(57) **ABSTRACT**

A pump health analysis method and a pump health analysis device using the same are provided. A standard vibration curve of a standard pump is obtained. The standard vibration curve is converted from a time domain to a frequency domain to obtain a first frequency distribution curve. A sample vibration curve of a sample pump is obtained. The sample vibration curve is converted from the time domain to the frequency domain to obtain a second frequency distribution curve. The first frequency distribution curve is compared with the second frequency distribution curve by using a cosine similarity algorithm to obtain a health index of the sample pump.

**PUMP HEALTH ANALYSIS METHOD AND  
PUMP HEALTH ANALYSIS DEVICE USING  
THE SAME**

This application claims the benefit of People's Republic of China application Serial No. 202211153487.8, filed Sep. 21, 2022, the subject matter of which is incorporated herein by reference.

**BACKGROUND OF THE INVENTION**

**Field of the Invention**

The invention relates in general to an analysis method and an analysis device using the same, and more particularly to a pump health analysis method and a pump health analysis device using the same.

**Description of the Related Art**

In a semiconductor factory, many items of semiconductor equipment are equipped with a pump to vacuum or ventilate the gas. However, if the pump suddenly breaks down after a long period of operation, the manufacturing process of semiconductor will be severely affected, and a whole batch of wafers may even be damaged.

Therefore, it has become a prominent task for the research personnel to develop and provide a technology for monitoring and predicting the health of the pump.

**SUMMARY OF THE INVENTION**

The invention is directed to a pump health analysis method and a pump health analysis device using the same capable of quickly analyzing the health state of a sample pump using a cosine similarity algorithm according to an analysis of comparison between the vibrations of the sample pump with the vibrations of a standard pump.

According to one embodiment of the present invention, a pump health analysis method is provided. The pump health analysis method includes the following steps. A standard vibration curve of a standard pump is obtained. The standard vibration curve is converted from a time domain to a frequency domain to obtain a first frequency distribution curve. A sample vibration curve of a sample pump is obtained. The sample vibration curve is converted from the time domain to the frequency domain to obtain a second frequency distribution curve. The first frequency distribution curve is compared with the second frequency distribution curve by using a cosine similarity algorithm to obtain a health index of the sample pump.

According to another embodiment of the present invention, a pump health analysis device is provided. The pump health analysis device includes a data reception unit, a conversion unit and a similarity analysis unit. The data reception unit is configured to obtain a standard vibration curve of a standard pump and a sample vibration curve of a sample pump. The conversion unit is configured to convert the standard vibration curve from a time domain to a frequency domain to obtain a first frequency distribution curve and to convert the sample vibration curve from the time domain to the frequency domain to obtain a second frequency distribution curve. The similarity analysis unit is configured to compare the first frequency distribution curve and the second frequency distribution curve by using a cosine similarity algorithm to obtain a health index of the sample pump.

2

The above and other aspects of the invention will become better understood with regard to the following detailed description of the preferred but non-limiting embodiment(s). The following description is made with reference to the accompanying drawings.

**BRIEF DESCRIPTION OF THE DRAWINGS**

FIG. 1 is a schematic diagram of semiconductor equipment and pumps according to an embodiment.

FIG. 2 is a block diagram of a pump health analysis device according to an embodiment.

FIG. 3 is a flowchart of a pump health analysis method according to an embodiment.

FIG. 4 exemplifies each step of FIG. 3.

FIG. 5 is a detailed flowchart of step S170 according to an embodiment.

**DETAILED DESCRIPTION OF THE  
INVENTION**

Referring to FIG. 1, a schematic diagram of semiconductor equipment **900** and pumps **800** according to an embodiment is shown. Each of the pumps **800** is connected to the semiconductor equipment **900** to extract or vacuum the gas. For example, these pumps **800** could be identical and could be used for different kinds of semiconductor equipment **900**.

After a long period of operations, the vibrations of the pump **800** may change. In the present embodiment, a vibration curve VC of the pump **800** is obtained by a vibration sensor **810**. After the vibration curve VC is transmitted to a pump health analysis device **100** through a network **700**, the health index of the pump **800** can be quickly analyzed according to the vibration curve VC.

Referring to FIG. 2, a block diagram of the pump health analysis device **100** according to an embodiment is shown. The pump health analysis device **100** includes a data reception unit **110**, a filter unit **120**, a conversion unit **130**, a similarity analysis unit **170** and a machine learning model **180**. Brief descriptions of the functions of each element are disclosed below. The data reception unit **110** is used to receive various types of data from such as a network transmission module, a transmission line, an LTE module, a Bluetooth module, or a combination thereof. The filter unit **120** is used to filter signals. The conversion unit **130** is used to convert signals. The similarity analysis unit **170** is used to analyze similarity. After the machine learning model **180** is trained, the machine learning model **180** can output forecasting information according to various characteristic indexes inputted thereto. The filter unit **120**, the conversion unit **130**, the similarity analysis unit **170** and machine learning model **180** could be realized by a chip, a circuit, a circuit board, a code, a storage device that stores the code, or a combination thereof.

The similarity analysis unit **170** includes an extractor **171**, a sorter **172**, a comparator **175**, a mean calculator **176** and an index creator **177**. The extraction element **171**, the sorter **172**, the comparator **175**, the mean calculator **176** and the index creator **177** are used to execute various calculations of similarity analysis.

In the present embodiment, as indicated in FIG. 2, the standard pump **800A** is a pump that has just been calibrated or new production, and therefore has the best state of health. The sample pump **800B** is a pump to be measured. In the present embodiment, the health state of the sample pump **800B** can be quickly analyzed according to a comparison between the sample pump **800B** and the standard pump

800A. The operations of each element of the pump health analysis device 100 are disclosed below with a flowchart.

Refer to FIG. 2 to FIG. 4. FIG. 3 is a flowchart of a pump health analysis method according to an embodiment. FIG. 4 exemplifies each step of FIG. 3. In step S110, a standard vibration curve VC\_A of a sample pump 800A is obtained by a data reception unit 110. The standard vibration curve VC\_A is obtained by a vibration sensor 810A arranged on the sample pump 800A. Although the sample pump 800A is at the best state, it still has a certain degree of vibrations. The standard vibration curve VC\_A records the vibration situation of the sample pump 800A within 0.2, 0.3, 0.4, or 0.5 seconds.

Next, the method proceeds to step S120, part of the standard vibration curve VC\_A whose frequency if higher than 1K Hz is filtered out by the filter unit 120. The frequencies higher than 1K Hz normally are noises, therefore the filter unit 120 filter out these noises to increase the accuracy in subsequent analysis. As indicated in FIG. 2 and FIG. 4, after the standard vibration curve VC\_A is inputted to the filter unit 120, the standard vibration curve VC\_A is filtered to obtain a standard vibration curve VC\_A'. In an embodiment, step S120 can be omitted and the standard vibration curve VC\_A can be directly inputted to the conversion unit 130.

Then, the method proceeds to step S130, the standard vibration curve VC\_A' (or standard vibration curve VC\_A) is converted from a time domain to a frequency domain by the conversion unit 130 to obtain a first frequency distribution curve VC\_A". In the present embodiment, the conversion unit 130 converts the standard vibration curve VC\_A' (or standard vibration curve VC\_A) using a Fourier transform technique. The first frequency distribution curve VC\_A" records accumulative intensities of each frequency band. In the example of FIG. 4, the first frequency distribution curve VC\_A" has peaks at frequencies F1, F2, and F3.

Then, the method proceeds to step S140, a sample vibration curve VC\_B of the sample pump 800B is obtained by the data reception unit 110. The sample vibration curve VC\_B is obtained by a vibration sensor 810B arranged on the sample pump 800B. Normally, after a long period of operation, the vibration situation of the sample pump 800B may change. The sample vibration curve VC\_B records the vibration situations of the sample pump 800B within 0.2, 0.3, 0.4, or 0.5 seconds. To compare the sample pump 800B with the sample pump 800A, the time lengths recorded in the sample vibration curve VC\_B are the same as that recorded in the standard vibration curve VC\_A.

Next, the method proceeds to step S150, part of the sample vibration curve VC\_B whose frequency is higher than 1K Hz is filtered out by the filter unit 120. The frequencies higher than 1K Hz normally are noises, therefore the filter unit 120 filter off these noises to increase the accuracy of subsequent analysis. As indicated in FIG. 2, FIG. 4, after the sample vibration curve VC\_B is inputted to the filter unit 120, the sample vibration curve VC\_B is filtered to obtain a sample vibration curve VC\_B'. In an embodiment, step S180 can be omitted and the sample vibration curve VC\_B can be directly inputted to the conversion unit 130. To maintain a consistent benchmark of comparison, step S120 and step S150 must be concurrently deleted or maintained.

Then, the method proceeds to step S160, the sample vibration curve VC\_B' (or sample vibration curve VC\_B) is converted from the time domain to the frequency domain by the conversion unit 130 to obtain a second frequency dis-

tribution curve VC\_B". In the present embodiment, the conversion unit 130 converts the sample vibration curve VC\_B' (or sample vibration curve VC\_B) using the Fourier transform technique. The second frequency distribution curve VC\_B" records accumulative intensities of each frequency band. In the example of FIG. 4, the second frequency distribution curve VC\_B" has peaks at frequencies F1, F2, F3 and F4. In comparison to the first frequency distribution curve VC\_A", the second frequency distribution curve VC\_B" has one more frequency peak, and the intensity at the frequency F2 is significantly stronger than that in the first frequency distribution curve VC\_A".

Next, the method proceeds to step S170, the similarity analysis unit 170 compares the first frequency distribution curve VC\_A" and the second frequency distribution curve VC\_B" by using a cosine similarity algorithm to obtain a health index IX\_H of the sample pump 800B.

Refer to FIG. 2 and FIG. 5. FIG. 5 a detailed flowchart of step S170 according to an embodiment. Step S170 includes steps S171 to S177. In step S171, N items of first data with N highest intensities are extracted from the first frequency distribution curve VC\_A" by the extractor 171. N is such as 100. Take Table 1 for instance. The first frequency scope corresponding to each item of data of the first frequency distribution curve VC\_A" is such as 3.6 Hz. The first frequency distribution curve VC\_A" is exemplarily divided into 278 items of data, and the first 100 items of the first data with the 100 highest intensities are extracted from the 278 items of data and defined as the first data DA\_i.

TABLE 1

Frequency (Hz)	Intensity (dB)	Extracted?
0-3.6	XX	
3.6-7.2	XXX	V
...	...	
993.6-997.2	XXX	V
997.2-1000	XX	

Next, the method proceeds to step S172, the sorter 172 sorts these first data DA\_i by frequency. For instance, these first data DA\_i are sorted using a quick sorting method.

Then, the method proceeds to step S173, the N items of the second data with the N highest intensities are extracted from the second frequency distribution curve VC\_B" by the extractor 171. N is such as 100. The second frequency scope corresponding to each item of data of the second frequency distribution curve VC\_B" is also 3.6 Hz. The second frequency distribution curve VC\_B" is exemplarily divided into 278 items of data, and the first 100 items of second data with the 100 highest intensities are extracted from the 278 items of data and defined as the second data DB\_i.

Next, the method proceeds to step S174, the sorter 172 sorts these second data DB\_i by frequency. For instance, these second data DB\_i are sorted using the quick sorting method.

Then, the method proceeds to step S175, the comparator 175 compares each of the first data DA\_i and each of the corresponding second data DB\_i to obtain a vector similarity. The frequency and the intensity of each item of the first data DA\_i form a vector; the frequency and the intensity of each item of the second data DB\_i also form a vector. The comparator 175 compares the N corresponding vectors to obtain N items of vector similarities SD\_i.

Next, the method proceeds to step S176, a similarity mean SDM of these vector similarities SD\_i is calculated by the mean calculator 176. In the present step, a weighted average

of these vector similarities  $SD_i$  can be calculated by the mean calculator 176 according to the sensitivity information. For instance, if a particular model of pump has significant vibration within certain particular frequency scopes, this indicates that this pump will be broken soon. Meanwhile, a larger weight can be assigned to this particular frequency scope through the setting of the sensitivity information.

Then, the method proceeds to step S177, a health index  $IX_H$  is obtained by the index creator 177 according to the similarity mean SDM. The relationship between the similarity mean SDM and the health index  $IX_H$  is such as a curve, and the index creator 177 can obtain a corresponding health index  $IX_H$  according to the similarity mean SDM.

After obtaining the health index  $IX_H$ , the pump health analysis device 100 can immediately determine the health situation of the health index  $IX_H$ . In the present embodiment, as long as the data of a standard vibration curve  $VC_A$  of the sample pump 800A is stored in advance, the sample pump 800B can be compared and analyzed every 0.3 second. The pump health analysis method of the present embodiment is extremely fast, and does not need to be trained with big data which is time-consuming, and therefore is very suitable to be used in the real-time monitoring of production line. If the health situation of a pump is found to be unsatisfactory, this pump can be replaced immediately to avoid causing problems to the manufacturing process.

As indicated in FIG. 2, the health index  $IX_H$  can also be inputted to the machine learning model 180 to perform training. The machine learning model 180 can be trained with such as 12 characteristic indexes  $IX_j$  (such as temperature, total time of use, sound, and the number of times of oil change) and the historical data of the health index  $IX_H$ . The obtained characteristic indexes  $IX_j$  and the health index  $IX_H$  can be inputted to the trained machine learning model 180 to predict a residual lifetime of the sample pump 800B.

According to the above embodiments, the pump health analysis device 100 can quickly analyze the health state of the sample pump 800B using the cosine similarity algorithm according to an analysis of comparison between the vibration state of the sample pump 800B and the vibration state of the sample pump 800A.

While the invention has been described by way of example and in terms of the preferred embodiment(s), it is to be understood that the invention is not limited thereto. Based on the technical features embodiments of the present invention, a person ordinarily skilled in the art will be able to make various modifications and similar arrangements and procedures without breaching the spirit and scope of protection of the invention. Therefore, the scope of protection of the present invention should be accorded with what is defined in the appended claims.

What is claimed is:

1. A pump health analysis method, comprising:

obtaining a standard vibration curve of a standard pump;  
converting the standard vibration curve from a time domain to a frequency domain to obtain a first frequency distribution curve;

obtaining a sample vibration curve of a sample pump;  
converting the sample vibration curve from the time domain to the frequency domain to obtain a second frequency distribution curve; and

comparing the first frequency distribution curve and the second frequency distribution curve by using a cosine similarity algorithm to obtain a health index of the sample pump;

wherein the step of comparing the first frequency distribution curve and the second frequency distribution curve comprises:

extracting N items of first data with highest intensities from the first frequency distribution curve;

sorting the N items of first data by frequency;

extracting N items of second data with highest intensities from the second frequency distribution curve;

sorting the N items of second data by frequency;

comparing each of the first data and each of the second data to obtain a vector similarity;

calculating a similarity mean of the vector similarities; and

obtaining the health index according to the similarity mean.

2. The pump health analysis method according to claim 1, further comprising:

filtering out part of the standard vibration curve whose frequency is higher than 1K Hz; and

filtering out part of the sample vibration curve whose frequency is higher than 1K Hz.

3. The pump health analysis method according to claim 1, wherein in the step of calculating the similarity mean of the vector similarities, a weighted average of the vector similarities is calculated according to a frequency sensitivity information.

4. The pump health analysis method according to claim 1, wherein the first data correspond to a plurality of first frequency scopes having identical width; the second data correspond to a plurality of second frequency scopes having identical width.

5. The pump health analysis method according to claim 4, wherein each of the first frequency scopes has a width of 3.6 Hz; each of the second frequency scopes has a width of 3.6 Hz.

6. The pump health analysis method according to claim 1, wherein N is 100.

7. The pump health analysis method according to claim 1, wherein the first data are sorted via a quick sorting algorithm; the second data are sorted via the quick sorting algorithm.

8. The pump health analysis method according to claim 1, wherein the health index is inputted to a machine learning model for training, and the machine learning model is used to predict a residual lifetime of the sample pump.

9. The pump health analysis method according to claim 1, wherein the standard vibration curve records vibrations of the standard pump within 0.3 second, and the sample vibration curve records vibrations of the sample pump within 0.3 second.

10. A pump health analysis device, comprising:

a data reception unit configured to obtain a standard vibration curve of a standard pump and a sample vibration curve of a sample pump;

a conversion unit configured to convert the standard vibration curve from a time domain to a frequency domain to obtain a first frequency distribution curve, and to convert the sample vibration curve from the time domain to the frequency domain to obtain a second frequency distribution curve; and

a similarity analysis unit configured to compare the first frequency distribution curve and the second frequency distribution curve by using a cosine similarity algorithm to obtain a health index of the sample pump;

wherein the similarity analysis unit comprises:

an extractor configured to extract N items of first data with highest intensities from the first frequency

distribution curve and to extract N items of second data with highest intensities from the second frequency distribution curve;

a sorter configured to sort the first data and the second data by frequency;

a comparator configured to compare each of the first data and each of the second data to obtain a vector similarity;

a mean calculator configured to calculate a similarity mean of the vector similarities; and

an index creator configured to obtain the health index according to the similarity mean.

11. The pump health analysis device according to claim 10, further comprising:

a filter unit configured filter out part of the standard vibration curve and part of the sample vibration curve whose frequency is higher than 1K Hz.

12. The pump health analysis device according to claim 10, wherein the mean calculator calculates a weighted average of the vector similarities according to a sensitivity information.

13. The pump health analysis device according to claim 10, wherein the first data correspond to a plurality of first

frequency scopes having identical width; the second data correspond to a plurality of second frequency scopes having identical width.

14. The pump health analysis device according to claim 13, wherein each of the first frequency scopes has a width of 3.6 Hz; each of the second frequency scopes has a width of 3.6 Hz.

15. The pump health analysis device according to claim 10, wherein N is 100.

16. The pump health analysis device according to claim 10, wherein the first data are sorted via a quick sorting algorithm; the second data are sorted via the quick sorting algorithm.

17. The pump health analysis device according to claim 10, wherein the health index is inputted to a machine learning model for training, and the machine learning model is used to predict a residual lifetime of the sample pump.

18. The pump health analysis device according to claim 10, wherein the standard vibration curve records vibrations of the standard pump within 0.3 second, and the sample vibration curve records vibrations of the sample pump with 0.3 second.

\* \* \* \* \*
