relay 600 so that the first set of code ring con-15 ductors are used to signal the other group of ten subscribers on this line.

Another modification is shown for reversing the application of ringing current to the called line by the energization of ring reversing relay 20 314. In this modification the circuit for relay 314 extends from ground at armature 456 over the dotted conductor 446 (inshunt of armature 438), conductor 392, over the dotted conductor 392' (connected in shunt of armature 666), conductor 25 379, and through the winding of ring reversing relay 314 to battery. In this case whenever connector group relay 471 is energized in response to the group digit 7, relay 314 is energized to reverse the application of ringing current to the called line so as to ring such subscribers which have their ringers connected to the positive line conductor and ground. In order to ring the subscribers having their ringers connected to the negative line conductor and ground of this same 35 line some other group selecting digit will be dialled to cause corresponding connector relays to operate and extend the connection to this line. In this case the operated connector group relay does not complete a circuit for relay 314 with 40 the result that ringing current is connected to the negative line conductor when the ringing relay 313 is operated.

Reverting calls

45

In order to describe a reverting call it will be assumed that substation S desires to call another subscriber on his own line, for example, subscriber SI. Subscriber S therefore removes his receiver 50 and dials the line selecting digits 1 and 7 and then the code selecting digit assigned to subscriber S1. The finder group relays 110 and 111 and the finder unit relay 107 operate to connect the control relays of the link to line 17. The connector group 55 relay 411, the connector unit relay 497, and the code selecting relays in Fig. 6 operate also in the same manner as previously described. Since the called subscriber, subscriber S!, is on the same line as the calling subscriber S, line 17 is marked 60 busy and busy relay 365 energizes in the same manner as previously described to transmit the busy tone to the calling subscriber. In response to the receipt of busy tone subscriber S now replaces his receiver, thereby opening the circuit 65 of line relay 207 which accordingly deenergizes. At armature 230 relay 207 opens the circuit of the relay 303. Relay 303, upon deenergizing, at armature 325 opens the circuit of relay 301 and at armature 324 grounds the test conductor 382 70 to maintain the line busy and to hold the cutoff relay 2 and slow release relay 302 in energized position as follows: from grounded armature 324 and resting contact, armature 332, conductor 382, armature 478, armature 497, test conductor 16 of 75 line 17, armature 6 and resting contact, one

branch extending to the winding of relay 2 to hold said relay and the other branch extending by way of armature 9, armatures !14 and 174, conductor 152, armature 222, armature 239, conductor 272, and through the winding of relay 302 5 to battery for holding the latter relay.

Slow to release relay 301, upon deenergizing, at armature 318 and working contact, opens the original energizing circuit of relay 302 now maintained energized over the previously traced cir- 10 cuit, and at the resting contact of armature 318 completes a circuit for energizing reverting call relay 205. This circuit may be traced as follows: from ground at the resting contact of armature 324 over the previously traced circuit for holding 15 cut-off relay 2 and relay 302 energized to conductor 152, conductor 271, armature 318 and resting contact, armature 335, conductor 273 and through the winding of reverting call relay 205 to battery. At armature 225 relay 205 opens the 20 circuit to finder group relay 110 which deenergizes, at armature 226 opens one of the multiple circuits to relay 302, and at armature 227 completes a circuit for energizing test relay 315 as follows: from ground at the normally closed 25 springs controlled by armature 228, conductor 275, armature 322, conductor 153, armature 227, conductor 274, and through the lower winding of relay 315 to battery. Relay 110, upon deenergizing, at armatures 112 and 113 disconnects 30 the line conductors 14 and 15 from the link conductors 150 and 151 thereby opening the circuit to line relay 201. At armature 377 relay 315 completes a locking circuit for itself, at armature 378 prepares a circuit for energizing pick-up re- 35 lay 670, at armature 376 completes the circuit for energizing relay 410, at armature 375 grounds the test lead 382 to maintain this line busy, and at armatures 313 and 314 prepares points in the ringing circuit. The circuit for energizing re- 40 lay 410 may be traced as follows: from grounded armature 376 and working contact, conductor 268, armature 492 and through the winding of relay 410 to battery. At armatures 495 and 496 relay 410 connects the line conductors 14 and 15 45 to the link conductors 252 and 255.

At the beginning of the code ringing cycle the pick-up conductor is grounded in the ringing machine to cause the energization of pick-up relay 679 as previously described. At armature 672 50 pick-up relay 670 completes its own locking circuit, and at armature 671 prepares the circuit for ringing relay 313. When the selected code ring conductor is grounded by the ringing machine ringing relay 313 is energized over the previously 55 traced circuit in accordance with the number of times the code ringing conductor is grounded by the ringing machine in order to transmit ringing current to line 17. The ringing circuit may be traced as follows: from generator, resting con- 60 tact of armature 371, working contact and armature 368, armature 373, conductor 252, armatures 475 and 495 to negative line conductor 14 of the line 17 and thence through the ringers on line 17 to positive line conductor 15, armatures 496 65 and 476, conductor 255, armature 374, armature 369, and working contact, armature 372 and resting contact, to ground.

At completion of the code ring and in response to either the calling or called subscriber answer- 70 ing during the silent period relay 211 energizes in series with relay 212 over the following circuit: from ground through the winding of relay 212, lower right-hand winding of repeating coil RC, conductor 256, resting contact and arma-75

ture 369, and thence over the previously traced ringing circuit through the substation loop, back to armature 368 and resting contact, conductor 253, upper right-hand winding of repeating coil RC, armature 238 and resting contact, and through the winding of relay 211 to battery. At armature 242 relay 211 completes the circuit for energizing relay 210 and opens a point in the circuit to the disconnect relay 206. Relay 219, 10 upon energizing, at armature 237 closes its own locking circuit and opens its original energizing circuit, at armature 236 removes the short circuit from around relay 208, at armature 241 disconnects ground from conductor 279 to deener-15 gize the code selecting relays, at armature 238 opens the circuit to relays 211 and 212 which accordingly deenergize, and at armature 239 opens the circuit to relay 302 to cause its deenergization. After an interval slow to release re-20 lay 302 deenergizes and at armature 323 opens the locking circuit of relays 497 and 411; and at armature 322 opens the circuit to relays 315, 111, 107, 204, and 202. Relay 407, upon deenergizing, at armatures 475, 476 and 478 disconnects 25 the link conductors 252, 255 and 382 from line 17. Relay 411, upon deenergizing, opens at armature 497 the circuit to test conductor 16 and at armature 492 opens the circuit of relay 419 which accordingly deenergizes. Relay 315, upon deen-30 ergizing, at armatures 373 and 374 opens further points in the talking and ringing circuits, at armature 375 disconnects ground from test conductor 382, at armature 376 disconnects ground from conductor 268, at armature 377 opens a 25 point in the locking circuit, and at armature 378 opens a point in the original energizing circuit of pick-up relay 670. Relay III, upon deenergizing, at armature 118 opens the circuit to relay 110 which accordingly deenergizes, and at arma-40 ture 114 disconnects the test lead of line 17 from the link. Relay 107, upon deenergizing, at armatures 172, 173 and 174 opens further points in the link circuit. Relay 204, upon deenergizing, at armature 221 opens the locking circuit of 45 relays 210, 304 and 305. Relay 202, upon deenergizing, at armature 217 transfers relay 201 from direct ground to the in start lead 281. Reverting call relay 205, upon deenergizing, at armature 227 opens a point in the original ener-50 gizing circuit of relay 315.

Cut-off relay 2, upon deenergizing, at armature 10 opens the circuit of lock-out relay 3, and at armatures 8 and 10 reconnects line relay to the conductors of line 17. Line relay I now 55 energizes over the subscriber's loop as follows: ground by way of armature 10 and resting contact, lower winding of line relay 1, conductor 15, the substation loop conductor 14, armature 8, and through the upper winding of relay I to 60 battery. At armature 6 line relay I grounds the test conductor 16 to busy this line in the connector end of the link circuit, and at armature 7 completes the locking circuit for lock-out relay 3. Lock-out relay 3 is maintained energized to pre-65 vent grounding of the start lead 61. Relays 305, 210 and 304 now deenergize. Relay 201 deenergizes in case the in lead 281 is not grounded, as previously described. The entire link is now released and talking battery is furnished through 70 line relay I to the subscribers on line I7. After conversation and in response to both parties replacing their receivers line relay I restores and opens the circuit of lock-out relay 3 which is likewise deenergized and restores the line cir-75 cuit to normal.

Call to switchthrough trunk

It will now be assumed that subscriber S desired to call a subscriber in a distant automatic exchange, and in order to do so dials the digit 8 5 and 1 to connect with the trunk line extending to this automatic exchange. In response to subscriber S removing his receiver and dialling the digits 8 and 1 the finder relays, the control relays and the connector relays are operated as previ- 10 ously described to complete a connection with the called trunk line. In this case, since the digits 8 and 1 have been dialled, connector relays 481 and 401 are energized. At armatures 484 and 494 relays 481 and 401 connect the test lead 15 of the trunk line 81 to test lead 382. At armatures 437 and 445 busy relay 305 is connected in series with the upper winding of switchthrough relay 213 to the test conductor 382 to test the busy or idle condition of this trunk line. In 20 case the trunk line 3! is busy, ground on the test conductor 487 of trunk line 81 completes a circuit for energizing busy relay 305 to close its "X" contacts, thereby preparing a circuit for fully energizing itself then relay 306 deenergizes 25 shortly after the impulsing period. This circuit may be traced as follows: from grounded test conductor 437, armatures 484 and 494, conductor 382, armatures 437 and 445, conductor 270, upper winding of switch-through relay 213, 30 conductor 269, armature 317, resistance 341, armature 339, and through the winding of busy relay 305 to battery. Due to resistance 341 in the circuit relay 213 is not energized over the above traced circuit and the busy relay 305 oper- 35 ates to close only its "X" contact at armature 334. When relay 306 deenergizes shortly after the second impulsing period, as previously described, said relay at armature 339 closes the circuit for fully energizing busy relay 305 from 40 grounded conductor 259. Busy relay 305 now operates as previously described and connects busy tone to the calling line. The calling subscriber then hangs up to restore the link.

In case the trunk line 81 is idle when called, 45 then there is no ground on test conductor 487 and busy relay 395 is not energized. Now when relay 306 deenergizes shortly after the second impulsing period a circuit is completed for energizing switchthrough relay 213 in series with 50 the cut-off relay of trunk line 81 as follows: from grounded conductor 259, armature 334 and resting contact, armature 340, armature 317, conductor 269, upper winding of switch-through relay 213, conductor 270, armatures 445 and 437, 55 conductor 397, armatures 494 and 484, conductor 487, and through the cut-off relay associated with this trunk line to battery. At armature 250 relay 213 closes its own locking circuit to ground at armature 318 and at armatures 246 and 247 60 disconnects the calling line from the left-hand windings of the repeating coil and connects the calling line to conductors 252 and 255 direct. At armature 248 relay 213 opens a point in the circuit to disconnect relay 206, at armature 249 65 disconnects ground from conductor 262 to open one of the multiple grounds to relay 301 and to open the locking circuit of relay 304. At armature 249 and working contact relay 213 grounds conductor 268 to complete an energizing cir- 70 cuit for relay 489 by way of armature 444, and at armature 251 connects grounded conductor 271 to test conductor 382 by way of armatures 445 and 437 to maintain the test conductor 487 grounded. Line relay 207 deenergizes when its 75

circuit is opened at armatures 246 and 247 and at armature 230 opens the circuit to relay 303. Relay 430, upon energizing, at armatures 482 and 483 connects the trunk conductors 485 and 486 to the link conductors 252 and 255. Relay 303, upon deenergizing, at armature 325 opens the circuit of slow release relay 301 which deenergizes after an interval. The trunk equipment operates and connects ground to test conductor 487 to hold relays 213, 302 and cut-off relay 2 energized. The circuit for holding relay 213 energized extends from grounded conductor 487, armatures 484 and 494, conductor 382, armatures 437 and 445, conductor 270, armatures 251 and 250, through the lower winding of cutthrough relay 213 to battery. The circuit for maintaining relay 302 in energized position extends from grounded conductor 437 over the previously traced circuit to armature 251 and thence 20 over armatures 239 and 226 in multiple to conductor 272 and through the winding of relay 302 to battery. The circuit for maintaining cut-off relay 2 in energized position is the same as that previously traced and extends from armature 251 25 by way of conductor 271, armature 222, conductor 152, armatures 174 and 114, armature 9, and through the winding of cut-off relay 2 to battery. The calling line conductors 14 and 15 are now both connected directly to the trunk 30 conductors 485 and 486 whereby the calling subscriber may now dial the digits of the desired subscriber at the automatic exchange to operate the automatic switches therein to complete the desired connection in the well known 35 manner. Talking battery to both the calling and called subscriber is furnished from the automatic exchange.

After conversation and in response to the calling subscriber replacing his receiver, the switches 40 in the automatic exchange release and disconnect ground from test conductor 487, thereby opening the holding circuit of relays 213, 302 and cut-off relay 2. Relay 213, upon deenergizing, at armature 249 opens the circuit of relay 489. 45 Cut-off relay 2 deenergizes and opens the circuit to lock-out relay 3 and connects the line relay I to the line conductors of line I7. Slow to release relay 392 deenergizes and at armature 322 opens the circuit to the finder relays 110, 111 50 and 107 and relays 204 and 202. At armature 323 relay 302 opens the circuit to connector relays 401 and 481. Relay 480, upon deenergizing, at armatures 482 and 483 disconnects the talking conductors of the link from the trunk line. The 55 lock-out relay 3, the finder relays 110, 111, and 107, deenergize as previously described. Relays 204 and 202 deenergize and the latter relay connects the transfer relay 201 to the in lead 281. Connector relays 401 and 481 likewise deenergize. 60 In case the in lead 28! is grounded transfer relay 201 is maintained energized, otherwise relay 201 deenergizes and the link may be used on subsequent calls.

Incoming trunk calls operate the link circuit
the same as previously described for a local subscriber calling another local subscriber. In this
case, however, reverse battery supervision is
needed and when the local called subscriber answers relay 211 energizes and at armature 243
closes the circuit for battery reversing relay 209
to reverse battery over the calling trunk line.

Calls to ring-down trunks are made in the same manner as described for calls between local subscribers' lines. On disconnect, however, it is 75 necessary to transmit a disconnect signal over

the ring-down trunk to signal the distant operator. After the completion of conversation over a ring-down trunk the calling subscriber replaces his receiver to cause the deenergization of relay 207. At armature 230 relay 207 opens the 5 circuit of relay 303 which deenergizes and at armature 327 disconnects battery through the winding of relay 211 from the negative conductor 252 whereby battery is disconnected from the negative ring-down trunk conductor to cause the 10 distant operator to receive a disconnect supervision. Relay 211, upon deenergizing, at armature 243 opens the circuit to reversing relay 209 which deenergizes if operated and at armature 242 closes a holding circuit for slow to release 15 relay 301 before the same deenergizes in response to the deenergization of relay 303. This circuit may be traced from ground at armature 321, conductor 265, armature 242 and resting contact, armature 245 and working contact, conductor 264, 20 and through the winding of relay 301 to battery. The restoration of the link circuit is now controlled by the operator over the ring-down trunk. When the operator at the distant end disconnects the circuit to relay 212 is opened and said relay 25 deenergizes to open the circuit of relay 30! at armature 245 to cause the deenergization of relay 301 and the release of the link as previously described.

Permanents

The link circuit is considered held by a permanent if it remains in non-talking position for a minimum of two minutes after seizure or after the called subscriber disconnects. Relays 580 35 and 590 and interrupter 593 in Fig. 5 comprise a timing device for causing the operation of disconnect relay 206 if a fault, such as a permanent, appears. At two minute intervals interrupter contacts 593 are closed to complete a cir- 40 cuit for relay 590. At armature 592 relay 590 disconnects ground from conductor 284 and at the working contact of armature 592 completes an obvious circuit for energizing relay 580. At armature 581 relay 580 prepares the circuit for 45 connecting battery to conductor 285 to energize the disconnect relay 206 if a permanent exists. When interrupter spring 593 opens relay 599 deenergizes and at armature 591 momentarily connects battery to conductor 285 to energize discon- 50 nect relay 206 if a permanent exists. At armature 592 and its working contact relay 590 opens the circuit of relay 580 which deenergizes after an interval and at the resting contact of armature 592 grounds conductor 284. Relay 580, upon 55 deenergizing, at armature 581 disconnects battery from conductor 285.

In case the link is held by a permanent condition and the same is not in talking position, that is in case relays 211, 212 or 213 are not energized, 60 a circuit is completed for disconnect relay 203 when relay 580 is energized and relay 590 deenergizes as follows: from grounded armature 321, conductor 265, armature 242, 245 and 248 and their resting contacts, winding of disconnect re- 65 lay 206, normally closed springs controlled by armature 229, conductor 285, armatures 581 and 591, resistance 594 to battery. Relay 206 at armature 228 disconnects the ground at the normally closed springs controlled by armature 228 70 and connects the ground on conductor 284 extending from the resting contact of armature 592 to conductor 275 to maintain a holding condition on conductor 275 until the relay 590 is again operated. At armature 229 relay 206 opens 75

30

a point in its original energizing circuit and completes a locking circuit for itself over conductor Now, in case the link circuit has not switched through to talking position by the energization of either relays 211, 212 or 213, before relay 593 again energizes, then relay 590 at armature 592 disconnects ground from hold conductor 275 with the result that the link is released and the calling line is locked out. In case a calling 10 subscriber fails to dial or the subscriber's line is held by a short circuit the disconnection of ground from conductor 284 at armature 592 opens the circuit to the finder relays such as 110, 111 and 107 and the link control relays 202 and 204. 15 Restoration of the finder relays disconnects the calling line from the link causing the deenergization of line relay 201 and cut-off relay 2. At armature 221 relay 204 opens the circuit of relay 312 which thereupon deenergizes. At armature 20 217 relay 202 connects the transfer relay 201 to the in start lead 281. Relays 207, 312 and 303 deenergize in the same manner as previously described. Relay 303 at armature 325 opens the circuit of slow to release relay 301 which accordingly deenergizes and at armature 318 opens the circuit for relay 302. Relay 302 deenergizes and causes the release of the remaining operated relays in the same manner as previously described.

In case the calling subscriber dials only one digit and then fails to disconnect, the removal of ground from conductor 284 causes the release of the link as just described and in addition in this case since relay 311 is energized, such relay is deenergized in response to the restoration of 35 relays 284, which at armature 22! opens the circuit thereto. The operated connector group relay is deenergized in response to the removal of ground from lock conductor 278 by the restoration of relay 302. In case the calling subscriber dials two digits and then fails to disconnect the removal of ground from conductor 284 causes the release as previously described and in addition causes the release of the operated connector relays in response to the restoration of relay 302.

In case the called subscriber does not answer within the predetermined time the removal of ground from conductor 284 causes the deenergization of the relays as previously described and in addition the deenergization of relay 315. At 50 armature 375 relay 315 opens a circuit to the connector group relay, at armatures 373 and 374 disconnects generator from the called line, at armature 378 opens the circuit of relay 670, at armature 375 disconnects ground from the test 15 lead to free the called line. Relay 302, upon deenergizing, at armature 323 opens the locking circuit of the operated connector relays and the operated code selecting relays. Pick-up relay 670, upon deenergizing, at armature 671 opens the 60 circuit to ringing relay 313. The operated connector relays deenergize to disconnect the called line from the link and the code selecting relays deenergize thereby restoring the link to normal. In case the calling subscriber fails to hang up 65 his receiver after the called subscriber disconnects, then the removal of ground from conductor 284 causes the release of relays as previously described, and in this case relay 210 deenergizes in response to the deenergization of relay 294 70 when the locking circuit of relay 210 is opened at armature 221. In a similar manner in case the calling subscriber fails to disconnect after receipt of busy tone then the link is released as previously described, and relay 204 at armature 75 221 opens the circuit of busy relay 305 and re-

lay 304 which thereupon deenergize. In case both the calling and called subscribers fail to answer a reverting call, then the removal of ground from conductor 284 causes the release of relays 110, 111, 107, 202, 204, and 315, as previously described. The deenergization of relays 111 and 107 opens the test leads over which relays 302 and 205 were held energized on a reverting call. Relays 304, 305, 410, 302, 205, 670, 411, and 401 and the operated code selecting relays deenergize as previously described to free the link.

When ground is removed from the test lead the cut-off relay such as relay 2, deenergizes and at armatures 8 and 10 reconnects the line relay 1 to the line conductor to cause its reenergization 15 in case a permanent condition exists on the line. At armature 10 relay 2 opens the circuit of lockout relay 3. Line relay I immediately reenergizes in case the line is permanent and at armature 7 locks the lock-out relay 3 in energized position 20 before the same deenergizes. At armature 6 relay I grounds the line to make this line busy. When the permanent condition is cleared from the line the circuit of line relay I is opened and this relay deenergizes to free the line at arma- 25 ture 6 and at armature 7 opens the locking circuit of lock-out relay 3 which accordingly deenergizes. The line circuit is now at normal and may be used for both incoming and outgoing calls.

In case the finder unit relays fail to find the 30 calling line relay 107 at armature 148 completes a circuit for energizing relay 202 as follows: from grounded conductor 153, armature 223 and resting contact, armature 220 and working contact, conductor 155, armatures 142, 145, and similar 35 armatures on the finder unit relays, armature 148 and working contact, conductor 154, and through the lower winding of relay 202 to battery. At armature 217 relay 202 completes the circuit for energizing transfer relay 201. Relay 201 at ar- $_{
m 40}$ mature 215 closes a point in the all link busy chain, at armature 214 completes its own locking circuit, at armature 215 and working contact transfers the in start lead 281 to the out lead 282 to start the next idle link searching for the call- 45 ing line, and at armature 215 and its resting contact opens the circuit to line relay 207. The deenergization of line relay 207 causes the release of the link as previously described.

When all the links become busy a circuit is 50 completed for energizing all link busy relay 500 as follows: from ground at terminal 573, over conductors similar to conductors 283 and 280 to terminal 574, in a similar manner over conductors from terminals 575 to 576, and from ter-55 minals 557 to 573 to conductor 283, armature 216, conductor 280, and through the winding of all link busy relay 500. At armature 501 all link busy relay 500 removes ground from the start circuit to prevent a waiting call from holding the 60 transfer relays 201 energized. As soon as any one link becomes idle all link busy relay 500 deenergizes.

If the circuit of start relay 510 remains closed for a predetermined time ground from springs 503 65 operated by the time switch TS completes the circuit for relay 560. Relay 530 at armature 561 prepares the circuit to relay 570 and the start lamp ST, at armature 562 completes a locking circuit for itself by way of armatures 541, 512, and 591. At armature 563 opens a point in its original energizing circuit, at armature 564 prepares a circuit for relay 549, and at armature 565 prepares the circuit for the alarm lamp AL 75

and opens a point in the circuit to relay 550. When time switch TS closes springs 502 a circuit for energizing relay 540 is completed as follows: ground by way of springs 502, armature 5 554, through the normally closed springs controlled by armature 542, and through the winding of relay 540 to battery. At armature 541 relay 540 opens the locking circuit of relay 560 which thereupon deenergizes, at armature 542 10 completes its own locking circuit, at armature 543 opens the circuit to relay 530 if the same is energized, and at armature 544 opens the circuit to relay 529 and removes the shunt from around relay 539 in case relay 520 is energized. Relay 15 550, upon deenergizing, at armature 565 completes the circuit for energizing relay 550, and at armature 553 prepares a point in its original energizing circuit. If relay 520 is energized at this time relay 539 energizes in series with relay 20 529 when the shant is removed at armature 544. At armature 531 relay 530 transfers the start lead to the middle of the chain so as to select the next idle link near the middle of the chain. If relay 530 is already energized the same is 25 now deenergized in response to the operation of armature 543, because its circuit is open thereat. Relay 530, upon deenergizing, transfers the start circuit from the middle to the beginning of the chain. The circuit for energizing relay 30 559 may be traced as follows: from ground by way of armature 545, armature 565 and resting contact, through the normally closed spring controlled by armature 553, and through the winding of relay 550 to battery. At armature 553 35 relay 550 completes its locking circuit and opens its original energizing circuit, at armature 552 prepares a locking circuit for relay 560, at armature 551 prepares a circuit to the start lamp ST. and at armature 554 prepares a circuit to the 40 alarm lamp AL. When the time switch TS again closes springs 503 relay 560 again energizes. At armature 562 relay 560 completes its locking circuit, at armature 561 completes the circuit for lighting the start lamp ST and for energizing 45 relay 570, at armature 565 closes the circuit for lighting the alarm lamp AL. At armature 572 relay 570 closes a multiple circuit to the alarm lamp or alarm sender. When the circuit to start relay 510 is opened relay 510 deenergizes and at 50 armature 5!! removes ground from the start circuit, at armature 512 opens the locking circuit of relays 540, 550 and 560, and opens the circuit to the time switch TS to stop the same. Relay 540, upon deenergizing, at armature 545 opens 55 one of the multiple circuits to the alarm lamp AL. Relay 560, upon deenergizing, at armature 501 opens the circuit to the start lamp ST and relay 570. Relay 550, upon deenergizing, at armature 55! opens a point in the circuit to 60 the start lamp ST and relay 570, and at armature 554 opens the circuit to lamp AL. Relay 570, upon deenergizing, at armature 572 opens the circuit to the alarm lamp AL or the alarm sender. From the foregoing, it will therefore be seen that 65 if the start relay 510 is maintained energized for a predetermined time which time in this case would indicate some fault, then the time switch TS which is started in operation in response to the operation of relay 510 will have had sufficient time to cause the operation just described. The operation of the time switch is slow enough so that under normal conditions no alarm is operated. Having described the invention, what is con-

75 sidered new and is desired to be protected by

Letters Patent will be set forth in the following claims:

What is claimed is:

1. In a telephone system, subscribers' lines, each line having a pair of talking conductors, a 5 calling test conductor, and a called test conductor. a link having a pair of incoming talking conductors, an incoming test conductor, a pair of outgoing talking conductors, an outgoing test conductor, and groups of relays corresponding to 10 said lines, contacts on said relays terminating said conductors, means responsive to a subscriber on one of said lines initiating a call for operating certain of said relays and their contacts to connect the calling test conductor of the calling 15 line to the incoming test conductor and thereafter to connect the talking conductors of the calling line to the incoming talking conductors, means responsive to the calling subscriber dialling the digits of a called subscriber for operating 20 certain other of said relays and their contacts to connect the called test conductor of the called line to the outgoing test conductor, and means for operating a further one of said relays and its contacts in case the called line is idle to connect 25 the talking conductors of the called line to the outgoing talking conductors.

2. In a telephone system, subscribers' lines, each line having a pair of talking conductors and a calling test conductor, a link having a pair $_{
m 30}$ of incoming talking conductors, an incoming test conductor, and relays, contacts on said relays terminating said conductors, means responsive to a subscriber on one of said lines initiating a call for operating certain of said relays and their $_{35}$ contacts to sequentially connect the calling test conductors of said lines to said incoming test conductor until the calling line test conductor is connected with said incoming test conductor, and means for operating a further one of said relays $_{
m 40}$ and its contacts in response to the connection of the calling test conductor to said incoming test conductor to connect the talking conductors of the calling line to said incoming talking conductors.

3. In a telephone system, subscribers' lines, each line having a pair of talking conductors and an incoming test conductor, a link having a pair of outgoing talking conductors, an outgoing test conductor, and relays, contacts on said relays 50 terminating said conductors, means responsive to a calling subscriber dialling the digits of a called subscriber for operating certain of said relays and their contacts to connect said outgoing test conductor to the incoming test con- 55 ductor of the called line, and means for operating a further one of said relays and its contacts in case the called line is idle to connect said outgoing talking conductors to the talking conductors of the called line.

4. In a telephone system, subscribers' lines, each line having a pair of talking conductors and an incoming test conductor, a link having a pair of outgoing talking conductors, an outgoing test conductor, and relays, contacts on said re- 65 lays terminating said conductors, means responsive to a calling subscriber dialling the digits of a called subscriber for operating certain of said relays and their contacts to connect said outgoing test conductor to the incoming test con-70 ductor of the called line, a busy relay in said link, and means for operating said busy relay over said test conductors in case the called line is busy to transmit a busy tone to the calling subscriber.

2,022,503

5. In a telephone system, subscribers' lines, each line having a pair of talking conductors and an incoming test conductor, a link having a pair of outgoing talking conductors, an outgoing test conductor, and relays, contacts on said relays terminating said conductors, means responsive to a calling subscriber dialling the digits of a called subscriber for operating certain of said relays and their contacts to connect said out-10 going test conductor to the incoming test conductor of the called line, a busy relay in said link, means for operating said busy relay over said test conductors in case the called line is busy to transmit a busy tone to the calling subscriber, 15 and means operated in case the called line is on the same line as the calling line for operating a further one of said relays and its contacts to connect said outgoing talking conductors to the talking conductors of said line.

6. In a telephone system, a group of lines, each line having a pair of talking conductors and a test conductor, a link for interconnecting said lines, a first and a second relay in said link corresponding to said group of lines, a group of re-25 lays in said link, each of said group relays corresponding to a line in said group, means responsive to a calling subscriber dialling the digits of a called one of said lines for operating said first relay to connect the test conductors of all said lines to said group of relays and for operating the relay in said group corresponding to the called line to connect the test conductor of the called line to said link, and means in said link operated in case the called line is idle for operating said second relay to connect the line conductors of the called line to said link.

7. In a telephone system, groups of lines, a plurality of links for interconnecting said lines, a first group of relays in each link, each such re-40 lay corresponding to a group of lines, a test conductor for each line terminating in contacts on a first group relay in each link corresponding to the group such line is located in, a second group of relays in each link, the number of relays in a second group corresponding to the number of lines in any one group, each relay in each second group having contacts terminating the line and test conductors of its associated link, means responsive to a calling subscriber initiating a call for connecting the calling line to one of said links, means responsive to the calling subscriber dialling the digits of a called one of said lines for operating the first group relay in the connected link corresponding to the group the called line 55 is located in to connect all the test conductors of the called line group to the contacts of said second group relays in the connected link and for operating the second group relay in said link corresponding to the called line to connect the test conductor of the called line to the test conductor of said link, a third group of relays in each link, each such relay corresponding to a group of lines, line conductors for each line terminating in contacts on a third group relay in each 65 link corresponding to the group such line is located in, and means in said link operated in case the called line tests idle over the said connected test conductors for operating the third group relay in said link corresponding to the called line group to connect the line conductors of the called line to the line conductors of said link.

8. In a telephone system, a group of lines, each line having a pair of talking conductors and a test conductor, a link circuit for interconnecting said lines, a first relay in said link, a second re-

lay in said link, a group of relays in said link, means responsive to a line in said group initiating a call for marking its individual test conductor with calling potential and for operating said first relay to connect all the test conductors of said group of lines to said group of relays, means for sequentially operating said relays in said group in search of the test conductor having the calling potential thereon, and means operated when the calling potential is found for 10 stopping further sequential operation of said group of relays and for operating said second relay to connect the line conductors of the calling line to said link.

9. In a telephone system, groups of lines, each 15 line having a pair of talking conductors and a test conductor, a plurality of links for interconnecting said lines, a first and a second group of relays in each of said links, said line and test conductors of said lines normally connected to 20 the contacts of said first group link relays in all said links in accordance with the line groups such lines are located in, means responsive to a line in one of said groups initiating a call for seizing an idle one of said links, for operating 25 the relay corresponding to the calling group in the first relay link group of the selected link and for marking the test conductor of the calling line with calling potential, means for connecting all the test conductors of the lines in the calling 30 group to said second relay link group, means for sequentially operating the relays in the second group of the selected link in search of said calling potential on the test conductor of the calling line, means operated when the calling poten- 35 tial is found for stopping the sequential operation of said second group link relays, and means responsive thereto for connecting the line conductors of the calling line to the selected link.

10. In a telephone system, groups of lines, a 40 plurality of links for interconnecting said lines, a first and a second group of relays in each link, a relay in each group corresponding to a group of lines, a line test conductor for each line terminating in contacts on each first group relay 45 corresponding to the group such line is located in, line conductors for each line terminating in contacts on each second group relay corresponding to the group such line is located in, a third group of relays in each link, the number of re- 50lays in a third group corresponding to the number of lines in any one group, each relay in each third group having contacts terminating the line and the line test conductors of its associated link, a group test conductor for each group of 55lines terminating in contacts on the corresponding first group relay in each link, means responsive to a line in one of said groups initiating a call for marking the corresponding group test conductor with group calling potential, for mark- 60 ing its line test conductor with calling line potential, for seizing an idle one of said links, and for sequentially operating the first group relays in the seized link in search of said marked group calling potential, means in said link operated 65 when the group calling potential is found for stopping further sequential operation of said first group link relays and for sequentially operating the third group relays in said link in search of said marked line calling potential, the 70 last operated first group relay connecting the test conductors of the lines of the corresponding group to the contacts of said third group relays and said third group relays sequentially connecting the line conductors and the line test con- 75

ductors to the line conductors and to the line test conductor of said link until said marked calling line potential is found, means operated when the calling line potential is found for stopping 5 further sequential operation of said third group relays, and means responsive thereto for operating the second group relay in said link corresponding to the calling group to connect the line conductors of the calling line to the line con-10 ductors of said link.

11. In a telephone system, a called line having a first and a second group of subscribers thereon, a ringing code assigned to each subscriber on said line, means operated in response 15 to dialling either one of two different group selecting digits and the same units digit for connecting with said line, means responsive to dialling a code ring digit for selecting two ringing codes, the first selected code corresponding to 20 the digit dialled and being the ringing code of a subscriber in the first group, the second selected code also corresponding to the digit dialled and being the ringing code of a corresponding subscriber in the second group, and means de-25 pendent upon the group selecting digit dialled for determining whether the ringing code of the first group subscriber or the ringing code of the second group subscriber is to be transmitted.

12. In a telephone system, a called line hav-30 ing two different tens digits and the same units digit in its called number, a first group of substations on said line each having a different code ring digit in its called number, a second group of substations on said line each having the same code ring digit as a corresponding substation in said first group in its called number, means for transmitting a different ringing code for each substation on said line, and means dependent upon the tens digit and the code ring digit dialled for determining the substation ringing code to be transmitted.

13. In a telephone system, a called line, means operated in response to dialling either one of two different group selecting digits and the same unit 45 digit for connecting with said line, means thereafter responsive to dialling any one code ring digit for transmitting one of two different ringing codes corresponding to this digit over the called line, and means jointly dependent upon both the group selecting and code ring digits dialled for determining the particular ringing code to be transmitted over said line.

14. In a divided code ringing telephone system, a called line having a positive and a nega-55 tive line conductor, means responsive to a group selecting digit and a line selecting digit dialled by a calling subscriber for extending a connection to said line, ringing means including a set of counting relays responsive to the receipt of 60 a code ring digit for operating said counting relays to select a particular ringing code in accordance with the code ring digit dialled by the calling subscriber, a source of ringing current, a ringing relay for connecting said ringing source 65 to said line in accordance with said selected code, and means dependent upon the group selecting digit dialled for determining whether said ringing source is to be connected to said positive line conductor or said negative line conductor.

15. In a telephone system, a subscriber's line having a pair of individual talking conductors and an individual test conductor, a link circuit for completing telephone connections, means responsive to the initiation of a call on said line 75 for operatively connecting only said test con-

70

ductor to said link circuit, and means controlled by said last means for thereafter operatively connecting said talking conductors to said link

16. In a telephone system, a subscriber's line 5 having a pair of talking conductors and a test conductor, a plurality of link circuits for completing telephone connections, means responsive to the initiation of a call on said line for marking said test conductor with calling poten- 10 tial and for seizing an idle one of said link circuits, means in said link circuit responsive to said seizure for operatively connecting only said test conductor to said link circuit, and means in said link circuit operated in response to the con- 15 nection of said calling potential on said test conductor to said link circuit for operatively connecting said talking conductors to said link cir-

17. In a telephone system, a subscriber's line 20 having a pair of talking conductors and a test conductor, a link circuit for completing telephone connections, a first relay having contacts terminating said pair of talking conductors, a second relay having contacts terminating said 25 test conductor, means responsive to the initiation of a call on said line for operating said second relay and its contacts to operatively connect only the test conductor to said link, and means for thereafter operating said first relay 30 and its contacts to operatively connect said talking conductors to said link circuit.

18. In a telephone system, a subscriber's line having a pair of talking conductors and a test conductor, a link circuit for completing telephone 35 connections, a first relay having contacts terminating said pair of talking conductors, a second relay having contacts terminating said test conductor, a third relay having contacts for connecting said talking conductors and said test 40 conductor to said link circuit, means responsive to the initiation of a call on said line for operating said second and third relays and their contacts to operatively connect only the test conductor to said link circuit, and means operated 45 responsive to said last connection for operating said first relay and its contacts to operatively connect said talking conductors to said link circuit by way of the operated contacts of said third relay.

19. In a telephone system, a group of lines, each line having a pair of talking conductors and a test conductor, a link circuit for interconnecting said lines, a first relay in said link circuit, a second relay in said link circuit, a 55 group of relays in said link circuit, each group relay corresponding to a line in said group, means responsive to a line in said group initiating a call for operating said second relay and the group relay corresponding to the calling line to operatively connect only the test conductor of the calling line to said link circuit, and means operated responsive to said connection for operating said first relay to operatively connect only 65 the talking conductors of the calling line to said link circuit by way of said operated group relay.

20. In a telephone system, a group of lines, each line having a pair of talking conductors and a test conductor, a link circuit for interconnect- 70 ing said lines, a first relay in said link circuit, a second relay in said link circuit, a group of relays in said link circuit, each group relay corresponding to a line in said group, means responsive to a line in said group initiating a call 75 for operating said second relay to operatively connect all the test conductors of said group of lines to said group of relays, means operated responsive to the operation of said second relay for operating the group relay corresponding to the calling line to operatively connect only the test conductor of the calling line to said link

circuit, and means operated responsive to said last connection for operating said first relay to operatively connect only the talking conductors of the calling line to the link circuit by way of said operated group relay.

HARRY G. EVERS.
