TECHNICAL FIELD

The present invention relates generally to plant molecular biology. More specifically, it relates to nucleic acids and methods for modulating their expression thereby controlling flowering time and flower/seed production in plants.

BACKGROUND OF THE INVENTION

Flowering in plants is a consequence of the transition of the shoot apical meristems from vegetative to reproductive growth in response to environmental and internal signals. Currently, there is little information about the regulation of flowering time in maize. Id1 gene (indeterminate 1) is the only maize cloned gene with a clear role in the floral transition (Colasanti, et al., (1998) Cell 93:593-603). The Id1 gene encodes a transcription factor and regulates the production of a transmissible signal in the immature leaves that induces the transition of the shoot apical meristems from vegetative to reproductive development.

Flowering time determines maturity and that is an important agronomic trait. Genes that control the transition from vegetative to reproductive growth are essential for manipulation of flowering time. Flowering genes will provide opportunities for enhanced crop yield, adaptation of germplasm to different climatic zones and synchronous flowering for hybrid seed production. Developing early-flowering inbred lines will facilitate the movement of elite germplasm across maturity zones. Flowering genes also provide an opportunity for engineering vernalized corn, enabling fall planting and over-wintering. Vernalization may be achieved by the over expression of the activator of flowering or the down-regulation of repressors of flowering in transgenic plants.

SUMMARY OF THE INVENTION

Generally, it is the object of the present invention to provide nucleic acids and proteins relating to floral transition. It is an object of the present invention to provide transgenic plants comprising the nucleic acids of the present invention and methods for modulating, in a transgenic plant, the expression of the nucleic acids of the present invention.

Therefore, in one aspect the present invention relates to an isolated nucleic acid comprising a member selected from the group consisting of (a) a polynucleotide having a specified sequence identity to a polynucleotide of the present invention; (b) a polynucleotide which is complementary to the polynucleotide of (a) and (c) a polynucleotide comprising a specified number of contiguous nucleotides from a polynucleotide of (a) or (b). The isolated nucleic acid can be DNA.

In other aspects the present invention relates to: 1) recombinant expression cassettes, comprising a nucleic acid of the present invention operably linked to a promoter, 2) a host cell into which has been introduced the recombinant expression cassette and 3) a transgenic plant comprising the recombinant expression cassette. The host cell or plant is optionally a maize cell or maize plant, respectively.

The present invention provides compositions and methods for modulating flowering time in plants. Overexpression of he disclosed sequences leads to early flowering and inhibition causes late flowering and indeterminate ear initiation. Methods for expressing these sequences in a plant for modifying maturity and flowering time in plants are provided as well as expression constructs, vectors, transformed cells and plants. The sequences disclosed include regulatory elements and promoter sequences that are natively associated with the polynucleotides disclosed herein, thereby providing the meristem specific promoters that can be used to control plant growth, development, herbicide and insect resistance. The over-expression of genes that are activators or repressors of flowering in transgenes under direction of tissue and/or gene specific promoters allows one to control the timing of flower formation without ectopic expression of unwanted proteins in other tissues. Controlled manipulation of flowering time will provide opportunities for enhancing crop yield, adaptation of germplasm to different climatic zones and synchronous flowering for hybrid seed production.

BRIEF DESCRIPTION OF THE DRAWINGS

Fig. 1 provides a phylogenetic analysis of novel MADS box genes SVP and FTM and delimits them into three separate clades, SQUAMOSA-like (FTM1,2), AGL2-like (FTM3) and SVP-like (SVP1,2,3).

Fig. 2 provides an expression pattern of MADS genes related to flowering. TAGs distribution was analyzed across different plant tissues representing all organs of the corn plant. All SVP genes have a very similar pattern of expression. The expression patterns of FTM genes are opposite to SVPs. TAGS distribution in LYNX database indicate that FTM genes are expressed in reproductive, not vegetative tissues.

Fig. 3 provides SVP genomic structures. The gene sizes ranged from 6.9-10.1 kb, which are average for plant genes. Genomic structures of SVP1 and 2 genes are very similar, comprising 8 exons and 7 introns.

Fig. 4 provides genomic structures for FTM. All three FTM genes are composed of 8 exons of identical sizes, which are produced as cDNA of 1.4-1.5 kb. Overall FTM1 and FTM2 genomic sequences across exons and introns share greater than 70% homology indicating that they are recently duplicated genes in the maize genome. However the entire sizes of the gene regions including introns are 41 kb for FTM1; 20.5 kb for FTM2 and 10 kb for FTM3. FTM2 and FTM3 genes are linked to each other being separated only by one retro element.

Fig. 5 provides expression of FTM2 and SVP1/2 in transgenic plants. Transgenic plants over-expressing FTM2, SVP1 and SVP2 genes were produced according the standard Pioneer procedure for Agro-bacterium transformation. cDNA were constitutively expressed under the UBIQUITIN
promoter. The transition from vegetative to reproductive development can be measured by the number of leaves that plant produced at the maturity of the plant. A leaf number analysis indicated FTM2 and SVP1 genes contribute to early flowering. However, FTM2 had stronger effects on flowering than SVP2, because FTM2 transgenics began shedding (pollen production) and silking a week earlier (on average) than SVP2 plants. The FTM2 and SVP1 transgenic plants did not show any phenotypic abnormalities. They produced normal ears and tassels suggesting that ectopic expression of FTM2 and SVP1 MADS box genes did not change meristem identity but changed only the flowering time. Ectopic expression of SVP2 caused abnormalities in ears and tassels, which can be described as changing the organ identity. Some spikelets on the tassels were converted into female gametophytes, producing silking ovules that were fertile and produced kernels after pollination. Multiple ears (up to 4) emerged from the same lateral bud. Glumes surrounding ovules were overgrown and greenish, making ears with vegetative appearance. The SVP2 gene may be characterized functionally as the flower-meristem identity gene.

**DETAILED DESCRIPTION OF THE INVENTION**

**Overview**

[0014] A set of new maize MADS box genes regulating flowering time were discovered in the shoot apical meristems using the massively parallel signature sequencing (MPSS) technology from Lynx Pharmaceuticals (Haywood, Calif.). Six MADS box genes were identified that show changes in transcriptional activity during the floral transition. Genes named FTM1, FTM2 and FTM3 (stands for Floral Transition MADS) are up-regulated during floral transition consistent with their functions as activators of flowering. Genes named SVP1, SVP2 and SVP3 by homology to the Arabidopsis gene SVP (stands for Short Vegetative Phase, Hartmann, et al., (2000) *Plant Journal* 21:351-360) are down-regulated during the floral transition consistent with their function as repressors of flowering.

[0015] MADS-box genes belong to a large family of regulatory genes that possess a characteristic DNA binding domain, MADS-box. Members of this gene family display primarily floral-specific expression and play important roles in plant development. Phylogenetic analyses demonstrate that members of the plant MADS-box gene family are organized into a dozen distinct gene groups which reflect the true phylogeny of the MADS box gene families and their functional similarity (Thiessen, et al., (1996) *J Mol Evol* 43:484-516). Phylogenetic analysis of discovered MADS box genes, SVP and FTM delimits them into separate clades, STMADS11 (SVP) SQUAMOSA-like (FTM1,2) and AG1-like (FTM3). STMADS11 family includes tomato STMADS genes and the Arabidopsis SVP (Hartmann, et al., (2000) *Plant Journal* 21:351-360). Those genes are known to be negative regulators of the floral transition. SQUAMOSA-like family determines the identity of the floral meristem (Klein, et al., (1996) *Mol Gen Genet. 250:7-16*). Because the shared evolutionary history appears to reflect the distinct functional roles of MADS families in flower development, we proposed that discovered maize SVP genes are negative regulators of flowering and FTM genes are activators of the floral development.

[0016] The present invention also provides, among other things, compositions and methods for modulating (i.e., increasing or decreasing) the level of polynucleotides and polypeptides of the present invention in plants. In particular, the polynucleotides and polypeptides of the present invention can be expressed temporally or spatially, e.g., at developmental stages, in tissues and/or in quantities, which are uncharacteristic of non-recombinantly engineered plants. Thus, the present invention provides utility in such exemplary applications as providing a means to control expression of genes involved in enhancing crop yield, adaptation of germplasm to different climatic zones and synchronous flowering for hybrid seed production. For example, in plants of interest, manipulation of the floral transitional genes of the present invention could affect the expression of the activator of flowering or the down-regulation of repressors of flowering. The over-expression of activators in transgenics or inhibition of repressors by chemical treatment, co-suppression, RNAi, antisense RNA or mutations may lead to early flowering phenotypes which may find utilities in crops such as corn, soybean, rice and wheat due to effects on yield, seed production and germplasm adaptation to a wide range of environmental conditions. Conversely, the over-expression of repressors or inhibition of activators by chemical treatment, co-suppression, RNAi, antisense RNA or mutations, may suppress flower formation, which is useful for crops such as spinach or lettuce where leaves are desired and seed formation is not. The use of conditional promoters to control activators and repressors allows one to control the timing of flower formation, to delay flowering when vegetative growth is advantageous or accelerate flowering in breeding where reduced generation time is desired.

[0017] The present invention provides useful alleles for breeding programs through association mapping of flowering phenotypes with specific haplotypes of flowering genes. Nucleotide sequencing polymorphisms defining specific haplotypes (alleles, orthologues, derivatives) may be converted into molecular markers and used during the breeding programs for selection of "early" and "late" inbred lines in marker assisted selection.

[0018] The present invention also provides isolated nucleic acids comprising polynucleotides of sufficient length and complementarity to a gene of the present invention to use as probes or amplification primers in the detection, quantitation or isolation of gene transcripts. For example, isolated nucleic acids of the present invention can be used as probes in detecting deficiencies in the level of mRNA in screenings for desired transgenic plants, for detecting mutations in the gene (e.g., substitutions, deletions, or additions), for monitoring upregulation of expression or changes in enzyme activity in screening assays of compounds, for detection of any number of allelic variants (polymorphisms), orthologs or paralogs of the gene or for site directed mutagenesis in eukaryotic cells (see, e.g., U.S. Pat. No. 5,565,350). The isolated nucleic acids of the present invention can also be used for recombinant expression of their encoded polypeptides or for use as immunogens in the preparation and/or screening of antibodies. The isolated nucleic acids of the present invention can also be employed for use in sense or antisense suppression of one or more genes of the present invention in a host cell, tissue or plant. Attachment of chemical agents which bind, intercalate, cleave and/or crosslink to the isolated nucleic acids of the present invention can also be used to modulate transcription or translation.

[0019] The present invention also provides isolated proteins comprising a polypeptide of the present invention (e.g.,
proenzyme, preproenzyme, or enzymes). The present invention also provides proteins comprising at least one epitope from a polypeptide of the present invention. The proteins of the present invention can be employed in assays for enzyme agonists or antagonists of enzyme function or for use as immunogens or antigens to obtain antibodies specifically immunoactive with a protein of the present invention. Such antibodies can be used in assays for expression levels, for identifying and/or isolating nucleic acids of the present invention from expression libraries, for identification of homologous polypeptides from other species or for purification of polypeptides of the present invention.

[0020] The isolated nucleic acids and polypeptides of the present invention can also be used in a broad range of plant types, particularly monocots such as the species of the family Gramineae including Hordeum, Secale, Triticum, Sorghum (e.g., S. bicolor) and Zea (e.g., Z. mays). The isolated nucleic acid and proteins of the present invention can also be used in species from the genera: Cucurbita, Rosa, Vitis, Juglans, Fragaria, Lotus, Medicago, Onobrychis, Trifolium, Trigonella, Vigna, Citrus, Linum, Geranium, Manihot, Daucus, Arabidopsis, Brassica, Raphanus, Sinapis, Artrica, Capsicum, Datura, Hyoscyamus, Lycopersicon, Nicotiana, Solanum, Petunia, Digitalis, Majorana, Cichorium, Helianthus, Lactuca, Bromus, Asparagus, Antirrhinum, Heterocalis, Nemesis, Polargonium, Paniceum, Pennisetum, Ranunculus, Senecio, Salpiglossis, Cucumis, Browallia, Glycine, Pisum, Phaseolus, Lolium, Oryza, and Avena.

DEFINITIONS

[0021] Units, prefixes and symbols may be denoted in their SI accepted form. Unless otherwise indicated, nucleic acids are written left to right in 5' to 3' orientation: amino acid sequences are written left to right in amino to carboxyl orientation, respectively. Numeric ranges recited within the specification are inclusive of the numbers defining the range and include each integer within the defined range. Amino acids may be referred to herein by either commonly known three letter symbols or by the one-letter symbols recommended by the IUPAC-IUB Biochemical Nomenclature Commission. Nucleotides, likewise, may be referred to by their commonly accepted single-letter codes. Unless otherwise provided for, software, electrical and electronics terms as used herein are as defined in The New IEEE Standard Dictionary of Electrical and Electronics Terms (5th edition, 1993). The terms defined below are more fully defined by reference to the specification as a whole.

[0022] By “amplified” is meant the construction of multiple copies of a nucleic acid sequence or multiple copies complementary to the nucleic acid sequence using at least one of the nucleic acid sequences as a template. Amplification systems include the polymerase chain reaction (PCR) system, ligase chain reaction (LCR) system, nucleic acid sequence based amplification (NASBA, Cangene, Mississauga, Ontario), 0-Beta Replicate systems, transcription-based amplification system (TAS) and strand displacement amplification (SDA). See, e.g., Diagnostic Molecular Microbiology: Principles and Applications, Persing, et al., Ed., American Society for Microbiology, Washington, D.C. (1993). The product of amplification is termed an amplicon.

[0023] As used herein, “antisense orientation” includes reference to a duplex polynucleotide sequence that is operably linked to a promoter in an orientation where the antisense strand is transcribed. The antisense strand is sufficiently complementary to an endogenous transcription product such that translation of the endogenous transcription product is often inhibited.

[0024] By “encoding” or “encoded”, with respect to a specified nucleic acid, is meant comprising the information for translation into the specified protein. A nucleic acid encoding a protein may comprise non-translated sequences (e.g., introns) within translated regions of the nucleic acid or may lack such intervening non-translated sequences (e.g., as in cDNA). The information by which a protein is encoded is specified by the use of codons. Typically, the amino acid sequence is encoded by the nucleic acid using the “universal” genetic code. However, variants of the universal code, such as are present in some plant, animal and fungal mitochondria, the bacterium Mycoplasma capricolum or the ciliate Macronucleus, may be used when the nucleic acid is expressed therein.

[0025] When the nucleic acid is prepared or altered synthetically, advantage can be taken of known codon preferences of the intended host where the nucleic acid is to be expressed. For example, although nucleic acid sequences of the present invention may be expressed in both monocotyledonous and dicotyledonous plant species, sequences can be modified to account for the specific codon preferences and GC content preferences of monocotyledons or dicotyledons as these preferences have been shown to differ (Murray, et al., (1989) Nucl. Acids Res. 17:477-498). Thus, the maize preferred codon for a particular amino acid may be derived from known gene sequences from maize. Maize codon usage for 28 genes from maize plants is listed in Table 4 of Murray, et al., supra.

[0026] As used herein “full-length sequence” in reference to a specified polynucleotide or its encoded protein means having the entire amino acid sequence of, a native (non-synthetic), endogenous, biologically active form of the specified protein. Methods to determine whether a sequence is full-length are well known in the art including such exemplary techniques as northern or western blots, primer extension, 51 protection, and ribonuclease protection. See, e.g., Plant Molecular Biology: A Laboratory Manual, Clark, Ed., Springer-Verlag, Berlin (1997). Comparison to known full-length homologous (orthologous and/or paralogous) sequences can also be used to identify full-length sequences of the present invention. Additionally, consensus sequences typically present at the 5' and 3' untranslated regions of mRNA aid in the identification of a polynucleotide as full-length. For example, the consensus sequence ANNNNAUGG, where the underlined codon represents the N-terminal methionine, aids in determining whether the polynucleotide has a complete 5' end. Consensus sequences at the 3' end, such as polyadenylation sequences, aid in determining whether the polynucleotide has a complete 3' end.

[0027] The term “gene activity” refers to one or more steps involved in gene expression, including transcription, translation and the functioning of the protein encoded by the gene.

[0028] As used herein, “heterologous” in reference to a nucleic acid is a nucleic acid that originates from a foreign species, or, if from the same species, is substantially modified from its native form in composition and/or genomic locus by deliberate human intervention. For example, a promoter operably linked to a heterologous structural gene is from a species different from that from which the structural gene was derived, or, if from the same species, one or both are substantially modified from their original form. A heterologous pro-
tein may originate from a foreign species or, if from the same species, is substantially modified from its original form by deliberate human intervention.

[0029] By “host cell” is meant a cell which contains a vector and supports the replication and/or expression of the vector. Host cells may be prokaryotic cells such as E. coli or eukaryotic cells such as yeast, insect, amphibian or mammalian cells. Preferably, host cells are monocotyledonous or dicotyledonous plant cells. A particularly preferred monocotyledonous host cell is a maize host cell.

[0030] The term “introduced” in the context of inserting a nucleic acid into a cell, means “transfection” or “transformation” or “transduction” and includes reference to the incorporation of a nucleic acid into a eukaryotic or prokaryotic cell where the nucleic acid may be incorporated into the genome of the cell (e.g., chromosome, plasmid, plastid or mitochondrial DNA), converted into an autonomous replicon or transiently expressed (e.g., transfected mRNA).

[0031] The term “isolated” refers to material, such as a nucleic acid or a protein, which is: (1) substantially or essentially free from components which normally accompany or interact with it as found in its natural environment. The isolated material optionally comprises material not found with the material in its natural environment or (2) if the material is in its natural environment, the material has been synthetically altered or synthetically produced by deliberate human intervention and/or placed at a different location within the cell. The synthetic alteration or creation of the material can be performed on the material within or apart from its natural state. For example, a naturally-occurring nucleic acid becomes an isolated nucleic acid if it is altered or produced by non-natural, synthetic methods or if it is transcribed from DNA which has been altered or produced by non-natural, synthetic methods. See, e.g., Compounds and Methods for Site Directed Mutagenesis in Eukaryotic Cells, Kmiec, U.S. Pat. No. 5,565,350; In Vivo Homologous Sequence Targeting in Eukaryotic Cells; Zarling, et al., PCT/US93/03868. The isolated nucleic acid may also be produced by the synthetic re-arrangement (“shuffling”) of a part or parts of one or more allelic forms of the gene of interest. Likewise, a naturally-occurring nucleic acid (e.g., a promoter) becomes isolated if it is introduced to a different locus of the genome. Nucleic acids which are “isolated,” as defined herein, are also referred to as “heterologous” nucleic acids.

[0032] Unless otherwise stated, the term “floral transition nucleic acid” is a nucleic acid of the present invention and means a nucleic acid comprising a polynucleotide of the present invention (a “floral transition polynucleotide”) encoding a floral transition polypeptide. A “floral transition gene” is a gene of the present invention and refers to a full-length floral transition polynucleotide.

[0033] As used herein, “nucleic acid” includes reference to a deoxyribonucleotide or ribonucleotide polymer or chimeras thereof, in either single- or double-stranded form, and unless otherwise limited, encompasses known analogues having the essential nature of natural nucleotides in that they hybridize to single-stranded nucleic acids in a manner similar to naturally occurring nucleotides (e.g., peptide nucleic acids).

[0035] As used herein “operably linked” includes reference to a functional linkage between a promoter and a second sequence, wherein the promoter sequence initiates and mediates transcription of the DNA sequence corresponding to the second sequence. Generally, operably linked means that the nucleic acid sequences being linked are contiguous and, where necessary to join two protein coding regions, contiguous and in the same reading frame.

[0036] As used herein, the term “plant” includes reference to whole plants, plant parts or organs (e.g., leaves, stems, roots, etc.), plant cells, seeds and progeny of same. Plant cell, as used herein, further includes, without limitation, cells obtained from or found in: seeds, suspension cultures, embryos, meristemetic regions, callus tissue, leaves, roots, shoots, gametophytes, sporophytes, pollen and microspores. Plant cells can also be understood to include modified cells, such as protoplasts, obtained from the aforementioned tissues. The class of plants which can be used in the methods of the invention is generally as broad as the class of higher plants amenable to transformation techniques, including both monocotyledonous and dicotyledonous plants. A particularly preferred plant is Zea mays.

[0037] As used herein, “polynucleotide” includes reference to a deoxyribopolynucleotide, ribopolynucleotide or chimeras or analogs thereof that have the essential nature of a natural deoxy- or ribo-nucleotide in that they hybridize, under stringent hybridization conditions, to substantially the same nucleotide sequence as naturally occurring nucleotides and/or allow translation into the same amino acid(s) as the naturally occurring nucleotide(s). A polynucleotide can be full-length or a subsequence of a native or heterologous structural or regulatory gene. Unless otherwise indicated, the term includes reference to the specified sequence as well as the complementary sequence thereof. Thus, DNAs or RNAs with backbones modified for stability or for other reasons are “polynucleotides” as that term is intended herein. Moreover, DNAs or RNAs comprising unusual bases, such as inosine, or modified bases, such as triethylated bases, to name just two examples, are polynucleotides as the term is used herein. It will be appreciated that a great variety of modifications have been made to DNA and RNA that serve many useful purposes known to those of skill in the art. The term polynucleotide as it is employed herein embraces such chemically-, enzymatically- or metabolically-modified forms of polynucleotides, as well as the chemical forms of DNA and RNA characteristic of viruses and cells, including among other things, simple and complex cells.

[0038] The terms “polypeptide”, “peptide” and “protein” are used interchangeably herein to refer to a polymer of amino acid residues. The terms apply to amino acid polymers in which one or more amino acid residue is an artificial chemical analogue of a corresponding naturally-occurring amino acid, as well as to naturally-occurring amino acid polymers. The essential nature of such analogues of naturally-occurring amino acids is that, when incorporated into a protein, that protein is specifically reactive to antibodies elicited to the
same protein but consisting entirely of naturally occurring amino acids. The terms “polypeptide”, “peptide” and “protein” are also inclusive of modifications including, but not limited to, glycosylation, lipid attachment, sulfation, gamma-carboxylation of glutamic acid residues, hydroxylation and ADP-ribosylation. Further, this invention contemplates the use of both the methionine-containing and the methionine-less amino terminal variants of the protein of the invention.

As used herein “promoter” includes reference to a region of DNA upstream from the start of transcription and involved in recognition and binding of RNA polymerase and other proteins to initiate transcription. A “plant promoter” is a promoter capable of initiating transcription in plant cells whether or not its origin is a plant cell. Exemplary plant promoters include, but are not limited to, those that are obtained from plants, plant viruses, and bacteria which comprise genes expressed in plant cells such as Agrobacterium or Rhizobium. Examples of promoters under developmental control include promoters that preferentially initiate transcription in certain tissues, such as leaves, roots or seeds. Such promoters are referred to as “tissue preferred”. Promoters which initiate transcription only in certain tissues are referred to as “tissue specific”. A “cell type” specific promoter primarily drives expression in certain cell types in one or more organs, for example, vascular cells in roots or leaves. An “inducible” or “repressible” promoter is a promoter which is under environmental control. Examples of environmental conditions that may effect transcription by inducible promoters include anaerobic conditions or the presence of light. Tissue specific, tissue preferred, cell type specific and inducible promoters represent the class of “non-constitutive” promoters. A “constitutive” promoter is a promoter which is active in most tissues under most environmental conditions.

The term “floral transitional polypeptide” is a polypeptide of the present invention and refers to one or more amino acid sequences, in glycosylated or non-glycosylated form. The term is also inclusive of fragments, variants, homologs, alleles or precursors (e.g., preproteins or proproteins) thereof. A “floral transitional protein” is a protein of the present invention and comprises a floral transitional polypeptide.

As used herein “recombinant” includes reference to a cell or vector that has been modified by the introduction of a heterologous nucleic acid or to a cell derived from a cell so modified. Thus, for example, recombinant cells express genes that are not found in identical form within the native (non-recombinant) form of the cell or exhibit altered expression of native genes, as a result of deliberate human intervention. The term “recombinant” as used herein does not encompass the alteration of the cell or vector by events (e.g., spontaneous mutation, natural transformation, transduction or transposition) occurring without deliberate human intervention.

As used herein, a “recombinant expression cassette” is a nucleic acid construct, generated recombinantly or synthetically, with a series of specified nucleic acid elements which permit transcription of a particular nucleic acid in a host cell. The recombinant expression cassette can be incorporated into a plasmid, chromosome, mitochondrial DNA, plastid DNA, virus or nuclear acid fragment. Typically, the recombinant expression cassette portion of an expression vector includes, among other sequences, a nucleic acid to be transcribed and a promoter.

The term “residue” or “amino acid residue” or “amino acid” are used interchangeably herein to refer to an amino acid that is incorporated into a protein, polypeptide or peptide (collectively “protein”). The amino acid may be a naturally occurring amino acid and, unless otherwise limited, may encompass non-natural analogs of natural amino acids that can function in a similar manner as naturally occurring amino acids.

The term “selectively hybridizes” includes reference to hybridization, under stringent hybridization conditions, of a nucleic acid sequence to a specified nucleic acid target sequence to a detectably greater degree (e.g., at least 2-fold over background) than its hybridization to non-target nucleic acid sequences and to the substantial exclusion of non-target nucleic acids. Selectively hybridizing sequences typically have about at least 80% sequence identity, preferably 90% sequence identity and most preferably 100% sequence identity (i.e., complementary) with each other.

The term “stringent conditions” or “stringent hybridization conditions” includes reference to conditions under which a probe will selectively hybridize to its target sequence, to a detectably greater degree than to other sequences (e.g., at least 2-fold over background). Stringent conditions are sequence-dependent and will be different in different circumstances. By controlling the stringency of the hybridization and/or washing conditions, target sequences can be identified which are 100% complementary to the probe (homologous probing). Alternatively, stringency conditions can be adjusted to allow some matching sequences so that lower degrees of similarity are detected (heterologous probing). Generally, a probe is less than about 1000 nucleotides in length, optionally less than 500 nucleotides in length.

Typically, stringent conditions will be those in which the salt concentration is less than about 1.5 M Na ion, typically about 0.01 to 1.0 M Na ion concentration (or other salts) at pH 7.0 to 8.3 and the temperature is at least about 30°C. For short probes (e.g., 10 to 50 nucleotides) and at least about 60°C. For long probes (e.g., greater than 50 nucleotides). Stringent conditions may also be achieved with the addition of destabilizing agents such as formamide. Example low stringency conditions include hybridization with a buffer solution of 30 to 35% formamide, 1 M NaCl, 1% SDS (sodium dodecyl sulphate) at 37°C. and a wash in 1x to 2xSSC (20xSSC=3.0 M NaCl/0.3 M trisodium citrate) at 50 to 55°C. Exemplary moderate stringency conditions include hybridization in 40 to 45% formamide, 1 M NaCl, 1% SDS at 37°C. and a wash in 0.5x to 1xSSC at 55 to 60°C. Exemplary high stringency conditions include hybridization in 50% formamide, 1 M NaCl, 1% SDS at 37°C. and a wash in 0.1xSSC at 60 to 65°C.

Specificity is typically the function of post-hybridization washes, the critical factors being the ionic strength and temperature of the final wash solution. For DNA-DNA hybrids, the Tm can be approximated from the equation of Meinikoth and Wahl, Anal. Biochem., 138:267-284 (1984): Tm=81.5°C+16.6 (log M)+0.41 (% GC)-0.61 (% form)×500/L; where M is the molarity of monovalent cations, % GC is the percentage of guanine and cytosine nucleotides in the DNA, % form is the percentage of formamide in the hybridization solution, and L is the length of the hybrid in base pairs. The Tm is the temperature (under defined ionic strength and pH) at which 50% of a complementary target sequence hybridizes to a perfectly matched probe. Tm is reduced by about 1°C. for each 1% of mismatching; thus, Tm, hybridization and/or wash conditions can be adjusted to hybridize to
sequences of the desired identity. For example, if sequences with 90% identity are sought, the \( T_m \) can be decreased 10°C. Generally, stringent conditions are selected to be about 5°C lower than the thermal melting point (\( T_m \)) for the specific sequence and its complement at a defined ionic strength and pH. However, severely stringent conditions can utilize a hybridization and/or wash at 1, 2, 3 or 4°C lower than the thermal melting point (\( T_m \)); moderately stringent conditions can utilize a hybridization and/or wash at 6, 7, 8, 9 or 10°C lower than the thermal melting point (\( T_m \)); low stringency conditions can utilize a hybridization and/or wash at 11, 12, 13, 14, 15 or 20°C lower than the thermal melting point (\( T_m \)).

Using the equation, hybridization and wash compositions, and desired \( T_m \), those of ordinary skill will understand that variations in the stringency of hybridization and/or wash solutions are inherently described. If the desired degree of mismatching results in a \( T_m \) of less than 45°C (aqueous solution) or 32°C (formamide solution) it is preferred to increase the SSC concentration so that a higher temperature can be used. An extensive guide to the hybridization of nucleic acids is found in Tijssen, Laboratory Techniques in Biochemistry and Molecular Biology—Hybridization with Nucleic Acid Probes, Part I, Chapter 2 “Overview of principles of hybridization and the strategy of nucleic acid probe assays”, Elsevier, N.Y. (1993) and Current Protocols in Molecular Biology, Chapter 2, Ausubel, et al., Eds., Greene Publishing and Wiley-Interscience, New York (1995). Hybridization and/or wash conditions can be applied for at least 10, 30, 60, 90, 120 or 240 minutes.

As used herein, “transcription factor” includes reference to a protein which interacts with a DNA regulatory element to affect expression of a structural gene or expression of a second regulatory gene. “Transcription factor” may also refer to the DNA encoding said transcription factor protein. The function of a transcription factor may include activation or repression of transcription initiation.

As used herein, “transgenic plant” includes reference to a plant which comprises within its genome a heterologous polynucleotide. Generally, the heterologous polynucleotide is stably integrated within the genome such that the polynucleotide is passed on to successive generations. The heterologous polynucleotide may be integrated into the genome alone or as part of a recombinant expression cassette. “Transgenic” is used herein to include any cell, cell line, callus, tissue, plant part or plant, the genotype of which has been altered by the presence of heterologous nucleic acid including those transgenics initially so altered as well as those created by sexual crosses or asexual propagation from the initial transgenic. The term “transgenic” as used herein does not encompass the alteration of the genome (chromosomal or extra-chromosomal) by conventional plant breeding methods or by naturally occurring events such as random cross-fertilization, non-recombinant viral infection, non-recombinant bacterial transformation, non-recombinant transposition or spontaneous mutation.

As used herein, “vector” includes reference to a nucleic acid used in introduction of a polynucleotide of the present invention into a host cell. Vectors are often replicons. Expression vectors permit transcription of a nucleic acid inserted therein.

The following terms are used to describe the sequence relationships between a polynucleotide/polypeptide of the present invention with a reference polynucleotide/polypeptide: (a) “reference sequence”, (b) “comparison window”, (c) “sequence identity” and (d) “percentage of sequence identity”.

As used herein, “reference sequence” is a defined sequence used as a basis for sequence comparison with a polynucleotide/polypeptide of the present invention. A reference sequence may be a subset or the entirety of a specified sequence; for example, as a segment of a full-length cDNA or gene sequence or the complete cDNA or gene sequence.

As used herein, “comparison window” includes reference to a contiguous and specified segment of a polynucleotide/polypeptide sequence, wherein the polynucleotide/polypeptide sequence may be compared to a reference sequence and wherein the portion of the polynucleotide/polypeptide sequence in the comparison window may comprise additions or deletions (i.e., gaps) compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two sequences. Generally, the comparison window is at least 20 contiguous nucleotides/amino acids residues in length, and optionally can be 30, 40, 50, 100 or longer. Those of skill in the art understand that to avoid a high similarity to a reference sequence due to inclusion of gaps in the polynucleotide/polypeptide sequence, a gap penalty is typically introduced and is subtracted from the number of matches.

Software for performing BLAST analyses is publicly available, e.g., through the National Center for Biotechnology Information. This algorithm involves first identifying high scoring sequence pairs (HSPs) by identifying short words of length W in the query sequence, which either match or satisfice some positive-valued threshold score \( T \) when aligned with a word of the same length in a database sequence. \( T \) is referred to as the neighborhood word score threshold. These initial neighborhood word hits act as seeds
for initiating searches to find longer HSPs containing them. The word hits are then extended in both directions along each sequence for as far as the cumulative alignment score can be increased. Cumulative scores are calculated using, for nucleotide sequences, the parameters M (reward score for a pair of matching residues; always >0) and N (penalty score for mismatching residues; always <0). For amino acid sequences, a scoring matrix is used to calculate the cumulative score. Extension of the word hits in each direction are halted when: the cumulative alignment score falls off by the quantity X from its maximum achieved value; the cumulative score goes to zero or below, due to the accumulation of one or more negative-scoring residue alignments or the end of either sequence is reached. The BLAST algorithm parameters W, T and X determine the sensitivity and speed of the alignment. The BLASTN program (for nucleotide sequences) uses as defaults a wordlength (W) of 11, an expectation (E) of 10, a cutoff of 100, M=5, N=−4 and a comparison of both strands. For amino acid sequences, the BLASTP program uses as defaults a wordlength (W) of 3, an expectation (E) of 10 and the BLOSUM62 scoring matrix (see, Henikoff and Henikoff, (1989) Proc. Natl. Acad. Sci. USA 86:10915).

[0057] In addition to calculating percent sequence identity, the BLAST algorithm also performs a statistical analysis of the similarity between two sequences (see, e.g., Karlin and Altschul, Proc. Natl. Acad. Sci. USA 90:5873-5877 (1993)). One measure of similarity provided by the BLAST algorithm is the smallest sum probability (P(N)), which provides an indication of the probability by which a match between two nucleotide or amino acid sequences would occur by chance.

[0058] BLAST searches assume that proteins can be modeled as random sequences. However, many real proteins comprise regions of nonrandom sequences which may be homopolymeric tracts, short-period repeats or regions enriched in one or more amino acids. Such low-complexity regions may be aligned between unrelated proteins even though other regions of the protein are entirely dissimilar. A number of low-complexity filter programs can be employed to reduce such low-complexity alignments. For example, the SEG (Wooten and Federhen, (1993) Comput. Chem., 17:149-163) and XNU (Claverie and States, (1993) Comput. Chem., 17:191-201) low-complexity filters can be employed alone or in combination.

[0059] Unless otherwise stated, nucleotide and protein identity/similarity values provided herein are calculated using GAP (GGG Version 10) under default values.

[0060] GAP (Global Alignment Program) can also be used to compare a polynucleotide or polypeptide of the present invention with a reference sequence. GAP uses the algorithm of Needleman and Wunsch ((1970) J. Mol. Biol. 48:443-453) to find the alignment of two complete sequences that maximizes the number of matches and minimizes the number of gaps. GAP considers all possible alignments and gap positions and creates the alignment with the largest number of matched bases and the fewest gaps. It allows for the provision of a gap creation penalty and a gap extension penalty in units of matched bases. GAP must make a profit of gap creation penalty number of matches for each gap it inserts. If a gap extension penalty greater than zero is chosen, GAP must, in addition, make a profit for each gap inserted of the length of the gap times the gap extension penalty. Default gap creation penalty values and gap extension penalty values in Version 10 of the Wisconsin Genetics Software Package® for protein sequences are 8 and 2, respectively. For nucleotide sequences the default gap creation penalty is 50 while the default gap extension penalty is 3. The gap creation and gap extension penalties can be expressed as an integer selected from the group of integers consisting of from 0 to 100. Thus, for example, the gap creation and gap extension penalties can each independently be: 0, 1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 15, 20, 30, 40, 50, 60 or greater.

[0061] GAP presents one member of the family of best alignments. There may be many members of this family, but no other member has a better quality. GAP displays four figures of merit for alignments: Quality, Ratio, Identity and Similarity. The Quality is the metric maximized in order to align the sequences. Ratio is the quality divided by the number of bases in the shorter segment. Percent Identity is the percent of the symbols that actually match. Percent Similarity is the percent of the symbols that are similar. Symbols that are across from gaps are ignored. A similarity is scored when the scoring matrix value for a pair of symbols is greater than or equal to 0.50, the similarity threshold. The scoring matrix used in Version 10 of the Wisconsin Genetics Software Package® is BLOSUM62 (see, Henikoff and Henikoff, (1989) Proc. Natl. Acad. Sci. USA 89:10915).

[0062] Multiple alignment of the sequences can be performed using the CLUSTAL method of alignment (Higgins and Sharp, (1989) CABIOS, 5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the CLUSTAL method are KITUPLE 1, GAP PENALTY=3, WINDOW=5 and DIAGONAL SAVED=5.

[0063] (c) As used herein, “sequence identity” or “identity” in the context of two nucleic acid or polypeptide sequences includes reference to the residues in the two sequences which are the same when aligned for maximum correspondence over a specified comparison window. When percentage of sequence identity is used in reference to proteins it is recognized that residue positions which are not identical often differ by conservative amino acid substitutions, where amino acid residues are substituted for other amino acid residues with similar chemical properties (e.g., charge or hydrophobicity) and therefore do not change the functional properties of the molecule. Where sequences differ in conservative substitutions, the percent sequence identity may be adjusted upwards to correct for the conservative nature of the substitution. Sequences which differ by such conservative substitutions are said to have “sequence similarity” or “similarity”.

[0064] (d) As used herein, “percentage of sequence identity” means the value determined by comparing two optimally aligned sequences over a comparison window, wherein the portion of the polynucleotide sequence in the comparison window may comprise additions or deletions (i.e., gaps) as compared to the reference sequence (which does not comprise additions or deletions) for optimal alignment of the two
sequences. The percentage is calculated by determining the number of positions at which the identical nucleic acid base or amino acid residue occurs in both sequences to yield the number of matched positions, dividing the number of matched positions by the total number of positions in the window of comparison and multiplying the result by 100 to yield the percentage of sequence identity.

Nucleic Acids

[0065] The present invention provides, among other things, isolated nucleic acids of RNA, DNA, and analogs and/or chimeras thereof, comprising a polynucleotide of the present invention.

[0066] A polynucleotide of the present invention is inclusive of:

[0067] (a) a polynucleotide encoding a polypeptide of SEQ ID NOS: 2, 4, 6, 8, 10, 12 or 14 including the exemplary polynucleotide of SEQ ID NOS: 1, 3, 5, 7, 9, 11 or 13;

[0068] (b) a polynucleotide which is the product of amplification from a Zea mays nucleic acid library using primer pairs which selectively hybridize under stringent conditions to loci within a polynucleotide selected from SEQ ID NOS: 1, 3, 5, 7, 9, 11 or 13;

[0069] (c) a polynucleotide which selectively hybridizes to a polynucleotide of (a) or (b);

[0070] (d) a polynucleotide having a specified sequence identity with polynucleotides of (a), (b) or (c);

[0071] (e) a polynucleotide encoding a protein having a specified number of contiguous amino acids from a prototype polypeptide, wherein the protein is specifically recognized by antisera elicited by presentation of the protein and wherein the protein does not detectably immunoreact to antisera which has been fully immunosorbed with the protein;

[0072] (f) sequences complementary to polynucleotides of (a), (b), (d) or (e); and

[0073] (g) a polynucleotide comprising at least 50 contiguous nucleotides from a polynucleotide of (a), (b), (c), (d), (e) or (f).

A Polynucleotides Encoding A Polypeptide of the Present Invention

[0074] As indicated in (a), above, the present invention provides isolated nucleic acids comprising a polynucleotide of the present invention, wherein the polynucleotide encodes a polypeptide of the present invention. Every nucleic acid sequence herein that encodes a polypeptide also, by reference to the genetic code, describes every possible silent variation of the nucleic acid. One of ordinary skill will recognize that each codon in a nucleic acid (except AUG, which is ordinarily the only codon for methionine; and UGG, which is ordinarily the only codon for tryptophan) can be modified to yield a functionally identical molecule. Thus, each silent variation of a nucleic acid which encodes a polypeptide of the present invention is implicit in each described polynucleotide sequence and is within the scope of the present invention. Accordingly, the present invention includes the polynucleotide of SEQ ID NOS: 1, 3, 5, 7, 9, 11 or 13 and polynucleotides encoding a polypeptide of SEQ ID NO: 2, 4, 6, 8, 10, 12 or 14.

B. Polynucleotides Amplified from a Zea mays Nucleic Acid Library

[0075] As indicated in (b), above, the present invention provides an isolated nucleic acid comprising a polynucleotide of the present invention, wherein the polynucleotides are amplified from a Zea mays nucleic acid library. Zea mays lines B73, PHRE1, A632, BMS-P2#10, W23 and Mo17 are known and publicly available. Other publicly known and available maize lines can be obtained from the Maize Genetics Cooperation (Urbana, III.). The nucleic acid library may be a cDNA library, a genomic library or a library generally constructed from nuclear transcripts at any stage of in vitro processing. cDNA libraries can be normalized to increase the representation of relatively rare cDNA's. In optional embodiments, the cDNA library is constructed using a full-length cDNA synthesis method. Examples of such methods include Oligo-Capping (Marnylma and Sugano, (1994) Gene 138: 171-174), Biotinylated CAP Trapper (Carmine, et al., (1992) Genomics 37:327-336) and CAP Retention Procedure (Edery, et al. (1995) Molecular and Cellular Biology 15:3363-3371). cDNA synthesis is often catalyzed at 50-55° C. to prevent formation of RNA secondary structure. Examples of reverse transcriptase that are relatively stable at these temperatures are SuperScript II Reverse Transcriptase (Life Technologies, Inc.), AMV Reverse Transcriptase (Boehringer Mannheim) and RetroAmp Reverse Transcriptase (Epitentre). Rapidly-growing tissues or rapidly-dividing cells are preferably used as mRNA sources, particularly lateral root initiation regions of adventitious roots in soil-grown maize plants.

[0076] The present invention also provides subsequences of the polynucleotides of the present invention. A variety of subsequences can be obtained using primers which selectively hybridize under stringent conditions to at least two sites within a polynucleotide of the present invention or to a site within a polynucleotide of the present invention and a site within the nucleic acid which comprises it. Primers are chosen to selectively hybridize, under stringent hybridization conditions, to a polynucleotide of the present invention. Generally, the primers are complementary to a subsequence of the target nucleic acid which they amplify but may have a sequence identity ranging from about 85% to 99% relative to the polynucleotide sequence which they are designed to anneal to. As those skilled in the art will appreciate, the sites to which the primer pairs will selectively hybridize are chosen such that a single contiguous nucleic acid can be formed under the desired amplification conditions.

[0077] In optional embodiments, the primers will be constructed so that they selectively hybridize under stringent conditions to a sequence (or its complement) within the target nucleic acid, which comprises the coding encoding the carboxy or amino terminal amino acid residue (i.e., the 3' terminal coding region and 5' terminal coding region, respectively) of the polynucleotides of the present invention. Optionally within these embodiments, the primers will be constructed to selectively hybridize entirely within the coding region of the target polynucleotide of the present invention such that the product of amplification of a cDNA target will consist of the coding region of that cDNA. The primer length in nucleotides is selected from the group of integers consisting of from at least 15 to 50. Thus, the primers can be at least 15, 18, 20, 25, 30, 40 or 50 nucleotides in length. Those of skill will recognize that a lengthened primer sequence can be employed to increase specificity of binding (i.e., annealing) to a target sequence. A non-anchoring sequence at the 5' end of a primer (a "tail") can be added, for example, to introduce a cloning site at the terminal ends of the amplification.
[0078] The amplification products can be translated using expression systems well known to those of skill in the art and as discussed, infra. The resulting translation products can be confirmed as polypeptides of the present invention by, for example, assaying for the appropriate catalytic activity (e.g., specific activity and/or substrate specificity) or verifying the presence of one or more epitopes, which are specific to a polypeptide of the present invention. Methods for protein synthesis from PCR derived templates are known in the art and available commercially. See, e.g., Amersham Life Sciences, Inc, Catalog '97, p.354.

C. Polynucleotides which Selectively Hydridize to a Poly-nucleotide of (A) or (B)

[0080] As indicated in (c), above, the present invention provides isolated nucleic acids comprising polynucleotides of the present invention, wherein the polynucleotides selectively hybridize, under selective hybridization conditions, to a polynucleotide of sections (A) or (B) as discussed above. Thus, the polynucleotides of this embodiment can be used for isolating, detecting, and/or quantifying nucleic acids comprising the polynucleotides of (A) or (B). For example, polynucleotides of the present invention can be used to identify, isolate, or amplify partial or full-length clones in a deposited library. In some embodiments, the polynucleotides are genomic or cDNA sequences isolated or otherwise complementary to a cDNA from a dicot or monocot nucleic acid library. Exemplary species of monocots and dicots include, but are not limited to: maize, canola, soybean, cotton, wheat, sorghum, sunflower, alfalfa, oats, sugar cane, millet, barley and rice. Optionally, the cDNA library comprises at least 30% to 95% full-length sequences (for example, at least 30%, 40%, 50%, 60%, 70%, 80%, 90% or 95% full-length sequences). The cDNA libraries can be normalized to increase the representation of rare sequences. Low stringency hybridization conditions are typically, but not exclusively, employed with sequences having a reduced sequence identity relative to complementary sequences. Moderate and high stringency conditions can optionally be employed for sequences of greater identity. Low stringency conditions allow selective hybridization of sequences having about 70% to 80% sequence identity and can be employed to identify orthologous or paralogous sequences.

D. Polynucleotides Having a Specific Sequence Identity with the Polynucleotides of (A), (B) or (C)

[0081] As indicated in (d), above, the present invention provides isolated nucleic acids comprising polynucleotides of the present invention, wherein the polynucleotides have a specified identity at the nucleotide level to a polynucleotide as disclosed in sections (A), (B) or (C), above. Identity can be calculated using, for example, the BLAST, CLUSTALW, or GAP algorithms under default conditions. The percentage of identity to a reference sequence is at least 57% and, rounded upwards to the nearest integer, can be expressed as an integer selected from the group of integers consisting of from 57 to 99. Thus, for example, the percentage of identity to a reference sequence can be at least 60%, 75%, 80%, 85%, 90% or 95%.

[0082] Optionally, the polynucleotides of this embodiment will encode a polypeptide that will share an epitope with a polypeptide encoded by the polynucleotides of sections (A), (B) or (C). Thus, these polynucleotides encode a first polypeptide which elicits production of antibodies which are specifically reactive to a second polypeptide encoded by a polynucleotide of (A), (B) or (C). However, the first polypeptide does not bind to antibodies raised against itself when the antigen has been fully immunosorbed with the first polypeptide. Hence, the polynucleotides of this embodiment can be used to generate antibodies for use in, for example, the screening of expression libraries for nucleic acids comprising polynucleotides of (A), (B) or (C) or for purification of, or in immunoassays for, polypeptides encoded by the polynucleotides of (A), (B) or (C). The polynucleotides of this embodiment encode nucleic acid sequences, which can be employed for selective hybridization to a polynucleotide encoding a polypeptide of the present invention.

[0083] Screening polypeptides for specific binding to antisera can be conveniently achieved using peptide display libraries. This method involves the screening of large collections of peptides for individual members having the desired function or structure. Antibody screening of peptide display libraries is well known in the art. The displayed peptide sequences can be from 3 to 5000 or more amino acids in length, frequently from 5-100 amino acids long, and often from about 8 to 15 amino acids long. In addition to direct chemical synthetic methods for generating peptide libraries, several recombinant DNA methods have been described. One type involves the display of a peptide sequence on the surface of a bacteriophage or cell. Each bacteriophage or cell contains the nucleotide sequence encoding the particular displayed peptide sequence. Such methods are described in PCT Patent Publication Numbers WO 1991/17271, WO 1991/18980, WO 1991/19818 and WO 1993/08278. Other systems for generating libraries of peptides have aspects of both in vitro chemical synthesis and recombinant methods. See, PCT Patent Publication Numbers WO 1992/05258, WO 1992/14843 and WO 1997/20078. See also, U.S. Pat. Nos. 5,658,754 and 5,643,768. Peptide display libraries, vectors and screening kits are commercially available from such suppliers as Invitrogen (Carlsbad, Calif.).

E. Polynucleotides Encoding a Protein Having a Subsequence from a Prototype Polypeptide and is Cross-Reactive to the Prototype Polypeptide

[0084] As indicated in (e), above, the present invention provides isolated nucleic acids comprising polynucleotides of the present invention, wherein the polynucleotides encode a protein having a subsequence of contiguous amino acids from a prototype polypeptide of the present invention such as are provided in (a), above. The length of contiguous amino acids from the prototype polypeptide is selected from the group of integers consisting of from at least 10 to 20 amino acids within the prototype sequence. Thus, for example, the polynucleotide can encode a polypeptide having a subsequence having at least 10, 15, 20, 25, 30, 35, 40, 45 or 50, contiguous amino acids from the prototype polypeptide. Further, the number of such subsequences encoded by a polynucleotide of the instant embodiment can be any integer selected from the group consisting of from 1 to 20, such as 2,
The subsequences can be separated by any integer of nucleotides from 1 to the number of nucleotides in the sequence such as at least 5, 10, 15, 25, 50, 100 or 200 nucleotides.

The proteins encoded by polynucleotides of this embodiment, when presented as an immunogen, elicit the production of polyclonal antibodies, which specifically bind to a prototype polypeptide such as but not limited to, a polypeptide encoded by the polynucleotide of (a) or (b), above. Generally, however, a protein encoded by a polynucleotide of this embodiment does not bind to antisera raised against the prototype polypeptide when the antisera has been fully immunosorbed with the prototype polypeptide. Methods of making and assaying for antibody binding specificity/affinity are well known in the art. Exemplary immunoassay formats include ELISA, competitive immunoassays, radioimmunoassays, Western blots, indirect immunofluorescent assays and the like.

In a preferred assay method, fully immunosorbed and pooled antisera, which is elicited to the prototype polypeptide can be used in a competitive binding assay to test the protein. The concentration of the prototype polypeptide required to inhibit 50% of the binding of the antisera to the prototype polypeptide is determined. If the amount of the protein required to inhibit binding is less than twice the amount of the prototype protein, then the protein is said to specifically bind to the antisera elicited to the immunogen. Accordingly, the proteins of the present invention embrace allelic variants, conservatively modified variants and minor recombinant modifications to a prototype polypeptide.

A polynucleotide of the present invention optionally encodes a protein having a molecular weight as the non-glycosylated protein within 20% of the molecular weight of the full-length non-glycosylated polypeptides of the present invention. Molecular weight can be readily determined by SDS-PAGE under reducing conditions. Optionally, the molecular weight is within 15% of a full-length polypeptide of the present invention, more preferably within 10% or 5% and most preferably within 3%, 2% or 1% of a full-length polypeptide of the present invention.

Optionally, the polynucleotides of this embodiment will encode a protein having a specific enzymatic activity at least 50%, 60%, 80% or 90% of a cellular extract comprising the native, endogenous full-length polypeptide of the present invention. Further, the proteins encoded by polynucleotides of this embodiment will optionally have a substantially similar affinity constant (K_d) and/or catalytic activity (i.e., the microscopic rate constant, k_cat) as the native endogenous, full-length protein. Those of skill in the art will recognize that k_cat/K_d value determines the specificity for competing substrates and is often referred to as the specificity constant. Proteins of this embodiment can have a k_cat/K_d value at least 10% of a full-length polypeptide of the present invention as determined using the endogenous substrate of that polypeptide. Optionally, the K_d/K_w value will be at least 20%, 30%, 40%, 50% and most preferably at least 60%, 70%, 80%, 90% or 95% the K_d/K_w value of the full-length polypeptide of the present invention. Determination of K_d and k_cat/K_w can be determined by any number of means well known to those of skill in the art. For example, the initial rates (i.e., the first 5% or less of the reaction) can be determined using rapid mixing and sampling techniques (e.g., continuous-flow, stopped-flow or rapid quenching techniques), flash photolysis or relaxation methods (e.g., temperature jumps) in conjunction with such exemplary methods of measuring as spectrophotometry, spectrofluorimetry, nuclear magnetic resonance or radioactive procedures. Kinetic values are conveniently obtained using a Lineweaver-Burk or Eadie-Hofstee plot.

F. Polynucleotides Complementary to the Polynucleotides of (A)-(E)

As indicated in (f), above, the present invention provides isolated nucleic acids comprising polynucleotides complementary to the polynucleotides of paragraphs (A), (B), (D) or (E), above. As those of skill in the art will recognize, complementary sequences base-pair throughout the entirety of their length with the polynucleotides of sections (A), (B), (D) or (E) (i.e., have 100% sequence identity over their entire length). Complementary bases associate through hydrogen bonding in double-stranded nucleic acids. For example, the following base pairs are complementary: guanine and cytosine; adenine and thymine and adenosine and uracil.

G. Polynucleotides which are Subsequences of the Polynucleotides of (A)-(F)

As indicated in (h), above, the present invention provides isolated nucleic acids comprising polynucleotides which comprise at least 50 contiguous bases from the polynucleotides of sections (A) through (G) as discussed above. The length of the polynucleotide is given as an integer selected from the group consisting of from at least 50 to the length of the nucleic acid sequence of which the polynucleotide is a subsequence. Thus, for example, polynucleotides of the present invention are inclusive of polynucleotides comprising at least 50, 60, 75 or 100 contiguous nucleotides in length from the polynucleotides of (A)-(G). Optionally, the number of such subsequences encoded by a polynucleotide of the instant embodiment can be any integer selected from the group consisting of from 1 to 20, such as 2, 3, 4 or 5. The subsequences can be separated by any integer of nucleotides from 1 to the number of nucleotides in the sequence such as at least 5, 10, 15, 25, 50, 100 or 200 nucleotides.

A subsequence of the present invention can comprise structural characteristics of the sequence from which it is derived. Alternatively, a subsequence can lack certain structural characteristics of the larger sequence from which it is derived, such as a poly (A) tail. Optionally, a subsequence from a polynucleotide encoding a polypeptide having at least one epitope in common with a prototype polypeptide sequence as provided in (a), above, may encode an epitope in common with the prototype sequence. Alternatively, the subsequence may not encode an epitope in common with the prototype sequence but can be used to isolate the larger sequence by, for example, nucleic acid hybridization with the sequence from which it is derived. Subsequences can be used to modulate or detect gene expression by introducing into the subsequences compounds, which bind, intercalate, cleave and/or crosslink to nucleic acids. Exemplary compounds include acridine, psoralen, phenanthroline, naphthoquinone, daunomycin or chloroethylnitroaryl conjugates.

Construction of Nucleic Acids

The isolated nucleic acids of the present invention can be made using (a) standard recombinant methods, (b) synthetic techniques or combinations thereof. In some embodiments, the polynucleotides of the present invention
will be cloned, amplified, or otherwise constructed from a monocot. In preferred embodiments the monocot is Zea mays.

[0093] The nucleic acids may conveniently comprise sequences in addition to a polynucleotide of the present invention. For example, a multi-cloning site comprising one or more endonuclease restriction sites may be inserted into the nucleic acid to aid in isolation of the polynucleotide. Also, translatable sequences may be inserted to aid in the isolation of the translated polynucleotide of the present invention. For example, a hexa-histidine marker sequence provides a convenient means to purify the proteins of the present invention. A polynucleotide of the present invention can be attached to a vector, adapter or linker for cloning and/or expression of a polynucleotide of the present invention. Additional sequences may be added to such cloning and/or expression sequences to optimize their function in cloning and/or expression, to aid in isolation of the polynucleotide, or to improve the introduction of the polynucleotide into a cell. Typically, the length of a nucleic acid of the present invention less the length of its polynucleotide of the present invention is less than 20 kilobase pairs, often less than 15 kb and frequently less than 10 kb. Use of cloning vectors, expression vectors, adapters and linkers is well known and extensively described in the art. For a description of various nucleic acids see, for example, Stratagene Cloning Systems, Catalogs 1995, 1996, 1997 (La Jolla, Calif.) and Amersham Life Sciences, Inc, Catalog ‘97 (Arlington Heights, Ill.).

A. Recombinant Methods for Constructing Nucleic Acids

[0094] The isolated nucleic acid compositions of this invention, such as RNA, cDNA, genomic DNA or a hybrid thereof, can be obtained from plant biological sources using any number of cloning methodologies known to those of skill in the art. In some embodiments, oligonucleotide probes which selectively hybridize, under stringent conditions, to the polynucleotides of the present invention are used to identify the desired sequence in a cDNA or genomic DNA library. Isolation of RNA, and construction of cDNA and genomic libraries is well known to those of ordinary skill in the art. See, e.g., Plant Molecular Biology: A Laboratory Manual, Clark, Ed., Springer-Verlag, Berlin (1997) and Current Protocols in Molecular Biology, Ausubel, et al., Eds., Greene Publishing and Wiley-Interscience, New York (1995).

[0095] A number of cDNA synthesis protocols have been described which provide substantially full-length cDNA libraries. Substantially pure full-length cDNA libraries are constructed to comprise at least 90% and more preferably at least 93% or 95% full-length inserts amongst clones containing inserts. The length of insert in such libraries can be from 0 to 8, 9, 10, 11, 12, 13 or more kilobase pairs. Vectors to accommodate inserts of these sizes are known in the art and commercially available. See, e.g., Stratagene’s lambda ZAP Express (cDNA cloning vector with 0 to 12 kb cloning capacity). An exemplary method of constructing a greater than 95% pure full-length cDNA library is described by Carninci, et al., (1996) Genomics, 37:327-336. Other methods for producing full-length libraries are known in the art. See, e.g., Edery, et al., (1995) Mol. Cell Biol. 15(6):3363-3371; and PCT Application WO 1996/34981.

[0096] A non-normalized or Subtracted cDNA Libraries

[0100] The cDNA or genomic library can be screened using a probe based upon the sequence of a polynucleotide of the present invention such as those disclosed herein. Probes may be used to hybridize with genomic DNA or cDNA sequences to isolate homologous genes in the same or different plant species. Those of skill in the art will appreciate that various degrees of stringency of hybridization can be employed in the assay and whether the hybridization or the wash medium can be stringent.

[0101] The nucleic acids of interest can also be amplified from nucleic acid samples using amplification techniques. For instance, polymerase chain reaction (PCR) technology can be used to amplify the sequences of polynucleotides of the present invention and related genes directly from genomic DNA or cDNA libraries. PCR and other in vitro amplification methods may also be useful, for example, to clone nucleic acid sequences that code for proteins to be expressed, to make nucleic acids to use as probes for detecting the presence of the desired mRNA in samples, for nucleic acid sequencing or for
other purposes. The T4 gene 32 protein (Boehringer Mannheim) can be used to improve yield of long PCR products. [0102] PCR-based screening methods have been described. Willinger et al., describe a PCR-based method in which the longest cDNA is identified in the first step so that incomplete clones can be eliminated from study. BioTechniques, 22(3):481-486 (1997). Such methods are particularly effective in combination with a full-length cDNA construction methodology, above.

B. Synthetic Methods for Constructing Nucleic Acids

Recombinant Expression Cassettes

[0104] The present invention further provides recombinant expression cassettes comprising a nucleic acid of the present invention. A nucleic acid sequence coding for the desired polypeptide of the present invention, for example a cDNA or a genomic sequence encoding a full-length polypeptide of the present invention, can be used to construct a recombinant expression cassette, which can be introduced into the desired host cell. A recombinant expression cassette will typically comprise a polynucleotide of the present invention operably linked to transcriptional initiation regulatory sequences, which will direct the transcription of the polynucleotide in the intended host cell, such as tissues of a transformed plant.

[0105] For example, plant expression vectors may include (1) a cloned plant gene under the transcriptional control of 5’ and 3’ regulatory sequences and (2) a dominant selectable marker. Such plant expression vectors may also contain, if desired, a promoter regulatory region (e.g., one conferring inducible or constitutive, environmentally- or developmentally-regulated or cell- or tissue-specific/selective expression), a transcription initiation start site, a ribosome binding site, an RNA processing signal, a transcription termination site and/or a polyadenylation signal.

[0106] A plant promoter fragment can be employed which will direct expression of a polynucleotide of the present invention in all tissues of a regenerant plant. Such promoters are referred to herein as “constitutive” promoters and are active under most environmental conditions and states of development or cell differentiation. Examples of constitutive promoters include the cauliflower mosaic virus (CaMV) 35S transcription initiation region, the 1’- or 2’-promoter derived from T-DNA of Agrobacterium tumefaciens, the ubiquitin 1 promoter, the Smas promoter, the cinnamyl alcohol dehydrogenase promoter (U.S. Pat. No. 5,683,439), the Nos promoter, the pEMU promoter, the rubisco promoter, the GRP1-8 promoter and other transcription initiation regions from various plant genes known to those of skill.

[0107] Alternatively, the plant promoter can direct expression of a polynucleotide of the present invention in a specific tissue or may be otherwise under more precise environmental or developmental control. Such promoters are referred to here as “inducible” promoters. Environmental conditions that may effect transcription by inducible promoters include pathogen attack, anaerobic conditions or the presence of light. Examples of inducible promoters are the Adh1 promoter, which is inducible by hypoxia or cold stress, the Hsp70 promoter, which is inducible by heat stress and the PPDK promoter, which is inducible by light.

[0108] Examples of promoters under developmental control include promoters that initiate transcription only or preferentially, in certain tissues, such as leaves, roots, fruit, seeds or flowers. Exemplary promoters include the root ecd2a promoter (Doerner, et al., (1996) Nature 380:520-523), the root peroxidase promoter from wheat (Hertig, et al., (1991) Plant Mol. Biol. 16:171-174) or flowering specific promoters (Maizel, et al., (2004) Plant J. April; 38(1):164-171). The operation of a promoter may also vary depending on its location in the genome. Thus, an inducible promoter may become fully or partially constitutive in certain locations.

[0109] Both heterologous and non-heterologous (i.e., endogenous) promoters can be employed to direct expression of the nucleic acids of the present invention. These promoters can also be used, for example, in recombinant expression cassettes to drive expression of antisense nucleic acids to reduce, increase or alter concentration and/or composition of the proteins of the present invention in a desired tissue. Thus, in some embodiments, the nucleic acid construct will comprise a promoter functional in a plant cell, such as in Zea mays, operably linked to a polynucleotide of the present invention. Promoters useful in these embodiments include the endogenous promoters driving expression of a polypeptide of the present invention.

[0110] In some embodiments, isolated nucleic acids which serve as promoter or enhancer elements can be introduced in the appropriate position (generally upstream) of a non-heterologous form of a polynucleotide of the present invention so as to up- or down-regulate expression of a polynucleotide of the present invention. For example, endogenous promoters can be altered in vivo by mutation, deletion, and/or substitution (see, Kmiec, U.S. Pat. No. 5,565,350; Zarling, et al., PCT/US93/03868) or isolated promoters can be introduced into a plant cell in the proper orientation and distance from a gene of the present invention so as to control the expression of the gene. Gene expression can be modulated under conditions suitable for plant growth so as to alter the total concentration and/or alter the composition of the polypeptides of the present invention in plant cell. Thus, the present invention provides compositions and methods for making, heterologous promoters and/or enhancers operably linked to a native, endogenous (i.e., non-heterologous) form of a polynucleotide of the present invention.

[0111] If polypeptide expression is desired, it is generally desirable to include a polyadenylation region at the 3’-end of a polynucleotide coding region. The polyadenylation region can be derived from the natural gene, from a variety of other
plant genes or from T-DNA. The 3' end sequence to be added can be derived from, for example, the nopaline synthase or octopine synthase genes or alternatively from another plant gene or less preferably from any other eukaryotic gene.

**[0112]** An intron sequence can be added to the 5' untranslated region or the coding sequence of the partial coding sequence to increase the amount of the mature message that accumulates in the cytosol. Inclusion of a spliceable intron in the transcription unit in both plant and animal expression constructs has been shown to increase gene expression at both the mRNA and protein levels up to 1000-fold. Buchman and Berg, (1988) *Mol. Cell Biol.* 8:4395-4405; Callis et al., *Genes Dev.* 1:1183-1200 (1987). Such intron enhancement of gene expression is typically greatest when placed near the 5' end of the transcription unit. Use of maize introns Adh1-S intron 1, 2, and 6, the Bronze-1 intron are known in the art. See generally, *The Maize Handbook*, Chapter 116, Freeling and Walbot, Eds., Springer, New York (1994). The vector comprising the sequences from a polynucleotide of the present invention will typically comprise a marker gene which confers a selectable phenotype on plant cells. Typical vectors useful for expression of genes in higher plants are well known in the art and include vectors derived from the tumor-inducing (Ti) plasmid of *Agrobacterium tumefaciens* described by Rogers, et al., (1987) *Meth. in Enzymol.* 153:253-277.

**[0113]** A polynucleotide of the present invention can be expressed in either sense or anti-sense orientation as desired. It will be appreciated that control of gene expression in either sense or anti-sense orientation can have a direct impact on the observable plant characteristics. Antisense technology can be conveniently used to inhibit gene expression in plants. To accomplish this, a nucleic acid segment from the desired gene is cloned and operably linked to a promoter such that the anti-sense strand of RNA will be transcribed. The construct is then transformed into plants and the antisense strand of RNA is produced. In plant cells, it has been shown that antisense RNA inhibits gene expression by preventing the accumulation of mRNA which encodes the enzyme of interest, see, e.g., Sheehy, et al., (1988) *Proc. Natl. Acad. Sci.* (USA) 85:8805-8809 and Hiatt, et al., U.S. Pat. No. 4,801,340.

**[0114]** Another method of suppression is sense suppression. Introduction of a nucleic acid configured in the sense orientation has been shown to be an effective means by which to block frame shift. For an example of the use of this method to modulate expression of endogenous genes see, Napoli et al., (1990) *The Plant Cell* 2:779-289 and U.S. Pat. No. 5,034,323.

**[0115]** Catalytic RNA molecules or ribozymes can also be used to inhibit expression of plant genes. It is possible to design ribozymes that specifically pair with virtually any target RNA and cleave the phosphodiester backbone at a specific location, thereby functionally inactivating the target RNA. In carrying out this cleavage, the ribozyme is not itself altered and is thus capable of recycling and cleaving other molecules, making it a true enzyme. The inclusion of ribozyme sequences within antisense RNAs confers RNA-cleaving activity upon them, thereby increasing the activity of the constructs. The design and use of target RNA-specific ribozymes is described in Haseloff, et al., (1988) *Nature* 334:585-591.

**[0117]** In certain embodiments the nucleic acid sequences of the present invention can be used in combination (“stacked”) with other polynucleotide sequences of interest in order to create plants with a desired phenotype. The combinations generated can include multiple copies of any one or more of the polynucleotides of interest. The polynucleotides of the present invention may be stacked with any gene or combination of genes to produce plants with a variety of desired trait combinations, including but not limited to traits desirable for animal feed such as high oil genes (e.g., U.S. Pat. No. 6,232,529); balanced amino acids (e.g., hordothionins (U.S. Pat. Nos. 5,990,389; 5,885,801; 5,885,802 and 5,703,409); barley high lysine (Williamson, et al., (1987) *Eur. J. Biochem.* 165:99-106 and WO 1998/2012) and high methionine proteins (Pedersen, et al., (1986) *J. Biol. Chem.* 261:6279; Kirihara, et al., (1988) *Gene* 71:359 and Musumura, et al., (1989) *Plant Mol. Biol.* 12:123); increased digestibility (e.g., modified storage proteins (U.S. application Ser. No. 10/053,410, filed Nov. 7, 2001) and thiorodoxins (U.S. application Ser. No. 10/005,429, filed Dec. 3, 2001)), the disclosures of which are herein incorporated by reference. The polynucleotides of the present invention can also be stacked with traits desirable for insect, disease or herbicide resistance (e.g., *Bacillus thuringiensis* toxic proteins (U.S. Pat. Nos. 5,366,892; 5,747,450; 5,737,514; 5,723,756; 5,593,881; Geiser, et al., (1986) *Gene* 48:109); lectins (Van Damme, et al., (1994) *Plant Mol. Biol.* 24:825); fumonisin detoxification genes (U.S. Pat. No. 5,792,931); avirulence and disease resistance genes (Jones, et al., (1994) *Science* 266:789; Martin, et al., (1993) *Science* 262:1432; Mindrinos, et al., (1994) *Cell* 78:1089); acetolactate synthase (ALS) mutants that lead to herbicide resistance such as the S4 and/or Hra mutations; inhibitors of glutamine synthetase such as phosphinotricin or basta (e.g., bar gene) and glyphosate resistance (EPSPS gene) and traits desirable for processing or process products such as high oil (e.g., U.S. Pat. No. 5,232,529); modified oils (e.g., fatty acid desaturase genes (U.S. Pat. No. 5,952,544; WO 1994/11516); modified starches (e.g., ADPG pyrophosphorylases (ADPase), starch synthases (SS), starch branching
enzymes (SBE) and starch debranching enzymes (SDBE)); and polymers or bioplastics (e.g., U.S. Pat. No. 5,602,321; beta-ketothiolase, polyhydroxybutyrate synthase, and acetacetly-CoA reductase (Schmibert et al., [1988] J. Bacteriol. 170:5837-5847) facilitate expression of polyhydroxalkanoates (PHAs)), the disclosures of which are herein incorporated by reference. One could also combine the polynucleotides of the present invention with polynucleotides affecting agronomic traits such as male fertility (e.g., see, U.S. Pat. No. 5,583,210), stalk strength, flowering time, drought or other abiotic stress resistance or transformation technology traits such as cell cycle regulation or gene targeting (e.g., WO 1999/61619; WO 2000/17364; WO 1999/25821), the disclosures of which are herein incorporated by reference.

These stacked combinations can be created by any method, including but not limited to cross breeding plants by any conventional or TopCross methodology or genetic transformation. If the traits are stacked by genetically transforming the plants, the polynucleotide sequences of interest can be combined at any time and in any order. For example, a transgenic plant comprising one or more desired traits can be used as the target to introduce further traits by subsequent transformation. The traits can be introduced simultaneously in a co-transformation protocol with the polynucleotides of interest provided by any combination of transformation cassettes. For example, if two sequences will be introduced, the two sequences can be contained in separate transformation cassettes (trans) or contained on the same transformation cassette (cis). Expression of the sequences of interest can be driven by the same promoter or by different promoters. In certain cases, it may be desirable to introduce a transformation cassette that will suppress the expression of a polynucleotide of interest. This may be accompanied by any combination of other suppression cassettes or overexpression cassettes to generate the desired combination of traits in the plant.

The random insertion of introduced DNA into the genome of host cells can be lethal if the foreign DNA happens to insert into, and thus mutate, a critically important native gene. In addition, even if a random insertion event does not impair the functioning of a host cell gene, the expression of an inserted foreign gene may be influenced by “position effects” caused by the surrounding genomic DNA. In some cases, the gene is inserted into sites where the position effects are strong enough to prevent the synthesis of an effective amount of product from the introduced gene.

Integration of polynucleotides of interest at a target site is possible using site-specific recombination systems (see, for example, WO 1999/25821, herein incorporated by reference).

Another variation to minimize expression from random integration includes providing a promoter or transcription initiation region operably linked with the target site in an organism. The promoter will be 5’ to the first recombination site. By transforming the organism with a transfer cassette comprising a coding region flanked by recombination sites corresponding to the sites in the target site and providing recombinase activity, functional linkage and expression of the coding region will occur upon integration of the transfer cassette into the target site by site-specific recombination. Alternatively, the target site may comprise a promoter and a translation start codon (ATG) operably linked 5’ to the first recombination site. A transfer cassette comprising an ATG-less coding region is used. This arrangement further minimizes expression due to random integration of the transfer cassette, since expression would require the random integration to occur behind and endogenous promoter, and in the correct reading frame. (See, for example, WO 1999/25821, herein incorporated by reference).

Proteins

The isolated proteins of the present invention comprise a polypeptide having at least 10 amino acids encoded by any one of the polynucleotides of the present invention as discussed more fully, above or polypeptides which are conservatively modified variants thereof. The proteins of the present invention or variants thereof can comprise any number of contiguous amino acid residues from a polypeptide of the present invention, wherein that number is selected from the group of integers consisting of from 10 to the number of residues in a full-length polypeptide of the present invention. Optionally, this subsequence of contiguous amino acids is at least 15, 20, 25, 30, 35 or 40 amino acids in length, often at least 50, 60, 70, 80 or 90 amino acids in length. Further, the number of such subsequences can be any integer selected from the group consisting of from 1 to 20, such as 2, 3, 4 or 5.

The present invention further provides a protein comprising a polypeptide having a specified sequence identity with a polypeptide of the present invention. The percentage of sequence identity is an integer selected from the group consisting of from 50 to 99. Exemplary sequence identity values include 60%, 65%, 70%, 75%, 80%, 85%, 90% and 95%. Sequence identity can be determined using, for example, the BESTFIT, GAP, CLUSTALW or BLAST algorithms.

As those of skill will appreciate, the present invention includes catalytically active polypeptides of the present invention (i.e., enzymes). Catalytically active polypeptides have a specific activity of at least 20%, 30% or 40% and preferably at least 50%, 60% or 70% and most preferably at least 80%, 90% or 95% that of the native (non-synthetic), endogenous polypeptide. Further, the substrate specificity (ka/Km) is optionally substantially similar to the native (non-synthetic), endogenous polypeptide. Typically, the ka/Km will be at least 30%, 40% or 50%, that of the native (non-synthetic), endogenous polypeptide and more preferably at least 60%, 70%, 80% or 90%. Methods of assaying and quantifying measures of enzymatic activity and substrate specificity (ka/Km), are well known to those of skill in the art.

Generally, the proteins of the present invention will, when presented as an immunogen, elicit production of an antibody specifically reactive to a polypeptide of the present invention. Further, the proteins of the present invention will not bind to antisera raised against a polypeptide of the present invention which has been fully immunosorbed with the same polypeptide. Immunoassays for determining binding are well known to those of skill in the art. A preferred immunoassay is a competitive immunoassay as discussed, supra. Thus, the proteins of the present invention can be employed as immunogens for constructing antibodies immunoreactive to a protein of the present invention for such exemplary utilities as immunoassays or protein purification techniques.

Expression of Proteins in Host Cells

Using the nucleic acids of the present invention, one may express a protein of the present invention in a recombi-
nantly engineered cell such as bacteria, yeast, insect, mammalian or preferably plant cells. The cells produce the protein in a non-natural condition (e.g., in quantity, composition, location and/or time), because they have been genetically altered through human intervention to do so.

[0127] It is expected that those of skill in the art are knowledgeable in the numerous expression systems available for expression of a nucleic acid encoding a protein of the present invention. No attempt to describe in detail the various methods known for the expression of proteins in prokaryotes or eukaryotes will be made.

[0128] In brief summary, the expression of isolated nucleic acids encoding a protein of the present invention will typically be achieved by operably linking, for example, the DNA or cDNA to a promoter (which is either constitutive or regulatable), followed by incorporation into an expression vector. The vectors can be suitable for replication and integration in either prokaryotes or eukaryotes. Typical expression vectors contain transcription and translation terminators, initiation sequences and promoters useful for regulation of the expression of the DNA encoding a protein of the present invention. To obtain high level expression of a cloned gene, it is desirable to construct expression vectors which contain, at the minimum, a strong promoter to direct transcription, a ribosome binding site for translational initiation and a transcription/translation terminator. One of skill would recognize that modifications can be made to a protein of the present invention without diminishing its biological activity. Some modifications may be made to facilitate the cloning, expression or incorporation of the targeting molecule into a fusion protein. Such modifications are well known to those of skill in the art and include, for example, a methionine added at the amino terminus to provide an initiation site or additional amino acids (e.g., poly His) placed on either terminus to create conveniently located purification sequences. Restriction sites or termination codons can also be introduced.

Transfection/Transformation of Cells

[0129] The method of transformation/transfection is not critical to the instant invention; various methods of transformation or transfection are currently available. As newer methods are available to transform crops or other host cells they may be directly applied. Accordingly, a wide variety of methods have been developed to insert a DNA sequence into the genome of a host cell to obtain the transcription and/or translation of the sequence to effect phenotypic changes in the organism. Thus, any method which provides for effective transformation/transfection may be employed.

A. Plant Transformation

[0130] A DNA sequence coding for the desired polypeptide of the present invention, for example a cDNA or a genomic sequence encoding a full-length protein, will be used to construct a recombinant expression cassette which can be introduced into the desired plant.

[0131] Isolated nucleic acid acids of the present invention can be introduced into plants according to techniques known in the art. Generally, recombinant expression cassettes as described above and suitable for transformation of plant cells are prepared. Techniques for transforming a wide variety of higher plant species are well known and described in the technical, scientific, and patent literature. See, for example, Weising, et al., (1988) _Ann. Rev. Genet._ 22:421-477. For example, the DNA construct may be introduced directly into the genomic DNA of the plant cell using techniques such as electroporation, polyethylene glycol (PEG), poration, particle bombardment, silicon fiber delivery, or microinjection of plant cell protoplasts or embryogenic callus. See, e.g., Tomes, et al., Direct DNA Transfer into Intact Plant Cells Via Microprojectile Bombardment. pp. 197-213 in _Plant Cell, Tissue and Organ Culture, Fundamental Methods_, Eds. Gamburg and Phillips. Springer-Verlag Berlin Heidelberg New York, 1995. Alternatively, the DNA constructs may be combined with suitable T-DNA flanking regions and introduced into a conventional _Agrobacterium tumefaciens_ host vector. The virulence functions of the _Agrobacterium tumefaciens_ host will direct the insertion of the construct and adjacent marker into the plant cell DNA when the cell is infected by the bacteria. See, U.S. Pat. No. 5,591,616.

B. Transfection of Prokaryotes, Lower Eukaryotes, and Animal Cells

[0136] Animal and lower eukaryotic (e.g., yeast) host cells are competent or rendered competent for transfection by various means. There are several well-known methods of introducing DNA into animal cells. These include: calcium phos-
phate precipitation, fusion of the recipient cells with bacterial protoplasts containing the DNA, treatment of the recipient cells with liposomes containing the DNA, DEAE dextran, electroporation, biolistics and micro-injection of the DNA directly into the cells. The transfected cells are cultured by means well known in the art. Kucher, Biochemical Methods in Cell Culture and Virology, Dowden, Hutchinson and Ross, Inc. (1977).

Synthesis of Proteins

Purification of Proteins

[0138] The proteins of the present invention may be purified by standard techniques well known to those of skill in the art. Recombinantly produced proteins of the present invention can be directly expressed or expressed as a fusion protein. The recombinant protein is purified by a combination of cell lysis (e.g., sonication, French press) and affinity chromatography. For fusion products, subsequent digestion of the fusion protein with an appropriate proteolytic enzyme releases the desired recombinant protein.

[0139] The proteins of this invention, recombinant or synthetic, may be purified to substantial purity by standard techniques well known in the art, including detergent solubilization, selective precipitation with such substances as ammonium sulfate, column chromatography, immunopurification methods and others. See, for instance, Scopes, (1982) Protein Purification: Principles and Practice, Springer-Verlag: New York; Deutscher, (1990) Guide to Protein Purification, Academic Press. For example, antibodies may be raised to the proteins as described herein. Purification from E. coli can be achieved following procedures described in U.S. Pat. No. 4,511,503. The protein may then be isolated from cells expressing the protein and further purified by standard protein chemistry techniques as described herein. Detection of the expressed protein is achieved by methods known in the art and include, for example, radioimmunossays, Western blotting techniques or immunoprecipitation.

Transgenic Plant Regeneration

[0140] Transformed plant cells which are derived by any of the above transformation techniques can be cultured to regenerate a whole plant which possesses the transformed genotype. Such regeneration techniques often rely on manipulation of certain phytohormones in a tissue culture growth medium. For transformation and regeneration of maize, see, Gordon-Kamm, et al., (1990) The Plant Cell, 2:603-618.

[0141] Plants cells transformed with a plant expression vector can be regenerated, e.g., from single cells, callus tissue or leaf discs according to standard plant tissue culture techniques. It is well known in the art that various cells, tissues and organs from almost any plant can be successfully cultured to regenerate an entire plant. Plant regeneration from cultured protoplasts is described in Evans, et al., (1983) Protoplasts Isolation and Culture, Handbook of Plant Cell Culture, Macmillan Publishing Company, New York, pp. 124-176 and Binding, (1985) Regeneration of Plants, Plant Protoplasts, CRC Press, Boca Raton, pp. 21-73.

[0142] The regeneration of plants containing the foreign gene introduced by Agrobacterium from leaf explants can be achieved as described by Horsch, et al., (1985) Science, 227: 1229-1231. In this procedure, transformants are grown in the presence of a selection agent and in a medium that induces the regeneration of shoots in the plant species being transformed as described by Fraley, et al., (1983) Proc. Natl. Acad. Sci. (U.S.A.) 80:4803. This procedure typically produces shoots within two to four weeks and these transformant shoots are then transferred to an appropriate root-inducing medium containing the selective agent and an antibiotic to prevent bacterial growth. Transgenic plants of the present invention may be fertile or sterile.

[0144] One of skill will recognize that after the recombinant expression cassette is stably incorporated in transgenic plants and confirmed to be operable, it can be introduced into other plants by sexual crossing. Any of a number of standard breeding techniques can be used, depending upon the species to be crossed.

[0145] In vegetatively propagated crops, mature transgenic plants can be propagated by the taking of cuttings or by tissue culture techniques to produce multiple identical plants. Selection of desirable transgenics is made and new varieties are obtained and propagated vegetatively for commercial use. In seed propagated crops, mature transgenic plants can be self crossed to produce a homozygous inbred plant. The inbred plant produces seed containing the newly introduced heterologous nucleic acid. These seeds can be grown to produce plants that would produce the selected phenotype. Parts obtained from the regenerated plant, such as flowers, seeds, leaves, branches, fruit and the like are included in the invention, provided that these parts comprise cells comprising the isolated nucleic acid of the present invention. Progeny and variants and mutants of the regenerated plants are also included within the scope of the invention, provided that these parts comprise the introduced nucleic acid sequences.
genic plants expressing the selectable marker can be screened for transmission of the nucleic acid of the present invention by, for example, standard immunoblot and DNA detection techniques. Transgenic lines are also typically evaluated on levels of expression of the heterologous nucleic acid. Expression at the RNA level can be determined initially to identify and quantitate expression-positive plants. Standard techniques for RNA analysis can be employed and include PCR amplification assays using oligonucleotide primers designed to amplify only the heterologous RNA templates and Southern hybridization assays using heterologous nucleic acid-specific probes. The RNA-positive plants can then be analyzed for protein expression by Western immunoblot analysis using the specifically reactive antibodies of the present invention. In addition, in situ hybridization and immunocytochemistry according to standard protocols can be done using heterologous nucleic acid-specific polynucleotide probes and antibodies, respectively, to localize sites of expression within transgenic tissue. Generally, a number of transgenic lines are usually screened for the incorporated nucleic acid to identify and select plants with the most appropriate expression profiles.

[0146] A preferred embodiment is a transgenic plant that is homozygous for the added heterologous nucleic acid; i.e., a transgenic plant that contains two added nucleic acid sequences, one gene at the same locus on each chromosome of a chromosome pair. A homozygous transgenic plant can be obtained by sexually matting (selfing) a heterozygous transgenic plant that contains a single added heterologous nucleic acid, germinating some of the seed produced and analyzing the resulting plants produced for altered expression of a polynucleotide of the present invention relative to a control plant (i.e., native, non-transgenic). Back-crossing to a parental plant and out-crossing with a non-transgenic plant are also contemplated.

Modulating Polypeptide Levels and/or Composition

[0147] The present invention further provides a method for modulating (i.e., increasing or decreasing) the concentration or ratio of the polypeptides of the present invention in a plant or part thereof. Modulation can be effected by increasing or decreasing the concentration and/or the ratio of the polypeptides of the present invention in a plant. The method comprises introducing into a plant cell a recombinant expression cassette comprising a polynucleotide of the present invention as described above to obtain a transformed plant cell, culturing the transformed plant cell under plant cell growing conditions, and inducing or repressing expression of a polynucleotide of the present invention in the plant for a time sufficient to modulate concentration and/or the ratios of the polypeptides in the plant or plant part.

[0148] In some embodiments, the concentration and/or ratios of polypeptides of the present invention in a plant may be modulated by altering, in vivo or in vitro, the promoter of a gene to up- or down-regulate gene expression. In some embodiments, the coding regions of native genes of the present invention can be altered via substitution, addition, insertion, or deletion to decrease activity of the encoded enzyme. See, e.g., Kmiec, U.S. Pat. No. 5,565,350; Zalinger, et al., PCT/US93/03868. And in some embodiments, an isolated nucleic acid (e.g., a vector) comprising a promoter sequence is transfected into a plant cell. Subsequently, a plant cell comprising the promoter operably linked to a polynucleotide of the present invention is selected by means known to those of skill in the art such as, but not limited to, Southern blot, DNA sequencing or PCR analysis using primers specific to the promoter and to the gene and detecting amplicons produced therefrom. A plant or plant part altered or modified by the foregoing embodiments is grown under plant-forming conditions for a time sufficient to modulate the concentration and/or ratios of polypeptides of the present invention in the plant. Plant-forming conditions are well known in the art and discussed briefly, supra.

[0149] In general, concentration or the ratios of the polypeptides is increased or decreased by at least 5%, 10%, 20%, 30%, 40%, 50%, 60%, 70%, 80% or 90% relative to a native control plant, plant part or cell lacking the aforementioned recombinant expression cassette. Modulation in the present invention may occur during and/or subsequent to growth of the plant to the desired stage of development. Modulating nucleic acid expression temporally and/or in particular tissues can be controlled by employing the appropriate promoter operably linked to a polynucleotide of the present invention in, for example, sense or antisense orientation as discussed in greater detail, supra. Induction of expression of a polynucleotide of the present invention can also be controlled by exogenous administration of an effective amount of inducing compound. Inducible promoters and inducing compounds which activate expression from these promoters are well known in the art. In preferred embodiments, the polypeptides of the present invention are modulated in monocots, particularly maize.

UTRs and Codon Preference

[0150] In general, translational efficiency has been found to be regulated by specific sequence elements in the 5′ non-coding or untranslated region (5′ UTR) of the RNA. Positive sequence motifs include translational initiation consensus sequences (Kozak, (1987) Nucleic Acids Res. 15:8125) and the 7-methylguanosine cap structure (Drummond, et al., (1985) Nucleic Acids Res. 13:7375). Negative elements include stable intramolecular 5′ UTR stem-loop structures (Muesing et al., (1987) Cell 48:691) and AUG sequences or short open reading frames preceded by an appropriate AUG in the 5′ UTR (Kozak, supra, Rao, et al., (1988) Mol. and Cell. Biol. 8:284). Accordingly, the present invention provides 5′ and/or 3′ untranslated regions for modulation of translation of heterologous coding sequences.

[0151] Further, the polypeptide-encoding segments of the polynucleotides of the present invention can be modified to alter codon usage. Altered codon usage can be employed to alter translational efficiency and/or to optimize the coding sequence for expression in a desired host such as to optimize the codon usage in a heterologous sequence for expression in maize. Codon usage in the coding regions of the polynucleotides of the present invention can be analyzed statistically using commercially available software packages such as “Codon Preference” available from the University of Wisconsin Genetics Computer Group (see, Devereaux, et al., (1984) Nucleic Acids Res. 12:387-395) or MacVector 4.1 (Eastman Kodak Co., New Haven, Conn.). Thus, the present invention provides a codon usage frequency characteristic of the coding region of at least one of the polynucleotides of the present invention. The number of polynucleotides that can be used to determine a codon usage frequency can be any integer from 1 to the number of polynucleotides of the present invention as provided herein. Optionally, the polynucleotides will be full-length sequences. An exemplary number of sequences for statistical analysis can be at least 1, 5, 10, 20, 50 or 100.
Sequence Shuffling

[0152] The present invention provides methods for sequence shuffling using polynucleotides of the present invention and compositions resulting therefrom. Sequence shuffling is described in PCT Publication Number WO 1997/20078. See also, Zhang, et al., (1997) Proc. Natl. Acad. Sci. USA: 94:4504-4509. Generally, sequence shuffling includes the synthetic re-arrangement ("shuffling") of a part or parts of one or more allelic forms of the gene of interest. Libraries of recombinant polynucleotides are generated from a population of related sequence polynucleotides which comprise sequence regions which have substantial sequence identity and can be homologously recombined in vitro or in vivo. The population of sequence-recombined polynucleotides comprises a subpopulation of polynucleotides which possess desired or advantageous characteristics and which can be selected by a suitable selection or screening method. The characteristics can be any property or attribute capable of being selected for or detected in a screening system, and may include properties of: an encoded protein, a transcriptional element, a sequence affecting transcription, RNA processing, RNA stability, chromatin conformation, translation or other expression property of a gene or transgene, a replicative element, a protein-binding element, or the like, such as any feature which confers a selectable or detectable property. In some embodiments, the selected characteristic will be a decreased $K_{m}$ and/or increased $K_{a}$ over the wild-type protein as provided herein. In other embodiments, a protein or polynucleotide generated from sequence shuffling will have a lower binding affinity than the non-shuffled wild-type polynucleotide. The increase in such properties can be at least 110%, 120%, 130%, 140% or at least 150% of the wild-type value.

Generic and Consensus Sequences

[0153] Polynucleotides and polypeptides of the present invention further include those having: (a) a generic sequence of at least two homologous polynucleotides or polypeptides, respectively, of the present invention and (b) a consensus sequence of at least three homologous polynucleotides or polypeptides, respectively, of the present invention. The generic sequence of the present invention comprises each species of polynucleotide or polynucleotide embraced by the generic polypeptide or polynucleotide sequence, respectively. The individual species encompassed by a polynucleotide having an amino acid or nucleic acid consensus sequence can be used to generate antibodies or produce nucleic acid probes or primers to screen for homologs in other species, genera, families, orders, classes, phyla or kingdoms. For example, a polynucleotide having a consensus sequence from a gene family of Zea mays can be used to generate antibody or nucleic acid probes or primers to other Gramineae species such as wheat, rice or sorghum. Alternatively, a polynucleotide having a consensus sequence generated from orthologous genes can be used to identify or isolate orthologs of other taxa. Typically, a polynucleotide having a consensus sequence will be at least 9, 10, 15, 20, 25, 30 or 40 amino acids in length, or 20, 30, 40, 50, 100 or 150 nucleotides in length. As those of skill in the art are aware, a conservative amino acid substitution can be used for amino acids which differ amongst aligned sequence but are from the same conservative substitution group as discussed above. Optionally, no more than 1 or 2 conservative amino acids are substituted for each 10 amino acid length of consensus sequence.

[0154] Similar sequences used for generation of a consensus or generic sequence include any number and combination of allelic variants of the same gene, orthologous or paralogous sequences as provided herein. Optionally, similar sequences used in generating a consensus or generic sequence are identified using the BLAST algorithm's smallest sum probability (P(Ni)). Various suppliers of sequence-analysis software are listed in chapter 7 of Current Protocols in Molecular Biology, Ausibel et al., Eds., Current Protocols, a joint venture between Greene Publishing Associates, Inc. and John Wiley & Sons, Inc. (Supplement 30). A polynucleotide sequence is considered similar to a reference sequence if the smallest sum probability in a comparison of the test nucleic acid to the reference nucleic acid is less than about 0.1, more preferably less than about 0.01, or 0.001, and most preferably less than about 0.0001 or 0.00001. Similar polynucleotides can be aligned and a consensus or generic sequence generated using multiple sequence alignment software available from a number of commercial suppliers such as the Genetics Computer Group's (Madison, Wis.) PILEUP software, Vector NTI's (North Bethesda, Md.) ALIGNX, or Genecode's (Ann Arbor, Mich.) SEQUENCHEIR. Conveniently, default parameters of such software can be used to generate consensus or generic sequences.

Computer Applications

[0155] The present invention provides machines, data structures and processes for modeling or analyzing the polynucleotides and polypeptides of the present invention.

A. Machines and Data Structures

[0156] The present invention provides a machine having a memory comprising data representing a sequence of a polynucleotide or polypeptide of the present invention. The machine of the present invention is typically a digital computer. The memory of such a machine includes, but is not limited to, ROM or RAM or computer readable media such as, but not limited to, magnetic media such as computer disks or hard drives or media such as CD-ROM. Thus, the present invention also provides a data structure comprising a sequence of a polynucleotide of the present invention embodied in a computer readable medium. As those of skill in the art will be aware, the form of memory of a machine of the present invention or the particular embodiment of the computer readable medium is not a critical element of the invention and can take a variety of forms.

B. Homology Searches

[0157] The present invention provides a process for identifying a candidate homologue (i.e., an ortholog or paralog) of a polynucleotide or polypeptide of the present invention. A candidate homologue has statistically significant probability of having the same biological function (e.g., catalyzes the same reaction, binds to homologous proteins/nucleic acids) as the reference sequence to which it's compared. Accordingly, the polynucleotides and polypeptides of the present invention have utility in identifying homologs in animals or other plant species, particularly those in the family Gramineae such as, but not limited to, sorghum, wheat or rice.
[0158] The process of the present invention comprises obtaining data representing a polynucleotide or polypeptide test sequence. Test sequences are generally at least 25 amino acids in length or at least 50 nucleotides in length. Optionally, the test sequence can be at least 50, 100, 150, 200, 250, 300 or 400 amino acids in length. A test polynucleotide can be at least 50, 100, 200, 300, 400 or 500 nucleotides in length. Often the test sequence will be a full-length sequence. Test sequences can be obtained from a nucleic acid of an animal or plant. Optionally, the test sequence is obtained from a plant species other than maize whose function is uncertain but will be compared to the test sequence to determine sequence similarity or sequence identity; for example, such plant species can be of the family Gramineae, such as wheat, rice or sorghum. The test sequence data are entered into a machine, typically a computer, having a memory that contains data representing a reference sequence. The reference sequence can be the sequence of a polypeptide or a polynucleotide of the present invention and is often at least 25 amino acids or 100 nucleotides in length. As those of skill in the art are aware, the greater the sequence identity/similarity between a reference sequence of known function and a test sequence, the greater the probability that the test sequence will have the same or similar function as the reference sequence.

[0159] The machine further comprises a sequence comparison means for determining the sequence identity or similarity between the test sequence and the reference sequence. Exemplary sequence comparison means are provided for in sequence analysis software discussed previously. Optionally, sequence comparison is established using the BLAST or GAP suite of programs.

[0160] The results of the comparison between the test and reference sequences can be displayed. Generally, a smallest sum probability value (P(N)) of less than 0.1, or alternatively, less than 0.01, 0.001, 0.0001 or 0.00001 using the BLAST 2.0 suite of algorithms under default parameters identifies the test sequence as a candidate homologue (i.e., an allele, ortholog or paralog) of the reference sequence. A nucleic acid comprising a polynucleotide having the sequence of the candidate homologue can be constructed using well known library isolation, cloning or in vitro synthetic chemistry techniques (e.g., phosphoramidite) such as those described herein. In addition, in some embodiments, a nucleic acid comprising a polynucleotide having a sequence represented by the candidate homologue is introduced into a plant; typically, these polynucleotides are operably linked to a promoter. Confirmation of the function of the candidate homologue can be established by operably linking the candidate homolog nucleic acid to, for example, an inducible promoter or by expressing the antisense transcript and analyzing the plant for changes in phenotype consistent with the presumed function of the candidate homolog. Optionally, the plant into which these nucleic acids are introduced is a monocot such as from the family Gramineae. Exemplary plants include maize, sorghum, wheat, rice, canola, alfalfa, cotton and soybean.

C. Computer Modeling

[0161] The present invention provides a process of modeling/analyzing data representative of the sequence a polynucleotide or polypeptide of the present invention. The process comprises entering sequence data of a polynucleotide or polypeptide of the present invention into a machine, manipulating the data to model or analyze the structure or activity of the polynucleotide or polypeptide, and displaying the results of the modeling or analysis. A variety of modeling and analytic tools are well known in the art and available from such commercial vendors as Genetics Computer Group (Version 10, Madison, Wis.). Included amongst the modeling/analysis tools are methods to: 1) recognize overlapping sequences (e.g., from a sequencing project) with a polynucleotide of the present invention and create an alignment called a “contig”; 2) identify restriction enzyme sites of a polynucleotide of the present invention; 3) identify the products of a T1 ribonuclease digestion of a polynucleotide of the present invention; 4) identify PCR primers with minimal self-complementarity; 5) compare two protein or nucleic acid sequences and identifying points of similarity or dissimilarity between them; 6) compute pairwise distances between sequences in an alignment, reconstruct phylogenetic trees using distance methods, and calculate the degree of divergence of two protein coding regions; 7) identify patterns such as coding regions, terminators, repeats, and other consensus patterns in polynucleotides of the present invention; 8) identify RNA secondary structure; 9) identify sequence motifs, isoelectric point, secondary structure, hydrophobicity, and antigenicity in polypeptides of the present invention and 10) translate polynucleotides of the present invention and backtranslate polypeptides of the present invention.

Detection of Nucleic Acids

[0162] The present invention further provides methods for detecting a polynucleotide of the present invention in a nucleic acid sample suspected of containing a polynucleotide of the present invention, such as a plant cell lysate, particularly a lysate of maize. In some embodiments, a gene of the present invention or portion thereof can be amplified prior to the step of contacting the nucleic acid sample with a polynucleotide of the present invention. The nucleic acid sample is contacted with the polynucleotide to form a hybridization complex. The polynucleotide hybridizes under stringent conditions to a gene encoding a polypeptide of the present invention. Formation of the hybridization complex is used to detect a gene encoding a polypeptide of the present invention in the nucleic acid sample. Those of skill will appreciate that an isolated nucleic acid comprising a polynucleotide of the present invention should lack cross-hybridizing sequences in common with non-target genes that would yield a false positive result. Detection of the hybridization complex can be achieved using any number of well known methods. For example, the nucleic acid sample, or a portion thereof, may be assayed by hybridization formats including but not limited to, solution phase, solid phase, mixed phase or in situ hybridization assays.

[0163] Detectable labels suitable for use in the present invention include any composition detectable by spectroscopic, radioisotopic, photochemical, biochemical, immunochemical, electrical, optical or chemical means. Useful labels in the present invention include biotin for staining with labeled streptavidin conjugate, magnetic beads, fluorescent dyes, radiolabels, enzymes and colorimetric labels. Other labels include ligands which bind to antibodies labeled with fluorophores, chemiluminescent agents and enzymes. Labeling the nucleic acids of the present invention is readily achieved such as by the use of labeled PCR primers.

[0164] Although the present invention has been described in some detail by way of illustration and example for purposes
of clarity of understanding, it will be obvious that certain changes and modifications may be practiced within the scope of the appended claims.

EXAMPLES

Example 1

Construction of a cDNA Library

[0165] Total RNA can be isolated from maize tissues with TRIZol Reagent (Life Technology Inc. Gaithersburg, Md.) using a modification of the guanidine isothiocyanate/acid-phenol procedure described by Chomczynski and Sacchi (Chomczynski and Sacchi, (1987) Anal. Biochem. 162:156). In brief, plant tissue samples are pulverized in liquid nitrogen before the addition of the TRIZol Reagent and then further homogenized with a mortar and pestle. Addition of chloroform followed by centrifugation is conducted for separation of an aqueous phase and an organic phase. The total RNA is recovered by precipitation with isopropanol alcohol from the aqueous phase.

[0166] The selection of poly(A) RNA from total RNA can be performed using PolyAtract system (Promega Corporation, Madison, Wis.). Biotinylated oligo(dT) primers are used to hybridize to the 3' poly(A) tails on mRNA. The hybrids are captured using streptavidin coupled to paramagnetic particles and a magnetic separation stand. The mRNA is then washed at high stringency conditions and eluted by RNase-free deionized water.

[0167] cDNA synthesis and construction of unidirectional cDNA libraries can be accomplished using the SuperScript Plasmid System (Life Technology Inc. Gaithersburg, Md.). The first strand of cDNA is synthesized by priming an oligo(dT) primer containing a Not I site. The reaction is catalyzed by SuperScript Reverse Transcriptase II at 45° C. The second strand of cDNA is labeled with alpha-32PdCTP and a portion of the reaction is run on agarose gel electrophoresis to determine cDNA sizes. cDNA molecules smaller than 500 base pairs and unligated adapters are removed by Sephacryl-S400 chromatography. The selected cDNA molecules are ligated into pSPORT1 vector in between of Not I and Sal I sites.

[0168] Alternatively, cDNA libraries can be prepared by any one of many methods available. For example, the cDNAs may be introduced into plasmid vectors by first preparing the cDNA libraries in Uni-ZAP® XR vectors according to the manufacturer's protocol (Stratagene Cloning Systems, La Jolla, Calif.). The Uni-ZAP® XR libraries are converted into plasmid libraries according to the protocol provided by Stratagene. Upon conversion, cDNA inserts will be contained in the plasmid vector pBluescript. In addition, the cDNAs may be introduced directly into precut Bluescript SK(+) vectors (Stratagene) using T4 DNA ligase (New England Biolabs), followed by transfection into DH10B cells according to the manufacturer's protocol (GIBCO BRL Products). Once the cDNA inserts are in plasmid vectors, plasmid DNAs are prepared from randomly picked bacterial colonies containing recombinant pBluescript plasmids or the insert cDNA sequences are amplified via polymerase chain reaction using primers specific for vector sequences flanking the inserted cDNA sequences. Amplified insert DNAs or plasmid DNAs are sequenced in dye-primer sequencing reactions to generate partial cDNA sequences (expressed sequence tags or "ESTs").

Example 2

Construction of a Full-Length Enriched cDNA Library

[0169] An enriched full-length cDNA library can be constructed using one of two variations of the method of Carninci, et al., (1996) Genomics 37:327-336. These variations are based on chemical introduction of a biotin group into the dial residue of the 5' cap structure of eukaryotic mRNA to select full-length first strand cDNA. The selection occurs by trapping the biotin residue at the cap sites using streptavidine-coated magnetic beads followed by RNase I treatment to eliminate incompletely synthesized cDNAs. Second strand cDNA is synthesized using established procedures such as those provided in "Life Technologies'" (Rockville, Md.) "SuperScript Plasmid System for cDNA Synthesis and Plasmid Cloning" kit. Libraries made by this method have been shown to contain 50% to 70% full-length cDNAs.

[0170] The first strand synthesis methods are detailed below. An asterisk denotes that the reagent was obtained from Life Technologies, Inc.

A. First Strand cDNA Synthesis Method 1 (with Trehalose)

[0171] The mRNA and Not I primer are mixed and denatured at 65°C for 10 min. They are then chilled on ice and other components added to the tube. Incubation is at 45°C for 2 min. Twenty microliters of RT (reverse transcriptase) is added to the reaction and start program on the thermocycler (MJ Research, Waltham, Mass.):

C. Oxidization of the Diol Group of mRNA for Biotin Labeling

First strand cDNA is spun down and washed once with 70% EtOH. The pellet resuspended in 23.2 µl of DEPC treated water and put on ice. Prepare 100 mM of NaIO₄ freshly, and then add the following reagents:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>mRNA: 1st cDNA (start with 20 µg mRNA)</td>
<td>46.4 µl</td>

<td>2.5 µl</td>
</tr>
<tr>
<td>NaOAc 3M pH 4.5</td>
<td>1.1 µl</td>
</tr>
</tbody>
</table>

To make 100 mM NaIO₄, use 21.39 µg of NaIO₄ for 1 µl of water.

Wrap the tube in a foil and incubate on ice for 45 min.

After the incubation, the reaction is then precipitated in:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>5M NaCl</td>
<td>10 µl</td>
</tr>
<tr>
<td>20% SDS</td>
<td>0.5 µl</td>
</tr>
<tr>
<td>isopropanol</td>
<td>61 µl</td>
</tr>
</tbody>
</table>

Incubate on ice for at least 30 min, then spin it down at max speed at 4° C. for 30 min and wash once with 70% ethanol and then 80% EtOH.

D. Biotinylation of the mRNA Diol Group

Resuspend the DNA in 110 µl DEPC treated water, then add the following reagents:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>20% SDS</td>
<td>5 µl</td>
</tr>
<tr>
<td>2M NaOAc pH 6.1</td>
<td>5 µl</td>
</tr>
<tr>
<td>10 mM biotin hydrazide (freshly made)</td>
<td>300 µl</td>
</tr>
</tbody>
</table>

Wrap in a foil and incubate at room temperature overnight.

E. RNase I Treatment

Precipitate DNA in:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>5M NaCl</td>
<td>10 µl</td>
</tr>
<tr>
<td>2M NaOAc pH 6.1</td>
<td>75 µl</td>
</tr>
<tr>
<td>biotinylated mRNA/cDNA</td>
<td>420 µl</td>
</tr>
<tr>
<td>100% EtOH (2.5 V/s)</td>
<td>1262.5 µl</td>
</tr>
</tbody>
</table>

(Perform this precipitation in two tubes and split the 420 µl of DNA into 210 µl each, add 5 µl of 5M NaCl, 37.5 µl of 2M NaOAc pH 6.1 and 631.25 µl of 100% EtOH). Store at -20°C. for at least 30 min. Spin the DNA down at 4° C. at maximal speed for 30 min. and wash with 80% EtOH twice, then dissolve DNA in 70 µl RNase free water. Pool two tubes and end up with 140 µl.

Add the following reagents:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>RNase One 10 U/µl</td>
<td>40 µl</td>
</tr>
<tr>
<td>1st cDNA:RNA</td>
<td>140 µl</td>
</tr>
<tr>
<td>10X buffer</td>
<td>20 µl</td>
</tr>
</tbody>
</table>

Incubate at 37° C. for 15 min.

F. Full Length 1st cDNA Capturing

Blocking the beads with yeast tRNA:

<table>
<thead>
<tr>
<th>Reagent</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beads</td>
<td>1 ml</td>
</tr>
<tr>
<td>Yeast tRNA 40 µg/µl</td>

</tr>
</tbody>
</table>

Incubate on ice for 30 min with mixing. Wash 3 times with 1 ml of 2M NaCl, 50 mM EDTA, pH 8.0. Resuspend the beads in 800 µl of 2M NaCl, 50 mM EDTA, pH 8.0, add RNase I treated sample 200 µl, and incubate the reaction for 30 min at room temperature. Capture the beads using the magnetic stand, save the supernatant, and start following washes:

2 washes with 2M NaCl, 50 mM EDTA, pH 8.0, 1 ml each time,
1 wash with 0.4% SDS, 50 µg/ml tRNA,
1 wash with 10 mM Tris-Cl pH 7.5, 0.2 mM EDTA, 10 mM NaCl, 20% glycerol,
1 wash with 50 µg/ml tRNA,
1 wash with 1st cDNA buffer
G. Second Strand cDNA Synthesis

Resuspend the beads in:

<table>
<thead>
<tr>
<th>Component</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>5X first buffer</td>
<td>8 µl</td>
</tr>
<tr>
<td>0.1 mM DTT</td>

<td>2 µl</td>
</tr>
<tr>
<td>P32 dCTP 10 µCi/µl</td>
<td>2 µl</td>
</tr>
<tr>
<td>Or water up to 300 µl</td>
<td>208 µl</td>
</tr>
</tbody>
</table>

Incubate at 16°C for 2 hr with mixing the reaction in every 30 min.

Add 4 µl of T4 DNA polymerase and incubate for additional 5 min at 16°C.

Elute 2nd cDNA from the beads.

Use a magnetic stand to separate the 2nd cDNA from the beads, then resuspend the beads in 200 µl of water and then resuspend again, pool the samples (about 500 µl).

Add 200 µl of water to the beads, then 200 µl of phenol: chloroform, vortex and spin to separate the sample with phenol.

Pool the DNA together (about 700 µl) and use phenol to clean the DNA again. DNA is then precipitated in 2 µg of glycogen and 0.5 vol of 7.5M NH4OAc and 2 vol of 100% EtOH. Precipitate overnight. Spin down the pellet and wash with 70% EtOH, air-dry the pellet.

H. Sal I adapter ligation

Resuspend the pellet in 26 µl of water and use 1 µl for TAE gel.

Set up reaction as following:

<table>
<thead>
<tr>
<th>Component</th>
<th>Volume</th>
</tr>
</thead>
<tbody>
<tr>
<td>2nd strand cDNA</td>
<td>25 µl</td>
</tr>
<tr>
<td>5X T4 DNA ligase buffer</td>

precipitate at -20°C overnight

Spin down the pellet at 4°C and wash in 70% EtOH, dry the pellet.

I. Not 1 Digestion

Mix gently and incubate the reaction at 37°C for 2 hr.

Add 50 µl of water and 100 µl of phenol, vortex, and take 90 µl of the upper phase to a new tube, then add 50 µl of NH4OAc and 300 µl of EtOH. Precipitate overnight at -20°C.

Cloning, ligation and transformation are performed per the Superscript cDNA synthesis kit.

Example 3
cDNA Sequencing and Library Subtraction

Individual colonies can be picked and DNA prepared either by PCR with M13 forward primers and M13 reverse primers, or by plasmid isolation. cDNA clones can be sequenced using M13 reverse primers.

cDNA libraries are plated out on 22 x 22 cm2 agar plate at density of about 3,000 colonies per plate. The plates are incubated in a 37°C incubator for 12-24 hours. Colonies are picked into 384-well plates by a robot colony picker, Q-bot (GENETIX Limited). These plates are incubated overnight at 37°C. Once sufficient colonies are picked, they are pinned onto 22 x 22 cm2 nylon membranes using Q-bot. Each membrane holds 5,216 or 36,864 colonies. These membranes are placed onto an agar plate with an appropriate antibiotic. The plates are incubated at 37°C overnight.

After colonies are recovered on the second day, these filters are placed on filter paper prewetted with denaturing solution for four minutes, then incubated on top of a boiling water bath for an additional four minutes. The filters are then placed on filter paper prewetted with neutralizing solution for four minutes. After excess solution is removed by placing the filters on dry filter papers for one minute, the colony side of the filters is placed into Proteinase K solution, incubated at 37°C for 40-50 minutes. The filters are placed on dry filter papers to dry overnight. DNA is then cross-linked to nylon membrane by UV light treatment.

Colony hybridization is conducted as described by Sambrook, Frisch and Maniatis, (in Molecular Cloning: A Laboratory Manual, 2nd Edition). The following probes can be used in colony hybridization:

1. First strand cDNA from the same tissue as the library was made from to remove the most redundant clones.
2. 48-192 most redundant cDNA clones from the same library based on previous sequencing data.
3. 192 most redundant cDNA clones in the entire maize sequence database.
4. A Sal-A20 oligo nucleotide: SEQ ID NO: 15: TCG ACC CAC GGC TCC GAA AAA AAA AAA AAA AAA AAA removes clones containing a poly A tail but no cDNA.
5. cDNA clones derived from rRNA.

The image of the autoradiogram is scanned into computer and the signal intensity and cold colony addresses for each colony is analyzed. Re-arraying of cold-colonies from 384 well plates to 96 well plates is conducted using Q-bot.
Example 4

Identification of the gene from a computer homology search

[0189] Gene identities can be determined by conducting BLAST (Basic Local Alignment Search Tool; Altschul et al., 1997 J. Mol. Biol. 215:403-410; searches under default parameters for similarity to sequences contained in the BLAST “nr” database (comprising all non-redundant GenBank CDS translations, sequences derived from the 3-dimensional structure Brookhaven Protein Data Bank, the last major release of the SWISS-PROT protein sequence database, EMBL, and DDBJ databases). The cDNA sequences are analyzed for similarity to all publicly available DNA sequences contained in the “nr” database using the BLASTN algorithm. The DNA sequences are translated in all reading frames and compared for similarity to all publicly available protein sequences contained in the “nr” database using the BLASTX algorithm (Gish and States, 1993 Nature Genetics 3:266-272) provided by the NCBI. In some cases, the sequencing data from two or more clones containing overlapping segments of DNA are used to construct contiguous DNA sequences.

[0190] Sequence alignments and percent identity calculations can be performed using the Megalign program of the LASERGENE bioinformatics computing suite (DNASTAR Inc., Madison, Wis.). Multiple alignment of the sequences can be performed using the Clustal method of alignment (Higgins and Sharp, 1989 CABIOS 5:151-153) with the default parameters (GAP PENALTY=10, GAP LENGTH PENALTY=10). Default parameters for pairwise alignments using the Clustal method are KTUPLE=1, GAP PENALTY=3, WINDOW=5 and DIAGONALS SAVED=5.

Example 5

Expression of transgenes in monocot cells

[0191] A transgene comprising a cDNA encoding the instant polypeptides in sense orientation with respect to the maize 27 kDa zein promoter that is located 5' to the cDNA fragment and the 10 kDa zein 3' end that is located 3' to the cDNA fragment, can be constructed. The cDNA fragment of this gene may be generated by polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites (Neor or SmaI) can be incorporated into the oligonucleotides to provide proper orientation of the DNA fragment when inserted into the digested vector pML103 as described below. Amplification is then performed in a standard PCR. The amplified DNA is then digested with restriction enzymes Neor and SmaI and fractionated on an agarose gel. The appropriate band can be isolated from the gel and combined with a 4.9 kb Neor-SmaI fragment of the plasmid pML103. Plasmid pML103 has been deposited under the terms of the Budapest Treaty at ATCC (American Type Culture Collection, 10801 University Blvd., Manassas, Va. 20110-2209) and bears accession number ATCC 97366. The DNA segment from pML103 contains a 1.05 kb SalI-Neor promoter fragment of the maize 27 kDa zein gene and a 0.96 kb SmaI-SalI fragment from the 3' end of the maize 10 kDa zein gene in the vector pGemZf(+) (Promega). Vector and insert DNA can be ligated at 15°C overnight, essentially as described (Maniatis). The ligated DNA may then be used to transform E. coli XL1-Blue (Epicurian Coli XL-1 Blue; Stratagene). Bacterial transformants can be screened by restriction enzyme digestion of plasmid DNA and limited nucleotide sequence analysis using the dyeoxygen chain termination method (Sequenase DNA Sequencing Kit; US Biochemical). The resulting plasmid construct would comprise a transgene encoding, in the 5' to 3' direction, the maize 27 kDa zein promoter, a cDNA fragment encoding the instant polypeptides and the 10 kDa zein 3' region.

[0192] The transgene described above can then be introduced into maize cells by the following procedure. Immature maize embryos can be dissected from developing caryopses derived from crosses of the inbred maize lines H99 and LH132. The embryos are isolated 10 to 11 days after pollination when they are 1.0 to 1.5 mm long. The embryos are then placed with the axis-side facing down and in contact with agarose-solidified N6 medium (Chu et al., 1975 Sci. Sin. Peking 18:659-668). The embryos are kept in the dark at 27°C. Friable embryogenic callus consisting of undifferentiated masses of cells with somatic proembryoids and embryoids borne on suspensor structures proliferates from the scutellum of these immature embryos. The embryogenic callus isolated from the primary explant can be cultured on N6 medium and sub-cultured on this medium every 2 to 3 weeks.

[0193] The plasmid, p355S/Ac (Hoechst AG, Frankfurt, Germany) or equivalent may be used in transformation experiments in order to provide for a selectable marker. This plasmid contains the Pat gene (see, European Patent Publication 0 242 236) which encodes phosphinothricin acetyl transferase (PAT). The enzyme PAT confers resistance to herbicidal glutamine synthetase inhibitors such as phosphinothricin. The put gene in p355S/Ac is under the control of the 3SS promoter from Cauliflower Mosaic Virus (Odell et al., 1985 Nature 313:810-812) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of Agrobacterium tumefaciens.

[0194] The particle bombardment method (Klein et al., 1987 Nature 327:70-73) may be used to transfer genes to the callus culture cells. According to this method, gold particles (1 µm in diameter) are coated with DNA using the following technique. Ten µg of plasmid DNAs are added to 50 µL of a suspension of gold particles (60 mg per mL). Calcium chloride (50 µL of a 2.5 M solution) and spermidine free base (20 µL of a 1.0 M solution) are added to the particles. The suspension is vortexed during the addition of these solutions. After 10 minutes, the tubes are briefly centrifuged (5 sec at 15,000 rpm) and the supernatant removed. The particles are resuspended in 200 µL of absolute ethanol, centrifuged again and the supernatant removed. The ethanol rinse is performed again and the particles resuspended in a final volume of 30 µL of ethanol. An aliquot (5 µL) of the DNA-coated gold particles can be placed in the center of a Kapton flying disc (Bio-Rad Labs). The particles are then accelerated into the maize tissue with a Biolistic BDS-1000/He (Bio-Rad Instruments, Hercules Calif.), using a helium pressure of 1000 psi, a gap distance of 0.5 cm and a flying distance of 1.0 cm.

[0195] For bombardment, the embryogenic tissue is placed on filter paper over agarose-solidified N6 medium. The tissue is arranged as a thin lawn and covers a circular area of about 5 cm in diameter. The petri dish containing the tissue can be placed in the chamber of the BDS-1000/He approximately 8 cm from the stopping screen. The air in the chamber is then evacuated to a vacuum of 28 inches of Hg. The macrocarrier
is accelerated with a helium shock wave using a rupture membrane that bursts when the He pressure in the shock tube reaches 1000 psi.

[0196] Seven days after bombardment the tissue can be transferred to N6 medium that contains glufosinate (2 mg per liter) and lacks casein or proline. The tissue continues to grow slowly on this medium. After an additional 2 weeks the tissue can be transferred to fresh N6 medium containing glufosinate. After 6 weeks, areas of about 1 cm in diameter of actively growing callus can be identified on some of the plates containing the glufosinate-supplemented medium. These calli may continue to grow when sub-cultured on the selective medium.

[0197] Plants can be regenerated from the transgenic callus by first transferring clusters of tissue to N6 medium supplemented with 0.2 mg per liter of 2,4-D. After two weeks the tissue can be transferred to regeneration medium (Fromm, et al., (1990) Bio/Technology 8:833-839).

Example 6

Expression of Transgenes in Dicot Cells

[0198] A seed-specific expression cassette composed of the promoter and transcription terminator from the gene encoding the β subunit of the seed storage protein phascolin from the bean Phaseolus vulgaris (Doyle, et al., (1986) J. Biol. Chem. 261:9228-9238) can be used for expression of the instant polypeptides in transformed soybean. The phascolin cassette includes about 500 nucleotides upstream (5') from the translation initiation codon and about 1650 nucleotides downstream (3') from the translation stop codon of phascolin. Between the 5' and 3' regions are the unique restriction endonuclease sites Neo I (which includes the ATG translation initiation codon), Smal, Kpnl and Xbal. The entire cassette is flanked by Hind III sites.

[0199] The cDNA fragment of this gene may be generated by polymerase chain reaction (PCR) of the cDNA clone using appropriate oligonucleotide primers. Cloning sites can be incorporated into the oligonucleotides to provide proper orientation of the DNA fragment when inserted into the expression vector. Amplification is then performed as described above, and the isolated fragment is inserted into a pUC18 vector carrying the seed expression cassette.

[0200] Soybean embryos may then be transformed with the expression vector comprising sequences encoding the instant polypeptides. To induce somatic embryos, cotyledons, 3-5 mm in length dissected from surface sterilized, immature seeds of the soybean cultivar A2872, can be cultured in the light or dark at 26°C on an appropriate agar medium for 6-10 weeks. Somatic embryos, which produce secondary embryos are then excised and placed into a suitable liquid medium. After repeated selection for clusters of somatic embryos, which multiplied as early, globular staged embryos, the suspensions are maintained as described below.

[0201] Soybean embryogenic suspension cultures can be maintained in 35 mL liquid media on a rotary shaker, 150 rpm, at 26°C, with fluorescent lights on a 16:8 hour day/night schedule. Cultures are subcultured every two weeks by inoculating approximately 35 mg of tissue into 35 mL of liquid medium.

[0203] A selectable marker gene which can be used to facilitate soybean transformation is a transgene composed of the 35S promoter from Cauliflower Mosaic Virus (Odell, et al., (1985) Nature 313:810-812), the hygromycin phosphotransferase gene from plasmid pJR225 (from E. coli; Griz, et al., (1983) Gene 25:179-188) and the 3' region of the nopaline synthase gene from the T-DNA of the Ti plasmid of Agrobacterium tumefaciens. The seed expression cassette comprising the phascolin 5' region, the fragment encoding the instant polypeptides and the phascolin 3' region can be isolated as a restriction fragment. This fragment can then be inserted into a unique restiction site of the vector carrying the marker gene.

[0204] To 50 µL of a 60 mg/mL 1 µg/mL gold particle suspension is added (in order): 5 µL DNA (1 µg/µL), 20 µL spermidine (0.1 M) and 50 µL CaCl₂ (2.5 M). The particle preparation is then agitated for three minutes, spun in a microfuge for 10 seconds and the supernatant removed. The DNA-coated particles are then washed once in 400 µL 70% ethanol and resuspended in 40 µL of anhydrous ethanol. The DNA/particle suspension can be sonicated three times for one second each. Five microliters of the DNA-coated gold particles are then loaded on each macro carrier disk.

[0205] Approximately 300-400 mg of a two-week-old suspension culture is placed in an empty 60x15 mm petri dish and the residual liquid removed from the tissue with a pipette. For each transformation experiment, approximately 5-10 plates of tissue are normally bombarded. Membrane rupture pressure is set at 1100 psi and the chamber is evacuated to a vacuum of 28 inches mercury. The tissue is placed approximately 3.5 inches away from the returning screen and bombarded three times. Following bombardment, the tissue can be divided in half and placed back into liquid and cultured as described above.

[0206] Five to seven days post bombardment, the liquid media may be exchanged with fresh media and eleven to twelve days post bombardment with fresh media containing 50 mg/mL hygromycin. This selective media can be refreshed weekly. Seven to eight weeks post bombardment, green, transformed tissue may be observed growing from untransformed, necrotic embryogenic clusters. Isolated green tissue is removed and inoculated into individual flasks to generate new, clonally propagated, transformed embryogenic suspension cultures. Each new line may be treated as an independent transformation event. These suspensions can then be subcultured and maintained as clusters of immature embryos or regenerated into whole plants by maturation and germination of individual somatic embryos.

Example 7

Expression of a Transgene in Microbial Cells

[0207] The cDNAs encoding the instant polypeptides can be inserted into the T7 E. coli expression vector pBT430. This vector is a derivative of pET-3a (Rosenberg, et al., (1987) Gene 56:125-135) which employs the bacteriophage T7 RNA polymerase/T7 promoter system. Plasmid pBT430 was constructed by first destroying the EcoRI 1 and Hind III sites in pET-3a at their original positions. An oligonucleotide adaptor containing EcoRI 1 and Hind III sites was inserted at the BamHI site of pET-3a. This created pET-3aM with additional unique cloning sites for insertion of genes into the expression vector.
Then, the Nde I site at the position of translation initiation was converted to an Neo I site using oligonucleotide-directed mutagenesis. The DNA sequence of pET-3aM in this region, 5'-CATATGG, was converted to 5'-CCCATGG in pBT430.

[0208] Plasmid DNA containing a cDNA may be appropriately digested to release a nucleic acid fragment encoding the protein. This fragment may then be purified on a 1% NuSieve GTG low melting agarose gel (FMC). Butler and agarose contain 10 μg/ml ethidium bromide for visualization of the DNA fragment. The fragment can then be purified from the agarose gel by digestion with Gelase (Epicentre Technologies) according to the manufacturer’s instructions, ethanol precipitated, dried and resuspended in 20 μL of water. Appropriate oligonucleotide adapters may be ligated to the fragment using T4 DNA ligase (New England Biolabs, Beverly, Mass.). The fragment containing the ligated adapters can be purified from the excess adapters using low melting agarose as described above. The vector pBT430 is digested, dephosphorylated with alkaline phosphatase (NEB) and deproteinized with phenol/chloroform as described above. The prepared vector pBT430 and fragment can then be ligated at 16°C for 15 hours followed by transformation into DH5 electrocompetent cells (GIBCO BRL). Transformants can be selected on agar plates containing LB media and 100 μg/mL ampicillin. Transformants containing the gene encoding the instant polypeptides are then screened for the correct orientation with respect to the T7 promoter by restriction enzyme analysis.

[0209] For high level expression, a plasmid clone with the cDNA inserted in the correct orientation relative to the T7 promoter can be transformed into E. coli strain BL21(DE3) (Studier, et al., (1986) J. Mol. Biol. 189:113-130). Cultures are grown in LB medium containing ampicillin (100 μg/mL) at 25°C. At an optical density of 600 nm of approximately 1, IPTG (isopropyl-β-D-galactoside, the inducer) can be added to a final concentration of 0.4 mM and incubation can be continued for 3 h at 25°C. Cells are then harvested by centrifugation and re-suspended in 50 μL of 50 mM Tris-HCl at pH 8.0 containing 0.1 mM DTT and 0.2 mM phenyl methyl sulfonyl fluoride. A small amount of 1 mm glass beads can be added and the mixture sonicated 3 times for about 5 seconds each time with a microprobe sonicator. The mixture is centrifuged and the protein concentration of the supernatant determined. One microgram of protein from the soluble fraction of the culture can be separated by SDS-polyacrylamide gel electrophoresis. Gels can be observed for protein bands migrating at the expected molecular weight.

Example 8

Phylogenetic Analysis of MADS Box Proteins Encoded by Maize Genes—FTM1, 2, 3 and SVP1, 2, 3

[0210] A phylogenetic analysis of the FTM and SVP proteins was made using Genetics Computer Group’s (Madison, Wis.) PILEUP software, Vector NTI’s (North Bethesda, Md.) ALIGNX. Various suppliers of sequence-analysis software are listed in chapter 7 of Current Protocols in Molecular Biology, Ausubel et al., et al., Eds., Current Protocols, a joint venture between Greene Publishing Associates, Inc. and John Wiley & Sons, Inc. (Supplement 50). These methods allow similar polynucleotides to be aligned and a consensus or generic sequence generated using the multiple sequence alignment software. The phylogenetic analysis of the MADS box genes is found in FIG. 1.

[0211] MADS-box genes belong to a family of regulatory genes that possess a characteristic DNA binding domain, MADS-box. Members of this gene family display primarily floral-specific expression and play important roles in plant development. Phylogenetic analysis demonstrates that members of the plant MADS-box gene family are organized into a dozen distinct gene groups (clades), which reflect the true phylogeny of the MADS box gene families and their functional similarity (Theissen, et al., (1996) J Mol Evol. 43:484-516). Phylogenetic analysis of novel MADS box genes, SVP’s and FTM’s delimits them into three separate clades, SQUAMOSA-like (FTM1,2), AGL2-like (FTM3), and SVP-like (SVP1,2,3) (FIG. 1).

[0213] FTM3 belongs to the agl2 (agamous-like 2) Glade. The function of this group is less defined and very divergent. Potential activities as mediators between the floral meristem and floral organ identity genes (Theissen, et al., (1996) J Mol Evol. 43:484-5160) are probable. FTM3 gene is highly expressed in silks, suggesting its possible role in silk development.

[0214] SVP genes form a clear Glade with the Arabidopsis SVP gene (Hartmann, et al., (2000) Plant Journal 21:351-360) and agl124 genes (agamous-like 24) (Yu, et al., (2002) PNAS 99:16336-16341). The SVP gene is a dosage dependent repressor of flowering in arabidopsis. AGL24 gene works in an opposite manner, as a dosage dependent mediator of flowering in arabidopsis (Yu, et al., (2002) PNAS 99:16336-16341). Thus members of the SVP Glade control flowering time in arabidopsis. Maize SVP 1, 2, 3 genes demonstrate a pattern of expression similar to the arabidopsis SVP genes, such as expression in vegetative tissues and absence of expression in the generative tissues. The shared evolutionary history, which appears to reflect distinct functional roles of MADS families in flower development, supports the function of SVP genes as negative regulators and FTM genes as positive regulators of flowering time in maize.

Example 9

Expression of FTM and SVP Genes in Different Plant Tissues

messages. The MPSS profiling database is searchable by BLAST to identify gene specific 17-mer tags.

TABLE 1

<table>

</tbody>
</table>

The distribution pattern of TAGs was analyzed across different plant tissues, which represent all organs of the corn plant. All SVP genes have a very similar pattern of expression (FIG. 2). They are expressed in all vegetative tissues, including leaves, roots, stems, stalks, seedlings and the shoot apical meristem before the floral transition. SVP TAGs are not detected in reproductive tissues, such as ears, silk, tassels or kernels. Transcription of SVP genes is reduced by 3-8 times in the shoot apical meristems (SAM) after switching to reproductive development. During further meristem development into inflorescence, transcription of SVP genes is reduced to a non-detectable level. These results were confirmed by RT-PCR. The SVP gene expression pattern is similar to the expression pattern of the Arabidopsis SVP gene, which is a repressor of flowering (Hartmann, et al., (2000) Plant J. 21:351-360). Expression patterns of maize SVP genes are consistent with their function as flowering repressors.

Expression patterns of FTM genes are opposite of SVP genes. FTM TAG distributions in the LYNX database indicate that FTM genes are expressed in reproductive, not vegetative tissues (FIG. 2). TAGs are not detected in seedlings, leaves and the shoot apical meristem. A low level of expression is found in root and stalk meristems, suggesting that FTM genes may be active in different meristem tissues. In the shoot apical meristem there are no TAGs for FTM genes, but they appeared sharply in the early stages of the floral transition. RT-PCR demonstrates a low level expression of FTMs in the shoot apical meristems before the transition, and significant activation during and after the transition, to reproductive development of the meristem. The FTM3 gene is more active in silks, which suggests its role in silk development. Expression patterns of maize FTM genes are consistent with their function as flowering activators.

Genomic Sequences of Maize FTM1, 2, 3 and SVP1, 2, 3 Genes

Genomic sequences of FTM-SVP genes were obtained by screening BAC (bacterial artificial chromosome) libraries with inserts of EST's SEQ ID NO: 1, 3, 5, 7, 9. BAC's were sequenced by a shot-gun approach at DuPont sequencing facilities. Genomic structures are shown in FIGS. 3 and 4. The gene sizes range from 6.9-10.1 kb, which are average for plant genes (FIG. 3). Genomic structures of SVP1 and 2 genes are very similar, comprised of 8 exons and 7 introns (FIG. 3). Overall genomic sequences of these two genes across exons and introns share greater than 70% homology, which indicates that they are recently duplicated genes in the maize genome. The SVP3 gene structure is significantly different and shows no nucleotide homology to SVP1 and 2. Nevertheless, at the amino acid levels those proteins share common domains and phylogenetically are very closely related.

All three FTM genes are composed of 8 exons of identical size, which produce cDNA of 1.4-1.5 kb (FIG. 4). Overall FTM1 and FTM2 genomic sequences across exons and introns share greater than 70% homology, indicating that they are recently duplicated genes in the maize genome. However the entire sizes of the gene regions including introns are 41 kb for FTM1; 20.5 kb for FTM2; and 10 kb for FTM3 (FIG. 4). FTM genes are exceptionally large among known plant genes. These huge sizes are created by the 1st and 2nd introns, which range from 10 kb up to 30 kb. Exons 3 through 8 are divided by small introns 100-200 nt long. These unusual genomic structures suggest that 1st and 2nd introns are involved in regulation of MADS FTM gene expression. Most likely, they play a role in repression of the FTM genes at the vegetative stage through epigenetic silencing.

Inactivation of FTM1, 2 and SVP2, 3 Genes by the Mutator Transposon Insertions

As a method of confirming the function of FTM and SVP genes in flowering time, each genes inactivation was achieved. Pioneer proprietary system TUSC (Trait Utility System for Corn) was used to screen FTM and SVP genes disrupted by the Mutator transposable element insertion. F2 families segregating for the Mutator insertions were screened by PCR with the Mu specific primer (SEQ ID NO: 22) and
gene specific primers SEQ ID NO: 23, 24, 25 and 26. Positive signals were found for the Mutator insertions in FTM1, FTM2, SVP2, SVP3. No TUSC alleles were found for the SVP1 gene. Mu insertion sites were identified by sequencing PCR products. Results are summarised in Table 3. All the genes have at least one Mu insertion into protein-coding exons, which should produce the gene knock-outs.

Example 13

Inactivation of FTM3 Genes by the Mutator Transposon Insertions

To investigate the function of FTM1, 2, 3 and SVP1, 2, 3 in the floral transition expression, analysis by quantitative RT-PCR (QRT-PCR) was conducted on RNA samples isolated from the shoot apical meristems and immature leaves. These tissues are important in determining flowering time. Immature leaves are responsible for generating the flowering-inducing signal flower (Colasanit, et al., (1998) Cell 93: 593-603). The shoot apical meristem is the organ where transition from the vegetative to reproductive development occurs. Tissues were collected from the greenhouse grown seedlings at 7 days after germination through the floral transition and up to one week after flowering. Three genetic backgrounds were used: wild type (a public line B73), flowering mutants ID1 (indeterminate 1) and dlf (delay flowering). QRT-PCR analyses were set up for each gene with gene-specific primers using the maize ubiquitin gene for normalization. FTM1 and 2 sequences were found to be quite closely related, therefore their expression was tested with the same set of primers. The FTM3 sequence is different from FTM1 and 2, so individual primers were developed for this gene. FTM1, 2 and 3 are expressed in the SAM at the basal level during vegetative stages but their transcription level increases sharply during the transition and declines a week later following the transition from vegetative to reproductive development. The correlation between the level of FTM1, 2 and 3 gene expression suggests that they are positive regulators (activators) of flowering time in maize. However, the function of the FTM3 gene may be different than FTM1 and 2 because they belong to different clades of MADS genes (see, Example 8). Also FTM3 is expressed more strongly during the vegetative stage. FTM1, 2 and 3 genes are expressed in the immature leaves in a similar manner, being at a low level of expression at the vegetative stage and then activated sharply during the floral transition. However, the expression stays at high level after the floral transition in the immature and green leaves, suggesting their contribution to the formation of adult leaf tissues. FTM1 and 2 are not transcribed in the immature leaves of the late flowering mutant comprising ID1. ID1 is a DNA binding protein that expressed in the immature leaves, controlling the production of the "putative" flowering (Colasanit,
et al., (1998) Cell 93:593-603). The loss of FTM1 and 2 transcription in the ID1 mutant indicated that FTM1 and 2 are downstream from the ID1 gene in the same flowering pathway.

**0225**  SVP1, 2 and 3 genes show the distinct pattern of expression in the SAM and immature leaves. SVP1 and SVP3 genes are expressed in both tissues during the vegetative stage and decline sharply during and after the floral transition. They show no difference in the mutant backgrounds. This pattern of expression is consistent with their role as the repressors of flowering, working upstream of ID1 and DLF. However, the duplicate gene, SVP2 showed a pattern of expression similar to FTM1 and 2, being at the low level during the vegetative stage and increasing sharply during the floral transition. This pattern is more consistent with SVP2s role as an activator of flowering.

**Example 15**

In Situ Hybridization of FTM1, 2, 3 and SVP1, 2, 3 Genes

**0226** In situ localization of FTM 1, 2 and 3 transcripts was performed on the male inflorescence tissues (tassel primordial) at seedling stage V5-6 just after the floral transition. FTM1 and FTM2 transcripts showed signals evenly distributed across the rib zone of the primordial central spike (rachis). No signal was detected in the central zone of the apical meristem or in the lateral branches. Some signal was detected in the surrounding emerging leaves. These data suggest that the FTM1 and 2 function may be associated with switching development programs from leaf formation to initiation of floral formation. The FTM1 and 2 function most likely as flowering-time genes. In situ localization of FTM3 transcripts showed that FTM3 was expressed in the central zone of all tassel meristems, including the main inflorescence meristems, spikelet pair meristems and branch meristems. Strong signals were detected in the vascular stems of the central spike. Weak signals were seen in the immature leaves surrounding young tassels. Because the central zone of the meristems contains pluripotent stem cells, these data suggest that FTM3 plays a role in meristem maintenance.

**0227** In situ localization of SVP1, 2, and 3 transcripts was performed on the shoot apical meristem at seedling V3-V4 stages, before the floral transition. SVP1 signals were detected in the peripheral zone of the SAM mostly in the zone of leaf initiation. There was very little signal in the immature leaves. The SVP2 gene has a similar pattern, but overall it is much stronger and more significant in the leaf primordia and immature leaves. Neither SVP1 nor SVP2 were expressed in the central zone of the SAM. These data suggest the genes role in the fate of organ determination. SVP3 transcripts showed a different pattern from SVP1 and 2. SVP3 is expressed in the whole zone of the SAM, including the central, peripheral and rib zones and in leaf primordia and emerging immature leaves. The expression pattern suggests that SVP1 and 2 and SVP3 play a distinct role in the floral transition.

**Example 16**

Over Expression of FTM2 and SVP1 and 2 in Transgenic Plants

**0228** Transgenic plants over-expressing FTM2, SVP1 and SVP2 genes were produced according to standard procedures for Agrobacterium transformation, (see, U.S. Pat. No. 5,591,616.) The associated data is presented in FIG. 5. cDNA were constitutively expressed under the UBQ10QTIN promoter. The transition from vegetative to reproductive development can be measured by the number of leaves that plant produced at the maturity of the plant. Early flowering plants produce less leaves than later flowering plants (Koornneef, et al., (1998) A. Rev. Plant. Physiol. Plant Mol. Biol 49:345-370). FTM2 and SVP1 transgenic plants produced (on average) 2 leaves less than SVP2 transgenic plants. A leaf number analysis indicated FTM2 and SVP1 genes contribute to early flowering. However, FTM2 had stronger effects on flowering than SVP2, because FTM2 transgenics began shedding (pollen production) and silking a week earlier (on average) than SVP2 plants. The FTM2 and SVP1 transgenic plants did not show any phenotypic abnormalities. They produced normal ears and tassels suggesting that ectopic expression of FTM2 and SVP1 MADS box genes did not change meristem identity but changed only the flowering time. These two genes may be considered as flowering time genes with distinct functions: FTM2 as an activator and SVP1 as a repressor of the floral transition. Ectopic expression of SVP2 caused abnormalities in ears and tassels, which can be described as changing the organ identity. Some spikelets on the tassels were converted into female gametophytes, which produced silking ovules, that were fertile and produced kernels after pollination. Multiple ears (up to 4) emerged from the same lateral bud. Glumes surrounding ovules were overgrown and greenish, making ears with a vegetative appearance. The SVP2 gene may be characterized functionally as the flower-meristem identity gene.

**Example 17**

Chemically Regulated Floral Transition—a Method to Create Programmable Plants

**0229** Floral transition is an important agronomic trait affecting the time a plant sheds pollen and silks production, which influences crop yields. The floral transition results from the integration of endogenous and environmental signals. A chemically regulated system that controls the switch from vegetative to reproductive development can optimize flowering time for specific environmental conditions during particular growing seasons. For example, farmers can control the floral transition, thereby determining whether increased grain yields or silage-quality plants are produced, depending upon specific weather conditions of a particular year. Such a system may be designed using the FTM1 and FTM2 genes, which are major activators of flowering in corn, under a chemically inducible expression system. A number of chemically inducible systems are known in plants (reviewed in Inducible Gene Expression in Plants (1999) Reynolds, PHS (ed), CAB International Publishing Wallingford, Oxfordshire, Unger, et al., (2002) Transgenic Research 11:455-465 describe an inducible expression system (VGECR) for corn, successfully tested in the green house and in the field with reproducible results. Based on the VGECR system, an inducible cassette to regulate the floral transition would be composed of the FTM1/FTM2 cDNA downstream of the GAL4 DNA binding sites and any desirable promoter (e.g., a strong promoter such as the S35 promoter) that drives expression of the chimeric ecdysone receptor fused with the GAL4 DNA binding domain. This chimeric ecdysone receptor will accumulate in the cytoplasm as an inactive molecule until the
ligand (methoxyfenozide) is applied. In the presence of the ligand, the ecdysone receptor is activated, transported into the nucleus and drives expression of the target gene(s), which are the FTM1 and 2 cDNAs. Therefore, application of the chemical inducer (methoxyfenozide) causes accumulation of FTM1 and FTM2 proteins that direct the switch from vegetative to reproductive development, inducing flowering. Other chemicals or inducible systems may be used in a similar manner to control FTM1 and FTM2 protein accumulation.

[0230] Using a similar inducible system, it will be possible to create vernalized (winter) corn varieties. Like typical winter crops such as winter rye, wheat and barley (reviewed in Andersen, et al., (2004) *Trends in Plant Sci.* 9:105-106), the corn flowering activators genes FTM1 and FMT2 may be placed under control of cold-inducible repressors such as the wheat VRN2 protein (Yan, et. al., (2004) *Science* 303:1640-1644). Stacked with cold-tolerance genes, such transgenic lines may be engineered in such a way as to mimic winter crops. This “winter” corn variety may be used in regions where winter crops are routinely grown.

Example 18

Meristem-Specific Promoters of FTM1, 2, 3 and SVP1, 2, 3 Genes

[0231] The FTM1, 2, 3 and SVP1, 2, 3 genes are expressed within different zones of the shoot apical meristem (see, example 15, In situ hybridization). These genes are the source of the meristem-specific promoters. The shoot apical meristem is a growing point of the plant. In corn, cell division in the shoot apical meristem occurs for only the first three to four weeks and stops at about the time that the collar of the fifth leaf becomes visible (V5). All of the leaves, all of the stem nodes and all of the ears are initiated from cells produced during cell division in the apical meristem. Once cell division stops, no additional ears or leaves can be formed. At V5, the apical meristem changes from an area of cell division to an embryonic tassel. Thus, the shoot apical meristem plays a vital role in corn organ generation.

[0232] Promoter sequences of the FTM and SVP genes were identified from the BAC genomic sequences as segments located between the translation initiation codon AFG and the intergenic regions marked by the sequence homology (see, example 11, Genomic Sequences). The promoter sequences are identified as follows:

[0233] FTM1 promoter—SEQ ID NO: 29

[0234] FTM2 promoter—SEQ ID NO: 30

[0235] FTM3 promoter—SEQ ID NO: 31

[0236] SVP1 promoter—SEQ ID NO: 32

[0237] SVP2 promoter—SEQ ID NO: 33

[0238] SVP3 promoter—SEQ ID NO: 34

[0239] The FTM1,2,3 promoters possess typical TATA-boxes, which are a characteristic feature of many plant genes. FTM1 and FTM2 promoters have an auxin response element TGTCTC (Goda, et. al., (2004) *Plant Phys* 1334:1555-1573), suggesting that FTM1 and FTM2 genes may be induced by hormone auxin. FTM1 and FTM3 promoters have A-box (TACGTA), C-box (GACGTC) and G-box (CAGTCG) elements which are binding sites for bZIP (basic leucine zipper) transcription factors in plants (Trends in Plant Sci (2002) 7:106-111). These features suggest that FTM1 and FTM3 genes are transcribed by bZIP transcription factors, which regulate diverse processes including light and stress signaling, seed maturation and flower development.

[0240] The promoters of SVP1 and SVP2 genes are TATA-less and do not have any recognizable motifs. However, there are two TATA-boxes within the SVP3 promoter suggesting a different type of regulation of this gene than SVP1 and SVP2 promoters.

[0241] Meristem specific or preferred promoters are extremely useful tools for genetic improvement and manipulations at the dividing and growing areas of the plant. The meristem promoter will allow one to target the expression of desired proteins in the meristem to modulate plant growth. It could also be used to protect these meristem areas from injury by herbicides or insects. This meristem promoter can be used to express regulatory proteins that control cell division and growth or enzymes that modulate plant hormone synthesis or other plant growth regulators. Meristem promoters can be used for protection against insect damage. Most insects like to feed on young growing tissues such as apical meristems, consequently stunting the plant growth. By using meristem promoters to express insecticidal proteins, the tender and rapidly growing parts of the meristem can be protected from insect damage. Meristem promoters can also be used to prevent damage by herbicides at the growing apical meristem. Rapidly growing apical meristem is extremely sensitive to herbicide damage. Therefore, to protect the meristem areas from injury by the herbicide and allow continue growth of the plant, a meristem promoter could be used to express additional herbicide deactivation enzyme or the herbicide insensitive catalytic enzyme in these sensitive meristem areas. This would effectively protect the tissues at the growing zones of the plants.

[0242] Meristem promoters can be used to modulate flowering time, an important agronomic trait. The over-expression of genes that are activators or repressors of flowering in transgenics under the direction of a meristem specific promoter allows one to control the timing of flower formation without ectopic expression of unwanted proteins in other tissues. Controlling manipulation of flowering time provides opportunities for enhancing crop yield, adaptation of germplasm to different climatic zones and synchronous flowering for hybrid seed production.

[0243] The above examples are provided to illustrate the invention but not to limit its scope. Other variants of the invention will be readily apparent to one of ordinary skill in the art and are encompassed by the appended claims. All publications, patents, patent applications, and computer programs cited herein are hereby incorporated by reference.

What is claimed is:

1. An isolated polynucleotide having at least 80% sequence identity, as determined by the GAP algorithm under default parameters, to the full length sequence of a polynucleotide selected from the group consisting of SEQ ID NOS: 29, 30, 31, 32, 33 or 34; wherein the polynucleotide functions as a promoter.

2. A polynucleotide selected from the group consisting of SEQ ID NOS: 29, 30, 31, 32, 33 or 34.

3. A recombinant expression cassette comprising the promoter of claim 1.

4. A host cell comprising the polynucleotide of claim 1.

5. A transgenic plant comprising the polynucleotide of claim 1.

6. The transgenic plant of claim 5, wherein said plant is a monocot.

7. The transgenic plant of claim 5, wherein said plant is a dicot.

8. The transgenic plant of claim 5, wherein said plant is selected from the group consisting of: maize, soybean, sunflower, sorghum, canola, wheat, alfalfa, cotton, rice, barley, millet, peanut and cocoa.

9. A transgenic seed from the transgenic plant of claim 5.
10. A method of modulating the flowering time in plants, comprising:
   a. introducing into a plant cell a recombinant expression cassette comprising the polynucleotide of claim 1; and
   b. culturing the plant under plant cell growing conditions;
   wherein the flowering time in said plant cell is modulated.

11. The method of claim 10, wherein the plant cell is from a plant selected from the group consisting of: maize, soybean, sunflower, sorghum, canola, wheat, alfalfa, cotton, rice, barley, millet, peanut and cocoa.

12. A method of modulating the flowering time in a plant, comprising:
   a. introducing into a plant cell a recombinant expression cassette comprising the polynucleotide of claim 1;
   b. culturing the plant cell under plant cell growing conditions; and
   c. regenerating a plant from said plant cell; wherein the flowering time in said plant is modulated.

13. The method of claim 12, wherein the plant is selected from the group consisting of: maize, soybean, sorghum, canola, wheat, alfalfa, cotton, rice, barley, millet, peanut, and cocoa.

14. The method of claim 12, wherein said plant is used to produce hybrid seed.
