(54) Titre : PROCEDE DE DISTILLATION DE DISTILLATS MOYENS
(54) Title: PROCESS FOR THE PREPARATION OF MIDDLE DISTILLATES

---

(57) Abrégé/Abstract:
Middle distillates are prepared from a hydrocarbon feed obtained by a Fischer-Tropsch synthesis and comprising a fraction having a boiling point above the boiling point range of the middle distillates, by a process which comprises contacting the said hydrocarbon feed at elevated temperature and pressure in the presence of hydrogen with a catalyst comprising platinum supported on a silica-alumina carrier prepared from an amorphous silica-alumina starting material having a pore volume of at least 1.0 ml/g.
PROCESS FOR THE PREPARATION OF MIDDLE DISTILLATES

Middle distillates are prepared from a hydrocarbon feed obtained by a Fischer-Tropsch synthesis and comprising a fraction having a boiling point above the boiling point range of the middle distillates, by a process which comprises contacting the said hydrocarbon feed at elevated temperature and pressure in the presence of hydrogen with a catalyst comprising platinum supported on a silica-alumina carrier prepared from an amorphous silica-alumina starting material having a pore volume of at least 1.0 ml/g.
PROCESS FOR THE PREPARATION OF MIDDLE DISTILLATES

The present invention relates to a process for the preparation of middle distillates from a hydrocarbon feed, which feed comprises a fraction having a boiling point above the boiling point range of the middle distillates and which is the product of a Fischer-Tropsch synthesis.

The preparation of hydrocarbons from a gaseous mixture comprising carbon monoxide and hydrogen by contacting the mixture with a suitable catalyst at elevated temperatures and pressures is a well known process, referred to in the art as the Fischer-Tropsch process.

Recently, much attention has been paid to processes for the preparation of middle distillate fuels, which processes comprise two stages; a first stage in which high boiling range hydrocarbons are prepared from a mixture of carbon monoxide and hydrogen by means of the Fischer-Tropsch process, and a second stage in which the hydrocarbons so-produced are subjected to a hydroconversion process yielding the desired middle distillates.

For the purposes of this specification, the term "middle distillates" as used herein is to be taken as a reference to hydrocarbons or hydrocarbon mixtures having a boiling point or boiling point range substantially corresponding to that of the kerosine and gasoil fractions obtained during the conventional atmospheric distillation of crude oil. In a typical distillation, the following fractions are consecutively recovered from the crude oil: one or more naphtha (sometimes referred to as gasoline) fractions boiling in the range of from 30 to 220 °C, one or more kerosine fractions boiling in the range of from 140 to 300 °C and one or more gasoil fractions boiling in the range of from 180 to 370 °C.

Thus, UK patent application publication No. 2 077 289 (GB-A-2 077 289) and European patent applications publication
numbers 0 127 220 and 0 147 873 (EP-A-0 127 220 and EP-A-0 147 873) each disclose a process for the preparation of middle distillates in which a mixture of carbon monoxide and hydrogen is converted in a first stage into high boiling range hydrocarbons by means of the Fischer-Tropsch process, which hydrocarbons are then subjected to a catalytic hydroconversion. The specifications of the aforementioned patent applications disclose a range of possible catalyst compositions for use in the hydroconversion stage of the process, with preference being given in each case to catalysts comprising a Group VIII metal as catalytically active component on a suitable carrier. Particular preference is given to catalysts comprising platinum. Suitable carriers are stated in GB-A-2 077 289 to be amorphous oxides of the elements in Groups II, III and IV of the Periodic Table of Elements, such as silica, alumina, magnesia, zirconia, as well as mixtures thereof, including silica-alumina, silica-magnesia and silica-zirconia, and zeolitic materials such as mordenite and faujasite. Alumina and silica-alumina are said to be preferred carrier materials.

The specifications of all of GB-A-2 077 289, EP-A-0 127 220 and EP-A-0 147 873 specifically exemplify the use of a platinum/-silica-alumina catalyst comprising 0.82 parts by weight of platinum per 100 parts by weight of carrier, which carrier consists of 14.6% by weight of alumina and 85.4% by weight of silica, in the hydroconversion stage of the middle distillate preparation.

In processes in which it is desired to produce middle distillates in high yields from the high boiling range products of the Fischer-Tropsch synthesis there is a need for a hydroconversion catalyst which exhibits both a high level of intrinsic activity in combination with a high selectivity to middle distillates.

Platinum/silica-alumina catalysts and processes for their preparation are known in the art for application in the hydroconversion of various hydrocarbon products.

For example, UK patent No. 1 451 617 (GB 1 451 617) discloses a process for the preparation of medicinal oils in which a hydrocarbon mixture having a low aromatic content is contacted at
elevated temperature and pressure with a catalyst comprising one or more noble metals from Group VIII on a carrier which contains 13 to 15% by weight of alumina, the remainder being silica. Catalysts specifically exemplified in GB 1 451 617 comprise nickel, molybdenum, tungsten and/or platinum as catalytically active metals supported on a silica-alumina carrier. Specific platinum-based catalysts comprise platinum supported on silica-alumina carriers having surface areas ranging from 110 to 518 m²/g and pore volumes ranging from 0.34 to 0.87 ml/g.

It has now been found that the platinum/silica-alumina catalysts described and exemplified in GB 1 451 617 are active in the preparation of middle distillates from higher boiling range hydrocarbons produced by the Fischer-Tropsch synthesis. However, most surprisingly, it has been found that the selectivity of the catalyst to middle distillates is dependant upon the pore volume of the amorphous silica-alumina starting material from which the catalyst is prepared. More specifically, it has been found that a catalyst comprising a silica-alumina carrier prepared from an amorphous starting material having a pore volume of at least 1.0 ml/g exhibits a significantly higher selectivity to middle distillates than catalysts comprising carriers prepared from starting materials having lower pore volumes.

Accordingly, the present invention provides a process for preparing middle distillates from a hydrocarbon feed obtained by a Fischer-Tropsch synthesis and comprising a fraction having a boiling point above the boiling point range of the middle distillates, which process comprises contacting the said hydrocarbon feed at elevated temperature and pressure in the presence of hydrogen with a catalyst comprising platinum supported on a silica-alumina carrier prepared from an amorphous silica-alumina starting material having a pore volume of at least 1.0 ml/g.

The carrier for the catalyst employed in the process of the present invention is prepared from an amorphous silica-alumina starting material. The term "amorphous" indicates a lack of
crystal structure, as defined by X-ray diffraction, in the carrier material, although some short range ordering may be present.

Amorphous silica-alumina suitable for use in preparing the catalyst is available commercially. Alternatively, the silica-alumina may be prepared by precipitating alumina or a silica hydrogel and subsequently drying and calcining the resulting material, as described in GB 1 451 617.

The catalyst may comprise any suitable silica-alumina. The silica-alumina preferably contains alumina in an amount in the range of from 5 to 30% by weight, more preferably from 10 to 20% by weight, especially from 12 to 15% by weight.

The pore volume of the amorphous silica-alumina starting material used in the preparation of the carrier is at least 1.0 ml/g. For the purposes of this specification, all pore volumes quoted in relation to the catalyst for use in the process of the present invention are, unless otherwise stated, references to pore volumes measured by a method involving the uptake of water into the pores of the material, often referred to as the incipient wetness method, and are generally indicated as pore volume (H₂O).

A typical procedure for determining the pore volume (H₂O) of a catalyst or carrier material comprises drying the material at a temperature of about 500°C; weighing the dried material; immersing the material in water for a period of about 15 minutes; removing the material from the water; removing the water on the surface of the material by means of a centrifuge; and weighing the resulting material. The pore volume of the material is determined from the difference between the weight of the dried material and the weight of the resulting material.

The pore volume of the amorphous silica-alumina is preferably in the range of from 1.0 to 2.0 ml/g, more preferably from 1.0 to 1.5 ml/g.

In addition to silica-alumina, the carrier may also comprise one or more binder materials. Suitable binder materials include inorganic oxides. Both amorphous and crystalline binders may be applied. Examples of binder materials comprise silica, alumina,
clays, magnesia, titania, zirconia and mixtures thereof. Silica and alumina are preferred binders, with alumina being especially preferred. The binder, if incorporated in the catalyst, is preferably present in an amount of from 5 to 50% by weight, more preferably from 15 to 30% by weight, on the basis of total weight of the carrier.

The carrier may be prepared from the amorphous silica-alumina by methods known to the person skilled in the art. A preferred method for the preparation of the carrier comprises mulling a mixture of the amorphous silica-alumina and a suitable liquid, extruding the mixture and drying the resulting extrudates.

The mixture to be extruded should, preferably, have a solids content in the range of from 20 to 60% by weight.

The liquid for inclusion in the mixture may be any of the suitable liquids known in the art. Examples of suitable liquids include water; alcohols, such as methanol, ethanol and propanol; ketones, such as acetone; aldehydes, such as proponal, and aromatic liquids, such as toluene. A most convenient and preferred liquid is water.

To obtain strong extrudates, the mixture preferably includes a peptizing agent. Suitable peptizing agents are acidic compounds, for example inorganic acids such as aqueous solutions of hydrogen fluoride, hydrogen bromide and hydrogen chloride, nitric acid, nitrous acid and perchloric acid. Preferably, the peptizing agent is an organic acid, for example a mono- or dicarboxylic acid. Preferred organic acids include acetic acid, propionic acid and butanoic acid. Acetic acid is a most preferred peptizing agent.

The amount of peptizing agent included in the mixture should be sufficient to fully peptize the alumina present in the carrier material, and can be readily determined by the pH of the mixture. During mulling, the pH of the mixture should preferably lie in the range of from 1 to 6, more preferably from 4 to 6.

To improve the flow properties of the mixture, it is preferred to include one or more flow improving agents and/or extrusion aids in the mixture prior to extrusion. Suitable additives for
inclusion in the mixture include fatty amines, quaternary ammonium compounds, aliphatic mono-carboxylic acids, ethoxylated alkyl amines, polyvinyl pyridine, and sulfoxonium, sulphonium, phosphonium and iodonium compounds, alkylated aromatic compounds, acyclic mono-carboxylic acids, fatty acids, sulphonated aromatic compounds, alcohol sulphates, ether alcohol sulphates, sulphated fats and oils, phosphonic acid salts, polyoxyethylene alkylphenols, polyoxyethylene alcohols, polyoxyethylene alkylamines, polyoxyethylene alkylamides, polyacrylamides, polyols and acetylenic glycols. Preferred agents are sold under the trademarks Nalco and Superfloc.

The flow improving agents/extrusion aids are preferably present in the mixture in a total amount in the range of from 1 to 20% by weight, more preferably from 2 to 10% by weight, on the basis of the total weight of the mixture.

In principle, the components of the mixture may be combined in any order, and the mixture mulled. Preferably, the amorphous silica-alumina and the binder, if present, are combined and the mixture mulled. Thereafter, the liquid and, if present, the peptizing agent are added and the resulting mixture further mulled. Finally, any flow improving agents/extrusion aids to be included are added and the resulting mixture mulled for a final period of time.

Typically, the mixture is mulled for a period of from 10 to 120 minutes, preferably from 15 to 90 minutes. During the mulling process, energy is input into the mixture by the mulling apparatus. The rate of energy input into the mixture is typically from 0.05 to 50 Wh/min/kg, preferably from 0.5 to 10 Wh/min/kg. The mulling process may be carried out over a broad range of temperatures, preferably from 15 to 50 °C. As a result of the energy input into the mixture during the mulling process, there will be a rise in the temperature of the mixture during the mulling. The mulling process is conveniently carried out at ambient pressure. Any suitable, commercially available mulling apparatus may be employed.
Once the mulling process has been completed, the resulting mixture is then extruded. Extrusion may be effected using any conventional, commercially available extruder. In particular, a screw-type extruding machine may be used to force the mixture through orifices in a suitable dieplate to yield extrudates of the desired form. The strands formed upon extrusion may be cut to the desired length.

The extrudates may have any suitable form known in the art, for example cylindrical, hollow cylindrical, multilobed or twisted multilobed. A most convenient shape for the catalyst particles of the present invention is cylindrical. Typically, the extrudates have a nominal diameter of from 0.5 to 5 mm, preferably from 1 to 3 mm.

After extrusion, the extrudates are dried. Drying may be effected at an elevated temperature, preferably up to 800 °C, more preferably up to 300 °C. The period for drying is typically up to 5 hours, preferably from 30 minutes to 3 hours.

Preferably, the extrudates are calcined after drying. Calcination is effected at an elevated temperature, preferably up to 1000 °C, more preferably from 200 °C to 1000 °C, most preferably from 300° to 800 °C. Calcination of the extrudates is typically effected for a period of up to 5 hours, preferably from 30 minutes to 4 hours.

The catalyst used in the process of the present invention comprises platinum as a catalytically active component. Platinum is preferably present in an amount in the range of from 0.05 to 5.0% by weight, more preferably from 0.1 to 2.0% by weight, especially from 0.2 to 1.0% by weight, on the basis of total weight of carrier material in the catalyst.

The platinum may deposited on the carrier by any of the methods known in the art, for example ion exchange, competitive ion exchange, comulling and impregnation. A preferred catalyst is one in which the platinum is deposited onto the carrier by means of impregnation, in which process the carrier is contacted with a platinum salt in the presence of a liquid. An especially preferred
catalyst for use in the process of the present invention is one in which the impregnation of the silica-alumina carrier is conducted under acidic conditions. Preferably, the acidic conditions are such that the pH is no greater than 4.0, more preferably no greater than 3.0.

Most conveniently in the impregnation of the carrier material, the platinum salt and liquid are selected so that the salt is soluble in the liquid and the carrier is contacted with a platinum salt solution. Suitable liquids for use in the impregnation are both organic liquids, for example alcohols and ethers, and inorganic liquids, for example water. Water is a most convenient and especially preferred liquid.

Any suitable platinum salt may be used in the impregnation procedure, with preference being given to salts soluble in the selected liquid. Suitable salts include both organic and inorganic salts. Examples of suitable salts are platinum dibromide, platinum dichloride, platinum trichloride, platinum tetrachloride, platinum dichlorocarbonyldichloride, platinum tetrafluoride and platinum sulphate.

A preferred catalyst is one prepared by an impregnation using a solution of an acidic platinum salt, the platinum salt providing both a source for the platinum and giving rise to the required conditions of acidity. Preferred acid salts for such functions are hexachloroplatinic acid, tetracyanoplatinic acid, hexahydroxyplatinic acid, platinum monohydroxychloric acid and platinum (III) sulphuric acid. Hexachloroplatinic acid is an especially preferred acid platinum salt.

If an acid platinum salt is not used in the impregnation of the carrier, the impregnation is effected in the presence of an additional acid. More preferably, both an acid platinum salt and an additional acid are present during the impregnation of the carrier. Suitable acids for use during the impregnation include both organic and inorganic acids, for example mono- and dicarboxylic acids, hydrochloric acid, sulphuric acid and nitric acid. Nitric acid is a particularly preferred acid. An especially
preferred catalyst is one prepared by impregnation of the carrier using a combination of hexachloroplatinic acid and nitric acid.

If the catalyst is prepared by means of impregnation in the presence of both an acidic platinum salt and an additional acid, the additional acid is preferably present in an amount in excess of the amount of acid platinum salt, the molar ratio of additional acid to acid platinum salt preferably being in the range of from 2 to 30, more preferably from 5 to 25.

A preferred impregnation technique for preparing the catalyst for use in the process of the present invention is the pore volume impregnation technique, in which the carrier is contacted with a solution of the platinum salt, the solution being present in a sufficient volume so as to substantially just fill the pores of the carrier material. A convenient method for effecting the impregnation is by spraying the carrier with the requisite quantity of the solution.

After impregnation, the resulting catalyst is preferably dried and, thereafter, preferably calcined. The conditions for drying and calcining are as set out hereinbefore.

In the process of the present invention, hydrocarbons comprising at least a fraction having a boiling point above the boiling point range of the middle distillates and prepared by a Fischer-Tropsch synthesis process are contacted with a catalyst as hereinbefore described at elevated temperature and pressure in the presence of hydrogen. The major reaction occurring during the process is a hydrocracking of the heavier components in the feed to yield the desired middle distillates. In addition, some hydroisomerization of the hydrocarbons in the feed may occur.

Typically, the temperature necessary to yield middle distillates will lie in the range of from 175 to 400°C, preferably from 250 to 375°C. Typical hydrogen partial pressures range from 10 to 250 bars and are preferably in the range of from 25 to 150 bars. The hydrocarbon feed may be provided at a space velocity in the range of from 0.1 to 5 kg/l/hr, preferably from 0.25 to 2 kg/l/hr. Hydrogen may be supplied at a gas hourly space velocity
of from 100 to 10000 Nl/l/hr, preferably from 500 to 5000 Nl/l/hr. The ratio of hydrogen to hydrocarbon feed may range from 100 to 5000 Nl/kg and is preferably from 250 to 2500 Nl/kg.

The hydrocarbon feed for the process of the present invention is prepared by the Fischer-Tropsch synthesis, in which a mixture comprising carbon monoxide and hydrogen is contacted with a Fischer-Tropsch catalyst at elevated temperature and pressure.

The catalyst employed in the Fischer-Tropsch synthesis may be any of the catalysts active in such synthesis, which catalysts are well known in the art. Typically, the catalyst comprises, as catalytically active component, one or more metals selected from Group VIIIB or Group VIII of the Periodic Table of Elements. Preference is given to catalysts comprising elements from Group VIII. In particular, catalysts comprising one or more metals from the iron group of elements, that is iron, cobalt and nickel, are especially preferred. Especially suitable are catalysts comprising cobalt as a catalytically active component.

The catalytically active components may be present in the Fischer-Tropsch catalyst together with one or more promoters or co-catalysts. The promoters may be present either as metals or metal oxides. Suitable metal oxide promoters include oxides of metals from Groups IIA, IIIB, IVB, VB, or VIB of the Periodic Table, from the lanthanides and/or actinides. Preferably, the catalyst comprises a source of an element in Group IVB of the Periodic Table, in particular titanium or zirconium. Catalysts containing zirconium are especially preferred. As an alternative to or in addition to the metal oxide promoter, the catalyst may comprise a metal promoter selected from Groups VIIIB and/or VIII of the Periodic Table. Preferred metal promoters include platinum and palladium. A most suitable Fischer-Tropsch catalyst comprises cobalt as the catalytically active component and zirconium as a promoter.

The catalyst employed in the Fischer-Tropsch synthesis typically also comprises a refractory oxide carrier, on which the catalytically active components and promoters, if present, are
supported. The carrier may comprise any suitable refractory oxide, for example alumina, silica, titania, zirconia or mixtures thereof. Silica and/or alumina are preferred carrier materials.

The Fischer-Tropsch catalyst typically comprises the catalytically active component in an amount in the range of from 1 to 100 parts by weight, preferably 10 to 50 parts by weight, per 100 parts by weight of carrier material. The promoter, if present, is typically present in an amount of from 1 to 60 parts by weight, preferably from 2 to 40 parts by weight, per 100 parts by weight of carrier material.

The catalysts employed in the Fischer-Tropsch synthesis of the hydrocarbon feed for the process of the present invention may be prepared by methods known in the art.

During the Fischer-Tropsch synthesis, a mixture of carbon monoxide and hydrogen is contacted with the Fischer-Tropsch catalyst at elevated temperature and pressure. Typically the reaction is effected at a temperature in the range of from 125 to 350°C, preferably from 175 to 250°C. The reaction pressure is typically in the range of from 5 to 100 bar, preferably from 12 to 50 bar. The hydrogen/carbon monoxide ratio of the feed mixture is typically greater than 1.5, preferably between 1.75 and 2.25. Unconverted hydrogen and carbon monoxide may be separated from the reaction product and recycled to the reactor inlet. In such an arrangement, the hydrogen/carbon monoxide ratio of the mixture contacting the catalyst may be significantly lower than that of the feed mixture, for example in the range of from 0.9 to 1.3, preferably about 1.1.

In a preferred embodiment of the process of the present invention, the hydrocarbon feed is the product of a Fischer-Tropsch synthesis in which a cobalt-containing catalyst has been employed. It is known in the art that cobalt is active in the Fischer-Tropsch synthesis in the preparation of hydrocarbon products comprising substantial quantities of paraffinic hydrocarbons. The process of the present invention has been found to be particularly
advantageous in the preparation of middle distillates from such paraffinic feeds.

The hydrocarbon feed to the process of the present invention comprises at least a fraction having a boiling point above the boiling point range of the middle distillates. If desired, the product of the Fischer-Tropsch synthesis may be separated into fractions, for example by conventional distillation techniques, and those fractions having a boiling point above the boiling point range of the middle distillates used as the hydrocarbon feed to the present process. In this case, substantially all of the hydrocarbon feed will have a boiling point greater than that of the middle distillates. Alternatively, the hydrocarbon feed may comprise both fractions boiling above and below the upper boiling point of the boiling point range of the middle distillates.

The present invention is further described in the following illustrative examples.

EXAMPLE 1

Catalyst Preparation

A catalyst (Catalyst A) was prepared using the following procedure:

A mixture comprising amorphous silica-alumina (ex Grace Davison, pore volume ($H_2O$) 1.10 ml/g, 13% wt alumina (dry basis); 1834.9g) and alumina (ex Criterion Catalyst Co.; 554.8g) was placed in a mulling machine and mulled for a period of 10 minutes. Acetic acid (10% wt aqueous solution; 200.0g) and water (2190.3g) were added and the resulting mixture mulled for a further 10 minutes. Thereafter, polyacrylamide (Superfloc A1839, 2% wt aqueous solution; 40.0g) was added and mulling continued for a further 10 minutes. Finally, polyelectrolyte (Nalco, 4% wt aqueous solution; 80.0g) was added and the mixture mulled for a final period of 5 minutes.

The resulting mixture was extruded using a 2.25" Bonnot extruder through a cylindrical dieplate, yielding 1.7mm diameter
cylindrical extrudates. The resulting extrudates were dried at a temperature of 120 °C for 2 hours and subsequently calcined at a temperature of 600 °C for 2 hours.

An aqueous solution was prepared comprising hexachloroplatinitic acid (H₂PtCl₆, 2.45% wt) and nitric acid (7.66% wt) having a pH of below 1. The cylindrical carrier particles were impregnated using this aqueous solution via the Pore Impregnation technique to give a final platinum loading on the carrier of 0.8% wt. The thus impregnated carrier particles were then calcined at a temperature of 500 °C for a period of 1 hour to yield the final catalyst.

Physical properties of Catalyst A are set out in Table I below.

EXAMPLE 2

Catalyst Preparation

Two further catalysts (Catalysts B and C) were prepared from the same starting materials using the general procedure set out in Example 1 above. Physical properties of Catalysts B and C are set out in Table I below.

EXAMPLE 3

Catalyst Preparation

A catalyst, Catalyst D, was prepared as follows:

A commercially available carrier material comprising 3.0mm diameter cylindrical extrudates prepared from an amorphous silica-alumina starting material having a pore volume (H₂O) of 1.10ml/g was obtained (ex Criterion Catalyst Co.).

An aqueous solution was prepared comprising hexachloroplatinitic acid (H₂PtCl₆, 2.45% wt) and nitric acid (7.66% wt) having a pH of below 1. The cylindrical carrier particles were impregnated using this aqueous solution via the Pore Impregnation technique to give a final platinum loading on the carrier of 0.8% wt. The thus
impregnated carrier particles were then calcined at a temperature of 500 °C for a period of 1 hour to yield the final catalyst. Physical properties of Catalyst D are set out in Table I below.

EXAMPLE 4

a) Fischer-Tropsch synthesis

A wax was prepared using the Fischer-Tropsch synthesis by the following method:

A catalyst comprising cobalt (18.3% wt, present as cobalt oxide), zirconium (8.5% wt, present as zirconium oxide) and silica was loaded into a fixed bed reactor. The catalyst was contacted with a mixture of carbon monoxide and hydrogen having a hydrogen to carbon monoxide molar ratio of 1.1, fed at a gas hourly space velocity of from 1120 to 1130 Nl/l/h at a pressure of 36 bars and a
temperature of from 210 to 225 °C. A heavy wax was produced, from which a fraction having a boiling point range of 370+ °C was separated.

b) **Middle Distillate Preparation**

Catalysts A, B, C and D prepared in Examples 1, 2 and 3 above were each used in experiments to prepare middle distillates by the hydroconversion of the 370+ °C fraction of the heavy wax produced in the Fischer-Tropsch synthesis process of (a) above. The experimental procedure used was as follows:

A sample of the catalyst was loaded into a fixed bed reactor. The catalyst was contacted with the 370+ °C fraction of heavy wax and hydrogen at a hydrogen gas hourly space velocity of 1000NL/1/hr, a wax hourly weight space velocity of 1.25 kg/l/hr and at a pressure of 30 bars. The operating temperature of the reactor in each experiment was altered within the range of from 320 to 340°C to vary the overall conversion of the hydrocarbon feed. As representative of a middle distillate product, the fraction of the reactor effluent having a boiling point range of from 220 to 370 °C was separated.

The performance data for Catalysts A, B, C and D in the various experiments are given in Table II below.

\(^1\) Conversion of 370+°C hydrocarbon feed.  
\(^2\) Selectivity of converted feed to hydrocarbons boiling in the range of from 220 to 370°C.
CLAIM:

1. A process for preparing middle distillates from a hydrocarbon feed obtained by a Fischer-Tropsch synthesis and comprising a fraction having a boiling point above the boiling point range of the middle distillates, which process comprises contacting the said hydrocarbon feed at elevated temperature and pressure in the presence of hydrogen with a catalyst comprising platinum supported on a silica-alumina carrier prepared from an amorphous silica-alumina starting material having a pore volume of at least 1.0 ml/g.

2. A process according to claim 1, wherein the pore volume of the amorphous silica-alumina is in the range of from 1.0 to 2.0 ml/g.

3. A process according to claim 1, wherein the pore volume of the amorphous silica-alumina is in the range of 1.0 to 1.5 ml/g.

4. A process according to any one of claims 1 to 3, wherein the amorphous silica-alumina comprises alumina in an amount in the range of from 5 to 30% by weight.

5. A process according to any one of claims 1 to 3, wherein the amorphous silica-alumina comprises alumina in an amount in the range of from 10 to 20% by weight.

6. A process according to any one of claims 1 to 3, wherein the amorphous silica-alumina comprises alumina in an amount in the range of from 12 to 15% by weight.

7. A process according to any one of claims 1 to 6, wherein the carrier comprises a binder.
8. A process according to claim 7, wherein the binder is selected from silica, alumina, clays, titania, magnesia, zirconia and mixtures thereof.

9. A process according to claim 8, wherein the binder is alumina.

10. A process according to any one of claims 7 to 9, wherein the binder is present in an amount in the range of from 5 to 50% by weight, on the basis of total weight of the carrier.

11. A process according to any one of claims 7 to 9, wherein the binder is present in an amount in the range of from 15 to 30% by weight, on the basis of total weight of the carrier.

12. A process according to any one of claims 1 to 11, wherein the catalyst comprises platinum in an amount in the range of from 0.05 to 5.0% by weight, on the basis of total weight of the carrier.

13. A process according to any one of claims 1 to 11, wherein the catalyst comprises platinum in an amount in the range of from 0.1 to 2.0% by weight, on the basis of total weight of the carrier.

14. A process according to any one of claims 1 to 11, wherein the catalyst comprises platinum in an amount in the range of from 0.2 to 1.0% by weight, on the basis of total weight of the carrier.

15. A process according to any one of claims 1 to 14, wherein the platinum has been deposited on the carrier by impregnation.
16. A process according to any one of claims 1 to 14, wherein the platinum has been deposited on the carrier by a pore volume impregnation.

17. A process according to claim 15 or 16, wherein the impregnation has been conducted by a process comprising contacting the carrier with a platinum salt in the presence of a liquid under acidic conditions.

18. A process according to claim 17, wherein the carrier is contacted with the platinum salt at a pH of no greater than 4.0.

19. A process according to claim 17, wherein the carrier is contacted with the platinum salt at a pH of no greater than 3.0.

20. A process according to any one of claims 17 to 19, wherein the carrier has been contacted with the platinum salt in the presence of an acid selected from monocarboxylic acids, dicarboxylic acids, hydrochloric acid, sulphuric acid and nitric acid.

21. A process according to claim 20, wherein the acid is nitric acid.

22. A process according to any one of claims 17 to 21, wherein the platinum salt is an acid platinum salt.

23. A process according to claim 22, wherein the acid platinum salt is selected from hexachloroplatinic acid, tetracyanoplatinic acid, hexahydroxyplatinic acid, platinum monohydroxychloric acid and platinum (III) sulphuric acid.

24. A process according to claim 22, wherein the acid platinum salt is hexachloroplatinic acid.
25. A process according to any one of claims 1 to 24, wherein the hydrocarbon feed is contacted with the catalyst at a temperature in the range of from 175 to 400°C.

26. A process according to any one of claims 1 to 24, wherein the hydrocarbon feed is contacted with the catalyst at a temperature in the range of from 250 to 375°C.

27. A process according to any one of claims 1 to 26, wherein the hydrocarbon feed is contacted with the catalyst at a pressure in the range of from 10 to 250 bars.

28. A process according to any one of claims 1 to 26, wherein the hydrocarbon feed is contacted with the catalyst at a pressure in the range of from 25 to 150 bars.

29. A process according to any one of claims 1 to 28, wherein the hydrogen partial pressure is in the range of from 10 to 250 bars.

30. A process according to any one of claims 1 to 28, wherein the hydrogen partial pressure is in the range of from 25 to 150 bars.

31. A process according to any one of claims 1 to 30, wherein the hydrocarbon feed is provided at a space velocity in the range of from 0.1 to 5 kg/l/hr.

32. A process according to any one of claims 1 to 30, wherein the hydrocarbon feed is provided at a space velocity in the range of from 0.25 to 2 kg/l/hr.

33. A process according to any one of claims 1 to 32, wherein the hydrocarbon feed is the product of a Fischer-Tropsch synthesis in which a catalyst comprising a metal selected from the elements of Group VIII of the Periodic Table is employed.
34. A process according to claim 33, wherein the metal is selected from iron, cobalt and nickel.

35. A process according to claim 34, wherein the metal is cobalt.

36. A process according to any one of claims 1 to 35, wherein the hydrocarbon feed is the product of a Fischer-Tropsch synthesis in which is employed a catalyst comprising, as promoter, an element from Group IVB of the Periodic Table.

37. A process according to claim 36, wherein the promoter is zirconium or titanium.

38. A process according to claim 36, wherein the promoter is zirconium.
