(54) Title: INHIBITORS OF TRANSGLUTAMINASES

(57) Abstract: The invention relates to the compound of general formula (I) as novel inhibitors of transglutaminases, to methods for producing the inventive compounds, to pharmaceutical compositions containing said inventive compounds and to their use for the prophylaxis and treatment of diseases associated with transglutaminases.

Inhibitors of Transglutaminases

Description

The invention relates to novel inhibitors or novel reversible inhibitors of transglutaminases, methods for their synthesis and to their use for the prophylaxis and treatment of diseases associated with transglutaminases.

Background of the invention

Transglutaminases are part of the class of transferases and according to EC nomenclature they are correctly designated as "protein-glutamine: amine γ-glutamyl transferases" (EC 2.3.2.13). They link the ε-amino group of the amino acid lysine and the γ-glutamyl group of the amino acid glutamine forming an isopeptide bond while ammonia is released. In the absence of suitable amines and/or under certain conditions, deamidation of the glutamine may occur resulting in the corresponding glutamic acid.

Additionally, transglutaminases play an important role in many therapeutic areas such as the cardiovascular diseases (thrombosis and atherosclerosis), autoimmune diseases (coeliac disease, Duhring-Brocq-disease, gluten ataxia), neurodegenerative diseases (Alzheimer's disease, Parkinson's disease, Huntington's disease), dermatological diseases (ichthyosis, psoriasis, acne) as well as in wound healing and inflammatory diseases (e.g. tissue fibrosis) (J.M. Wodzinska, Mini-Reviews in medical chemistry, 2005, 5, 279 - 292).

Coeliac disease, a gluten intolerance, however, is one of the most important indications. Coeliac disease is characterized by a chronic inflammation of the mucosa of the small intestine. In susceptible patients, the intestinal epithelium is successively destroyed after ingestion of gluten-containing food resulting in reduced absorption of nutrients which again has massive impact on the patients affected and is for example associated with symptoms such as loss of weight, anemia, diarrhea, nausea, loss of appetite and fatigue. Due to these findings, there is a large demand for the development of a medicament for the treatment of coeliac disease as well as of other diseases associated with tissue transglutaminase (transglutaminase 2, TG2). The tissue transglutaminase is a central element during pathogenesis. The endogenous enzyme catalyses the deamidation of gluten/gliadin in the small intestinal mucosa and

thus triggers the inflammatory response. Therefore inhibitors of tissue transglutaminase are suitable to be used as active agents for medication.
Another very important group of indications for tissue transglutaminase inhibitors are fibrotic disorders. Fibrotic disorders are characterized by the accumulation of cross-linked extracellular matrix proteins. Diabetic nephropathy, cystic fibrosis, idiopathic pulmonary fibrosis, kidney fibrosis as well as liver fibrosis belong to the most important fibrotic disorders to be addressed with the compounds disclosed.

The human transglutaminase family consists of eight members catalyzing the unique formation of "cross-links" or isopeptide bonds between distinct substrate proteins. Since blood coagulation factor XIII (FXIII, F13) is the major factor influencing clot maturation and accretion the enzyme is considered a suitable target to potentially achieve a safer and more efficient thrombolysis at even lower dosage of clot dissolving agents and also even for thrombus prevention.

The blood coagulation factor XIII (EC 2.3.2.13), also called plasma transglutaminase or fibrin stabilizing factor (FSF), has a unique function stabilizing the fibrin clot. The enzymatic introduction of covalent cross-links between the γ-chains and subsequently the α-chains of fibrin provides mechanical stability and modulates the visco-elastic properties.

In addition, the plasma transglutaminase decorates the clot with anti-fibrinolytic factors, especially with α_2-antiplasmin. For decades factor XIII is considered a suitable target for anti-coagulation in certain risk patients due to the unique mode-of-action. Targeting factor XIIIa with a direct acting blocker would not impair the thrombin level or the platelet activity avoiding critical bleeding episodes.

In addition, specific inhibitors may be of benefit for patients to prevent atherosclerosis. Very few inhibitors of factor XIIIa have been described so far. For example, a 66 amino acid peptide derived from the salivary gland of the giant Amazon leech *Haementeria ghilianii* is reported [Finney et al. *Biochem. J.* 1997, *324*, pp. 797-805]. Further, the pharmaceutical company Merck Sharp and Dohme developed a set of small molecule thioimidazole blockers targeting Factor XIII [Freund *et al.*, Biochemistry (1994), 33, 10109-10119].

However, also the other transglutaminases may be considered as targets for drug development. For example, TG6 is expressed in neuronal tissue. Therefore TG6 inhibitors may address neurodegenerative diseases characterized by intracellular or extracellular cross-linked and insoluble protein aggregates in the brain tissue.

Since TG1, TG3 and TG5 are expressed in the skin, inhibitors of said enzymes may be used to modulate dysregulated transglutaminase activity to therapy certain skin disorders. Inhibition of skin expressed transglutaminases can modulate the skin structure ("anti-aging") and improve skin conditions like acne or scarring.

The irreversible inhibitors of transglutaminase are developed by the applicants but the intrinsic reactivity of these warheads (e.g. Michael-acceptors like vinylesters) may lead to adverse drug reactions. It is known that electrophilic warheads can react with biological nucleophiles such as thiols. The unspecific reaction with off-targets can cause severe adverse effects and trigger certain immune responses. One example is idiosyncratic drug-related toxicity disfavoring such compounds from a more general perspective. Further, the direct damage of tissue has been described for irreversible acting compounds or metabolites. Also haptenization of proteins by reactive substances may elicit an immune response. Quite often, the liver is affected by such adverse effects.

Therefore, it is advantageous if the transglutaminase is inhibited reversibly.

The objective of the present invention is to provide novel, most probably reversible inhibitors of transglutaminases and methods for the synthesis of said inhibitors as well as several uses of these inhibitors.

Said objective is solved by the technical teachings of the independent claims. Further advantageous embodiments, aspects and details of the invention are evident from the dependent claims, the description and the examples.

Surprisingly, it has been found that reversible inhibitors having a chemical warhead as disclosed herein inhibit effectively transglutaminases including tissue transglutaminase called transglutaminase 2 or TG2 and plasma transglutaminase also called coagulation factor XIII. Herein these terms are used synonymous. However, depending on the respective backbone the warheads also address other human transglutaminases like TG1, TG3, TG4, TG5, TG6 and TG7 or transglutaminases derived from other species like animals or micororganisms.

Preferably, such chemical warhead moiety is particularly selected from aldehydes (including so called masked aldehydes), ketones, α-ketoaldehydes, α-ketoketones, α-ketoacids, α-ketoesters, and α-ketoamides as well as halogenmethylketones. The compounds of the present invention act most probably as reversible inhibitors of transglutaminases.

Thus, the present invention relates to compounds of the general formula (I):

The term “prodrug” describes compounds according to one of the general formulae (I) to (XIV-2), wherein the compounds comprises at least one carboxylate group which is modified with a rest that is generally known by a person skilled in the art in that way that the carboxylate group of the compound is released under physiological conditions and/or at least one modified hydroxyl group which is modified with a rest that is generally known by a person skilled in the art in that way that the hydroxyl group of the inventive compond is released under physiological conditions.

Due to the specially selected substituents $\mathbf{E^C}$ on the C-terminal side and substituents $\mathbf{E^N}$ on the N-terminal side of the inventive compound according to the invention the steric dimension can be adjusted very precisely, so that a binding pocket of a desired target molecule may be addressed with highly matching measurements.

Suprisingly, it was found that the inventive compounds bound to the transglutaminases reversibly and inhibit the transglutaminase effectively. The electrophilic warheads can react with highly nucleophilic thiols in the active site of the transglutaminase. Therefore, it was found that potential unspecific reactions with off-targets are reduced. It would be expected that the inventive compounds as reversible transglutaminase inhibitor may be less toxic than the irreversible transglutaminase inhibitors.

A further aspect of the present invention relates to the production of compounds of the general formula (I).

As shown in Scheme 1, a method for producing the compound of the present invention comprises:
Step (0): providing a protected amino acid having a chemical warhead;
Step 1A: deprotecting a carboxyl protecting group PG^3;
Step 2A: performing coupling reaction with a C-terminal building block E^C-AG^1;
Step 3A: deprotecting two amino protecting groups PG^1 and PG^2;
Step 4A: performing coupling reaction with a N-terminal building block E^N-AG^2;
to produce the compound of the formula (I).

Optionally, Step 1A´ is carried out between the step 1A and the step 2A:
The Step 1A´:

(a) performing coupling reaction of a resulting compound of Step 1A with a corresponding C-terminal amino acid building block H_2AS^{Ci}-OPG^4;
(b) deprotecting the protecting group PG^4;
(c) repeating the steps (a) and (b) *i* times, wherein *i* is 1-8.

In other option, Step 3A´ is carried out between the step 3A and the step 4A:
The Step 3A´:

(d) performing coupling reaction of a resulting compound of Step 3A with a corresponding N-terminal amino acid building block $(PG^5)HAS^{Nj}$-OH;

(e) deprotecting the protecting group PG^5;
(f) repeating the steps (a) and (b) *j* times, wherein *j* is 1-4.

Therefore, the following methods are preferred:

1. Step (0) – Step 1A – Step 1A´- Step 2A – Step 3A – Step 4A:

As shown in Scheme 4, an alternative method for producing the compound of the present invention comprises:

Step (0): providing a protected amino acid (**1C´**) having a chemical warhead precursor (**W´**);

Step 1D: performing coupling reaction of the protected amino acid (**1C´**) with a C-terminal peptide building block (**C-P**) or a C-terminal building block (**E^{C}**-H) to obtain a compound **1D-1** or **1D-2**;

Herein, **AS^{Ci}** represenst one of **AS^{C1}**, **AS^{C2}**, **AS^{C3}**, **AS^{C4}**, **AS^{C5}**, **AS^{C6}**, **AS^{C7}**, and **AS^{C8}**. **AS^{Nj}** represents one of **AS^{N1}**, **AS^{N2}**, **AS^{N3}**, and **AS^{N4}**. **H_2AS^{Ci}-OPG^4** means amino acid having AS^{Ci} (one of AS^{C1} – AS^{C8}) backbone and unprotected free amino (H_2N-) group and carboxyl moiety protected by PG^4 group. **(PG^5)HAS^{Nj}-OH**, means amino acid having AS^{Ni} (one of AS^{N1} – AS^{N4}) backbone and amino group protected by a PG^5 group [(PG^5)HN-)] and unprotected free carboxylic acid (–CO_2H).

In an alternative route first all protecting groups PG^1 and PG^2 and PG^3 are simultaneously removed and the protecting group PG^1 is selectively re-introduced.

The term “protecting groups” as used herein refers to commonly used protection groups in organic synthesis, preferably for amino and carboxyl groups. PG^1, PG^2, and PG^5 preferably are suitable protecting groups for amino groups. PG^3 and PG^4 preferably are suitable protecting groups for carboxyl groups. Prerfably, PG^1, PG^2, and PG^5 may be selected from the group consisting of or comprising: acetyl, benzoyl, benzyloxycarbonyl (Cbz), tert-butylcarbonyl, tert-butyloxycarbonyl (Boc), and fluorenylmethylenoxy group (Fmoc). PG^3 and PG^4 may be selected from the group consisting of or comprising: methoxy, ethoxy, isobutoxy, tert-butoxy, benzyloxy; preferably, tert-butoxy group.

The term “activating group” as used herein refers to commonly used activating groups in peptide synthesis, preferably for activaition of carboxyl acid and promote the

coupling reaction with amino group of intermediate compound. AG^1 is an activating group of carboxylic acid of amino acid. This group may be introduced separate reaction or *in situ* reaction. Prerfably, AG^1 may be selected from the group consisting of or comprising: halides such as –F, –Br, –Cl, –I, anhydride group such as -$OCOCH_3$, N-oxy-benzotriazol group and N-oxy-succinimide. Preferably, AG1 is introduced in situ and it is well-known in peptide chemistry. Any of the following coupling reagent can be used to introduce activating group AG1: BOP, PyBOP, AOP, PyAOP, TBTU, EEDQ, Polyphosphoric Acid (PPA), DPPA, HATU, HOBt, HOAt, DCC, EDCI, BOP-Cl, TFFH, Brop, PyBrop, and CIP.

In Scheme 4, the chemical warhead precursor represent  ,  . In the step 4D, said warhead precursor is converted to the corresponding chemical warhead,  by oxidation method, preferred, by using Dess-Martin periodinane (DMP), iodoxybenzoic acid (IBX), or hydrogen peroxide(H_2O_2) in a polar solvent, in particular in DMF as described in chemical examples.

Therefore another aspect of the present invention relates to compounds according to the general formula (I) as medicine as well as their use in medicine. Especially preferred is the use as inhibitors of transglutaminases.

The compounds according to general formula (I) described herein are especially suitable for the treatment and prophylaxis of diseases associated with and/or caused by transglutaminases.

TG1, TG3 and TG5 are expressed in the skin, inhibitors of said enzymes may be used to modulate transglutaminase activity to therapy certain skin disorders or to influence skin structure. TG6 inhibitors may address neurodegenerative diseases characterized by intracellular or extracellular cross-linked and insoluble protein aggregates.

Coeliac disease, a gluten intolerance is associated with tissue transglutaminase (TG 2). Another very important group of indications for tissue transglutaminase inhibitors are fibrotic disorders. Fibrotic disorders are characterized by the accumulation of cross-linked extracellular matrix proteins. Diabetic nephropathy, cystic fibrosis, idiopathic pulmonary fibrosis, kidney fibrosis as well as liver fibrosis belong to the most important fibrotic disorders to be addressed with the compounds disclosed.

Since blood coagulation factor XIII (FXIII, F13) is the major factor influencing clot maturation and accretion the enzyme is considered a suitable target to potentially achieve a safer and more efficient thrombolysis.

Therefore, another aspect of the present invention is the use of the inventive compounds of the general formula (I) for the treatment or prophylaxis of cardiovascular diseases, autoimmune diseases, neurodegenerative diseases, fibrotic disorders, dermatological diseases , wound healing, and inflammatory diseases.

In particular, the use of the inventive compounds of the general formula (I) for the treatment or prophylaxis of atherosclerosis, coeliac disease, Duhring-Brocq-disease, gluten ataxia, tissue fibrosis, cystic fibrosis, idiopathic pulmonary fibrosis, kidney fibrosis and diabetic nephropathy, liver fibrosis, thrombosis, Huntington's disease, Parkinson's disease, Alzheimer's disease, cataract, ichthyosis, acne, psoriasis, skin aging, candidosis, and other transglutaminase dependent diseases.

The term „transglutaminase dependent diseases" comprises all diseases, dysfunctions or other impairments of the health, which are caused by or in connection with a dysfunction, perturbance or hyperactivity of transglutaminases in the body. Alternatively, it might be of benefit for certain at risk patients to prophylactically block a transglutaminase like FXIII e.g. in thrombophilic patients.

The particular suitability of the inventive compounds of the general formula (I) is connected to the sterical and electronical properties which result from the molecule structure. The electrophilic warhead group appears to be an essential unit of the reversible transglutaminase inhibitors, and, especially in combination with the certain peptidomimetic backbone, the pyridinone-containing backbone, the conformationally constrained unnatural proline-based amino acids and the piperazine-containing backbone results in potent transglutaminase inhibitors, especially, transglutaminase 2 and blood coagulation factor XIII. Selectivity is obtained by implementing said components at selected positions within the backbone.

It is known from the literature on proteases that certain warheads form covalent but reversible complexes with the active site cysteine or serin. This is particularly relevant to provide affinity to the target while forming a thiohemiacetal or hemiacetal respectively. We surprisingly discovered that this principle is suitable for transglutaminase inhibitors. The discovered warheads need to be positioned in the correct orientation replacing the former substrate glutamine. The backbone positions the warhead so that the thiohemiacetal is formed.

In the biological example B-1, it is proven that the inventive compounds as reversible TG inhibitor effectively inhibit the activity of TGs, especially TG2 and FXIII.

Furthermore, it is also provent that the inventive compounds as reversible TG inhibitor have less toxicity comprared with irrevisible TG inhibitor. In the biological example B-2 that cytotoxicity of transglutaminase inhibitors is evaluated with two different assays. While irreversible TG inhibitor Z006 is cytotoxic at 125 µM, the inventive compound **E02** shows no influence on cell proliferation or metabolic activity up to 1 mM (highest concentration measured). It is drawback of the irreversible TG inhibitor that the unspecific reaction with off-targets can cause severe adverse effects and trigger certain immune responses. Further, the direct damage of tissue has been described for irreversible acting compounds or metabolites. Also haptenization of proteins by reactive substances may elicit an immune response. Quite often, the liver is affected by such adverse effects.
Threfore, it is technical advantage that the inventive compound has not cytotoxicity in a high contration, i.e. mmolar-range.

In addition, it is also demonstrated in the example B-3 that the tissue transglutaminase inhibition using the inventive comopund reduces transglutaminase activity and reduces ECM accumulation. These results indicate that the inventive comopund has an antifibrotic effect on renal cells in proximal tubular epithelial cells. Therefore, it is supported that the inventive compound is useful for treatment of fibrosis such as tissue fibrosis, cystic fibrosis, idiopathic pulmonary fibrosis, kidney fibrosis and liver fibrosis.

Biological Examples

Example B-1. Inhibitory effect of the compounds according to the invention

Method for inhibition studies of rec. human tissue transglutaminase (rhTG2)

250 µg lyophilized His-tagged recombinant human tissue transglutaminase (His_6-rhTG2, Zedira product T022) is reconstituted in H_2O (volume depends on original volume before lyophilization) resulting in a buffer containing 10 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 5 mM DTT, 189 mg/ml maltodextrin, pH = 8.1. The rhTG2 stock solution is diluted in buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to give a working solution of 100 U/ml (based on the amine-incorporation activity measured using T036, described below).

A 10 mM inhibitor stock solution is prepared in DMSO, and from this stock solution a serial 1:2-fold dilution series is prepared, also in DMSO. Each of these initial dilutions is subsequently diluted 1:50-fold with buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to yield the final working dilutions containing 2% (v/v) DMSO.

15 µl of inhibitor working dilution are added per well of a 96 well microtiter plate. As control, 15 µl of a 2% (v/v) DMSO solution prepared using the buffer mentioned above are added per well.

600 µl of His_6-rhTG2 working solution are added to 11.4 ml assay buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, 5 mM DTT, 13.4 mM glycine methylester, 50 µM Abz-APE(CAD-DNP)QEA-OH, (Zedira product A102; patent No.: EP 1781807B1), pH = 7.4). From this master-mix solution, 285 µl are added per well containing the inhibitor. Increase in fluorescence is measured using λ_{ex} = 313 nm and λ_{em} = 418 nm at 37°C for 20 min. A slope of the increase in fluorescence between 10 and 20 min is calculated for determination of the IC_{50} value (inhibitor concentration at which 50% of the initial TG2 activity is blocked).

Method for inhibition studies of rec. human coagulation Factor XIII (plasma Transglutaminase, rhFXIII-A)

50 µg lyophilized His-tagged recombinant human factor XIII A-subunit (His_6-rhFXIII, Zedira product T027) is reconstituted in H_2O (volume depends on original volume before lyophilization) resulting in a buffer containing 20 mM Tris-HCl, 150 mM NaCl, 1 mM EDTA, 1 mM DTT, 189 mg/ml maltodextrin, pH = 7.5. The rhFXIII stock solution is diluted in buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to give a working solution of 59 U/ml (based on the amine-incorporation activity measured using transglutaminase activity assay #T036 (Zedira GmbH), described below).

A 10 mM inhibitor stock solution is prepared in DMSO, and from this a serial 1:2-fold dilution series is prepared also in DMSO. Each of the initial dilutions is subsequently

diluted 1:50-fold with buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to yield the final working dilutions containing 2% (v/v) DMSO.

15 µl of inhibitor working dilution are added per well of a 96 well microtiter plate. As control, 15 µl of a 2% (v/v) DMSO solution prepared using the buffer mentioned above are added per well.

480 µl of His_6-rhFXIII working solution and 120 µl human alpha thrombin (0.5 NIH units/µl) are added to 10.8 ml assay buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, 5 mM DTT, 13.4 mM glycine methylester, 50 µM Abz-NE(CAD-DNP)EQVSPLTLLK-OH, (Zedira product A101; patent No.: EP 1781807B1), pH = 7.4). From this master-mix solution, 285 µl are added per well containing the inhibitor. Increase in fluorescence is measured using λ_{ex} = 313 nm and λ_{em} = 418 nm at 37°C for 35 min. A slope of the increase in fluorescence between 20 and 30 min is calculated for determination of the IC_{50} value (inhibitor concentration at which 50% of the initial FXIII activity is blocked).

This assay was also used to determine selectivity of inhibitors preferentially blocking FXIIIa by using TG2 instead of FXIII.

Selectivity Assay (general Transglutaminase assay; T036)

For the determination of selectivity of inhibitors against different transglutaminases, the incorporation of dansylcadaverine into dimethylcasein (Zedira product T036, Lorand *et al.*, Anal Biochem, 1971, 44:221-31) was measured using recombinant human transglutaminase 1 (Zedira Product T009), transglutaminase 2 (Zedira Product T022), transglutaminase 3 (Zedira Product T012), transglutaminase 6 (Zedira Product T021), and plasma transglutaminase (rhFXIII, Zedira Product T027).

The different transglutaminases are diluted in buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to the respective working concentrations.

A 10 mM inhibitor stock solution is prepared in DMSO, and from this a serial 1:2-fold dilution series is prepared also in DMSO. Each of the initial dilutions is subsequently diluted 1:50-fold with buffer (50 mM Tris-HCl, 7.5 mM $CaCl_2$, 150 mM NaCl, pH = 7.4) to yield the final working dilutions containing 2% (v/v) DMSO.

15 µl of inhibitor working dilution are added per well of a 96 well microtiter plate. As control, 15 µl of a 2% (v/v) DMSO solution prepared using the buffer mentioned above are added per well.

Immediately before starting the assay, 600 µl transglutaminase working solution are added to 11.4 ml assay buffer (50 mM Tris-HCl, 10 mM $CaCl_2$, 10 mM glutathione, 2.5% glycerol, 16.7 µM dansylcadaverine, 4 µM N,N-dimethylcasein, 200 mM NaCl, pH = 8.0). 285 µl of this reaction mix are added per well containing the inhibitor.

Increase in fluorescence is measured using λ_{ex} = 330 nm and λ_{em} = 500 nm at 37°C for 30 min. A slope of the increase in fluorescence between 20 and 30 min is calculated for

determination of the IC_{50} value (inhibitor concentration at which 50% of the initial activity is blocked).

Analysis of enzymatic activity is performed by calculation of the slope of an increase in fluorescence intensity. IC_{50} values are calculated by plotting the enzymatic activity (as percentage from control containing 2% DMSO instead of inhibitor) against the inhibitor concentration. IC_{50} is defined as the inhibitor concentration blocking 50 % of initial enzyme activity.

The inhibitory activity of the inventive compounds in regard to tissue transglutaminase (TG2) and FXIII-A is shown in the following table using IC_{50}-values.

Example B-2. Determination of cytotoxicity of transglutaminase inhibitors

The following cell lines are used for determination of cytotoxicity:

- CaCo2 (human colon carcinoma cell line)
- Huh7 (human liver carcinoma cell line).

Cells are cultivated in DMEM/10% FCS at 37°C and 5% CO_2 in a 96 well plate with an initial seeding density of $2x10^4$ cells/ well.

Transglutaminase inhibitors are added to the cells with final concentrations from 0.1 µM to 1 mM one hour after seeding. The different inhibitor dilutions are prepared in DMSO, resulting in a final concentration of 1% (v/v) DMSO in every well (2 µl inhibitor in 200 µl cell culture medium). Cycloheximide (2.5 µg/ml) and Camptothecin (0.2 µg/ml) are used as control compounds. All measurements are performed in triplicates.

Cytotoxicity of transglutaminase inhibitors is evaluated with two different assays:

Determination of proliferation using Cell Proliferation ELISA, BrdU (Roche, Cat. No. 11647229001).

After 24 h of incubation with inhibitors or controls, BrdU is added to the cells. After further incubation for 18 h, the cells are fixed and cellular DNA becomes denatured. A monoclonal antibody (conjugated with peroxidase) raised against BrdU is added to the wells and binds to BrdU which is incorporated into the DNA. Substrate solution is added and absorbance at 450 nm is recorded. Further analysis is performed according to the manufacturer's protocol.

Determination of metabolic activity using EZ4U-Assay (Biomedica, Cat. No. BI-5000).

After 48 h of incubation with inhibitors or controls, the tetrazolium substrate is added to the cells. Substrate turnover by the cells is measured over two hours at 450 nm (using 630 nm was reference wavelength).

Cytotoxicity of inhibitor pairs characterized by the same backbone, but either a reversible (alpha ketoamide) or irreversible (diazooxonorleucine) warhead are given in table 4. For the compounds with diazooxonorleucine-warhead, reduced cell proliferation and metabolic activity at concentrations from 100 µM to 500 µM (depending on the cell type) have been found. In sharp contrast, the reversible inhibitors showed no impact on both parameters up to the highest concentrations measured (1 mM). In order to demonstrate this effect, we compared the commercial available irreversible acting inhibitor Z006 (Z-DON-VPL-OMe, "Z-DON", Zedira)

carrying a 6-diazo-5-oxo-norleucine warhead with the reversible inhibitor **E02**. The peptidic backbone is the same, the warhead (α-ketoamide) and the mode-of-action (irreversible vs. reversible) is different. While Z006 is cytotoxic at 125 µM the novel compound **E02** shows no influence on cell proliferation or metabolic activity up to 1 mM (highest concentration measured).

Table 4. Cytotoxicity concentrations (>10% deviation from negative control) of tissue transglutaminase blockers with identical backbone but reversibly (alpha ketoamide) or irreversibly (diazooxonorleucine) reacting warhead in cell proliferation assays (BrdU) and metabolic activity assays (EZ4U).

Example B-3. Antifibrotic effect on renal cells

Fibrosis is a hallmark in diabetic nephropathy and chronic kidney diseases. Proximal tubular epithelial cells show increased TG2 activity and increased extracellular matrix proteins (ECM) accumulation under hyperglycemic conditions. ECM accumulation is a hall mark of fibrosis. In order to demonstrate the antifibrotic effect of reversible transglutaminase inhibitors, compounds **E06** and **E22** were tested on proximal tubular

epithelial cells cultured under normal versus hyperglycemic conditions. TG2-acitvity and ECM-accumulation was measured.

Rattus norvegicus kidney derived cell line NRK52E was grown at 37°C in a humidified atmosphere at 5% (v/v) CO_2 in DMEM (Dulbecco's modified Eagle's medium) containing 100 µg/mL streptomycin, 100 units/ml penicillin, 20 mM glutamine, and 10% (v/v) fetal calf serum. For simulation of normal physiological conditions 6 mM D-glucose were added to the medium, while addition of 24 mM and 36 mM D-glucose simulated hyperglycemic conditions. Reversible TG2 inhibitor **E06** in the concentrations indicated in Fig. 1A was added at the time of plating to the medium. Reversible TG2 inhibitor **E22** in the concentrations indicated in Fig. 2A was added at the time of plating to the medium.

TG2-activity was determined in cell homogenates. Therefore, cells were removed from plates with trypsin (2 mg/mL)-EDTA (2 mM) solution, centrifuged, washed with PBS and finally stored in sucrose (0.32 mM)-Tris (5mM)-EDTA (1mM)-buffer pH7.2, containing 1 µL/mL protease inhibitor (Halt™ Protease and Phosphatase Inhibitor Cocktail, EDTA-free, ThermoFisher, #1861279). Equal amounts of cells were homogenized by sonication.

TG2-activity was measured using the TG2-selective Tissue Transglutaminase Pico-Assay Kit (#M003, Zedira, Darmstadt, Germany) according to the manufacturer's instructions. One unit is defined as the amount of enzyme, which causes the formation of 1.0 µmole of hydroxamate per minute by catalysing the reaction between Z-Gln-Gly-OH and hydroxylamine at pH 6.0 at 37°C

For the determination of extracellular matrix proteins (ECM) deposition, cells grown in 10 cm Petri-dishes were removed with 1 mL sodium deoxycholate (0.1%) – EDTA (2 mM)-solution. ECM proteins remaining on the plate were solubilzed by digestion with trypsin (0.2 mg/mL) – EDTA (2 mM) solution. The resulting solution was concentrated by speed-vac. Protein concentration was determined using the DC-protein-assay (BioRad, #5000111).

Intracellular TG2 is increased inNRK52E-cells at hyperglycemic concentrations of 24 and 36 mM glucose (Fig.1A, 0 µM **E06**). With increasing concentrations of **E06** the TG2 activity determined in the cell homogenates decreases (Fig.1A, 10 – 100 µM **E06**). Production of extracellular matrix protein increases at hyperglycemic concentrations (Fig.1B, 0 µM **E06**). The increase of ECM was reduced in a dose dependent manner by the addition of **E06** to the culture medium.

Intracellular TG2 is increased inNRK52E-cells at hyperglycemic concentrations of 24 and 36 mM glucose (Fig.2A, 0 µM **E22**). With increasing concentrations of **E22** the TG2 activity determined in the cell homogenates decreases (Fig.2A, 10 – 100 µM **E22**).

Production of extracellular matrix protein increases at hyperglycemic concentrations (Fig.2B, 0 µM **E22**). The increase of ECM was reduced in a dose dependent manner by the addition of **E22** to the culture medium.

In summary these results show, that tissue transglutaminase inhibition using reversible tissue transglutaminase blocker **E06** and **E22** reduce transglutaminase activity and reduces ECM accumulation. These data indicate that **E06** and **E22** have an antifibrotic effect in proximal tubular epithelial cells.

Example B-4. Thromboelastometry (TEM)

Thromboelastometry is a visco-elastic method for the assessment of blood coagulation. In whole blood parameters like clotting time (CT), clot formation time (CFT), maximum clot firmness (MCF) and lysis index at 60 min (LI_{60}) were obtained using the ROTEM® delta device according to the manufacturer.

The potency of selected compounds (serial dilution covering 6.25 µM to 50 µM final concentration) in the presence of 0.02 µg/ml tissue plasminogen activator (t-PA, Zedira product P016) were investigated. Briefly, 20 µL star-TEM® (0.2 mol/l $CaCl_2$), 20 µL r ex-TEM® (recombinant tissue factor, phospholipids, heparin inhibitor), 10 µL inhibitor stock solution (1.8 - 0.23 mM), combined with 10 µL t-PA stock solution (0.72 µg/ml) to yield concentrations of 0.9 - 0.11 mM in 18 % DMSO/PBS with 0.36 µg/ml t-PA and 300 µL fresh citrated whole blood (human, from healthy consenting donors) were mixed in a disposable cuvette. As control the inhibitor stock solution was replaced by 36 % DMSO / 0.36 µg/ml t-PA in PBS.

The results of dose dependent influence of compounds **E25** and **E27** on TEM parameters are presented respectively in Figures 3A)/3B) and Figures 4A)/4B).

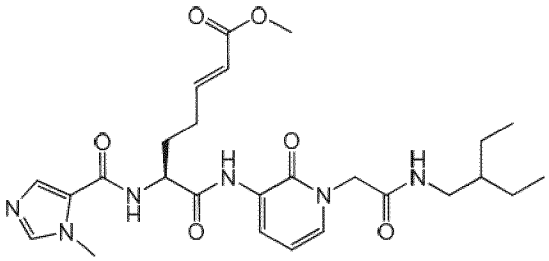
Figure 3A) and Figure 4A) show dose dependent influence of compounds **E25** and **E27** on the reduction of maximum clot firmness (MCF) compared to control (K).

Figure 3B) and Figure 4B) show dose dependent influence of compounds **E25** and **E27** on the clot lysis at 60 minutes (LI_{60}) in the presence of 0.02% t-PA.

Example B-5. Investigation of the reversible mode of inhibition of α-keto compounds

In order to investigate the reversibility of α-ketoamides as TG2-inhibitors, the inhibitor was removed stepwise using Vivaspin® centriufugal concentrators (VS2022, Sartorius Stedim) while the molecular weight of the TG2 prevents passing the ultrafiltration membrane. Briefly, recombinant human tissue transglutaminase (Zedira, T002) was incubated with the inhibitor **E16** at 1.6 µM. The transglutaminase activity was

determined using the casein / dansylcadaverine assay (Zedira, T036). Subsequently, buffer was added to dilute the inhibitor within the reaction mixture as shown in *table 5*. After concentration using the Vivaspin centrifugal concentrators to the original volume, the procedure was repeated twice to obtain 1:100 and 1:1,000 dilution. The activity rises with increasing dilution indicating that the inhibitor binds in equilibrium to TG2. Once the concentration of the inhibitor is decreased the ratio of non-inhibited transglutaminase rises and consequently the activity increases. As a control, the same experiment was performed using REF1. REF1 irreversibly binds to the active site cysteine of TG2 thereby blocking its activity.



REF1

As expected, we could not find any rebound of activity. Conclusively, the α-keto compounds claimed provide a reversible mode of inhibition.

Table 5

Inhibitor [1.6 µM]	**Activity after inhibition**	**Recovery of activity by dilution of inhibitor (constant TG2 concentration)**		
		1:10	**1:100**	**1:1,000**
E16	0 %	15 %	61 %	100 %
REF1	0 %	0 %	0 %	0 %

Example B-6. Blocking of neurite outgrowth

The irreversible-reversible inhibitor pair **Z007** and **E57** was further compared using a neurite outgrowth assay (Merck, #NS220) with mouse neuroblastoma cell line N1E-115. Laminin-coated Millicell® 12-well inserts were placed in a 12 well plate containing 1.2 mL differentiation medium (Merck, NS002). Then, 300 µL of a 10^6 N1E-115-cells/mL suspension were added. Differentiation medium contained 0 µM, 75 µM and 150 µM Nocadazole as positive controls, and 100 µM, 250 µM and 500 µM of inhibitors **Z007** or **E57**. Nocodazole interferes with the polymerization of microtubules resulting in an antineoplastic effect.

For neurite extension the plates were incubated at 37°C for 48 hours. Then the insert was transferred to a new 12 well plate with 1,200 µL of PBS per plate and finally to a

plate with 400 µL of -20°C methanol per well, where the cells were fixed for 20 min at room temperature. After rinsing with PBS, the insert was stained with Neurite Staining Solution for 20 min. After rinsing the inserts in PBS cell bodies were carefully swabbed off and inserts were washed again in PBS. Inserts were then transferred into 15 mL tubes and 100 µL Neurite Stain Extraction Buffer were added to the top of the inserts. After 5 min incubation at ambient temperature, tubes were centrifuged for 1 min at 1,200 rpm. Finally 75 µL extraction buffer were removed and the absorbance was determined at 590 nm.

The results are summarized in Figure 5. The irreversible TG2-blocker **Z007** reduced neurite outgrowth in a dose dependent manner. At 500 µM, a moderate 36% reduction was observed. For reversible TG2-inhibitor **E57** also a dose dependent, but even milder impact, on neurite outgrowth could be determined. At 500 µM the reduction of neurite outgrowth was 18%.

Example B-7 Effect of TG2-inhibition in a cellular system of Huntingtin producing cells.

Insoluble protein aggregates composed of the protein huntingtin (htt) are a hallmark of Chorea Huntington. Htt is characterized by polyglutamine (polyQ)-expansions, triggering aggregation and serving as substrate for transglutaminase catalyzed cross-linking.

N2a cells (mouse neuroblastoma cell line) transfected with Htt-exon1-97Q were grown in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal calf serum, 1 mM glutamine, 100 µg/mL streptomycin, and 100 U/mL penicillin in a humidified incubator with 5% CO_2 at 37°C.

For preparation of SDS-soluble and formic acid soluble extracts, cells were harvested in 0.5mL cold PBS, centrifugated, resuspended in 70 mM Tris-HCl pH 6.8, 1.5% SDS, 20% glycerol and lysed through sonication. DTT was added to a final concentration of 50 mM and the sample was boiled for 10 min in a ThermoMixer® at 1000 rpm, followed by centrifugation for 1 h at 14,000 rpm. The supernatant was transferred to a new tube and was stored at 4°C before coating of microtiter plates.

For solubilization of the SDS-insoluble proteins in the remaining pellet, 10 µl formic acid were added and mixed by pipetting 10 times up and down, followed by incubation at 37°C for 40 min at 1,000 rpm in a ThermoMixer®. Formic acid was then removed in a SpeedVac™ concentrator at 30°C under vacuum. The resulting protein pellet was dissolved in 70 mM Tris-HCl pH 6.8, 1.5% SDS, 20% glycerol. The sample was boiled for 10 min, and stored at 4°C before coating of microtiter plates.

SDS-soluble and formic acid soluble extracts were used subsequently for coating of 96-well micro-titer-plates. Therefore, 100 µL of the cell extracts were added in each well and incubated over night at 4°C. After washing with Tris-buffered saline, 0.1% Tween 20, plates were blocked with 150 µL 1%-BSA-solution in PBS for 60 min at 37°C. After washing, 100 µL detection antibody was added and incubated for 60 min at ambient temperature. This solution was removed, the plates washed again intensively and secondary antibody was applied (goat anti-mouse IgG-HRP-conjugate) for a further 30 minutes at ambient temperature. The plates were intensively washed and 100 µL substrate solution (TMB-H_2O_2) was added. After incubation for 60 min at room temperature the reaction was stopped by the addition of 0.2 M sulfuric acid. Extinction was measured at 450 nm in a plate reader device.

In order to analyze the effect of **E22** on huntingtin aggregation and cross-linking, Htt-exon1-97Q – transfected N2a-cells were grown in presence of 150 or 300 µM TG2-blocker **E22**. SDS-soluble and formic acid soluble extracts were generated and huntingtin and cross-links (isopeptide bonds) were determined in an ELISA-format as described above.

The results are summarized in Figures 6A and 6B. The amount of SDS-soluble htt increases along with higher **E22**-concentrations. Concomitantly, the mount of formic acid soluble htt decreases.

In the soluble extract as well as in the formic acid soluble extract the amount of cross-links decreases dose dependently.

Taken together, **E22** reduces protein cross-linking in a dose dependent manner. The increasing amount of htt protein in the SDS-soluble fraction may be explained by reduced enzymatic cross-linking of htt, which keeps the protein soluble, because concomitantly htt-protein is reduced in the formic acid soluble fraction.

The observed htt-aggregation reducing effect of TG2-blocker **E22** supports the potential of reversible acting transglutaminase blockers for treatment of neurodegenerative disorders characterized by cross-linked insoluble protein aggregates.

Example B-8. Antifibrotic effect on lung epithelial cells

Extracellular matrix deposition is a hallmark in pulmonary fibrosis. The BEAS-2B cell line is derived from normal human bronchial epithelium. In order to demonstrate the

antifibrotic effect of reversible transglutaminase inhibitors, compound **E22** was tested on BEAS-2B cells stimulated with lipopolysaccharides (LPS).

BEAS-2B cells were grown at 37°C and 5% CO_2 in 25mM HEPES-buffered M199-medium (Merck, Darmstadt) containing 10% FBS, 100 mg/ml streptomycin, 2 mM glutamine, 100 U/ml penicillin (supplemented with 2.5 mg/ml apotransferrin, 20 ng/ml human epidermal growth factor (EGF), 2.5 mg/ml insulin, and 0.361 mg/ml hydrocortisone). For the induction of airway fibrosis by epithelial-to-mesenchymal transition (EMT), cells were seeded at 80% confluence on six-well plates. After one day cultivation 4 µg/mL LPS as well as 0 µM, 100 µM or 200 µM **E22** were added and then incubated for further 72 h.

Subsequently, cells were harvested and TG2-acitvity as well as ECM-deposition was measured as described above for the demonstration of the antifibrotic effect in renal cells.

Transglutaminase activity measured in LPS-stimulated BEAS-2B-cells showed dose dependent reduction upon addition of increasing amounts of **E22** to the culture medium (Fig. 7A).

In parallel, the deposition of ECM-proteins was significantly reduced, also in a dose dependent manner (Fig. 7B). Taken together, these data indicate an antifibrotic effect of **E22** in pulmonary epithelial cells.

Example B-9. Antifibrotic effect on hepatic stellate cells

Liver fibrosis is characterized by the formation of scar tissue as a response to liver damage. Activated hepatic stellate cells (HSC) are the major cell type in liver fibrosis, deposing extracellular matrix protein, essentially collagens, in the space of Disse (perisinusoidal space). Hepatic fibrosis is the result of inflammation as a response to liver injury. Inflammation is characterized by HSC activation to a myofibroblast-like phenotype.

LX-2 Human Hepatic Stellate Cell Line

Human hepatic stellate cell line LX-2 was cultured on standard plastic 6 well plates in Dulbecco's Modified Eagle's Medium containing 100 µg/mL streptomycin, 100 units/ml penicillin, 2 mM glutamine, and 10% (v/v) fetal calf serum. **E22** was added to a concentration of 0 µM, 100 µM and 200 µM. Cells were grown at 37°C and 5% CO_2 humidified atmosphere. Medium was exchanged every two days. After 12 days cells

were harvested and analyzed for TG2-activity and extracellular matrix deposition as described above for the demonstration of the antifibrotic effect on renal cells.

Transglutaminase activity was reduced to <5% of the inhibitor free control already at 100 µM reversible transglutaminase-inhibitor **E22** in the culture medium (Fig. 8A).The extracellular matrix deposition on the plates was reduced to about 30% of control at both **E22** concentrations.

This observation shows that TG2-inhibition of HSCs reduces deposition of extracellular matrix proteins. TG2-inhibition may therefore provide an antifibrotic effect on liver fibrosis.

In parallel, the deposition of ECM-proteins was significantly reduced, also in a dose dependent manner (Fig. 8B). Taken together, these data indicate an antifibrotic effect of **E22** in hepatic stellate cells.
