Title: METHOD FOR TREATMENT OF PREMATURE EJACULATION IN HUMANS

Abstract: The present invention belongs to the fields of pharmacology, medicine and medicinal chemistry, and provides methods and compositions for treating sexual dysfunction; more particularly, the invention relates to treatment of premature ejaculation in humans.
Title: Method For Treatment Of Premature Ejaculation In Humans
Inventor: Chandra U. SINGH
Applicant: Azaya Therapeutics, Inc.

This regular utility patent application claims priority to U.S.
 Provisional Patent Application Serial No. 60/424,229, filed
 November 6, 2002, and is incorporated herein by reference for all
 purposes.

BACKGROUND OF THE INVENTION

Primitive premature ejaculation is regarded as the most
common sexual disorder of the male. This may cause a loss of the
ability to achieve sexual accommodation which is necessary for the
satisfaction of the human instinctive desire. Recently, it has been
determined that the number of cases manifesting various symptoms
caused by such loss of sexual accommodation is rather large. The
sexual problems due to premature ejaculation in men lead to social
difficulties, such as asthenia due to the loss of self-confidence, as
well as domestic discord. Premature ejaculation is defined as
persistent or recurrent ejaculation before, upon, or shortly after
penetration

By nature, a woman is so evolved that she experiences the sex
act markedly less intensely than a man, at least at the commencement
of sexual activity. She must, therefore, have more time in order to
reach the orgasm which provides natural relaxation of the whole
nervous system strained to the maximum during the act. To this day
the sense of touch plays an important role in human sex life;
particularly sensitive to touch are the erogenous zones, first and
foremost among them being the areas where skin borders on mucous
membrane as, for example, in the vicinity of the oral cavity, the
rectum, female genitals and breast nipples. The erogenous zone of a
woman can be her entire body surface. In such cases it is possible to
evoke lascivious feelings in her by touching any part of her body. But
it is most often the case that erogenous zones are localized in strictly
defined places such as: the clitoris, labia minora and the vagina.
There are, additionally, many such sensitive points apart from the sex
organs. These are: the lips, the ears, eyelids, neck, nipples, etc. In
some cases these points are so sensitive that merely touching them
can produce an orgasm in a woman.

However in the case of men, the erogenous zones are confined
solely to the genitals and adjacent areas. It is not surprising, therefore,
that an experienced male partner is sometimes obliged to undertake
veritable journeys of exploration, in his search for these points,
without which no one can activate the complex apparatus of female
sexual reflexes. That is one reason the male often needs incomparably
less time in order to reach orgasm - which usually concludes the sex
act not only for himself but also for his partner. At the
commencement of the sex act the man already finds himself at a certain level of excitement, which is essential to erection and without which this act becomes quite impossible. He is unable to continue the act out of consideration for his partner because immediately after orgasm and the associated ejaculation detumescence takes place and all further frictiones in vagina are impossible.

The ideal intercourse would be one in which, following immersing the penis into the vagina, both parties reached the boundary of orgasm simultaneously and, having crossed it, ended the sex act together (Figure 1). This happens sometimes where a woman experienced in sexual intercourse can compensate for the excitement missing at the beginning of the act and reach the finishing line together with her partner in spite of that. For young and middle-aged men the norm of normal ejaculation vacillates between 2 - 6 minutes after the immersing the penis into the vagina.

The premature ejaculation occurs very frequently in the modern human sexual act. It concerns the fact that shortly after immersing the penis into the vagina takes place (Figure 2), sometimes after 2-3 movements, ejaculation and orgasm occur; the erection vanishes and the sex act is ended. Obviously in such a situation the woman is only aroused, while there can be no question of release. Obviously there can be no question of sexual satisfaction and normal relaxation of the female partner in the presence of any kind of male
impotence, whether through inadequate erection or through premature ejaculation.

Erection of the penis may be a self-perpetuating process of three steps: 1) vasodilation; 2) release of endogenous smooth-muscle relaxants; and, 3) progression of these effects distal from the initial site of onset. This has been termed the "cascade effect". Papaverine is an opium alkaloid and works as a smooth muscle relaxer possibly by cyclic GMP phosphodiesterase inhibition. It relaxes the musculature of the vascular system of the penis and increases blood flow (Papaverine Topical Gel Treatment For Erectile Dysfunction, Urology, Vol. 133(2)(1995), pp. 361-365). Another compound found useful in the treatment of impotence is prostaglandin E1, a naturally occurring compound that acts to increase arterial inflow to the penis and may also restrict venous outflow. Prostaglandin E1 is preferred to other compounds used in injections for the treatment of impotence because it is metabolized locally in the penis and is less likely to cause systemic symptoms such as hypotension. As a modified vascular tissue, corpora cavernosa of the penis (ccp) produces and secretes the same range of autocrine and paracrine regulators as conventional vascular tissue. The smooth muscle tone of the ccp, however, does not appear to be regulated in the same manner as in the vascular wall. Presently it is postulated that the tone or contractility of ccp is modulated by adrenergic regulation and locally produced NO and endothelin. In the ccp, most studies have been
directed to observing the relaxing effects of NO, vasoactive intestinal
type (VIP), calcitonin gene-related peptide (CGRP) and
parasympathetic innervation, which also have similar effects on
conventional and cGP vascular smooth muscle.

During normal penile erections, when the inflow of blood to
the cGP engages the sinusoidal spaces, the trabecular tissue
compresses small cavernosal veins against the thick fibrous tissue
surrounding the corpora to maintain the erection. To mediate these
changes in blood flow, nitric oxide is released from postsynaptic
parasympathetic neurons and, to a lesser extent, endothelial cells and
α-adrenergic neurons are inhibited in the arterial and trabecular
smooth muscle. Nitric oxide, which is readily diffusible, stimulates
the formation of increased cyclic guanosine monophosphate (GMP)
in the corpus cavernosum by guanylate cyclase to relax the smooth
muscle cells.

Recently, the oral use of the citrate salt of sildenafil has been
approved by the U.S. Food and Drug Administration (FDA) for the
treatment of male erectile dysfunction. Sildenafil is reported to be a
selective inhibitor of cyclic-GMP-specific phosphodiesterase type 5
(PDE5), the predominant isozyme metabolizing cyclic GMP formed
in the corpus cavernosum. Since sildenafil is a potent inhibitor of
PDE5 in the corpus cavernosum, it is believed to enhance the effect
of nitric oxide, thereby increasing cavernosal blood flow in the penis,
especially with sexual stimulation. Inasmuch as sildenafil at the
currently recommended doses of 25-100 mg has little effect in the
absence of sexual stimulation, sildenafil is believed to restore the
natural erectile response to sexual stimulation but not cause erections
in the absence of such stimulation (Goldstein 1998). The localized
mechanism by which cyclic GMP stimulates relaxation of the smooth
muscles has not been elucidated.

Normal ejaculatory function in the human male implies a
coordinated sequence of smooth and striate muscular contractions to
promote projectile, antegrade transport of seminal fluid. This process
begins with transmission of afferent nerve stimuli via the internal
pudendal nerve from the penile shaft to higher centers. To complete
the ejaculatory reflex efferent stimuli are transmitted from the
anterolateral columns of the spinal cord and emerging from the
thoracolumbar level to comprise a hypogastric or sympathetic plexus.
From the interior mesenteric ganglion short adrenergic postganglionic
fibers terminate in the seminal vesicles, vasal ampullae, and bladder
neck. Sympathetic innervation of the seminal vesicles results in
semen emission into the posterior urethra. Appropriately timed
bladder neck closure prevents retrograde passage of this semen bolus,
which is propelled in the antegrade direction by clonic contracts of
the bulbocavernosus and ischiocavernosus muscles of the pelvic
floor. Ejaculation is a centrally, integrated peripheral evoked reflex,
which occurs as a result of α₁-adrenergic receptor activation.
Effective pharmacological drugs for the treatment of premature ejaculation exist, but they suffer from severe side effects, for example clomipramine and phenoxybenzamine. Other treatments have a limited effectiveness (metoclopramide and the like).

PGE2, PGF2α, PGF2β, PGA2, and PGB2, and their esters and pharmacologically acceptable salts, are extremely potent in causing various biological responses. For that reason, these compounds are useful for pharmacological purposes. See, for example, Bergstrom et al., Pharmacol. Rev. 20, 1 (168), and references cited therein. A few of those biological responses are systemic arterial blood pressure lowering in the case of PGE2, PGF2β, and PGA2 as measured, for example, in anesthetized (pentobarbital sodium) pentolinium-treated rats with indwelling aortic and right heart cannulas; pressor activity, similarly measured, for PGF2α; stimulation of smooth muscle as shown, for example, by tests on strips of guinea pig ileum, rabbit duodenum, or gerbil colon; potentiation of other smooth muscle stimulants; antilipolytic activity as shown by antagonism of epinephrine-induced mobilization of free fatty acids or inhibition of the spontaneous release of glycerol from isolated rat fat pads; inhibition of gastric secretion in the case of PGE2 and PGA2 as shown in dogs with secretion stimulated by food or histamine infusion; activity on the central nervous system; decrease of blood platelet adhesiveness as shown by platelet-to-glass adhesiveness, and inhibition of blood platelet aggregation and thrombus formation.
induced by various physical stimuli, e.g., arterial injury, and various
biochemical stimuli, e.g., ADP, ATP, serotonin, thrombin, and
collagen; and in the case of PGE2 and PGB2, stimulation of
epidermal proliferation and keratinization as shown when applied in
culture to embryonic chick and rat skin segments. PGE2 is extremely
potent in causing stimulation of smooth muscle, and is also highly
active in potentiating other known smooth muscle stimulators, for
example, oxytocic agents, e.g., oxytocin, and the various ergot
alkaloids including derivatives and analogs thereof. Therefore PGE2
is useful in place of or in combination with less than usual amounts of
these known smooth muscle stimulators, for example, to relieve the
symptoms of paralytic ileus, to control or prevent atonic uterine
bleeding after abortion or delivery, to aid in expulsion of the placenta,
and during the puerperium.

A synthetic form of prostaglandin E1, alprostadil USP
(alprostadil), is a long-chain carboxylic acid with vasodilatory
effects. Alprostadil acts to increase arterial inflow to the penis. In
vitro studies have shown that alprostadil causes a dose-dependent
smooth muscle relaxation in isolated corpus cavernosum and corpus
spongiosum preparations. When used in vivo, it is thought that
intraurethral alprostadil is absorbed from the urethra,
transported throughout the erectile bodies of the penis by way of
communicating vessels between the corpus spongiosum and corpus
cavernosum, and induces vasodilation of the targeted vascular beds.
US patent 5658936 teaches that similar to the vascular tissue, the corpus cavernosum penis produces and secretes angiotensin II, that plays an important role in modulation of the penile blood flow. Local, intracavernosal, or systemic administration of angiotensin II antagonists or ACE inhibitors has a powerful effect on the penile blood flow. (US 5658936: Enhancement of erectile function with renin-angiotensin system inhibitors)

Dextromethorphan (frequently abbreviated as DM) is the common name for (+)-3- methoxy-N-methylmorphinan (Figure 3). It is widely used as a cough syrup, and is described in references such as Rodd 1960 (full citations to articles are provided below) and Goodman and Gilman's Pharmacological Basis of Therapeutics. Briefly, DM is a non-addictive opioid comprising a dextrorotatory enantiomer (mirror image) of the morphinan ring structure which forms the molecular core of most opiates. DM acts at a class of neuronal receptors known as sigma receptors. These are often referred to as sigma opiate receptors, but there is some question as to whether they are opiate receptors, so many researchers refer to them simply as sigma receptors, or as high-affinity dextromethorphan receptors. They are inhibitory receptors, which means that their activation by DM or other sigma agonists causes the suppression of certain types of nerve signals. Dextromethorphan also acts at another class of receptors known as N-methyl-D-aspartate (NMDA) receptors, which are one type of excitatory amino acid (EAA)
receptor. Unlike its agonist activity at sigma receptors, DM acts as an antagonist at NMDA receptors, which means that DM suppresses the transmission of nerve impulses mediated via NMDA receptors. Since NMDA receptors are excitatory receptors, the activity of DM as an NMDA antagonist also leads to the suppression of certain types of nerve signals, which may also be involved in some types of coughing. Due to its activity as an NMDA antagonist, DM and one of its metabolites, dextrorphan, are being actively evaluated as possible treatments for certain types of excitotoxic brain damage caused by ischemia (low blood flow) and hypoxia (inadequate oxygen supply), which are caused by events such as stroke, cardiac arrest, and asphyxia. The anti-excitotoxic activity of dextromethorphan and dextrorphan, and the blockade of NMDA receptors by these drugs, are discussed in items such as Choi 1987, Wong et al 1988, Steinberg et al 1988, and U.S. Pat. No. 4,806,543 (Choi 1989). Dextromethorphan has also been reported to suppress activity at neuronal calcium channels (Carpenter et al 1988). Dextromethorphan and the receptors it interacts with are further discussed in Tortella et al 1989, Leander 1989, Koyuncuoglu & Saydam 1990, Ferkany et al 1988, George et al 1988, Prince & Feeser 1988, Feeser et al 1988, Craviso and Musacchio 1983, and Musacchio et al 1988.

DM disappears fairly rapidly from the bloodstream (see, e.g., Vetticaden et al 1989 and Ramachander et al 1977). DM is converted in the liver to two metabolites called dextrorphan and 3-
methoxymorphinan, by an enzymatic process called O-
demethylation; in this process, one of the two pendant methyl groups
is replaced by hydrogen. If the second methyl group is removed, the
resulting metabolite is called 5-hydroxymorphinan. Dextrorphan and
5-hydroxymorphinan are covalently bonded to other compounds in
the liver (primarily glucuronic acid or sulfur-containing compounds
such as glutathione) to form glucuronide or sulfate conjugates which
are eliminated fairly quickly from the body via urine bloodstream.
This enzyme is usually referred to as debrisoquin hydroxylase, since
it was discovered a number of years ago to carry out a hydroxylation
reaction on debrisoquin. It is also referred to in various articles as
P450DB or P450-2D6. It apparently is identical to an enzyme called
sparteine monooxygenase, which was shown years ago to metabolize
sparteine; it was not until recently that scientists realized that a single
isozyme appears to be primarily responsible for oxidizing both
debrisoquin and sparteine, as well as dextromethorphan and various
other substrates. Debrisoquin hydroxylase belongs to a family of
enzymes known as "cytochrome P-450" enzymes, or as "cytochrome
oxidase" enzymes. Monoxygenation of chemical materials has been
ascribed to cytochromes P450 (P450). These hemoprotein containing
monooxygenase enzymes displaying a reduced carbon monoxide
absorption spectrum maximum near 450 nm have been shown to
catalyze a variety of oxidation reactions including hydroxylation of
endogenous and exogenous compounds (Jachau, 1990). An extensive
amount of research has been conducted on the mechanism's by which

The P450 reaction cycle proceeds briefly as follows: initial binding of a substrate molecule (RH) to the ferric form of the cytochrome results in the formation of a binary complex and a shift in the spin equilibrium of the ferric enzyme from the low- to high-spin state. Some evidence has been presented that suggests this configuration more readily accepts an electron from the flavoprotein reductase to form the ferrous P450-substrate complex. However, not all P450s exhibit a relationship between high-spin content and reduction rate. Indeed, it has been proposed that several factors, including the nature of the P450 substrate, the topography of the enzyme/substrate complex, and the potentials of oxidizable atoms each play a role in regulation of the reduction rate. Molecular oxygen binds to the ferrous P450-substrate complex to form the ferrous dioxygen complex which is then reduced by a second electron from the P450 reductase (or perhaps, in some cases, from reduced nicotinamide adenine dinucleotide via cytochrome b5 and its reductase). Dioxygen bond cleavage in the reduced ferrous dioxygen complex results in the insertion of one atom of oxygen into the substrate, reduction of the other oxygen atom to water, and restoration of the ferric hemoprotein.
Individual members of the P450 family of enzymes and associated mixed function oxidase activities have been described in extrahepatic tissues including brain, adrenal, kidney, testis, ovary, lung and skin. Individual P450s have likewise been characterized in terms of their inducibility by selected chemical classes. Induction of specific P450 enzymes, such as the P450 1A1 and 1A2 subfamily have been extensively studied with respect to regulatory processes of increased mRNA transcription and expression of enzymatic activity. It has been ascertained that materials such as beta-naphthoflavone (beta-NF), 3-methylcholanthrene (3-MC), arochlor 1254 (ACLR) and 2,3,7,8-tetrachlorodibenzop-dioxin (TCDD) are materials that have been categorized as inducers of P450 enzymes bearing the designated P450 1A subfamily (Murray et al, 1990; and Guengerich, 1989).

A number of compounds inhibit the activity of the debrisoquin hydroxylase (sparteine monooxygenase) isozyme (Inaba et al 1985). The most powerful of these inhibitors is quinidine (Figure 3), a dextrorotatory stereoisomer of quinine; it is normally used to treat cardiac arrhythmias. Inaba et al (1986) and Nielsen et al (1990) discuss the ability of quinidine to inhibit the oxidation of sparteine in vivo animal tests, and Brinn et al (1986), Broersen et al (1987), and Broly et al (1989) discuss the ability of quinidine to inhibit DM metabolism in liver cell preparations. In addition to the inhibition of debrisoquin hydroxylase, which is exceptionally potent and easily demonstrated, other cytochrome P450 isozymes are also likely to be
suppressed by quinidine, with varying levels of binding affinity. Accordingly, even though quinidine exerts its most marked effect on debrisoquin hydroxylase, it is likely to suppress a number of other cytochrome P450 enzymes as well, thereby subjecting a patient to a more general loss of normal and desirable liver activity. The primary oxidized metabolic product of dextromethorphan is dextrorphan, which is widely believed among neurologists to be active in exactly the same manner as dextromethorphan; both drugs reportedly are sigma agonists, NMDA antagonists, and calcium channel antagonists. It has been shown that the administration of a compound which inhibits debrisoquin hydroxylase, in conjunction with DM, causes a major increase in the concentration and stability of DM in the blood of patients, compared to patients who receive only DM; and the administration of a debrisoquin hydroxylase inhibitor in conjunction with DM has a clear and substantial impact on the detectable effects of DM in humans.

Non-steroidal anti-inflammatory drugs (NSAIDs) are widely used for treating common inflammation. NSAIDs mainly inhibit the synthesis of prostaglandins in the human body by inhibiting the enzyme cyclo-oxygenase(COX) which is essential for the synthesis of prostaglandins. The enzyme COX has two isomers called COX-1 and COX-2. COX also known as prostaglandin H synthase, is an enzyme implicated in the mediation of pain, fever, and inflammation. It catalyzes the oxidative conversion of arachidonic acid into
prostaglandin H2, a key intermediate in the biosynthetic pathway of
prostaglandins, prostacyclins, and thromboxanes, which in turn
mediate a variety of physiological effects both beneficial and
pathological. Recently, it was discovered that two COX isoforms
exists: COX-1, expressed constitutively in many tissues, and COX-2,
an induced isoform having elevated expression in inflamed tissues.
COX-1 is thought to be involved in ongoing *housekeeping* functions,
for example gastric cytoprotection, while COX-2 is the isoform
implicated in the pathological effects mentioned above. Nonsteroidal
anti-inflammatory agents (NSAIDs) such as aspirin, ibuprofen and
indomethacin inhibit both COX-1 and COX-2. COX-2 inhibitors,
celecoxib (Celebrex) and rofecoxib (Vioxx), are recently introduced
prescription NSAIDs for osteoarthritis. Unlike previously available
NSAIDs, which inhibit cyclooxygenase-1 (COX-1) and COX-2,
celecoxib and rofecoxib specifically (about 350 fold) inhibit
cyclooxygenase-2 (COX-2). Both actions are beneficial in blocking
production of prostaglandins. However, inhibition of COX-1 is
responsible for some side effects of older NSAIDs, such as upper
gastrointestinal irritations and inhibition of platelet aggregation.
Because celecoxib and rofecoxib specifically target COX-2, they do
not affect platelet aggregation and are less likely to produce stomach
and upper intestinal irritations.

At present, the treatment of choice for premature ejaculation is
psychotherapy, either as a behavioural dual team sex therapy
according to Master & Johnson protocol, or individual psychotherapy
(Rifelli and Moro. Sessuologia Clinica. Bologna, 1989). Previous
methods of treating premature ejaculation include psychological
therapies, topical anesthetics and the use of devices (U.S. Pat. Nos.
5,535,758, 5,063,915, 5,327,910, and 5,468,212). All of these
methods may have significant drawbacks. Psychological therapies
benefit only a subset of patients and require specialized therapists
who may not be available to all patients, particularly in remote areas.
Furthermore, psychological therapies cannot alleviate premature
ejaculation resulting from non-psychological causes. Anesthetic
agents decrease sensitivity of tissues, thereby diminishing sexual
pleasure. Also, topical anesthetics can be transferred to sexual
partners and thereby decrease their sensitivity and pleasure as well.
With regard to devices, these can be awkward, inconvenient and
embarrassing to use. Devices are highly conspicuous, and reveal the
very condition which the suffering partner may prefer to conceal.
Additionally, devices can cause irritation to one or both partners.

Methods for treating premature ejaculation by systemic
administration of several different antidepressant compounds have
been described (U.S. Pat. Nos. 4,507,323, 4,940,731, 5,151,448, and
5,276,042; PCT Publication No. WO95/13072). However, these
drugs may not be effective for all patients, and the side effects of
these drugs can halt treatment or impair patient compliance. Disease
states or adverse interactions with other drugs may contraindicate the
use of these compounds or require lower dosages that may not be
effective to delay the onset of ejaculation. Additionally, the stigma of
mental illness associated with antidepressant therapy can discourage
patients from beginning or continuing such treatments.
Administration of the antidepressant fluoxetine has been claimed to
treat premature ejaculation (U.S. Pat. No. 5,151,448). However, the
administration of fluoxetine may have many undesired aspects.
Patients with hepatic or renal impairments may not be able to use
fluoxetine due to its metabolism in the liver and excretion via the
kidney. Systemic events during fluoxetine treatment involving the
lungs, kidneys or liver have occurred, and death has occurred from
overdoses. In addition, side effects of oral fluoxetine administration
include hair loss, nausea, vomiting, dyspepsia, diarrhea, anorexia,
anxiety, nervousness, insomnia, drowsiness, fatigue, headache,
tremor, dizziness, convulsions, sweating, pruritis, and skin rashes.
Fluoxetine interacts with a range of drugs, often by impairing their
metabolism by the liver.

U.S. Pat. No. 4,940,731 describes the oral or parenteral
administration of sertraline for treating premature ejaculation. It has
been recognized that sertraline shares many of the same problems as
fluoxetine; (see Martindale, The Extra Pharmacopoeia, 31st edition,
at p. 333 (London: The Royal Pharmaceutical Society, 1996)).
Sertraline is metabolized in the liver, and is excreted in the urine and
feces. Thus, patients with cirrhosis must take lower doses, and
caution must be exercised when administering sertraline to patients with renal impairment. Individuals taking monoamine oxidase inhibitors cannot take sertraline due to the risk of toxicity, leading to memory changes, confusion, irritability, chills, pyrexia and muscle rigidity. Side effects resulting from oral sertraline administration include nausea, diarrhea, dyspepsia, insomnia, somnolence, sweating, dry mouth, tremor and mania. Rare instances of coma, convulsions, fecal incontinence and gynecomastia have occurred in patients undergoing sertraline therapy. U.S. Pat. No. 5,276,042 describes the administration of paroxetine for the treatment of premature ejaculation. Paroxetine is predominantly excreted in the urine, and decreased doses are recommended in patients with hepatic and renal impairments. Like sertraline, paroxetine cannot be given to patients undergoing treatment with a monoamine oxidase inhibitor. Side effects from oral administration of paroxetine include hyponatremia, asthenia, sweating, nausea, decreased appetite, oropharynx disorder, somnolence, dizziness, insomnia, tremor, anxiety, impaired micturition, weakness and paresthesia. Thus there is a need for a method of treating premature ejaculation that requires no specialized psychological therapy, can be used conveniently and without embarrassment, and does not involve the problems associated with prior therapeutic methods.

US 6037360 discloses that administration of various serotonin agonists and antagonists is effective in the treatment of premature
ejaculation. The adverse effects occurring most frequently during
treatment with serotonin inhibitors are gastrointestinal disturbances,
such as, for example nausea, diarrhoea/loose stools, constipation.
(Drugs 43 (Suppl. 2), 1992). Nausea is the main adverse effect in
terms of incidence. Moreover it has been frequently observed that
after administration of serotonin inhibitors, patients suffer from
dyspepsia.

US 5707999 teaches that two specific α1-blockers, alfuzosine
and terazosine, are effective in the treatment of psychogenic
premature ejaculation and said drugs turned out to be effective in
patients who proved to have no benefit from psychological therapy.
However terazosine and its analogs have several side effects
including headache, nausea, weight gain, dizziness, somnolence,
dyspnea and blurred vision.

**SUMMARY OF THE INVENTION**

Applicant has now developed compositions, (combinations and
formulations) which are administered to a human in the treatment of
premature ejaculation. These compositions, (combinations and
formulations) employ, combine, or incorporate (as the case may be) a
plurality of effective non-toxic dosage amounts, each dosage amount
comprising an effective non-toxic dosage amount of a drug, for
example, a drug which inhibits prostaglandin synthesis, for example,
an NSAID and an effective non-toxic dosage amount of a form of
Dextromethorphan (preferably Dextromethorphan Hydrate or salt there of) and optionally, an effective non-toxic dosage amount of a cytochrome-P450 inhibitor, for example, quinidine (preferably quinidine hydrate or salt there of).

Applicant has also developed compositions, (combinations and formulations) which are administered to a human in the treatment of premature ejaculation and erection. These compositions, (combinations and formulations) employ, combine, or incorporate (as the case may be) a plurality of effective non-toxic dosage amounts, each dosage amount comprising an effective non-toxic dosage amount of a drug which inhibits cyclic-GMP-specific phosphodiesterase type 5 (PDE5), for example, sildenafil and an effective non-toxic dosage amount of a form of Dextromethorphan (preferably Dextromethorphan Hydrate or salt there of) and optionally, an effective non-toxic dosage amount of a cytochrome-P450 inhibitor, for example, quinidine (preferably quinidine hydrate or salt there of).

Accordingly, one object of the subject invention is to disclose that a combination of a non-steroidal anti-inflammatory substances or drugs (hereinafter referred to by the abbreviation NSAIDs) which involve in the prostaglandin biochemical pathways such as Ibuprofen, sodium salicylate, BW755c, BF389, naproxen, aspirin, acetaminophen, flurbiprofen, piroxicam, celecoxib, diclofenac,
etodolac, fenoprofen, indomethacin, ketoprofan, ketoralac, oxaprocin, nabumetone, sulindac, tolmetin, rofecoxib, meclofenamate, oxaprozin, in humans, dextromethorphan which involves in anti-excitotoxic activity in humans and optionally a cytochrome P450 inhibitor such as quinidine, is very effective in delaying the onset of ejaculation in male humans.

According to yet another aspect of the invention, applicant has provided pharmaceutical compositions (combinations and formulations) comprising a plurality of dosage amounts each comprising, together with pharmaceutical excipients suitable for oral or parenteral administration, a therapeutically effective (to treat and to assist to resolve diseases and conditions of premature ejaculation in human male non-toxic (to the patient) dosage amount of a drug for example which inhibits prostaglandin synthesis, preferably being a non-steroidal anti-inflammatory drug (NSAID) which inhibits the synthesis of prostaglandins, for example, Ibuprofen, sodium salicylate, BW755c, BF389, naproxen, aspirin, acetaminophen, flurbiprofen, piroxicam, celecoxib, diclofenac, etodolac, fenoprofen, indomethacin, ketoprofan, ketoralac, oxaprocin, nabumetone, sulindac, tolmetin, rofecoxib, meclofenamate, oxaprozin, celecoxib, rofecoxib and an effective non-toxic dosage amount dosage amount of a form of Dextromethorphan and/or salts thereof (for example the hydrobromide salt) and/or homologues, analogues, derivatives, complexes, prodrugs, esters, fragments, and optionally an effective
non-toxic dosage amount of a cytochrome-P450 inhibitor, for
example, quinidine (preferably quinidine hydrate or salt there of).

It is another object of the invention to provide such a method
wherein the pharmacologically active agent is administered orally. It
is a further object of the invention to provide such a method wherein
the pharmacologically active agent is administered parenterally.

In another object of the present invention, a method is provided
for treating premature ejaculation, the method comprising
administering to an individual in need of such treatment a
pharmaceutical formulation containing an anti-inflammatory agent,
dextromethorphan and optionally an agent which inhibits the
oxidative activity of cytochrome-P450, such as a naphthyridine,
xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine
imidazole, e.g. cimetidine (N-cyano-N'-methyl-N"-[(5-methyl-1H-
imidazol-4 yl)methyl]thio]ethyl]guanidine), quinoline, e.g.
chloroquine (7-chloro-4-(4-diethylamino-1-
methylbutylamino)quinoline) and primaquine (8-(4-amino-1-
methylbutylamino)-6-methoxyquinoline), a trifluoromethyl oxime
ether, e.g., fluvoxamine, also known as 5-methoxy-1-[4-
(trifluoromethyl)-phenyl]-1 pentanone 0-(2-aminoethyl) oxime.
Administration of the pharmaceutical formulation is carried out
within the context of a predetermined dosing regimen such that the
agent is effective in the treatment of premature ejaculation. Drug
delivery may be accomplished through any route effective to provide
relief from premature ejaculation, including oral, parenteral, buccal,
rectal, topical, transdermal, transurethral, and intracavernosal
injection.

In another aspect of the invention, a pharmaceutical
formulation is provided for carrying out the method of the invention.
The pharmaceutical formulation comprises an effective amount of a
selected anti-inflammatory agent, dextromethorphan, optionally, a
cytochrome-P450 inhibitor, a pharmacologically acceptable carrier or
vehicle, and, optionally (i.e., in topical, transdermal or transurethral
formulations), an enhancer. Other types of components may be
incorporated into the formulation as well, e.g., excipients, surfactants,
preservatives (e.g., antioxidants), stabilizers, enzyme inhibitors,
chelating agents, and the like, as will be appreciated by those skilled
in the art of pharmaceutical formulation preparation and drug
delivery.

Yet another object of the subject invention is to disclose that a
combination of cyclic-GMP-specific phosphodiesterase type 5
(PDE5) inhibitors such as sildenafil which facilitates the erection of
the penis in humans under sexual stimulation, dextromethorphan
which involves in anti-excitotoxic activity in humans and optionally a
cytochrome P450 inhibitor such as quinidine, is very effective in
delaying the onset of ejaculation in male humans who have erection
as well as ejaculation problems.

Thus, according to yet another aspect of the invention,
applicant has provided pharmaceutical compositions (combinations
and formulations) comprising a plurality of dosage amounts each
comprising, together with pharmaceutical excipients suitable for oral
or parenteral administration, a therapeutically effective (to treat and to
assist to resolve diseases and conditions of premature ejaculation in
human male non-toxic (to the patient) dosage amount of a drug for
example which inhibits cyclic-GMP-specific phosphodiesterase type
5 (PDE5), for example, sildenafil and an effective non-toxic dosage
amount dosage amount of a form of Dextromethorphan and/or salts
thereof (for example the hydrobromide salt) and/or homologues,
analogues, derivatives, complexes, prodrugs, esters, fragments, and
optionally an effective non-toxic dosage amount of a cytochrome-
P450 inhibitor, for example, quinidine (preferably quinidine hydrate
or salt thereof).

Yet in another object of the present invention, a method is
provided for treating premature ejaculation, the method comprising
administering to an individual in need of such treatment a
pharmaceutical formulation containing an cyclic-GMP-specific
phosphodiesterase type 5 (PDE5), dextromethorphan and optionally
an agent which inhibits the oxidative activity of cytochrome-P450,
such as a naphthyridine, xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine imidazole, e.g. cimetidine (N-cyano-N'-methyl-N''-[2][(5-methyl-1H-imidazol-4-yl)methyl]thio]ethyl]guanidine), quinoline, e.g. chloroquine (7-chloro-4-(4-diethylamino-1-methylbutylamino)quinoline) and primaquine (8-(4-amino-1-methylbutylamino)-6-methoxyquinoline), a trifluoromethyl oxime ether, e.g., fluvoxamine, also known as 5-methoxy-1-[4-(trifluoromethyl)-phenyl]-1 pentanone 0-(2-aminoethyl) oxime. Administration of the pharmaceutical formulation is carried out within the context of a predetermined dosing regimen such that the agent is effective in the treatment of premature ejaculation. Drug delivery may be accomplished through any route effective to provide relief from premature ejaculation, including oral, parenteral, buccal, rectal, topical, transdermal, transurethral, and intracavernosal injection.

Additional objects, advantages and novel features of the invention will be set forth in part in the description which follows, and in part will become apparent to those skilled in the art upon examination of the following, or may be learned by practice of the invention.

**BRIEF DESCRIPTION OF THE DRAWINGS**

Figure 1 illustrates the orgasm levels in a man and woman during the normal Sexual intercourse. (The orgasm level is an
arbitrary quantity describing the physical and emotional excitements
during sexual intercourse.)

Figure 2 illustrates the orgasm levels in male and female in the
case of pre-mature ejaculation. (The orgasm level is an arbitrary
quantity describing the physical and emotional excitements during
sexual intercourse.)

Figures 3A-3D illustrate the chemical structures of certain
compounds which may be used in practicing the present invention.

**DETAILED DESCRIPTIONS OF THE INVENTION**

Before describing the present invention in detail, it is to be
understood that this invention is not limited to particular drugs or
drug delivery systems, as such may vary. It is also to be understood
that the terminology used herein is for the purpose of describing
particular embodiments only, and is not intended to be limiting. It
must be noted that, as used in this specification and the appended
claims, the singular forms "a," "an" and "the" include plural referents
unless the context clearly dictates otherwise. Thus, for example,
reference to "a pharmacologically active agent" includes a
combination of two or more pharmacologically active agents, and the
like. In describing and claiming the present invention, the following
terminology will be used in accordance with the definitions set out
below. The terms "active agent," "drug" and "pharmacologically
active agent" are used interchangeably herein to refer to a chemical
material or compound which, when administered to an organism
(human or animal) induces a desired pharmacologic effect. Included
are derivatives and analogs of those compounds or classes of
compounds specifically mentioned which also induce the desired
pharmacologic effect. The term "topical administration" is used in its
conventional sense to mean delivery of a topical drug or
pharmacologically active agent to the skin or mucosa. "Carriers" or
"vehicles" as used herein refer to carrier materials suitable for drug
administration. Carriers and vehicles useful herein include any such
materials known in the art, e.g., any liquid, gel, solvent, liquid
diluent, solubilizer, or the like, which is nontoxic and which does not
interact with other components of the composition in a deleterious
manner. By an "effective" amount of a drug or pharmacologically
active agent is meant a nontoxic but sufficient amount of the drug or
agent to provide the desired effect.

The term "premature ejaculation" as used herein intends a
sexual dysfunction wherein a male is unable to control the ejaculatory
process to a degree sufficient to satisfy a partner. Generally,
"premature ejaculation" refers to persistent or recurring ejaculation
with minimal stimulation before or during sexual intercourse. The
term includes both "congenital" or "lifelong" premature ejaculation
and "primary" or "acquired" premature ejaculation as set forth, for
example, in U.S. Pat. No. 5,151,448, and in Male Infertility and
Sexual Dysfunction at p. 356 (New York: Springer-Verlag, 1997).
See also Diagnostic and Statistical Manual of Mental Disorders

The term "NSAID" refers to non-steroidal substances which inhibit the production of prostaglandins by binding with cyclo-oxygenase enzymes. The compound acetaminophen is included under this category even though acetaminophen does not have anti-inflammatory properties but bind with cyclo-oxygenase enzymes in the periphery and at the hypothalamic thermoregulatory center.

The term "sildenafil" as used herein includes the free base form of this compound as well as pharmacologically acceptable acid addition salts thereof formed with organo-carboxylic acids, organo-sulphonic acids or inorganic acids. For purposes of the present invention, the organo-carboxylic acid salt, sildenafil citrate, having a solubility in water of 3.5 mg/ml is particularly preferred. Reference to "sildenafil" includes sildenafil citrate.

The present inventor was searching for an effective treatment of premature ejaculation. Based on the previous arts described above the inventor reasoned that in order to control the ejaculation process for males who do not have any erection problem and to have satisfactory sexual intercourse, two steps have to be preferred (hereinafter referred to as CLASS I); (1) the blood flow to the penis has to be modulated so that the male will have longer time to achieve
full erection and the sexual partners will have sufficient time for foreplay to reach sexual arousal; (2) the ejaculation process has to be delayed so that the sexual partners would have sufficient time for intercourse to reach maximum sexual satisfaction.

In the case of males who have erection problem and can not control ejaculation once erection is achieved the following two steps have to be preferred; (1) the erection has to be achieved through certain pharmaceutical agents such as sildenafil such that the male will have full erection upon the stimulation by the sexual partner; (2) the ejaculation process has to be delayed so that the sexual partners would have sufficient time for intercourse to reach maximum sexual satisfaction (hereinafter referred to as CLASS II).

It is understood from the information presented in the background that anti-inflammation agents which regulate prostaglandin synthetic pathways in humans would have an effect on the blood flow and the subsequent erection of the male penis and administration of these anti-inflammatory agents would have a modulation effect on the erection and the hardness of the male penis. Further, these anti-inflammatory agents will have anti-stimulatory effects on smooth muscle such as that of the male penis. It is understood that the administration of DM has the anti-excitotoxic effect in humans and the administration of DM to human male would have an effect on the ejaculation process. Further it is understood that
administration of a debrisoquin hydroxylase inhibitor or a
cytochrome-P450 inhibitor concurrently with DM substantially
increases the observable therapeutic effects of DM in human clinical
trials, then the effectiveness of DM as an agent for treating premature
ejaculation can also be increased by the co-administration of a
cytochrome oxidase inhibitor. Based on these observations the
inventors reasoned that administration of a combination of these
agents would have a therapeutical effect on premature ejaculation for
CLASS I males. To their surprise, they now discovered that ingestion
of these agents indeed has profound effects on the premature
ejaculation and that they prolong the sexual intercourse to reach
maximal orgasm. Further they observed that these agents can be used
to have multiple orgasm during sexual intercourse.

In addition, the inventors have discovered that ingestion of
sildenafil and DM has profound effects on the premature ejaculation
in CLASS II males and that they prolong the sexual intercourse to
reach maximal orgasm. Further they observed that these agents can
be used to have multiple orgasm during sexual intercourse. Further
the inventor has discovered that ingestion of acetaminophen or other
NSAIDS along with sildenafil and DM does not affect the
therapeutical effect of sildenafil and DM combination in treating
premature ejaculation in CLASS II patients.
ACTIVE AGENTS FOR TREATING PREMATURE EJACULATION IN CLASS I MALES

In order to carry out the method of the invention to treat premature ejaculation in CLASS I males, selected pharmacologically active agent is administered to an individual. The active agents may be administered orally, parenterally, buccally, rectally, or locally by intracavernosal injection or by delivery to the urethra. Suitable pharmacologically active agents include: anti-inflammatory agents salicylates, acetaminophen, Diclofenac sodium, Etodolac, fenoprofen calcium, flurbiprofen, ibuprofen, ketoprofen, meclofenamate sodium monohydrate, nabumetone, naproxen, naproxen sodium, oxaprozin, phenylbutazone, piroxicam, sulindac, tolmetin sodium, hydroxychloroquine sulfate, penicillamine, sulfasalazine, aurothioglucose, gold sodium thiomalate, auranofin, and the like; anti-excitotoxic agents dextromethorphan and the like; cytochrome-P450 inhibitors quinine, quinidine, naphthyridine, xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine imidazole, e.g. cimetidine (N-cyano-N'-methyl-N"-[2][(5-methyl-1H-imidazol-4-yl)methyl]thio)ethyl]guanidine), quinoline, e.g. chloroquine (7-chloro-4-(4-diethylamino-1-methylbutylamino)quinoline) and primaquine (8-(4-amino-1-methylbutylamino)-6-methoxyquinoline), a trifluoromethyl oxime ether, e.g., fluvoxamine, also known as 5-methoxy-1-[4-(trifluoromethyl)-phenyl]-1 pentanone 0-(2-aminoethyl) oxime and the like.
PGE₂, PGF₂α, PGF₂β, PGA₂, and PGB₂, and their esters and pharmacologically acceptable salts, are extremely potent in causing various biological responses. Several anti-inflammatory agents interfere in the biosynthetic pathways of prostaglandin and thereby modulate the biological effects of prostaglandin in humans.

Dextromethorphan acts at a class of neuronal receptors known as sigma receptors. They are inhibitory receptors, which means that their activation by DM or other sigma agonists causes the suppression of certain types of nerve signals. Dextromethorphan also acts at another class of receptors known as N-methyl-D-aspartate (NMDA) receptors, which are one type of excitatory amino acid (EAA) receptor. Unlike its agonist activity at sigma receptors, DM acts as an antagonist at NMDA receptors, which means that DM suppresses the transmission of nerve impulses mediated via NMDA receptors. Since NMDA receptors are excitatory receptors, the activity of DM as an NMDA antagonist also leads to the suppression of certain types of nerve signals. The anti-excitotoxic activity of dextromethorphan and dextrorphan, and the blockade of NMDA receptors by these drugs, are discussed in items such as Choi 1987, Wong et al 1988, Steinberg et al 1988, and U.S. Pat. No. 4,806,543 (Choi 1989).

Dextromethorphan has also been reported to suppress activity at neuronal calcium channels (Carpenter et al 1988). Dextromethorphan and the receptors it interacts with are further discussed in Tortella et al 1989, Leander 1989, Koyuncuoglu & Saydam 1990, Ferkany et al.

DM disappears fairly rapidly from the bloodstream (see, e.g., Vetticaden et al 1989 and Ramachander et al 1977). DM is converted in the liver to two metabolites called dextrorphan and 3-methoxymorphinan, by an enzymatic process called O-demethylation. This enzyme is usually referred to as debrisoquin hydroxylase, since it was discovered a number of years ago to carry out a hydroxylation reaction on debrisoquin. It is also referred to in various articles as P450DB or P450-2D6. A number of compounds inhibit the activity of the debrisoquin hydroxylase (sparteine monooxygenase) isozyme; see Inaba et al 1985. The most powerful of these inhibitors is quinidine, a dextrorotatory stereoisomer of quinine; it is normally used to treat cardiac arrhythmias. Inaba et al 1986 and Nielsen et al 1990 discuss the ability of quinidine to inhibit the oxidation of sparteine in in vivo animal tests, and Brinn et al 1986, Brosen et al 1987, and Broly et al 1989 discuss the ability of quinidine to inhibit DM metabolism in liver cell preparations. In addition to the inhibition of debrisoquin hydroxylase, which is exceptionally potent and easily demonstrated, other cytochrome P450 isozymes are also likely to be suppressed by quinidine, with varying levels of binding affinity. Accordingly, even though quinidine exerts its most marked effect on debrisoquin hydroxylase, it is likely to suppress a number of other cytochrome P450 enzymes as well,
thereby subjecting a patient to a more general loss of normal and
desirable liver activity. The primary oxidized metabolic product of
dextromethorphan is dextrophan, which is widely believed among
neurologists to be active in exactly the same manner as
dextromethorphan; both drugs reportedly are sigma agonists, NMDA
antagonists, and calcium channel antagonists. It has been shown that
the administration of a compound which inhibits debrisoquin
hydroxylase, in conjunction with DM, causes a major increase in the
concentration and stability of DM in the blood of patients, compared
to patients who receive only DM; and the administration of a
debrisoquin hydroxylase inhibitor in conjunction with DM has a clear
and substantial impact on the detectable effects of DM in humans.
Eventhough debrisoquin hydroxylase inhibitors are preferred in the
potentiating activity of Dextromethorphan, other agents which inhibit
the oxidative activity of cytochrome-P450, such as a naphthyridine,
xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine
imidazole, e.g. cimetidine (N-cyano-N'-methyl-N''-[2][((5-methyl-1H-
imidazol-4 yl)methyl]thio]ethyl]guanidine), quinoline, e.g.
chloroquine (7-chloro-4-(4-diethylamino-1-
methylbutylamino)quinoline) and primaquine (8-(4-amino-1-
methylbutylamino)-6-methoxyquinoline), a trifluoromethyl oxime
ether, e.g., fluvoxamine, also known as 5-methoxy-1-[4-
(trifluoromethyl)-phenyl]-1 pentanone 0-(2-aminoethyl) oxime may
be useful in potentiating the activity of dextromethorphan.
In order to practice the invention, any one of the NSAID substances can be used. However, the invention is illustrated by using acetaminophen which is most commonly used under the brand name Tylenol. Similar in mechanism to aspirin, acetaminophen is a weak inhibitor of cyclo-oxygenase in the periphery and at the hypothalamic thermoregulatory center. It has antipyretic and analgesic effects, but no anti-inflammatory effect. Acetaminophen is relatively safe at normal dosages. Acetaminophen is able to cross the blood-brain barrier, unlike the NSAIDs and may be able to inhibit prostaglandin synthesis whether they are formed centrally or peripherally. It inhibits synthesis of prostaglandins by competing with arachidonic acid for the active site on the COX enzyme and COX isoenzyme that is most sensitive to the antipyretic activity of acetaminophen is more susceptible than either COX-1 or COX-2 which suggests the presence of either cell-specific factors that produce and altered COX-2 or possibly the presence of a COX-3 isoenzyme.

Oral combination dosage units preferably contain dextromethorphan in the range of about 30 to not more than 200 milligrams (mg), preferably in the range of about 60 and about 120 mg and of acetaminophen in the range of about 300 to about 1500 mg, preferably in the range of about 600 to about 1200 mg, so long as the combined dose received by the patient is accompanied by minimal or substantially no undesirable side effects. A particularly preferred oral combination dosage unit contains about 120 mg
dextromethorphan and not more than 1200 mg acetaminophen, more
preferably about 90 mg dextromethorphan and not more than about
1000 mg acetaminophen.

Alternatively, the dextromethorphan and acetaminophen may
be formulated separately in the foregoing compositions as the sole
active ingredient for practicing sequential administration of each
respective drug.

For sequential administration therapy, acetaminophen and
dextromethorphan each is administered in a separate dosage. For
sequential administration of acetaminophen, the dosage unit
preferably contains acetaminophen in a range of about 200 to about
1500 mg, more preferably in the range of about 500 to about 1200
mg, and for administration of dextromethorphan the dosage unit
preferably contains dextromethorphan in a range of about 30 to not
more than 120 mg, more preferably in the range of about 60 to about
90 mg so long as the total combined dose received by the patient is
accompanied by minimal or substantially no undesirable side effects.

A particularly preferred sequential administration dosage unit
of acetaminophen contains acetaminophen in the range of about 600
to about 1000 mg and of dextromethorphan contains
dextromethorphan in the range of about 45 to about 90 mg.
Preferably, each drug is administered orally. Alternatively, each drug
can be administered by different oral routes; i.e., one can be ingested and the other administered sublingually or by buccal patch.

For effective sequential administration of acetaminophen and dextromethorphan, the release of each drug is preferably staggered to maximize the beneficial delayed ejaculation by acetaminophen.

In order to potentiate the effect of dextromethorphan, optionally an effective amount of a cytochrome P450 enzyme inhibitor such as quinidine can be administered to the patient either in a combination dosage unit or in a sequential administration dosage unit. When a cytochrome P450 inhibitor is administered in order to augment the effect of dextromethorphan, the dosage of dextromethorphan can be suitably adjusted to have maximum efficacy with minimum side effects. Oral combination dosage units preferably can contain quinidine in the range of about 50 to not more than 200 milligrams (mg), preferably in the range of about 90 and about 120 mg. Oral combination dosage units preferably can contain quinidine in the range of about 50 to not more than 200 milligrams (mg), preferably in the range of about 90 and about 120 mg.

**ACTIVE AGENTS FOR TREATING PREMATURE EJACULATION IN CLASS II MALES**
In order to carry out the method of the invention to treat premature ejaculation in CLASS II males who have erection as well as ejaculation problems, selected pharmacologically active agent is administered to an individual. The active agents may be administered orally, parenterally, buccally, rectally, or locally by intracavernosal injection or by delivery to the urethra. Suitable pharmacologically active agents include, cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitors such as sildenafil, anti-excitotoxid agents such as dextromethorphan and optionally the cytochrome-P450 inhibitors such as quinine, quinidine, naphthyridine, xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine imidazole, e.g. cimetidine (N-cyano-N'-methyl-N"-[2][(5-methyl-1H-imidazol-4-yl)methyl]thio[ethyl]guanidine), quinoline, e.g. chloroquine (7-chloro-4-(4-diethylamino-1-methylbutylamino)quinoline) and primaquine (8-(4-amino-1-methylbutylamino)-6-methoxyquinoline), a trifluoromethyl oxime ether, e.g., fluvoxamine, also known as 5-methoxy-1-[4-(trifluoromethyl)-phenyl]-1 pentaone 0-(2-aminoethyl) oxime.

Sildenafil is designated chemically as 1-[[3-(6,7-dihydro-1-methyl-7-oxo-3-propyl-1H-pyrazolo[4,3-d] pyrimidin-5-yl)-4-ethoxyphenyl]sulfonyl]-4-methyl piperazine and has the following structural formula: Figure 3.

Sildenafil citrate is presently the active ingredient of a
commercial medication for impotence sold under the designation Viagra™ (Pfizer Labs, N.Y.) formulated in tablets equivalent to 25 mg, 50 mg and 100 mg sildenafil for oral administration. According to the manufacturer, in addition to the active ingredient, sildenafil citrate, each tablet contains the following inactive ingredients: microcrystalline cellulose, anhydrous dibasic calcium phosphate, croscarmellose sodium, magnesium stearate, hydroxypropyl methylcellulose, titanium dioxide, lactose, triacetin, and FD&C Blue #2 aluminum lake.

It is known from in vitro studies that sildenafil is approximately 4,000 fold more selective for inhibiting phosphodiesterase type 5 (PDE5) than on other known phosphodiesterases, such as PDE3, which is involved in control of cardiac contractility. Sildenafil is reportedly only about 10-fold as potent for PDE5 compared to PDE6, an enzyme found in the retina and it is this lower selectivity which is thought to be the basis for abnormalities related to color vision observed with higher doses or plasma levels.

Sildenafil, administered as the commercially available Viagra™ formulation, is reported to be rapidly absorbed after oral administration, with absolute bioavailability of about 40%. Its pharmacokinetics are dose-proportional over the recommended dose range. Based on the Viagra™ manufacturer's product literature,
maximum observed plasma concentrations are reached within 30 to 
120 minutes (median 60 minutes) of oral dosing in the fasted state. 
When the Viagra™ formulation is taken with a high fat meal, the rate 
of absorption is reduced, with a mean delay in Tmax of 60 minutes 
and mean reduction in Cmax of 29%. The mean steady state volume 
of distribution (Vss) for sildenafil is reportedly 105 L, indicating 
distribution into the tissues. Based upon reported measurements of 
sildenafil in the semen of healthy volunteers 90 minutes after dosing, 
less than 0.001% of the administered dose appeared in the semen of 
the patients.

Surprisingly, a therapeutically effective dosage combination of 
dextromethorphan and sildenafil employed with the compositions of 
this invention maximizes the beneficial erectogenic efficacy of 
sildenafil by delaying the premature ejaculation.

Oral combination dosage units preferably contain 
dextromethorphan in the range of about 30 to not more than 120 
milligrams (mg), preferably in the range of about 50 and about 100 
mg and of sildenafil in the range of about 10 to about 75 mg, 
preferably in the range of about 15 to about 50 mg, so long as the 
combined dose received by the patient is accompanied by minimal or 
substantially no undesirable side effects. A particularly preferred oral 
combination dosage unit contains about 100 mg dextromethorphan
and not more than 100 mg sildenafil, more preferably about 75 mg
dextromethorphan and not more than about 50 mg sildenafil.

Alternatively, the dextromethorphan and sildenafil may be
formulated separately in the foregoing compositions as the sole active
ingredient for practicing sequential administration of each respective
drug.

For sequential administration therapy, sildenafil and
dextromethorphan each is administered in a separate dosage. For
sequential administration of sildenafil, the dosage unit preferably
contains sildenafil in a range of about 10 to about 120 mg, more
preferably in the range of about 25 to about 100 mg, and for
administration of dextromethorphan the dosage unit preferably
contains dextromethorphan in a range of about 30 to not more than
120 mg, more preferably in the range of about 60 to about 90 mg so
long as the total combined dose received by the patient is
accompanied by minimal or substantially no undesirable side effects.

A particularly preferred sequential administration dosage unit
of sildenafil contains sildenafil in the range of about 50 to about 100
mg and of dextromethorphan contains dextromethorphan in the range
of about 45 to about 90 mg. Preferably, each drug is administered
orally. Alternatively, each drug can be administered by different oral
routes; i.e., one can be ingested and the other administered
sublingually or by buccal patch.

If desired, to facilitate absorption and thus bioavailability, absorption enhancing agents, such as cyclodextrins, particularly $\beta$-cyclodextrin, or a derivative thereof, such as hydroxypropyl-$\beta$-cyclodextrin (HPBCD) and the like may be included. Cyclodextrins are a group of cyclic, nonreducing oligosaccharides built up from six, seven or eight glucopyranose rings, respectively known as alpha, beta and gamma cyclodextrins. The cyclodextrins are a class of cavity-containing cyclic compounds possessing the property of forming a molecular inclusion complexes, which anchor or entrap another chemical compounds without the formation of covalent bonds. HPBCD is a cyclic polymer having a doughnut-shaped molecular structure including an inner cavity.

Hydroxypropyl-$\beta$-cyclodextrins are commercially available compounds that are derived from $\beta$-cyclodextrins by condensation with a propylene oxide to provide the corresponding hydroxypropyl derivatives having a degree of substitution (D.S.) of up to about 15 or higher. For the purposes of the present invention a D.S. value of about 5 to 7 is preferred.

The preparation of such suitable hydroxypropyl-$\beta$-cyclodextrins is described, inter alia, in the International Journal of Pharmaceutics, 29, 73-82 (1986) and in the Journal of Pharmaceutical
Sciences, 75 (6), 571-572 (1986). Also known and suitable for the present invention are the hydroxypropyl-β-cyclodextrins that are polyethers of cyclodextrins and are obtained by the condensation of an excess of hydroxypropylene oxide with β-cyclodextrin as described in U.S. Pat. No. 3,459,731. to Gramera et al. Hydroxypropyl-β-cyclodextrin (HPBCD) is particularly preferred cyclodextrin constituent, but is not limited thereto. The weight percent of the HPBCD in the composition is preferably in the range of about 1 to about 10 weight percent of the total composition.

Particularly in the case of sildenafil, it has been found that HPBCD enhances bioavailability. Thus, the desired therapeutic effect can be achieved with a relatively lower dose of sildenafil, thereby minimizing the likelihood of adverse affects.

For effective sequential administration of sildenafil and dextromethorphan, the release of each drug is preferably staggered to maximize the beneficial prolongation of erection by dextromethorphan and maintenance of erection by sildenafil upon sexual stimulation.

To augment the beneficial effect of dextromethorphan and sildenafil therapy, lesser amounts of erectogenic agents can be included. The term "erectogenic agents" as used herein refers to adrenal steroids, such as testosterone, dehydroepiandrosterone.
(DHEA) and the like. Preferably, the erectogenic agents are added in an amount in the range of about 5 to about 10 percent by weight, more preferably in the range of about 6 to about 8 percent by weight of the weight of sildenafil administered.

In order to potentiate the effect of dextromethorphan, optionally an effective amount of a cytochrome P450 enzyme inhibitor such as quinidine can be administered to the patient either in a combination dosage unit or in a sequential administration dosage unit. When a cytochrome P450 inhibitor is administered in order to augment the effect of dextromethorphan, the dosage of dextromethorphan can be suitably adjusted to have maximum efficacy with minimum side effects. Oral combination dosage units preferably can contain quinidine in the range of about 50 to not more than 200 milligrams (mg), preferably in the range of about 90 and about 120 mg. Oral combination dosage units preferably can contain quinidine in the range of about 50 to not more than 200 milligrams (mg), preferably in the range of about 90 and about 120 mg.

In addition, suitable amount of a COX inhibitor can be added to the composition of the invention containing sildenafil and dextromethorphan without affecting the therapeutic effect of the composition.
The active agents may be administered in the form of pharmaceutically acceptable salts, esters, amides or prodrugs or combinations thereof. However, conversion of inactive ester, amide or prodrug forms to an active form must occur prior to or upon reaching the target tissue or cell. Salts, esters, amides and prodrugs of the active agents may be prepared using standard procedures known to those skilled in the art of synthetic organic chemistry and described, for example, by J. March, Advanced Organic Chemistry: Reactions, Mechanisms and Structure, 4th Ed. (New York: Wiley-Interscience, 1992). For example, acid addition salts are prepared from the free base (typically wherein the neutral form of the drug has a neutral --NH2 group) using conventional means, involving reaction with a suitable acid. Generally, the base form of the drug is dissolved in a polar organic solvent such as methanol or ethanol and the acid is added thereto. The resulting salt either precipitates or may be brought out of solution by addition of a less polar solvent. Suitable acids for preparing acid addition salts include both organic acids, e.g., acetic acid, propionic acid, glycolic acid, pyruvic acid, oxalic acid, malic acid, malonic acid, succinic acid, maleic acid, fumaric acid, tartaric acid, citric acid, benzoic acid, cinnamic acid, mandelic acid, methanesulfonic acid, ethanesulfonic acid, ptoluenesulfonic acid, salicylic acid, and the like, as well as inorganic acids, e.g., hydrochloric acid, hydrobromic acid, sulfuric acid, nitric acid, phosphoric acid, and the like. An acid addition salt may be reconverted to the free base by treatment with a suitable base.
Conversely, preparation of basic salts of acid moieties which may be present on a drug are prepared in a similar manner using a pharmaceutically acceptable base such as sodium hydroxide, potassium hydroxide, ammonium hydroxide, calcium hydroxide, trimethylamine, or the like. Preparation of esters involves functionalization of hydroxyl and/or carboxyl groups which may be present within the molecular structure of the drug. The esters are typically acyl-substituted derivatives of free alcohol groups, i.e., moieties which are derived from carboxylic acids of the formula RCOOH where R is alkyl, and preferably is-lower alkyl. Esters can be reconverted to the free acids, if desired, by using conventional hydrogenolysis or hydrolysis procedures. Preparation of amides and prodrugs can be carried out in an analogous manner. Other derivatives and analogs of the active agents may be prepared using standard techniques known to those skilled in the art of synthetic organic chemistry, or may be deduced by reference to the pertinent literature. In addition, chiral active agents may be in enantiomerically pure form, or they may be administered as an enantiomeric mixture.

Depending on the intended mode of administration, the pharmaceutical compositions may be in the form of solid, semi-solid or liquid dosage forms, such as, for example, tablets, suppositories, pills, capsules, powders, liquids, suspensions, creams, ointments, lotions or the like, preferably in unit dosage form suitable for single administration of a precise dosage. The compositions will include an
effective amount of the selected drugs in combination with a
pharmaceutically acceptable carrier and, in addition, may include
other pharmaceutical agents, adjuvants, diluents, buffers, etc. The
compounds may thus be administered orally, parenterally,
transdermally, rectally, nasally, buccally, topically or via an
implanted reservoir in dosage formulations containing conventional
non-toxic pharmaceutically acceptable carriers, adjuvants and
vehicles. The term "parenteral" as used herein is intended to include
subcutaneous, intravenous, and intramuscular injection. The amount
of active compound administered will, of course, be dependent on the
subject being treated, the subject's weight, the manner of
administration and the judgment of the prescribing physician.

For solid compositions, conventional nontoxic solid carriers
include, for example, pharmaceutical grades of mannitol, lactose,
starch, magnesium stearate, sodium saccharin, talc, cellulose,
glucose, sucrose, magnesium carbonate, and the like. Liquid
pharmaceutically administrable compositions can, for example, be
prepared by dissolving, dispersing, etc., an active compound as
described herein and optional pharmaceutical adjuvants in an
excipient, such as, for example, water, saline, aqueous dextrose,
glycerol, ethanol, and the like, to thereby form a solution or
suspension. If desired, the pharmaceutical composition to be
administered may also contain minor amounts of nontoxic auxiliary
substances such as wetting or emulsifying agents, pH buffering
agents and the like, for example, sodium acetate, sorbitan mono-
laurate, triethanolamine sodium acetate, triethanolamine oleate, etc.
Actual methods of preparing such dosage forms are known, or will be
apparent, to those skilled in this art; for example, see Remington's
Pharmaceutical Sciences, referenced above. For oral administration,
the composition will generally take the form of a tablet or capsule, or
may be an aqueous or nonaqueous solution, suspension or syrup.
Tablets and capsules are preferred oral administration forms. Tablets
and capsules for oral use will generally include one or more
commonly used carriers such as lactose and corn starch. Lubricating
agents, such as magnesium stearate, are also typically added. When
liquid suspensions are used, the active agent may be combined with
emulsifying and suspending agents. If desired, flavoring, coloring
and/or sweetening agents may be added as well. Other optional
components for incorporation into an oral formulation herein include,
but are not limited to, preservatives, suspending agents, thickening
agents, and the like.

Parenteral administration, if used, is generally characterized by
injection. Injectable formulations can be prepared in conventional
forms, either as liquid solutions or suspensions, solid forms suitable
for solubilization or suspension in liquid prior to injection, or as
emulsions. Preferably, sterile injectable suspensions are formulated
according to techniques known in the art using suitable carriers,
dispersing or wetting agents and suspending agents. The sterile
injectable formulation may also be a sterile injectable solution or a suspension in a nontoxic parenterally acceptable diluent or solvent. Among the acceptable vehicles and solvents that may be employed are water, Ringer's solution and isotonic sodium chloride solution. In addition, sterile, fixed oils, fatty esters or polyols are conventionally employed as solvents or suspending media. A more recently revised approach for parenteral administration involves use of a slow release or sustained release system, such that a constant level of dosage is maintained. See, e.g., U.S. Pat. No. 3,710,795.

The active agent can be administered in a pharmaceutical formulation suitable for transurethral drug delivery. The formulation contains one or more selected carriers or excipients, such as water, silicone, waxes, petroleum jelly, polyethylene glycol ("PEG"), propylene glycol ("PG"), liposomes, sugars such as mannitol and lactose, and/or a variety of other materials, with polyethylene glycol and derivatives thereof particularly preferred. Depending on the drug administered, it may be desirable to incorporate a transurethral permeation enhancer in the urethral dosage form. Examples of suitable transurethral permeation enhancers include dimethylsulfoxide ("DMSO"), dimethyl formamide ("DMF"), N,N-dimethylacetamide ("DMA"), decylmethylsulfoxide ("C10 MSO"), polyethylene glycol monolaurate ("PEGML"), glycerol monolaurate, lecithin, the 1-substituted azacycloheptan-2-ones, particularly 1-n-dodecylcyclazacycloheptan-2-one (available under the trademark
Azone® from Nelson Research & Development Co. Irvine, Calif.), SEPA® (available from Macrochem Co., Lexington, Mass.), alcohols (e.g., ethanol), detergents (such as Tergitol®, Nonoxynol-9® and TWEEN-80®) and the like.

It is to be understood that while the invention has been described in conjunction with the preferred specific embodiments thereof, that the foregoing description as well as the examples which follow are intended to illustrate and not limit the scope of the invention. Other aspects, advantages and modifications within the scope of the invention will be apparent to those skilled in the art to which the invention pertains.

**EXAMPLE 1**

**Plasma Concentrations of DM**

Five patients with a symptom of having premature ejaculation were orally administered 120 mg of DM, with no co-administration of quinidine. Between 10 and 12 hours later, blood was sampled, blood plasma was isolated by centrifugation, and the plasma was analyzed to determine the DM concentration using the HPLC method. During a different week, the same patients were orally administered 60 mg of DM (half the control dosage) and 150 mg of quinidine. Between 10 and 12 hours later, blood was sampled and the plasma was analyzed for DM using thebaine/HPLC. The results, in
Table 1, indicate that quinidine causes a major increase in the concentration of DM in the blood plasma.

**EXAMPLE 2**
Capsule Formulations

The following ingredients in each one of the capsule formulations were weighed accurately, ground using a pestle and mortar to fine and homogeneous powders. These powders were sieved through 100 mesh and filled into hard gelatin capsules. The composition of each capsule formulation is listed below.

### Capsule Formulation 1

EXAMPLE 3

Capsule Formulations Containing Sildenafil

The following ingredients in each one of the capsule formulations were weighed accurately, ground using a pestle and mortar to fine and homogeneous powders. These powders were sieved through 100 mesh and filled into hard gelatin capsules. The composition of each capsule formulation is listed below.

**EXAMPLE 4**

A white male, born on May 3, 1957 was in the process of establishing a cosmetic business. He was in the midst of setting up
and manufacturing several products, making strategy for securing
capital for the company and marketing the product. He used to work
almost 14-16 hours a day. He noticed that during sexual activities
with his girl friend he could not control the ejaculation resulting in
disappointment from his female partner. Because of the premature
ejaculation problem he was trying to avoid sexual contact with his
female partner whenever possible and his partner was feeling
unfulfilled sexual experience and sometimes anger. The patient was
provided with 500 mg capsules of formulation 4 in example 3 and
advised to take 2 capsule approximately 3 hours before intercourse
and 1 capsule approximately 1 hour before intercourse. He took 2
capsules in the first night and according to his testimony, he felt
slightly numb in his penis and he was able to arouse his female
partner’s sexual feelings by performing pre-intercourse sexual
conducts and his partner was able to perform pre-intercourse sexual
conducts with his penis for almost half hour without any ejaculation
He was able to perform intercourse for more than 20 minutes and hi
partner felt exhaustion. His female partner was so ecstatic and he w
able to perform sexual intercourse 2 times that night. The patient is
periodically taking the capsules whenever he wants to have a good
and sound sexual intercourse for his otherwise stressful body.

EXAMPLE 5

An Indian male, age 47, was involved in various businesses.
He spent lot of his time in the business aspect and used to drink at
dinner meetings to alleviate his stress due to his hectic business activities. Whenever he had tried to engage in romantic and sexual activities with his wife, he noticed that he could not hold his erection due to early ejaculation. His wife used to feel that she was not being loved by her husband and she used to feel abandoned by her husband. He used to feel embarrassed whenever he was with his wife and he sought help to alleviate his miserable sexual life. He was provided the pharmaceutical formulation of formulation 5 in example 3. During the first day he took 2 capsules 3-4 hours before his sexual activity and 1 capsule 1 hour before. He felt slight numbness around his penis and he felt very relaxed during his sexual act with his wife. He and his wife had intercourse for more than an hour and his wife said afterwards she never felt this happy during her entire life. Both were exhausted after the sexual act. Now whenever he needs satisfaction and comfort in his sex life, he takes the pharmaceutical composition described in this invention.

EXAMPLE 6

A white male of hispanic origin, born on June 3, 1944 is working as a manager in a healthcare institution. He used to get up in the early morning and work late night attending various meetings. He has to bring quality patients to the hospital for treatment and has to find the proper physicians for taking care of these patients. He has to be on the phone for several hours a day and used to drink almost 4-5 cups of coffee a day. He used to feel exhausted and stressed out most
of the day. At night he used to be awake thinking about his business activities and he noticed that whenever he is doing sexual act with his girlfriend he ejaculated within 1 minute of intercourse and his girlfriend used to be restless the entire night. He was asked to take two capsules of formulation 4 in example 3, 3-4 hours and 1 capsule 1 hour before doing sexual act. According to him, after taking the capsules and when he was engaged in sexual act he was very calm and confident and his girlfriend had played with his penis for nearly an hour without any discomfort. He had intercourse for more than 30 minutes and both were exhausted after the sexual conduct. According to him, his girlfriend was so ecstatic she didn’t allow him to go to work the next day. Now he is constantly taking the capsules of whenever he needs a good and comfortable sexual conduct.

EXAMPLE 7

A white male of 39 yrs old who is living with his girl friend was keenly interested in the effect of the compositions of the present invention on his sexual activity. The subject consumed one (blue/yellow) capsule described as formulation 5 in example 3 at approximately 18:00. At 18:45 the subject reported a feeling of heaviness in the genitals with a slight feeling of flushing in the face. Sexual activity commenced at 19:15. Subject reported that his erection had a greater degree of stiffness and a sense of increased distension over that usually experienced. The subject reported that his staying power was increased by approximately 70% over his
usual experience. Sexual intercourse was continued for approximately 90 minutes concluding with a more powerful than usual orgasm.

EXAMPLE 8

The Effect of Sildenafil, Dextromethorphan Acetaminophen on CLASS II Males

In order to demonstrate the efficacy of Sildenafil and Dextromethorphan composition to treat premature ejaculation of CLASS II males, 22 volunteers have been chosen from the age groups of 28 and 57 who had premature ejaculation and erection problems. The volunteers were given capsules of formulation 4 in example 3. The volunteers were asked to take 2 capsules 2-3 hour before the sexual act and were asked to fill out a questionnaire (as outlined below) before and after the sexual acts. The study was conducted for 8 weeks and the results were compiled and analyzed for sexual satisfaction. The results show that more than 80% of the volunteers were extremely satisfied with the composition of the invention for pre-mature ejaculation problems.

SEXUAL FUNCTION STUDY HOME QUESTIONNAIRE

Male

Please answer questions within 3 – 6 hours of taking capsule.
The lines below represent the full range of feeling or response.

Please mark each line clearly with a vertical (straight up and down) stroke at the point which represents your response.

(There are no right or wrong answers. Do not write in boxes on right.)

1. What was your erection result after taking the capsules?

   No Rigid Erection [ ]

   Erection Suitable for Penetration [ ]

2. Did you have intercourse with wife/partner after taking tablet? [ ] Yes [ ] No

IF NO please circle all reasons that apply:

   0 - No erection. [ ]

   1 - Erection not sufficient for penetration. [ ]
2. Felt sick after taking the capsules.
3. I decided not to participate in intercourse.
4. Wife/partner decided not to participate.
5. Unrelated interruption (example, telephone call).
6. Wife/partner menstruating.
7. Other, explain:
   ____________________________________________
   ____________________________________________

3. What was your level of satisfaction with this attempt at sexual intercourse?

Extremely Satisfied [ ]
Extremely Unsatisfied: ____________________________________________ [ ]

3. How long you were able to keep the erection before ejaculation with this attempt at sexual intercourse?

Erection Time Less than 3 Minutes [ ]
Erection Time 3 - 6 Minutes [ ]
Erection Time 6 - 10 Minutes [ ]
Erection Time More than 10 Minutes [ ]

4. Please describe any adverse reactions you experienced after taking the capsules. (Indicate when the reaction started and stopped, and any intervention taken)

What is claimed is:

1. A method for delaying the onset of ejaculation in a male individual, comprising administering to the individual a pharmaceutical formulation containing pharmacologically active agents selected from the group consisting of non-steroid COX inhibitors, anti-excitotoxic agents and cytochrome P-450 inhibitors and in an amount effective to delay the onset of ejaculation by the individual during sexual intercourse, wherein the formulation is administered orally, parenterally or by intracavernosal injection.

2. The method of claim 1, wherein the formulation is administered parenterally.

3. The method of claim 1, wherein the formulation is administered by intracavernosal injection.

4. The method of claim 1, wherein the COX inhibitor is at least one selected from the group consisting of, but not limited to, salicylates, acetaminophen, Diclofenac sodium, Etodolac, indomethacin, tiaprofenic acid, fenoprofen calcium, flurbiprofen, ibuprofen, ketoprofen, meclofenamate sodium monohydrate, nabumetone, naproksen, naproksen sodium, oxaprozin, phenylbutazone, piroxicam, tenoxicam, meloxicam, sulindac, tolmetin sodium, hydroxychloroquine sulfate, penicillamine, sulfasalazine, aurothioglucose, gold sodium
thiomalate, auranofin, azathioprine, allopurinol, probenecid, celecoxib, rofecoxib, valdecoxib and sulfinpyrazone.

5. The method of claim 1, wherein the anti-excitotoxic agent is selected from dextromethorphan and its salts.

6. The method of claim 1, wherein the cytochrome P-450 inhibitor is at least one selected from the group consisting of, but not limited to, quinine, quinidine, naphthyridine, xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine imidazole, e.g. cimetidine (N-cyano-N'\text{-}methyl-N''-[2\text{[(5-methyl-1H-imidazol-4\text{-}yl)methyl]thio}jethyl]guanidine), quinoline, e.g. chloroquine (7-chloro-4-(4-diethylamino-1-methylbutylamino)quinoline) and primaquine (8-(4-amino-1-methylbutylamino)-6-methoxyquinoline), fluvoxamine, also known as 5-methoxy-1-[4-(trifluoromethyl)-phenyl]-1-pentanone 0-(2-aminoethyl) oxime, and grapefruit extract or its components.

7. The method of claim 1, wherein the dosing regimen comprises administration of a predetermined dose of the agents one to four times in a twenty-four hour period.

8. The method of claim 1, wherein the COX inhibitor and anti-excitotic agent are administered combined in a single dosage form.

9. The method of claim 1, wherein the COX inhibitor and anti-excitotic agent are administered as separate dosage forms substantially concurrently.
10. The method of claim 1, wherein the COX inhibitor, anti-
excitotic agent and cytochrome P-450 inhibitor are
administered combined in a single dosage form.

11. The method of claim 1, wherein the COX inhibitor, anti-
excitotic agent and cytochrome P-450 inhibitor are
administered as separate dosage forms substantially
concurrently.

12. A method for delaying the onset of ejaculation in a male
individual who has premature ejaculation problem, comprising
administering to the individual a pharmaceutical formulation
containing pharmacologically active agents selected from the
group consisting of cyclic-GMP-specific phosphodiesterase
type 5 (PDE5) inhibitors, non-steroid COX inhibitors, anti-
excitotoxic agents and cytochrome P-450 inhibitors and in an
amount effective to delay the onset of ejaculation by the
individual during sexual intercourse, wherein the formulation
is administered orally, parenterally or by intracavernosal
injection.

13. The method of claim 12, wherein the formulation is
administered parenterally.

14. The method of claim 12, wherein the formulation is
administered by intracavernosal injection.

15. The method of claim 12, wherein the cyclic-GMP-specific
phosphodiesterase type 5 (PDE5) inhibitor is sildenafil.
16. The method of claim 12, wherein the cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor is silendafil citrate.

17. The method of claim 12, wherein the anti-excitotoxic agent is selected from dextromethorphan and its salts.

18. The method of claim 12, wherein the cytochrome P-450 inhibitor is at least one selected from the group consisting of, but not limited to, quinine, quinidine, naphthylidine, xanthine, phenoxy amino alkane, carbamoyl imidazole, guanidine imidazole, e.g. cimetidine (N-cyano-N'-methyl-N''-[2,[(5-methyl-1H-imidazol-4-yl)methyl]thio]ethyl]guanidine), quinoline, e.g. chloroquine (7-chloro-4-(4-diethylamino-1-methylbutylamino)quinoline) and primaquine (8-(4-amino-1-methylbutylamino)-6-methoxyquinoline), fluvoxamine, also known as 5-methoxy-1-[4-(trifluoromethyl)-phenyl]-1-pentanone 0-(2-aminoethyl) oxime, and grapefruit extract or its components.

19. The method of claim 12, wherein the dosing regimen comprises administration of a predetermined dose of the agents one to four times in a twenty-four hour period.

20. The method of claim 12, wherein the cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor and anti-excitotic agent are administered combined in a single dosage form.

21. The method of claim 12, wherein the anti-excitotic agent and cyclic-GMP-specific phosphodiesterase type 5 (PDE5)
inhibitor are administered as separate dosage forms substantially concurrently.

22. The method of claim 12, wherein the cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor, anti-excitotic agent and cytochrome P-450 inhibitor are administered combined in a single dosage form.

23. The method of claim 12, wherein the anti-excitotic agent and cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor and cytochrome P-450 inhibitor are administered as separate dosage forms substantially concurrently.

24. The method of claim 12, wherein the cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor, anti-excitotic agent and the COX inhibitor are administered combined in a single dosage form.

25. The method of claim 12, wherein the COX inhibitor, anti-excitotic agent and cyclic-GMP-specific phosphodiesterase type 5 (PDE5) inhibitor are administered as separate dosage forms substantially concurrently.
Fig. 2
