(54) Title: METHOD FOR PRODUCING A HIGH STRENGTH COATED STEEL SHEET HAVING IMPROVED DUCTILITY AND FORMABILITY, AND OBTAINED COATED STEEL SHEET

(57) Abstract: A method for producing a coated steel sheet having a tensile strength TS of at least 100 MPa, a total elongation TE according to ISO standard 6892-1 of at least 12%, the product TSxTE of the tensile strength by the total elongation being at least 14200 MPa%, and a hole expansion ratio HER according to ISO standard 16630:2009 of at least 25%, comprising the following successive steps: - providing a cold-rolled steel sheet, the chemical composition of the steel containing in weight %: $0.15\% \leq C \leq 0.23\%$, $2.0\% \leq Mn \leq 2.7\%$, with $C+Mn/10 \geq 0.420\%$, $0 \leq Cr \leq 0.40\%$, with $Mn + Cr \geq 2.25\%$, $0.2\% \leq Si \leq 1.6\%$, $0.02\% \leq Al \leq 1.2\%$, with $1.0\% \leq Si+Al \leq 2.2\%$, $0 \leq Nb \leq 0.035\%$, $0 \leq Mo \leq 0.1\%$, the remainder being Fe and unavoidable impurities, - annealing the steel sheet at an annealing temperature T_A so as to obtain a structure comprising at least 65% of austenite and at most 35% of intercritical ferrite, - quenching the sheet from a temperature of at least 600°C at a cooling rate comprised between 20°C/s and 50°C/s down to a quenching temperature QT between 200°C and 270°C, - heating the sheet up to a partitioning temperature PT comprised between 400°C and 480°C and maintaining the sheet at this partitioning temperature PT for a partitioning time Pt comprised between 50s and 250s, - hot-dip coating the sheet at a temperature less than 515°C, - cooling the coated sheet down to the room temperature, the steel sheet having a microstructure consisting of, in surface fraction: between 3 % and 15% of retained austenite, at least 30% of tempered martensite, at most 5% of fresh martensite, at most 35% of bainite, the sum of the surface fractions of tempered martensite, fresh martensite and bainite being comprised between 55% and 92%, and between 5% and 35% of ferrite.

METHOD FOR PRODUCING A HIGH STRENGTH COATED STEEL SHEET HAVING IMPROVED DUCTILITY AND FORMABILITY, AND OBTAINED COATED STEEL SHEET

5 The present invention relates to a method for producing a high strength coated steel sheet having improved ductility and formability and to a coated sheet obtained with this method.

 To manufacture various equipments such as parts of body structural members and body panels for automotive vehicles, it is usual to use sheets made of DP (dual phase)
10 steels or TRIP (Transformation Induced Plasticity) steels.

 It is also known to use steels having a bainitic structure, free from carbides precipitates, with retained austenite, containing about 0.2% of C, about 2% of Mn, about 1.7% of Si, with a yield strength of about 750 MPa, a tensile strength of about 980 MPa, a total elongation of about 8%. These sheets are produced on continuous annealing lines by
15 cooling from an annealing temperature higher than the A_{c3} transformation point, down to a holding temperature above the M_s transformation point and maintaining the sheet at the temperature for a given time. Some of these sheets are coated by metallic coating such as galvanization or galvannealing.

 To reduce the weight of the automotive in order to improve their fuel efficiency in view of the global environmental conservation, it is desirable to have sheets having
20 improved yield and tensile strengths. But such sheets must also have a good ductility and a good formability and more specifically a good stretch flangeability.

 In this respect, it is desirable to have coated steel sheets having a tensile strength TS of at least 1100 MPa, a total elongation TE of at least 12%, preferably of at least 13%,
25 such that the product of the tensile strength and the total elongation is higher than or equal to 14200 MPa%, and a hole expansion ratio HER of at least 25% and preferably of at least 30%. The tensile strength TS and the total elongation TE are measured according to ISO standard ISO 6892-1, published in October 2009. It must be emphasized that, due to differences in the methods of measurement, in particular due to differences in the
30 geometries of the specimen used, the values of the total elongation TE according to the ISO standard are very different and are in particular lower than the values of the total elongation according to the JIS Z 2201-05 standard. The hole expansion ratio HER is measured according to ISO standard 16630:2009. Due to differences in the methods of measurement, the values of hole expansion ration HER according to the ISO standard
35 16630:2009 are very different and not comparable to the values of the hole expansion ratio λ according to the JFS T 1001 (Japan Iron and Steel Federation standard).

It is also desirable to have steel sheets having mechanical properties as mentioned above, in a thickness range from 0.7 to 3 mm, and more preferably in the range of 1 to 2 mm.

Therefore, the present invention aims at providing a coated steel sheet with the mechanical properties mentioned above and a method to produce it.

For this purpose, the invention relates to a method for producing a coated steel sheet having a tensile strength TS of at least 1100 MPa, a total elongation TE according to ISO standard 6892-1 of at least 12%, the product TSxTE of the tensile strength by the total elongation being at least 14200 MPa%, and a hole expansion ratio HER according to ISO standard 16630:2009 of at least 25%, wherein the method comprises the following successive steps:

- providing a cold-rolled steel sheet, the chemical composition of the steel containing in weight %:

$$0.15\% \leq C \leq 0.23\%,$$

$$2.0\% \leq Mn \leq 2.7\%,$$

$$\text{with } C+Mn/10 \geq 0.420\%,$$

$$0 \leq Cr \leq 0.40\%,$$

$$\text{with } Mn + Cr \geq 2.25\%,$$

$$0.2\% \leq Si \leq 1.6\%$$

$$0.02\% \leq Al \leq 1.2\%,$$

$$\text{with } 1.0\% \leq Si+Al \leq 2.2\%,$$

$$0 \leq Nb \leq 0.035\%,$$

$$0 \leq Mo \leq 0.1\%,$$

the remainder being Fe and unavoidable impurities,

- annealing the steel sheet at an annealing temperature T_A so as to obtain a structure comprising at least 65% of austenite and at most 35% of intercritical ferrite,

- quenching the sheet from a temperature of at least 600°C at a cooling rate comprised between 20°C/s and 50°C/s down to a quenching temperature QT between 200°C and 270°C,

- heating the sheet up to a partitioning temperature PT comprised between 400°C and 480°C and maintaining the sheet at this partitioning temperature PT for a partitioning time Pt comprised between 50s and 250s,

- hot-dip coating the sheet at a temperature less than 515°C,

- cooling the coated sheet down to the room temperature,

the steel sheet having a microstructure consisting of, in surface fraction :

- between 3 % and 15% of retained austenite,

- at least 30% of tempered martensite,
- at most 5% of fresh martensite,
- at most 35% of bainite,

the sum of the surface fractions of tempered martensite, fresh martensite and bainite
5 being comprised between 55% and 92%,

- between 5% and 35% of ferrite.

According to a particular embodiment, the method comprises, between the annealing step and the quenching step, a step of slow cooling the sheet at a cooling rate lower than 10°C/s for a time of at least 10 s down to a temperature higher than or equal to
10 600°C.

According to this embodiment, the ferrite preferably comprises, in area fraction with respect to the whole structure, between 0% and 5% of intercritical ferrite and between 0% and 35% of transformation ferrite, said transformation ferrite being formed during the slow cooling step.

15 According to another particular embodiment, the ferrite consists of intercritical ferrite.

Preferably, the quenched sheet has, just before the heating to the partitioning temperature PT, a structure consisting of between 5% and 35% of ferrite, at least 3% of austenite, at least 30% of martensite, the complement consisting of lower bainite.

According to a particular embodiment, the step of providing said cold-rolled steel
20 sheet comprises:

- hot rolling a sheet made of said steel to obtain a hot rolled steel sheet,
- coiling said hot-rolled steel sheet at a temperature Tc comprises between 400°C and 650°C,
- performing a heat treatment at a temperature THBA comprised between 400°C
25 and 700°C, the sheet being maintained at said temperature THBA for a time between 120 s and 15 hours,
- cold rolling said hot-rolled steel sheet to obtain said cold-rolled steel sheet.

For example, the heat treatment is a batch annealing performed on the hot-rolled and coiled sheet, at a temperature THBA comprised between 550°C and 700°C, the hot-
30 rolled and coiled sheet being maintained at said temperature THBA for a time between 5 and 15 hours.

According to another example, the heat treatment is a continuous annealing, said temperature THBA being comprised between 600°C and 700°C, the sheet being maintained at said temperature THBA for a time between 120 s and 360 s.

35 Preferably, after the sheet is quenched to the quenching temperature QT and before the sheet is heated to the partitioning temperature PT, the sheet is held at the quenching

temperature QT for a holding time comprised between 2 s and 8 s, preferably between 3 s and 7s.

Preferably, the chemical composition of the steel satisfies at least one of the following conditions: $C \geq 0.17\%$, $C \leq 0.21\%$, $Mn \leq 2.5\%$, $0.010\% \leq Nb$, $Cr \leq 0.05\%$, or $Cr \geq 0.10\%$.

According to a particular embodiment, the chemical composition of the steel is such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$.

According to this embodiment, the chemical composition of the steel is preferably such that $0.2\% \leq Si < 1.0\%$ and $0.4\% \leq Al \leq 1.2\%$, still preferably such that $0.2\% \leq Si \leq 0.8\%$ and $0.7\% \leq Al \leq 1.2\%$.

According to an embodiment, the hot-dip coating step is a galvanizing step, or a galvannealing step with an alloying temperature GAT comprised between 480°C and 515°C.

The steel sheet is for example coated with Zn or a Zn alloy.

The invention also relates to a process for producing a resistance spot weld of at least two steel sheets, said process comprising:

- producing a first steel sheet by a method according to the invention, such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$, the steel sheet being coated with Zn or a Zn alloy,

- providing a second steel sheet having a composition such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$,

- resistance spot welding said first steel sheet to said second steel sheet.

The invention also relates to a coated steel sheet, wherein the chemical composition of the steel contains in weight %:

$$\begin{aligned} 0.15\% &\leq C \leq 0.23\% \\ 2.0\% &\leq Mn \leq 2.7\%, \\ \text{with } C + Mn/10 &\geq 0.420\%, \\ 0 &\leq Cr \leq 0.40\%, \\ \text{with } Mn + Cr &\geq 2.25\%, \\ 0.2\% &\leq Si \leq 1.6\% \\ 0.02\% &\leq Al \leq 1.2\%, \\ \text{with } 1.0\% &\leq Si + Al \leq 2.2\%, \\ 0 &\leq Nb \leq 0.035\%, \\ 0 &\leq Mo \leq 0.1\%, \end{aligned}$$

the remainder being Fe and unavoidable impurities, said steel sheet having a microstructure consisting of, in surface percentage:

- between 3 % and 15% of retained austenite,
- at least 30% of tempered martensite,
- at most 5% of fresh martensite,
- at most 35% of bainite,

5 the sum of the surface fractions of tempered martensite, fresh martensite and bainite being comprised between 55% and 92%,

- between 5% and 35% of ferrite.

According to a particular embodiment, the ferrite comprises, in area fraction with respect to the whole structure, between 0% and 5% of intercritical ferrite and between 0%
10 and 35% of transformation ferrite.

According to another particular embodiment, the ferrite consists of intercritical ferrite.

Preferably, the C content in the retained austenite is comprised between 0.9% and 1.2%.

Preferably, the steel sheet has a yield strength of at least 500 MPa, a tensile
15 strength of at least 1100 MPa, a total elongation according to ISO 6892-1 of at least 12%, the product TSxTE of the tensile strength by the total elongation being at least 14200 MPa%, and a hole expansion ratio HER according to ISO 16630:2009 of at least 25%.

Preferably, the chemical composition of the steel satisfies at least one of the following conditions:

- 20 $C \geq 0.17 \%$,
 $C \leq 0.21 \%$,
 $Mn \leq 2.5 \%$,
 $0.010\% \leq Nb$,
 $Cr \leq 0.05\%$, or
25 $Cr \geq 0.10\%$.

According to a particular embodiment, the chemical composition of the steel is such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$.

In this embodiment, the chemical composition of the steel is preferably such that $0.2\% \leq Si < 1.0\%$ and $0.4\% \leq Al \leq 1.2\%$, still preferably such that $0.2\% \leq Si \leq 0.8\%$ and
30 $0.7\% \leq Al \leq 1.2\%$.

The steel sheet is for example coated with Zn or a Zn alloy.

For example, the thickness of said coated steel sheet is comprised between 0.7 and 3 mm, preferably between 1 and 2 mm.

The invention also relates to a welded structure comprising at least ten resistance
35 spot welds of at least two steel sheets, wherein a first steel sheet is according to the invention, coated with Zn or a Zn alloy and such that $C + Si/10 \leq 0.30\%$ and $Al \geq$

$6(C+Mn/10) - 2.5\%$, and a second steel sheet has a composition such that $C+Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$, and the mean number of cracks per resistance spot weld is less than 6.

Preferably, the second steel sheet is according to the invention.

5 The invention also relates to the use of a steel sheet manufactured according to the invention, or of a steel sheet according to the invention, for the manufacture of structural parts in motor vehicles.

The invention also relates to the use of a resistance spot weld produced by a process according to the invention, or of a welded structure according to the invention, for
10 the manufacture of structural parts in motor vehicles.

The invention will now be described in details but without introducing limitations, with reference to the appended Figure.

The composition of the steel according to the invention comprises, in weight percent:

- 0.15% to 0.23% of carbon for ensuring a satisfactory strength and improving the
15 stability of the retained austenite which is necessary to obtain a sufficient elongation. Preferably, the carbon content is higher than or equal to 0.16%, still preferably higher than or equal to 0.17%, and/or lower than or equal to 0.21%. If the carbon content is too high, the hot rolled sheet is too hard to cold roll and the weldability is insufficient. If the carbon content is below 0.15%, the tensile strength will not reach 1100 MPa.

20 - 2.0% to 2.7% of manganese. If the manganese content is lower than 2.0%, the steel does not have a sufficient hardenability, so that a microstructure containing at least 55% of the sum of martensite and bainite, and a tensile strength of more than 1100 MPa are not obtained. The maximum manganese content is defined to avoid having segregation issues which are detrimental for the ductility. Preferably, the manganese
25 content is lower than or equal to 2.5%.

- 0% to 0.40 % of chromium. Cr may be added to increase the hardenability and to stabilize the retained austenite in order to strongly reduce austenite decomposition during partitioning. But more than 0.40% of chromium is detrimental for the flangeability and if Cr content is more than 0.40% it is not possible to obtain an HER ratio of more than 25%.

30 According to an embodiment, the chromium can be not used and its content can remain less than 0.05%, a content of less than 0.05% corresponding to the presence of Cr as an impurity. When Cr is voluntarily added, its content is of at least 0.10%.

Furthermore, the carbon and manganese contents are such that $(C + Mn/10) \geq 0.420\%$ and the manganese and chromium contents are such that $(Mn + Cr) \geq 2.25\%$ in
35 order to obtain a tensile strength of more than 1100 MPa and/or a total elongation according to ISO 6892-1 of at least 12%. If $(C + Mn/10) < 0.420$ and/or $(Mn + Cr) <$

2.25%, a tensile strength of more than 1100 MPa and/or a total elongation of at least 12% are not achieved.

- 0.2% to 1.6% of silicon and 0.02% to 1.2% of aluminum, the sum of the silicon and aluminum contents being comprised between 1.0% and 2.2%.

5 A certain amount of aluminum is combined with oxygen as Al_2O_3 , and with nitrogen as AlN ; this amount depends on O and N contents and remains less than 0.025%. The remainder if it exists is not combined and consists in "free aluminum".

10 The aluminum which is combined with oxygen results from the deoxidation in the liquid stage. It is detrimental for to the ductility properties and therefore, its content has to be limited as much as possible.

 The aluminum which is combined with nitrogen slows down the austenitic grains growth during annealing. Nitrogen is a residual element resulting from the smelting and is less than 0.010% in the steel sheet.

15 The inventors have found that Si and free Al stabilize the austenite by delaying the formation of carbides. This occurs in particular if the steel sheet is cooled at a temperature so as to obtain a partial martensitic transformation, and immediately reheated and maintained at a temperature P_T during which the carbon is redistributed from martensite to austenite. If Si and free Al content additions are in sufficient amount, the carbon redistribution occurs without significant carbides precipitation. For this purpose Si + Al has
20 to be more than 1.0% in weight (but less than 2.2%). Moreover, Si provides a solid solution strengthening and improves the hole expansion ratio. But the Si content has to be limited to 1.6% to avoid the formation of silicon oxides at the surface of the sheet which would be detrimental to the coatability.

25 Moreover, the inventors have found that when $\text{Si}/10 > 0.30\% - \text{C}$ (Si and C being expressed in weight percentage), due to the LME (liquid metal embrittlement phenomenon), silicon is detrimental to the resistance spot welding of coated sheets and particularly to galvanized or galvanized or electrogalvanized sheets. LME occurrence causes cracks at the grain boundaries in the Heat Affected Zones and in the weld metal of welded joints. Therefore $(\text{C} + \text{Si}/10)$ has to be maintained less than or equal to 0.30%,
30 especially if the sheet is to be coated.

 They have also found that to reduce the LME occurrence, for the domain of compositions which is considered, Al content has to be higher than or equal to $6(\text{C} + \text{Mn}/10) - 2.5\%$.

35 Thus, according to a first embodiment, particularly when LME is not likely to appear, Al is added only to deoxidize or optionally to control the austenitic grains growth during annealing and its content remains less than 0.5%, for example less than 0.1%, but is

preferably at least 0.020%. According to this first embodiment, the Si content is between 1.2% and 1.6%. In this embodiment, $(C + Si/10)$ may be higher than 0.30%, or lower than or equal to 0.30%, depending on the C content. According to a second embodiment, particularly when the problem of LME has to be considered, C and Si contents have to be such that $(C + Si/10) \leq 0.30\%$. Thus, Al is added in more important quantities, in order to replace at least partly Si to stabilize austenite. In this second embodiment, the Al content is comprised between 0.4% and 1.2%, preferably between 0.7% and 1.2%, with $Al \geq 6(C + Mn/10) - 2.5\%$, and Si is comprised between 0.2% and 1.2%, preferably between 0.2% and 1.0%, still preferably between 0.2% and 0.8%. The Al content is limited to 1.2% in order to prevent the increase of the Ac3 transformation temperature, which would imply higher cost when heating at high temperature for obtaining austenitization of the steel sheet in the annealing step.

- optionally from 0.010% to 0.035% of niobium, in order to refine the austenite grains during hot-rolling and to provide precipitation strengthening. A Nb content of 0.010% to 0.035% makes it possible to obtain satisfactory yield strength and elongation, in particular a yield strength of at least 500 MPa.

- Optionally up to 0.1% of molybdenum.

The balance is iron and residual elements resulting from the steelmaking. In this respect, Ni, Cu, Ti, V, B, S, P and N at least are considered as residual elements which are unavoidable impurities. Therefore, their contents are less than 0.05% for Ni, 0.03% for Cu, 0.007% for V, 0.0010% for B, 0.003% for S, 0.02% for P and 0.007% for N. The Ti content is limited to 0.05% because above such values, large-sized carbonitrides would precipitate mainly in the liquid stage and the formability of the steel sheet would decrease, making the 12% target for the total elongation more difficult to reach, and the 25% target for the hole expansion ratio HER is difficult to reach.

When the sheets are coated with Zn or a Zn alloy, the hot spot weldability can be affected by the LME phenomenon (Liquid Metal Embrittlement).

The sensitivity of a particular steel to this phenomenon can be evaluated by tensile test performed at high temperature. In particular, this hot tensile test can be performed using a Gleeble RPI thermal simulator, such device being known per se in the art.

This test which is named "Gleeble LME test" is described as follows:

– samples of coated sheet having a thickness from 0.7 mm to 3 mm are submitted to high temperature tensile tests in order to determine which is the minimal critical displacement for which cracking around the welded zone occur. The samples which are cut in the sheet to be tested have a calibrated zone which is 10 mm long and 10 mm wide,

and heads which are 40 mm long and 30 mm wide, the radius of curvature between the heads and the calibrated part being 5 mm.

– the high temperature tensile tests are performed by heating rapidly (1000°C/s) each sample, maintaining the sample at a predetermined temperature and submitting the heated sample to a predetermined elongation or displacement, then cooling down the sample in air, the elongation or displacement being maintained, the displacements being the displacements of the grids of the Gleeble RPI thermal simulator. After cooling, the samples are observed in order to determine if there is LME cracking or not. It is determined that the sample has a crack if at least one crack of at least 2 mm is formed on the sample.

– the tests are made at a plurality of predetermined temperatures, such as 700°C, 750°C, 800°C, 850°C, 900°C and 950°C, and with elongations or displacements of 0.5 mm, 0.75 mm, 1 mm, 1.25 mm, 1.5 mm, 1.75 mm, 2 mm, and so on; the elongations or displacements are the elongations or displacements of the jaws maintaining the samples on the Gleeble simulator.

– the critical displacement for cracking onset is reported and the minimum critical displacement, i.e. the minimum displacement for which cracking occurs, is determined for the considered temperature range.

Usually, it is considered that when the minimum critical displacement is less than 1.5 mm at a temperature between 700°C and 800°C, the probability of occurrence of LME in resistance spot welding is high, and when the minimum critical displacement is at least 1.5 mm, the probability to observe many LME cracks in resistance spot welding is low.

In this respect, the inventors have discovered that for steels corresponding to the present invention or similar to these steels, if the composition is such that $(C+Si/10)$ is less than or equal to 0.30%, and Al is higher than or equal to $6(C+Mn/10)-2.5\%$, the minimum critical displacement is at least 1.5 mm. When $(C+Si/10)$ is higher than 0.30% and/or Al is lower than $6(C+Mn/10)-2.5\%$, the minimum critical displacement is less than 1.5 mm, and even less than 1 mm.

Another method for evaluating the spot weldability of the coated sheets is a “LME spot welding test” which allows determining the probability to have cracked welds in an important number of resistance spot welds, for example in an industrial production of products comprising parts which are assembled by resistance spot welding such as, for example, car bodies.

This “LME spot welding test” is derived from the electrode life test for resistance spot welding in which a plurality of resistance spot welds, for example 30, are performed on three sheets superposed together: the sheet to be tested and two support sheets made

of galvanized low carbon sheets, for example DX54D+Z according to EN 10346. The thicknesses of the sheets are 1.6 mm and the resistance spot welds are made according to the ISO Standard 18278 – 2 for heterogeneous assemblies. The parameters are:

- electrode tip diameter: 8 mm,
- 5 – welding force: 4.5 kN,
- welding time: 3 pulses of 180 ms separated by 40 ms periods (cool times),
- holding time: 400 ms.

For this test, the eventual occurrence of cracks in the resistance spot welds, the samples are cut and polished. The resistance spot welds are then etched with picric acid, and observed by microscope, for example with a 200x magnification, in order to determine the number of cracks in each observed resistance spot weld and the sum of the length of the cracks of each resistance spot weld.

For examples having a composition such that $(C+Si/10) \leq 0.30\%$ and $(C+Si/10) > 0.30\%$, respectively, the proportions of the numbers of cracks for each resistance spot weld are as follow:

- $(C+Si/10) \leq 0.30\%$: Gleeble LME test > 1.5 mm, at least 80% of the resistance spot welds have less than 10 cracks, and 0% have 20 or more cracks,
- $(C+Si/10) > 0.30\%$: Gleeble LME test < 1.5 mm, only 40% of the resistance spot welds have less than 10 cracks, and 30% have 20 or more cracks.

If the mean number of cracks in each resistance spot weld is considered, the results are as follows:

- for compositions such that $C+Si/10 \leq 0.30\%$, the mean number of cracks in each resistance spot weld is less than 6,
- for compositions such that $C+Si/10 > 0.30\%$, the mean number of cracks in each resistance spot weld is higher than 6.

Hot rolled sheet having a thickness between 2 and 5 mm can be produced in a known manner from the steel composition of the invention mentioned above. As an example, the reheating temperature before rolling can be comprised between 1200°C and 1280°C, preferably about 1250°C, the finish rolling temperature is preferably comprised between Ar₃ and 950°C, and the coiling is performed at a temperature preferably comprised between 400°C and 650°C. Preferably, if $(C+Si/10) \leq 0.30\%$, the coiling temperature is comprised between 450°C and 550°C.

After the coiling, the sheet has a ferrito-pearlitic or ferrito-pearlito-bainitic structure.

After the coiling, the sheet is optionally heat treated, for example batch annealed or continuously annealed in order to reduce the hardness of the steel sheet and therefore improve the cold-rollability of the hot-rolled and coiled steel sheet.

For example, the hot-rolled and coiled steel sheet is heat treated at a temperature between 400°C and 700°C, and maintained at the batch annealing temperature THBA for a time between 120s and 15h.

According to an embodiment, the heat-treatment is a batch annealing performed on the hot-rolled and coiled sheet, at a temperature of batch annealing THBA comprised between 550°C and 700°C, the hot-rolled and coiled sheet being maintained at the temperature THBA for a time between 5 and 15 hours.

According to another embodiment, the sheet is continuously annealed, the annealing temperature THBA being comprised between 600°C and 700°C, and the sheet being maintained at said temperature THBA for a time between 120 s and 360 s.

The sheet can be pickled and cold rolled to obtain a cold rolled sheet having a thickness between 0.7 mm and 3 mm, for example in the range of 1 mm to 2 mm.

Then, the sheet is heat treated on a continuous annealing and coating line.

The heat treatment comprises the steps of:

- annealing the sheet at an annealing temperature T_A such that, at the end of the annealing step, the steel has a structure comprising at least 65% of austenite, and up to 100%, and from 0% to 35% of intercritical ferrite. One skilled in the art knows how to determine the annealing temperature T_A from dilatometry tests, or from semi-empirical formulae. Preferably, the annealing temperature T_A is of at most $Ac3 + 20^\circ C$, in order to limit the coarsening of the austenitic grains, $Ac3$ designating the temperature of the end of the transformation into austenite during the heating step. Still preferably, the annealing temperature T_A is of at most $Ac3$. The sheet is maintained at the annealing temperature i.e. maintained between $T_A - 5^\circ C$ and $T_A + 10^\circ C$, for an annealing time t_A preferably of more than 30 s, but which does not need to be of more than 300 s.

- optionally slow cooling the sheet from the annealing temperature T_A to a cooling stop temperature, at a cooling rate lower than $10^\circ C/s$, preferably lower than $5^\circ C/s$, so as to obtain a total ferrite fraction (intercritical ferrite + transformation ferrite) comprised between 5% to 35%, without forming pearlite and bainite. This slow cooling step aims at forming ferrite, in particular if the fraction of intercritical ferrite after the annealing step is lower than 5%. In that case, the fraction of ferrite formed during the slow cooling is higher than or equal to $5\%-IF$, IF being the fraction of intercritical ferrite, and lower than or equal to $35\%-IF$. If the fraction of intercritical ferrite is at least 5%, the slow cooling is optional. In any case, the fraction of ferrite formed during the slow cooling is lower than or equal to $35\%-IF$, so that the total ferrite fraction remains of at most 35%. The cooling stop temperature is comprised between 750°C and 600°C. Indeed, a cooling stop temperature higher than 750°C does not allow the formation of enough ferrite, whereas a cooling stop

temperature lower than 600°C may lead to the formation of bainite. The slow cooling is preferably performed during a cooling time comprised between 10s and 40s. The ferrite which may be formed during the slow cooling step, further called "transformation ferrite", is different from the intercritical ferrite which remains in the structure at the end of the annealing step. In particular, contrarily to the transformation ferrite, the intercritical ferrite is polygonal. Besides, the transformation ferrite is enriched in carbon and manganese, i.e. has carbon and manganese contents which are higher than the carbon and manganese contents of the intercritical ferrite. The intercritical ferrite and the transformation ferrite can therefore be differentiated by observing a micrograph with a FEG-TEM microscope using secondary electrons, after etching with sodium metabisulfite. On the micrograph, as shown on the appended Figure, the intercritical ferrite appears in medium grey, whereas the transformation ferrite appears in dark grey, owing to its higher carbon and manganese contents. On the Figure, IF designates the intercritical ferrite, TF designates the transformation ferrite, FM designates the fresh martensite and RA designates the retained austenite. For each particular composition of the steel, one skilled in the art knows how to determine precisely the slow cooling conditions suitable to obtain the desired transformation ferrite fraction. The formation of transformation ferrite allows controlling more accurately the area fraction of ferrite in the final structure, and thus provides robustness of the process.

- just after the annealing or the slow cooling step, quenching the sheet by cooling down from a temperature of at least 600°C to a quenching temperature QT lower than the Ms transformation point of the austenite remaining after annealing and slow cooling, at a cooling rate fast enough to form essentially martensite and lower bainite, whilst avoiding the formation of upper and granular bainite. The cooling rate is preferably comprised between 20°C/s and 100°C/s. For each particular composition of the steel and each structure, one skilled in the art knows how to determine the Ms transformation point of the austenite remaining after annealing and slow cooling. He also knows how to determine the quenching temperature adapted to obtain a desired structure, just after quenching, consisting of between 5% to 35% of the sum of intercritical ferrite and transformation ferrite, at least 3% of austenite and at least 30% of martensite, the complement, if any, consisting of lower bainite. Generally, the quenching temperature QT lies between 200°C and 270°C. If the quenching temperature QT is lower than 200°C, the fraction of tempered (or partitioned) martensite in the final structure is too high to stabilize a sufficient amount of retained austenite above 3%, so that the total elongation measured according to ISO standard ISO 6892-1 does not reach 12%. Moreover, if the quenching temperature QT is higher than 270°C, the fraction of tempered martensite in the final structure is too low to

obtain the desired tensile strength. Preferably, the quenching temperature QT is comprised between 200°C and 250°C.

- optionally holding the quenched sheet at the quenching temperature QT for a holding time comprised between 2 s and 8 s, preferably between 3 s and 7 s.

5 - reheating the sheet from the quenching temperature up to a partitioning temperature PT comprised between 400°C and 480°C, and preferably comprised between 440°C and 470°C. The reheating rate can be high when the reheating is performed by induction heating, for example between 6 and 13°C/s. If the partitioning temperature PT is higher than 480°C or lower than 400°C, the elongation of the final product is not
10 satisfactory.

- maintaining the sheet at the partitioning temperature PT for a partitioning time Pt comprised between 50s and 250s, preferably between 50s and 200s. During this partitioning step, the carbon is partitioned, i.e. diffuses from the martensite into the austenite, which is thus enriched.

15 - hot dip coating the sheet. The hot dip coating can be, for example, galvanizing. When the sheet is galvanized, it is done with the usual conditions. The steel sheet according to the invention can be galvanized, at an alloying temperature GAT comprised between 480°C and 515°C, for example comprised between 480°C and 500°C, to alloy the Zn coating by inter-diffusion with Fe is performed after the steel is dipped in
20 the Zn bath. If the galvannealing temperature is higher than 515°C, the total elongation according to ISO 6892-1 decreases to less than 12%. The steel according to the invention can be galvanized Zn or with a Zn alloy like zinc-magnesium or zinc-magnesium-aluminum. But, all metallic hot dip coating is possible provided that the temperature at which the sheet is brought to during coating remain less than 501°C.

25 - cooling the sheet to the room temperature, at a cooling speed preferably higher than 10°C/s, for example comprised between 10°C/s and 20°C/s.

This heat treatment allows obtaining a final structure i.e. after partitioning and cooling to the room temperature, consisting of:

30 - retained austenite, with a surface fraction comprised between 3 % and 15%,
- tempered martensite, with a surface fraction of at least 30%,
- fresh martensite, with a surface fraction of at most 5%,
- bainite, with a surface fraction of at most 35%; the bainite includes lower bainite, for example consists of lower bainite,

the sum of the surface fractions of tempered martensite, fresh martensite and
35 bainite being comprised between 55% and 92%,

- between 5% and 35% of ferrite. The ferrite includes, with respect to the whole structure, between 0% (included) and 35% of intercritical ferrite and between 0% (included) and 35% of transformation ferrite, such that the surface fraction of the sum of intercritical ferrite and transformation ferrite is comprised between 5% and 35%. For example, the ferrite consists of intercritical ferrite. According to another example, the ferrite comprises, with respect to the whole structure, from 0% to 5% of intercritical ferrite and from 0% (excluded) and 35% of transformation ferrite.

A fraction of retained austenite of at least 3%, together with a surface fraction of ferrite between 5% and 35%, allows obtaining a total elongation according to ISO 6892-1 of at least 12%.

Furthermore, this treatment allows obtaining an increased C content in the retained austenite, which is of at least 0.9%, preferably even of at least 1.0%, and up to 1.2%.

The martensite comprises fresh martensite, and tempered martensite.

The tempered martensite, which is partitioned martensite, has a C content of at most 0.45%, this content resulting from the partitioning of carbon from austenite to martensite during the partitioning step. The fresh martensite, which results from the transformation of enriched austenite to martensite after the partitioning step, has a C content which is of at least 0.9%, and generally at most 1.2%. The fraction of fresh martensite in the structure is lower than or equal to 5%. Indeed, a fraction of fresh martensite higher than 5% would lead to a hole expansion ratio HER according to ISO 16630:2009 lower than 25 %.

With this heat-treatment, steel sheets having a yield strength YS of at least 500 MPa, a tensile strength TS of at least 1100 MPa, a total elongation TE according to ISO 6892-1 of at least 12%, and even higher than 13%, a product TSxTE of at least 14200 MPa%, and even higher than 16000 MPa%, and a hole expansion ratio HER according to the ISO standard 16630:2009 of at least 25%, and even at least 30%, can be obtained.

Examples

As examples and comparison, sheets made of steels compositions according to table I, have been manufactured, the elements being expressed in weight.

In this Table, "res." means that the element is only present as a residual, and that no voluntary addition of this element was made.

Table I

Steel	C %	Mn %	C + Mn/10	Cr %	Mn + Cr	Si %	Al %	Si+Al %	Nb %	S %	C +Si/10
<u>1</u>	0.162	2.540	<u>0.416</u>	res.	2.540	0.965	0.995	2.0	res.	0.001	0.26
<u>2</u>	0.228	<u>1.820</u>	<u>0.410</u>	0.20	<u>2.020</u>	1.220	0.02	1.2	res.	0.001	0.35
<u>3</u>	0.221	2.050	0.426	res.	<u>2.050</u>	0.724	0.775	1.5	0.020	0.001	0.29
4	0.222	2.050	0.427	0.26	2.310	0.722	0.770	1.5	0.020	0.001	0.29

The sheets were hot-rolled, then coiled at 540°C or 450°C. The sheets were pickled and cold rolled to obtain sheets having a thickness of 1.2 mm, annealed, quenched, partitioned, galvanized at 460°C and cooled to the room temperature. No slow cooling was performed. Before pickling and cold rolling, some sheets were batch annealed.

The conditions of treatment are reported in Table II.

In this table, Tcoil is the coiling temperature, THBA is the batch annealing temperature, tHBA is the time of batch annealing, T_A is the annealing temperature, t_A is the annealing time, QT the quenching temperature, PT the partitioning temperature, Pt the partitioning time. The transformation temperatures such as Ac1 and Ac3 are also reported in table II. Ac1 and Ac3 were calculated using Thermocalc®.

The mechanical properties were measured in the transverse direction relative to the direction of rolling. As it is well known in the art, the ductility level is slightly better in the direction of rolling than in the transverse direction for such high strength steel.

Measured properties are the hole expansion ratio HER measured according to the standard ISO 16630:2009, the yield strength YS, the tensile stress TS, the uniform elongation UE and the total elongation TE. The yield strength YS, the tensile stress TS, the uniform elongation UE and the total elongation TE were measured according to the ISO standard ISO 6892-1, published in October 2009. The microstructures are reported in Table III and the mechanical properties are reported in Table IV.

Table II

Example	Steel	Ac1 (°C)	Ac3 (°C)	Tcoil (°C)	THBA (°C)	tHBA (h)	T _A (°C)	t _A (s)	QT (°C)	PT (°C)	Pt (s)
A	<u>1</u>	720	995	540	-	-	850	114	250	460	100
B	<u>2</u>	727	820	540	550	10	850	100	250	460	60
C	<u>3</u>	721	905	540	-	-	850	60	250	460	100

H	7	47	0	15	62	26	31	7
I	8	52	0	10	62	26	31	7
J	8	47	0	30	77	14	19	4
K	8	51	0	15	66	26	31	3
L	9	58	0	20	78	5	10	12

These examples show that with a method according to the invention, steel sheets having a tensile strength TS of at least 1100 MPa and a total elongation TE according to ISO 6892-1 of at least 12%, and even of at least 13% can be obtained, the product TS*TE being higher than 14200 MPa%. These steel sheets also have a yield strength of at least 500MPa, a uniform elongation of at least 8%, and generally of more than 9%, and a hole expansion ratio HER according to ISO 16630:2009 of at least 25% and even often more than 30%.

Examples A and B show that when the C and Mn contents are such that $C+Mn/10 < 0.420\%$, the desired structure is not obtained, and the tensile strength and/or the total elongation obtained is not satisfactory.

Example C shows that when $Mn+Cr < 2.25\%$, the sum of the martensite and bainite fractions is too low, so that a tensile strength of at least 1100 MPa is not obtained.

Table IV

Example	Steel	YS (MPa)	TS (MPa)	UE (%)	TE (%)	TSxTE (MPa%)	HER (%)
<u>A</u>	<u>1</u>	467	<u>1065</u>	12	16.2	17253	31
<u>B</u>	<u>2</u>	1172	1276	6.1	<u>9.8</u>	<u>12505</u>	67
<u>C</u>	<u>3</u>	662	<u>998</u>	16.5	20.7	20659	33
D	4	612	1110	13.9	17.8	19758	26

J	8	1040	1175	12.1	16.5	19388	37
K	8	683	1191	11.8	15.3	18222	30
L	9	744	1249	11.1	14.7	18360	25

Regarding the spot weldability, the sheets according to the invention have a low LME sensitivity when the composition is such that $C+Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$. It means that which such steels it is possible to produce structures comprising resistance spot welds, such as car bodies, for which the probability of the number of cracks in the resistance spot welds is such that the mean value is less than 6 cracks per resistance spot weld and the probability to have less than 10 cracks is 98%.

In particular, a welded structure, including resistance spot weld, of at least two steel sheets, can be produced by producing a first steel sheet by a method according to the invention, the first sheet being such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$ and being coated with Zn or a Zn alloy, providing a second steel sheet having a composition such that $C+Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$, and resistance spot welding the first steel sheet to the second steel sheet. The second steel sheet may for example be produced by a method according to the invention, and coated with Zn or a Zn alloy.

Thus, a welded structure having a low LME sensitivity is obtained. For example, for such a welded structure comprising at least ten resistance spot welds, the mean number of cracks per resistance spot weld is less than 6.

5 The steel sheets optionally welded by resistance spot welding according to the invention are used with profit for the manufacture of structural parts in motor vehicles since they offer high formability during the fabrication process and high energy absorption in case of collision. The resistance spot welds according to the invention are also used with profit for the manufacture of structural parts in motor vehicles, since eventual initiation and propagation of cracks located in the welded zones are much reduced.

CLAIMS

1.- A method for producing a coated steel sheet having a tensile strength TS of at least 1100 MPa, a total elongation TE according to ISO standard 6892-1 of at least 12%,
 5 the product TSxTE of the tensile strength by the total elongation being at least 14200 MPa%, and a hole expansion ratio HER according to ISO standard 16630:2009 of at least 25%, wherein the method comprises the following successive steps:

- providing a cold-rolled steel sheet, the chemical composition of the steel containing in weight %:

$$0.15\% \leq C \leq 0.23\%,$$

$$2.0\% \leq Mn \leq 2.7\%,$$

$$\text{with } C+Mn/10 \geq 0.420\%,$$

$$0 \leq Cr \leq 0.40\%,$$

$$\text{with } Mn + Cr \geq 2.25\%,$$

$$0.2\% \leq Si \leq 1.6\%$$

$$0.02\% \leq Al \leq 1.2\%,$$

$$\text{with } 1.0\% \leq Si+Al \leq 2.2\%,$$

$$0 \leq Nb \leq 0.035\%,$$

$$0 \leq Mo \leq 0.1\%,$$

the remainder being Fe and unavoidable impurities,

- annealing the steel sheet at an annealing temperature T_A so as to obtain a structure comprising at least 65% of austenite and at most 35% of intercritical ferrite,

- quenching the sheet from a temperature of at least 600°C at a cooling rate comprised between 20°C/s and 50°C/s down to a quenching temperature QT between
 200°C and 270°C,

- heating the sheet up to a partitioning temperature PT comprised between 400°C and 480°C and maintaining the sheet at this partitioning temperature PT for a partitioning time Pt comprised between 50s and 250s,

- hot-dip coating the sheet at a temperature less than 515°C,

- cooling the coated sheet down to the room temperature,

the steel sheet having a microstructure consisting of, in surface fraction :

- between 3 % and 15% of retained austenite,

- at least 30% of tempered martensite,

- at most 5% of fresh martensite,

- at most 35% of bainite,

the sum of the surface fractions of tempered martensite, fresh martensite and bainite being comprised between 55% and 92%,

- between 5% and 35% of ferrite.

5 2.- The method according to claim 1, wherein the method comprises, between the annealing step and the quenching step, a step of slow cooling the sheet at a cooling rate lower than 10°C/s for a time of at least 10 s down to a temperature higher than or equal to 600°C.

10 3.- The method according to claim 2, wherein the ferrite comprises, in area fraction with respect to the whole structure, between 0% and 5% of intercritical ferrite and between 0% and 35% of transformation ferrite, said transformation ferrite being formed during the slow cooling step.

15 4.- The method according to claim 1, wherein the ferrite consists of intercritical ferrite.

5.- The method according to any one of claims 1 to 4, wherein the quenched sheet has, just before the heating to the partitioning temperature PT, a structure consisting of
20 between 5% and 35% of ferrite, at least 3% of austenite, at least 30% of martensite, the complement consisting of lower bainite.

6. – The method according to any one of claims 1 to 5, wherein the step of providing said cold-rolled steel sheet comprises:

25 - hot rolling a sheet made of said steel to obtain a hot rolled steel sheet,
 - coiling said hot-rolled steel sheet at a temperature Tc comprises between 400°C and 650°C,
 - performing a heat treatment at a temperature THBA comprised between 400°C and 700°C, the sheet being maintained at said temperature THBA for a time between 120 s
30 and 15 hours,
 - cold rolling said hot-rolled steel sheet to obtain said cold-rolled steel sheet.

7.— The method according to claim 6, wherein the heat treatment is a batch annealing performed on the hot-rolled and coiled sheet, at a temperature THBA
35 comprised between 550°C and 700°C, the hot-rolled and coiled sheet being maintained at said temperature THBA for a time between 5 and 15 hours.

8.— The method according to claim 6, wherein the heat treatment is a continuous annealing, said temperature THBA being comprised between 600°C and 700°C, the sheet being maintained at said temperature THBA for a time between 120 s and 360 s.

5

9.- The method according to any one of claims 1 to 8, wherein, after the sheet is quenched to the quenching temperature QT and before the sheet is heated to the partitioning temperature PT, the sheet is held at the quenching temperature QT for a holding time comprised between 2 s and 8 s, preferably between 3 s and 7s.

10

10.- The method according to any one of claims 1 to 9, wherein the chemical composition of the steel satisfies at least one of the following conditions:

$$C \geq 0.17 \%,$$

$$C \leq 0.21 \%,$$

15

$$Mn \leq 2.5 \%,$$

$$0.010\% \leq Nb,$$

$$Cr \leq 0.05\%, \text{ or}$$

$$Cr \geq 0.10\%.$$

20

11.- The method according to any one of claims 1 to 10, wherein the chemical composition of the steel is such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$.

12.- The method according to claim 11, wherein the chemical composition of the steel is such that $0.2\% \leq Si < 1.0\%$ and $0.4\% \leq Al \leq 1.2\%$.

25

13.- The method according to claim 12, wherein $0.2\% \leq Si \leq 0.8\%$ and $0.7\% \leq Al \leq 1.2\%$.

14.- The method according to any one of claims 1 to 13, wherein the hot-dip coating step is a galvanizing step, or a galvannealing step with an alloying temperature GAT comprised between 480°C and 515°C.

30

15.- The method according to any one of claims 1 to 14, wherein the steel sheet is coated with Zn or a Zn alloy.

35

16.- A process for producing a resistance spot weld of at least two steel sheets, said process comprising:

- producing a first steel sheet by a method according to claims 11 and 15,
- providing a second steel sheet having a composition such that $C+Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$,
- resistance spot welding said first steel sheet to said second steel sheet.

17.- A coated steel sheet, wherein the chemical composition of the steel contains in weight %:

- $0.15\% \leq C \leq 0.23\%$
- $2.0\% \leq Mn \leq 2.7\%$,
- with $C + Mn/10 \geq 0.420\%$,
- $0 \leq Cr \leq 0.40\%$,
- with $Mn + Cr \geq 2.25\%$,
- $0.2\% \leq Si \leq 1.6\%$
- $0.02\% \leq Al \leq 1.2\%$,
- with $1.0\% \leq Si+Al \leq 2.2\%$,
- $0 \leq Nb \leq 0.035\%$,
- $0 \leq Mo \leq 0.1\%$,

the remainder being Fe and unavoidable impurities,
said steel sheet having a microstructure consisting of, in surface percentage:

- between 3 % and 15% of retained austenite,
 - at least 30% of tempered martensite,
 - at most 5% of fresh martensite,
 - at most 35% of bainite,
- the sum of the surface fractions of tempered martensite, fresh martensite and bainite being comprised between 55% and 92%,
- between 5% and 35% of ferrite.

18.- The coated steel sheet according to claim 17, wherein the ferrite comprises, in area fraction with respect to the whole structure, between 0% and 5% of intercritical ferrite and between 0% and 35% of transformation ferrite.

19.- The coated steel sheet according to claim 17, wherein the ferrite consists of intercritical ferrite.

20.- The coated steel sheet according to any one of claims 17 to 19, wherein the C content in the retained austenite is comprised between 0.9% and 1.2%.

21.- The coated steel sheet according to any one of claims 17 to 20, wherein the steel sheet has a yield strength of at least 500 MPa, a tensile strength of at least 1100 MPa, a total elongation according to ISO 6892-1 of at least 12%, the product TSxTE of the tensile strength by the total elongation being at least 14200 MPa%, and a hole expansion ratio HER according to ISO 16630:2009 of at least 25%.

22.- The coated steel sheet according to any one of claims 17 to 21, wherein the chemical composition of the steel satisfies at least one of the following conditions:

$$C \geq 0.17 \%,$$

$$C \leq 0.21 \%,$$

$$Mn \leq 2.5 \%,$$

$$0.010\% \leq Nb,$$

$$Cr \leq 0.05\%, \text{ or}$$

$$Cr \geq 0.10\%.$$

23.- The coated steel sheet according to any one of claims 17 to 22, wherein the chemical composition of the steel is such that $C + Si/10 \leq 0.30\%$ and $Al \geq 6(C + Mn/10) - 2.5\%$.

24.- The coated steel sheet according to claim 23, wherein the chemical composition of the steel is such that $0.2\% \leq Si < 1.0\%$ and $0.4\% \leq Al \leq 1.2\%$.

25.- The coated steel sheet according to claim 24, wherein $0.2\% \leq Si \leq 0.8\%$ and $0.7\% \leq Al \leq 1.2\%$.

26.- The coated steel sheet according to any one of claim 23 to 25, wherein the steel sheet is coated with Zn or a Zn alloy.

27.- The coated steel sheet according to any one of claims 17 to 26, wherein the thickness of said coated steel sheet is comprised between 0.7 and 3 mm, preferably between 1 and 2 mm.

28.- Welded structure comprising at least ten resistance spot welds of at least two steel sheets, wherein a first steel sheet is according to claim 26, and a second steel sheet has a composition such that $C+Si/10 \leq 0.30\%$ and $Al \geq 6(C+Mn/10) - 2.5\%$, and wherein the mean number of cracks per resistance spot weld is less than 6.

5

29.- Welded structure according to claim 28, wherein the second steel sheet is according to claim 26.

30.- Use of a steel sheet manufactured according to any one of claims 1 to 15, or of a steel sheet according to any one of claims 17 to 27, for the manufacture of structural parts in motor vehicles.

31.- Use of a resistance spot weld produced by a process according to claim 16, or of a welded structure according to any one of claims 28 and 29, for the manufacture of structural parts in motor vehicles.

15
