It has been found that the present compounds of formula I are modulators for amyloid beta and thus, they may be useful for the treatment or prevention of a disease associated with the deposition of β-amyloid in the brain, in particular Alzheimer's disease, and other diseases such as cerebral amyloid angiopathy, hereditary cerebral hemorrhage with amyloidosis, Dutch-type (HCHWA-D), multi-infarct dementia, dementia pugilistica and Down syndrome.

Alzheimer's disease (AD) is the most common cause of dementia in later life. Pathologically, AD is characterized by the deposition of amyloid in extracellular plaques and intracellular neurofibrillary tangles in the brain. The amyloid plaques are mainly composed of amyloid peptides (Aβ peptides) which originate from the β-Amyloid Precursor Protein (APP) by a series of proteolytic cleavage steps. Several forms of APP have been identified of which the most abundant are proteins of 695, 751 and 770 amino acids length. They all arise from a single gene through differential splicing. The Aβ peptides are derived from the same domain of the APP.

Aβ peptides are produced from APP through the sequential action of two proteolytic enzymes termed β- and γ-secretase. β-Secretase cleaves first in the extracellular domain of APP just outside of the trans-membrane domain (TM) to produce a C-terminal fragment of APP containing the TM- and cytoplasmatic domain (CTFβ). CTFβ is the substrate for γ-secretase which cleaves at several adjacent positions within the TM to produce the Aβ peptides and the cytoplasmic fragment. Various proteolytic cleavages mediated by γ-secretase result in Aβ peptides of different chain length, e.g. Aβ38, Aβ40 and Aβ42. The latter one is regarded to be the more pathogenic amyloid peptide because of its strong tendency to form neurotoxic aggregates.

The β-secretase is a typical aspartyl protease. The γ-secretase is a proteolytic activity consisting of several proteins, its exact composition is incompletely understood. However, the presenilins are essential components of this activity and may represent a new group of atypical aspartyl proteases which cleave within the TM of their substrates and which are themselves polytopic membrane proteins. Other essential components of γ-secretase may be nicastrin and the products of the aphl and pen-2 genes. Proven substrates for γ-secretase are the APP and the proteins of the Notch receptor family, however, γ-secretase has loose substrate specificity and may cleave further membrane proteins unrelated to APP and Notch.
The γ-secretase activity is absolutely required for the production of Aβ peptides. This has been shown both by genetic means, i.e., ablation of the presenilin genes and by low-molecular-weight inhibitory compounds. Since according to the amyloid hypothesis for AD the production and deposition of Aβ is the ultimate cause for the disease, it is thought that selective and potent inhibitors of γ-secretase will be useful for the prevention and treatment of AD.

An alternative mode of treatment is the modulation of the γ-secretase activity which results in a selective reduction of the Aβ42 production. This will result in an increase of shorter Aβ isoforms, such as Aβ38, Aβ37 or others, which have reduced capability for aggregation and plaque formation, and hence less neurotoxic. Compounds which show this effect on modulating γ-secretase activity include certain non-steroidal anti-inflammatory drugs (NSAIDs) and related analogues (Weggen et al. Nature, 414 (2001) 212-16).

Thus, the compounds of this invention will be useful for the treatment or prevention of a disease associated with the deposition of β-amyloid in the brain, in particular Alzheimer's disease, and other diseases such as cerebral amyloid angiopathy, hereditary cerebral hemorrhage with amyloidosis, Dutch-type (HCHWA-D), multi-infarct dementia, dementia pugilistica and Down syndrome.

Numerous documents describe the current knowledge on γ-secretase modulation, for example the following publications:

The detailed description can be found below and in Examples 1 - 63. The aniline IV respectively the thiourea II, which can be used as starting materials for the preparation of compound I, may be prepared as described in Scheme 1. Nucleophilic substitution at room temperature or elevated temperature (e.g. reflux or under pressure using a microwave oven) under neutral or basic conditions in the presence of a base (like e.g. potassium carbonate etc.) neat or in a polar solvent (like e.g. THF or DMSO etc.) of a substituted 4-nitro-phenyl halide II with a 5-membered heteroaromatic ring (like e.g. imidazol preferred 5-methyl imidazol) yields the nitro derivative X which is reduced either under catalytic conditions (like e.g. 10% carbon on palladium) with hydrogen in a solvent (like e.g. ethanol or ethyl acetate) or with a metal (like e.g. iron) or metal salt (like e.g. stannous chloride) in a polar solvent (like e.g. acetic acid or tetrahydrofuran) to the aniline derivative IV. Alternatively aniline IV can be prepared from the corresponding N-protected 4-halo-aniline XI and the 5-membered heteroaromatic ring IX under catalytic conditions (like e.g. palladium(O) or copper(II) catalysis) after subsequent deprotection. The aniline IV can be converted to the thiourea II either by treatment with a thiophosgene derivative (like e.g. 1,r-thiocarbonyldi-2(IH)-pyridone) and subsequent aminolysis or by treatment with an acyl isothiocyanate (like e.g. benzoyl isothiocyanate) and subsequent hydrolysis.

Scheme 1
Alpha-halo-ketones III can be prepared from the corresponding ketones XII through halogenation with either elemental halogen or a halide transferring agent (like e.g. NXS etc.). Treatment of the carboxylic ester XIII (R = e.g. alkyl preferable methyl) with lithiated bromomethane at low temperature in an inert solvent (like e.g. tetrahydrofurane) yields the alpha-bromo-ketone III (X = Br). Alternatively the alpha-bromo-ketone III (X = Br) can be prepared from the acid XIII (X = H) through activation to the corresponding acid chloride or anhydride (e.g. with iPrOCO), treatment with diazomethane or trimethylsilyldiazomethane and subsequent decomposition with HBr in an inert solvent.

The alpha-chloroketone XV can be prepared in one pot from the corresponding aniline and the alpha,beta-unsaturated ketone via the Meerwein reaction through diazotation with a diazotation reagent (like e.g. tBuONO) and treatment with copper(II)chloride in an inert solvent (like e.g. acetonitrile) at low or elevated temperatures. Alternatively alpha-chloroketone XV can be prepared from the corresponding 2-benzyl-betaketoester through alpha chlorination with a chlorination agent (like NCS or sulfuryl chloride) and subsequent acidic keton cleavage (as described in Mcphee, W. D.; Klingsberg, E. J. Am Chem. Soc. (1944) 66, 1132 and Yang D., Yan Y. L., Lui B. J Org. Chem. 67 (21) 7429 (2002)).
Ph may be substituted as described in the definitions for R²/R³.

Condensation of the thiourea II with the alpha-halo- or alpha-sulfoxy-ketones III or XV in an inert solvent (like e.g. ethanol) at room temperature or elevated temperature in the presence or absence of a base (like e.g. potassium carbonate or Hünigs base) yields the aminothiazoles I as outlined in Scheme 3. Alternatively compounds of structure I can also be prepared through direct amination of a suitable 2-halo-thiazole V with the aniline IV in the presence of a catalyst and a ligand (like e.g. palladium(O) and a phosphine ligand or copper(II) and a phenanthrene ligand).

Annulated aminothiazol derivatives I-B or I-C can be obtained by the condensation of the thiourea II with the corresponding cyclic alpha-halo- or alpha-sulfoxy-ketones VI in an inert solvent (like e.g. ethanol) at room temperature or elevated temperature in the presence or absence of a base (like e.g. potassium carbonate or Hünigs base) as outlined in Scheme 4. When using the corresponding piperidine derivative the amino group has to be protected (for example with the tert.-butyloxycarbonyl group) prior to the condensation. After successful condensation the protective group (PG) can be removed.
and replaced by other substituents through reductive amination, alkylation, acylation or sulfonylation.

Description of γ-secretase assay

Cellular γ-secretase assay

Human neuroglioma H4 cells overexpressing human APP were plated at 30,000 cells/well/200 µl in 96-well plates in IMDM media containing 10% FCS, 0.2 mg/l Hygromycin B and incubated for 2h at 37°C, 5% CO2 prior to adding test compounds.

Compounds for testing were dissolved in 100% Me2SO yielding a 10 mM stock solution. Typically 12 µl of these solutions were further diluted in 1000 µl of IMDM media (w/o FCS.). Sub sequential 1:1 dilutions gave a ten point dose response curve. 100 µl of each dilution was added to the cells in 96-well plates. Appropriate controls using
vehicle only and reference compound were applied to this assay. The final concentration of Me₂SO was 0.4%.

After incubation for 22 hrs at 37°C, 5% CO₂, 50 μl supernatant was transferred into round-bottom 96-well polypropylene plates for detection of Aβ42. 50 μl assay buffer (50mM Tris/Cl, pH 7.4, 60mM NaCl, 0.5% BSA, 1% TWEEN 20) was added to the wells followed by the addition of 100 μl of detection antibody (ruthenylated BAP15 0.0625 μg/ml in assay buffer). 50 μl of a premix of capture antibody (biotinylated 6E10 antibody, 1 μg/ml) and Steptavidin-coated magnetic beads (Dynal M-280, 0.125 mg/ml) were preincubated for 1 hr at room temperature before adding the assay plates. Assay plates were incubated on a shaker for 3 hrs at room temperature and finally read in the Bioveris M8 Analyser according to the manufacturer's instructions (Bioveris).

Toxicity of compounds was monitored by a cell viability test of the compound-treated cells using a colorimetric assay (CellTiter 96TM AQ assay, Promega) according to the manufacturer's instructions. Briefly, after removal of 50μl cell culture supernatant for detection of Aβ42, 20μl of 1x MTS/PES solution was added to the cells and incubated for 30 min at 37°C, 5% CO₂. Optical density was then recorded at 490 nm.

IC₅₀ values for inhibition of Aβ42 secretion were calculated by nonlinear regression fit analysis using XLfit 4.0 software (IDBS).

The preferred compounds show a IC₅₀< 1.0 (μM). In the list below are described the data to the inhibition of Aβ42 secretion:

The compounds of formula I and the pharmaceutically acceptable salts of the compounds of formula I can be used as medicaments, e.g. in the form of pharmaceutical preparations. The pharmaceutical preparations can be administered orally, e.g. in the form of tablets, coated tablets, dragees, hard and soft gelatine capsules, solutions, emulsions or suspensions. The administration can, however, also be effected rectally, e.g. in the form of suppositories, parenterally, e.g. in the form of injection solutions.

The compounds of formula I can be processed with pharmaceutically inert, inorganic or organic carriers for the production of pharmaceutical preparations. Lactose, corn starch or derivatives thereof, talc, stearic acids or its salts and the like can be used, for example, as such carriers for tablets, coated tablets, dragees and hard gelatine capsules. Suitable carriers for soft gelatine capsules are, for example, vegetable oils, waxes, fats, semi-solid and liquid polyols and the like. Depending on the nature of the active substance no carriers are, however, usually required in the case of soft gelatine capsules.

Suitable carriers for the production of solutions and syrups are, for example, water, polyols, glycerol, vegetable oil and the like. Suitable carriers for suppositories are, for example, natural or hardened oils, waxes, fats, semi-liquid or liquid polyols and the like.

The pharmaceutical preparations can, moreover, contain preservatives, solubilizers, stabilizers, wetting agents, emulsifiers, sweeteners, colorants, flavorants, salts for varying the osmotic pressure, buffers, masking agents or antioxidants. They can also contain still other therapeutically valuable substances.

Medicaments containing a compound of formula I or a pharmaceutically acceptable salt thereof and a therapeutically inert carrier are also an object of the present invention, as is a process for their production, which comprises bringing one or more compounds of formula I and/or pharmaceutically acceptable acid addition salts and, if desired, one or more other therapeutically valuable substances into a galenical administration form together with one or more therapeutically inert carriers.

In accordance with the invention compounds of formula I as well as their pharmaceutically acceptable salts are useful in the control or prevention of illnesses based on the inhibition of Aβ42 secretion, such as of Alzheimer's disease.

The dosage can vary within wide limits and will, of course, have to be adjusted to the individual requirements in each particular case. In the case of oral administration the dosage for adults can vary from about 0.01 mg to about 1000 mg per day of a compound of general formula I or of the corresponding amount of a pharmaceutically acceptable salt thereof. The daily dosage may be administered as single dose or in divided doses and, in addition, the upper limit can also be exceeded when this is found to be indicated.
