(54) Freewheel or Unidirectional Clutch

(57) A freewheel of the cam type has a series of jamming cams 1 held by a cage 4 between a shaft 3 and an outer sleeve 2. The cams 1 are held in recesses 5 in the cage, which is a single integral moulding, by an integral spring strip 9 which extends around the outer periphery of the cage

4 and has elastic tabs 10 which project into the recesses 5 and bear against circumferentially extending surfaces 11 on the cams 1. They thus exert a substantially radial force 12 and a reaction on the contact line 13 to produce a torque 8 on the cams. The spring strip 9 is fixed angularly and axially with respect to the cage 4 by lugs 15 on the cage 4 fitting in openings 16 in the strip.

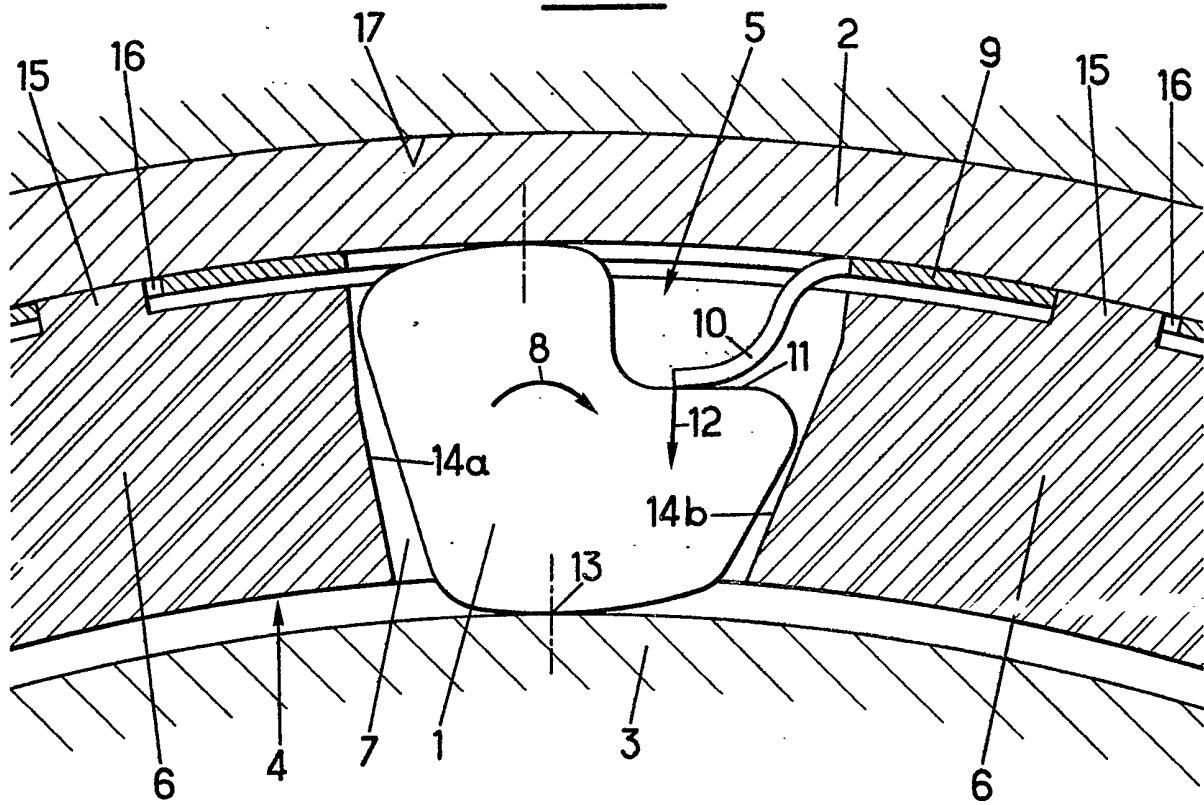

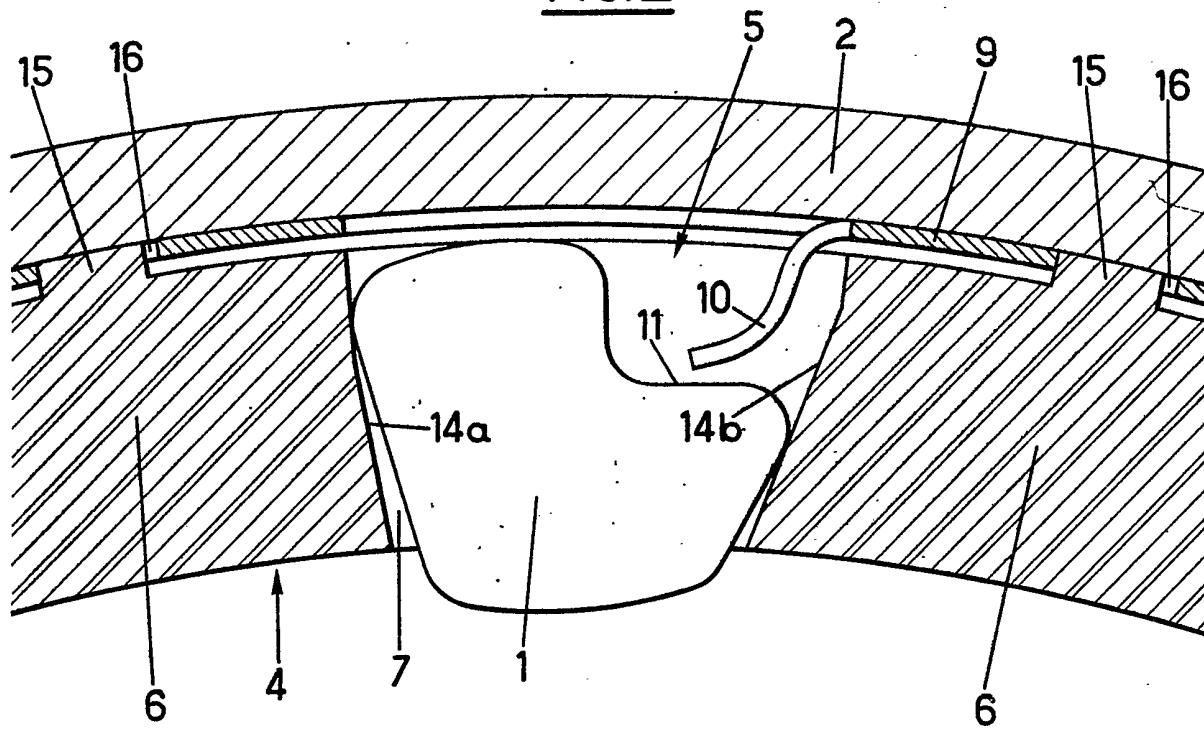

FIG.1FIG.2

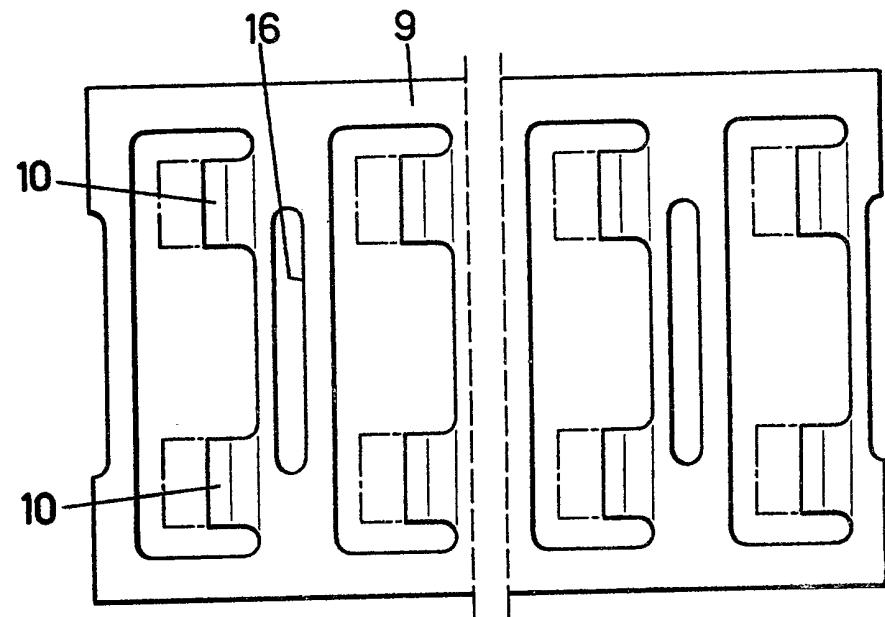

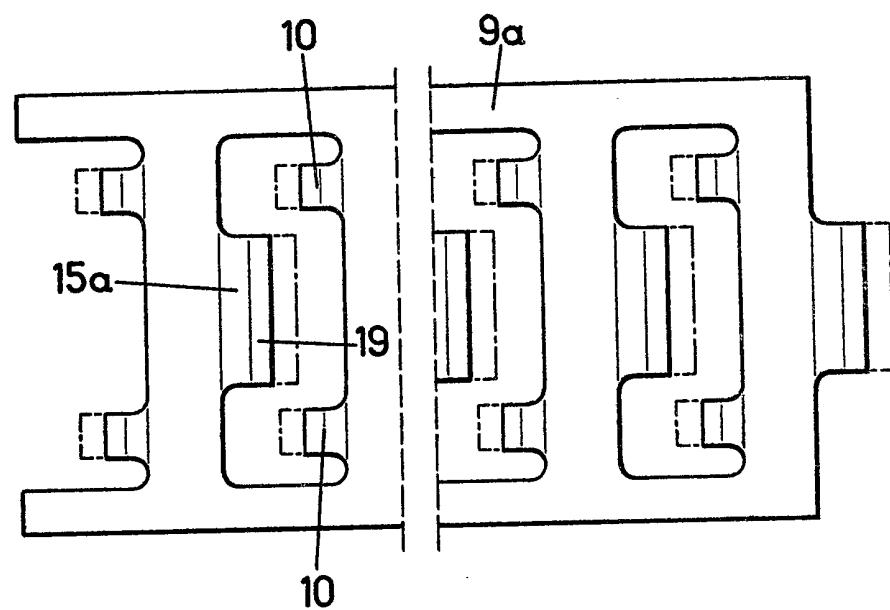

FIG.3FIG.6

FIG.4

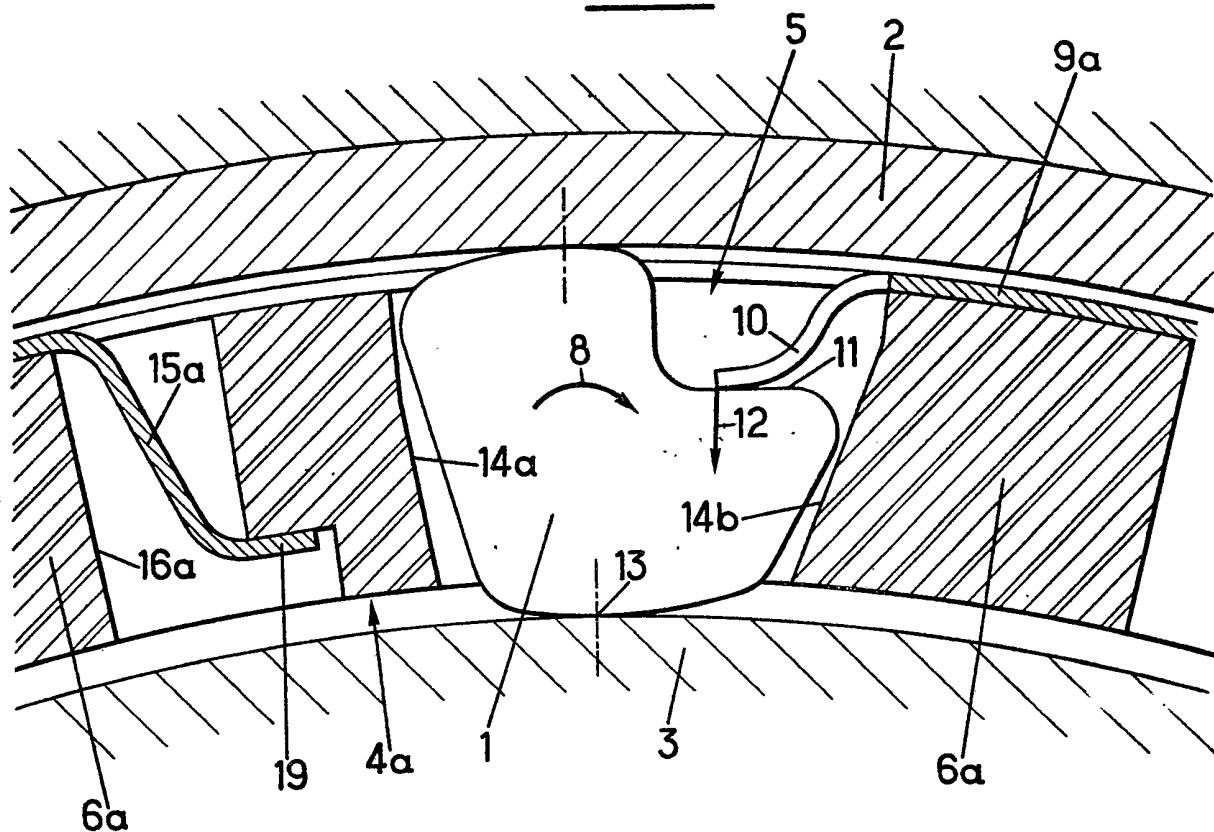

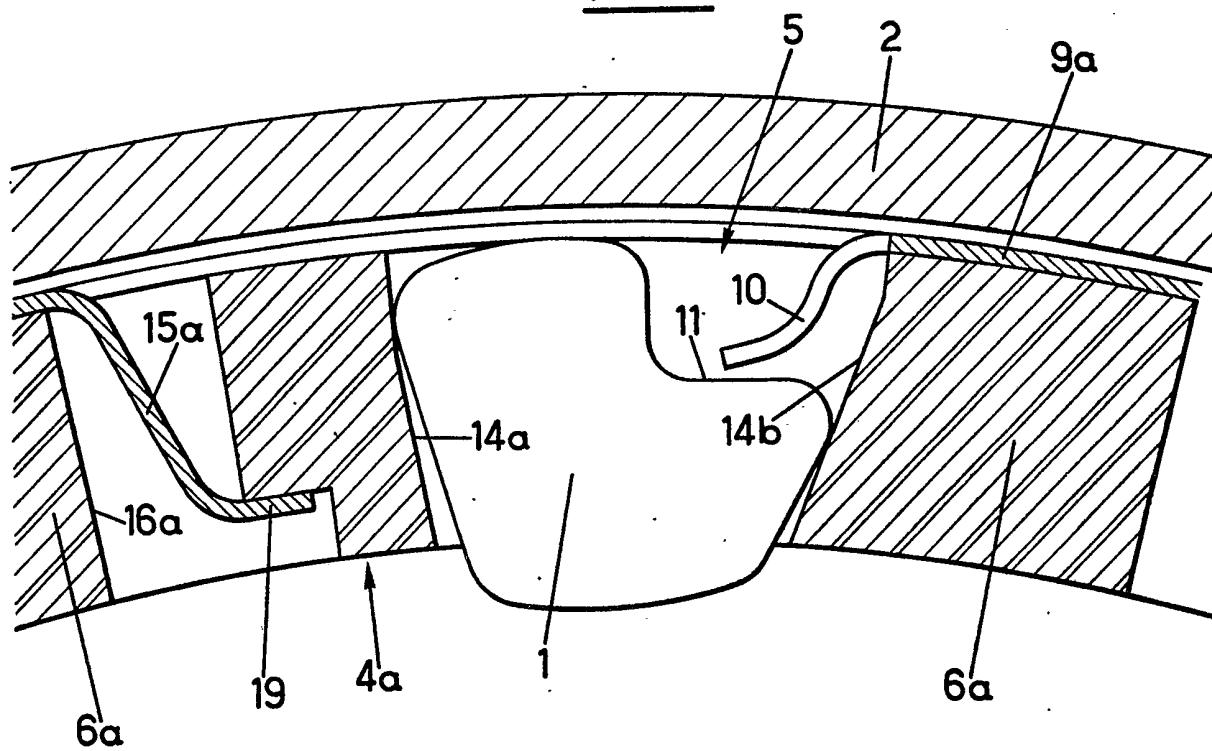

FIG.5

SPECIFICATION
Freewheel or Unidirectional Clutch

This invention relates to freewheels or unidirectional clutches which comprise cam profiled jamming elements which are held in a cage between the inside surface of revolution of an outer ring and the outside surface of revolution of an inner member which is concentric with the outer ring.

5 Freewheels such as this differ from each other primarily in the nature of the cage which must perform a number of functions. Firstly, it holds the jamming elements at a regular peripheral spacing. Secondly, it holds the elements with their 10 generatrices in the axial direction of the ring and inner member. Thirdly, it exerts individually upon each element a resilient restoring torque, and finally it usually ensures the retention of the elements in the cage during handling of the 15 assembled cage and elements prior to their introduction between the outer ring and inner member. For these purposes the cage comprises a rigid structural member and resilient members which are sometimes united into a single resilient 20 member formed in a continuous strip. However, in order to ensure that all of the preceding functions are carried out two members are generally essential and especially in the case of the resilient member a great complexity of shape and extreme 25 accuracy of dimensions has been necessary. The result of this is that freewheels of the type described above are generally relatively costly and can be employed in practice only for specialised uses and in large sizes.

30 35 The aim of the invention is to overcome the foregoing disadvantage of high cost by producing a freewheel, the elements, the cage and a single resilient member of which are simple in construction and can be made with wide tolerances in their dimensions.

40 45 According to this invention, we provide a freewheel or unidirectional clutch comprising a series of cam profiled jamming elements located between surfaces of revolution in an outer bush and on an inner member and a cage which holds the jamming elements in position, wherein the cage is made as a single integral moulding with recesses containing the elements, side walls of the recesses and adjacent sides of the elements 50 55 converging inwardly towards the inner member, and an integral spring strip extends around the outer periphery of the cage and has an elastic tab extending into each recess and bearing against a surface of the element which extends in a substantially tangential direction and is located at one side of the element to exert upon the surface a substantially radial thrust which is offset circumferentially from lines of contact between the element and the bush and the inner member, 60 65 the spring strip being fixed circumferentially and axially with respect to the cage by lugs on the cage or spring strip fitting in openings in the spring strip or the cage respectively.

The tabs of the spring strip exert upon the cam

65 a substantially radial off-centre force which co-operates with the reaction from the inner member to create the necessary preliminary jamming torque, and the tabs hold the elements in position in the cage against outward movement out of the

70 recesses, whilst the retention of the elements towards the inside is ensured by convergence of the walls of the recesses and of the element. The outward retention of the spring strip is in turn ensured by the surrounding outer bush.

75 The outer bush may consist in a sleeve with inwardly bent edge after the style of the sleeves used with needle bearings for retention of the needles, or as a variant the outer bush may consist of a temporary shipping sleeve which

80 enables the cage to be handled until it is installed in position by axial sliding from this temporary sleeve into a permanent outer bush or ring.

The lugs may be moulded on the outer periphery of the cage in order to co-operate with

85 openings cut out of the spring strip or they may consist of fingers extending from the spring strip and bent inwardly into openings moulded in the cage. In this latter case the ends of the fingers forming the lugs may be bent tangentially and be

90 hooked under portions of the cage to ensure or to contribute to the retention of the spring strip.

Two examples of freewheels or unidirectional clutches in accordance with the invention are illustrated accompanying drawings, in which:—

95 95 Figure 1 is a section of part of a first example shown in an engaged or driving position;

Figure 2 is a view corresponding to Figure 1 but of an assembly of parts of the freewheel or clutch before fitting on a shaft or other inner

100 member;

Figure 3 is a developed plan to a smaller scale of a spring forming part of the first example; and,

Figures 4, 5 and 6 are views corresponding to Figures 1, 2 and 3 but showing a second example.

105 110 As may be seen in Figure 1 the freewheel or clutch comprises in the usual way a number of jamming elements in the form of cams 1 arranged so that they can jam between an outer ring 2 and an inner ring or shaft 3.

115 120 A cage 4 for maintaining a regular separation between the cams 1 and maintaining their axial alignment is produced in a single piece of moulded material, preferably filled plastics material, and the cage has recesses 5 of

125 130 rectangular window shape as viewed radially defining between them successive solid bars 6 joined at their two ends by continuous annular cheeks 7.

In order to ensure the starting of the jamming

135 140 of the cams 1, that is to say, in order to exert upon each cam 1 a torque in a direction represented by an arrow 8, a single spring 9 is provided which projects into each recess 5 one, or preferably as shown, two flexible tabs 10 each of which acts

145 150 upon the axial ends of a surface 11 which each cam has at one side. The surface 11 extends in a substantially tangential direction and in a position between inner and outer bearing surfaces of the rings 2 and 3. The tabs 10 exert upon the surface

11 a substantially radial resilient force represented by an arrow 12. The cam 1 makes contact along a generatrix 13 with the shaft 3, which consequently exerts a reaction (not shown)

5 which co-operates with the force represented by the arrow 12 to produce the resilient torque 8 at a time preceding the generation of very much larger jamming forces which are exerted between the cam and the outer ring 2 and the shaft 3 by

10 friction when there is torque between the ring 2 and the shaft 3 in one direction.

As appears in the drawings, side faces 14a and 14b of the recess 5 as well as the opposing side faces of the cam 1 converge in an inward direction towards the shaft 3. This facilitates removal of the cage from the mould and ensures retention of the cams against inward removal. The single spring 9 is produced as a continuous strip in known manner by blanking out, bending and

20 heat treatment followed by cutting to length to fit the freewheel. Figure 3 shows the detail of the shape of the spring 9, the chain-dotted line indicating the shape as cut out before bending.

It is necessary to ensure the axial and

25 tangential fixing of the spring 9 to the cage 4 and also to ensure the retention of the spring around the periphery of the cage 4 where it is located.

The axial and tangential fixing are effected by lugs 15 which are moulded directly on the

30 periphery of the cage 4 and come in practice, into contact with the inside surface of the outer ring 2. The lugs 15 fit in openings 16 cut out of the spring 9 as shown in Figure 1. Between the inner periphery of the cage 4 and the inner surface of

35 the outer ring 2 there may be a considerable clearance of nearly twice the thickness of the spring 9. This avoids the necessity for extreme accuracy in manufacture. Since the spring is initially flat, it tends by its resilient to locate itself

40 around the outside of this clearance, that is to say, in contact with the outer ring 2, but it adjusts itself automatically to the inside of this clearance as a function of the tolerances upon the openings 16 and the lugs 15.

45 In order to ensure the retention of the spring 9 around the cage 4 and also to ensure the retention of the cams 1 in the recess 5 in an outward direction, provision is made as shown in Figure 2 for delivering the assembly consisting of

50 the cage 4, the spring 9 and the cams 1 inside a thin heat treated steel sleeve having edges extending radially inwards of the type employed with needle bearings for retention of the needles. This sleeve then itself forms the outer ring 2 and in view of its thinness it is itself fitted into a bore 17 in the part in which the freewheel is mounted.

Hence the assembly is supplied in the form shown in Figure 2, enclosed in its outer sleeve 2 but it will be seen that it is not necessary to

60 provide any inner ring next to the shaft 3 owing to the trapezoidal shape of the openings 5 as seen in an axial direction. This shape ensures the retention of the cams 1 in their openings 5 in an inward direction.

65 The whole freewheel may be produced very economically since the simple shapes and the low dimensional accuracy demanded of the moulded cage 4 and of the continuous blanked, bent and heat treated spring 9 make them relatively cheap parts. The sleeve 2 is furthermore a standard part which is relatively inexpensive and which makes unnecessary hardening and polishing of the bore 17 to a great hardness and a highly polished state as would otherwise be required.

75 In a modification, the heat-treated sleeve having retention edges is replaced by a simple tubular sleeve of any kind of material. This is intended solely for ensuring the retention of the cams in assembly during handling before

80 mounting. In this case the bore forming the outer jamming surface is directly machined in a part in which the freewheel is to be mounted and the assembly of the cage, the cams and the spring is transferred into the bore by axial sliding from the

85 temporary shipping sleeve which is then recovered or thrown away.

The example of Figures 4 to 6 is the same as that just described except that lugs 15a are integral with the spring 9a and openings 16a are formed in the cage 4. The bars 6 of the first example are then divided up into two bars 6a and 18 forming between them the openings 5 and 16a. Each lug 15a may then advantageously be provided with an end 19 bent tangentially in order

95 to hook under the bar 18 which for this purpose is recessed at its inner edge. This hooking of the lugs 15a enables retention of the spring around the periphery of the cage 4 to be ensured, so that the outer sleeve 2 no longer has to ensure the

100 retention of the cams 1.

As is the first example, one may employ for the ring 2 a heat-treated sleeve which remains in place, or a temporary shipping sleeve.

Claims

105 1. A freewheel or unidirectional clutch comprising a series of cam profiled jamming elements located between surfaces of revolution in an outer bush and on an inner member and a cage which holds the jamming elements in

110 position, wherein the cage is made as a single integral moulding with recesses containing the elements, side walls of the recesses and adjacent sides of the elements converging inwardly towards the inner member, and an integral spring

115 strip extends around the outer periphery of the cage and has an elastic tab extending into each recess and bearing against a surface of the element which extends in a substantially tangential direction and is located at one side of

120 the element to exert upon the surface a substantially radial thrust which is offset circumferentially from lines of contact between the element and the bush and the inner member, the spring strip being fixed circumferentially and axially with respect to the cage by lugs on the cage or spring strip fitting in openings in the

125 spring strip or the cage respectively.

2. A freewheel or clutch according to claim 1, in which the lugs are moulded on the periphery of the cage and the openings are cut out of the spring strip.

5 3. A freewheel or clutch according to claim 1, in which the openings are moulded in the cage and the lugs are cut in the spring and are bent inwards into the cage.

4. A freewheel or clutch according to claim 3,

10 in which each of the lugs has an edge bent tangentially and hooked under a portion of the cage between the opening which receives the lug and the recess containing the element, the said portion being recessed at its inner edge to receive the bent edge.

15 5. A freewheel or clutch according to any one of the preceding claims, in which the outer bush is a thin heat-treated steel sleeve having inwardly bent edges.

20 6. A freewheel or clutch according to any one of claims 1 to 4, in which the outer bush is a temporary cylindrical shipping sleeve.

7. A freewheel or clutch according to claim 1, substantially as described with reference to

25 Figures 1 to 3, or Figures 4 to 6 of the accompanying drawings.
