(54) Title: FIBROBLAST GROWTH FACTOR RECEPTOR-3 (FGFR-3) INHIBITORS AND METHODS OF TREATMENT

(57) Abstract: The present invention relates to an isolated antibody or fragment thereof, which specifically binds to human FGFR-3(IIIb) and FGFR-3 (IIIc), or mutant forms thereof. Further embodiments include pharmaceutical compositions comprising the antibody and methods of using the antibody to treat cancer. X18531

X-18531

1

## FIBROBLAST GROWTH FACTOR RECEPTOR-3 (FGFR-3) INHIBITORS AND METHODS OF TREATMENT

This invention is in immunology and cancer treatment. More specifically, the present invention is directed to a human antibody that binds to human fibroblast growth factor receptor 3 (FGFR-3) (SEQ ID NO 11). FGFR is also known as CD333, ACH, CEK2, HSFGFR-3EX and JTK4.

FGFR-3 has been shown to be involved in the development of cancer, including multiple myeloma, bladder and urothelial cell carcinoma. FGF ligand-receptor binding induces receptor dimerization and autophosphorylation, leading to down-stream activation of effector molecules. FGFR-3 signaling is capable of regulating a broad range of cellular activities such as proliferation, differentiation, migration, survival/apoptosis, cytoskeleton and cytokine regulation, and endocytosis/exocytosis. Hyper-activation of FGFR-3 signaling has been recognized as an important event that affords tumor cells with a growth or survival advantage and thus contributes to tumor malignancy.

Full length FGFR-3 has two splice forms called FGFR-3(IIIb) and FGFR-3(IIIc) that result from alternative exons encoding the third IgG-like domain of FGFR-3. FGFR-3 also has well documented mutant forms due to errors in DNA replication or translation. Given the active role of the FGFR-3 signaling pathway in a wide range of diseases including cancer, there is a need for a mechanism by which to regulate this pathway.

Anti-FGFR-3 antibodies that block ligand binding have been disclosed.

(Rauchenberger, R. et al., *J. Biol. Chem.* 2003 Oct 3; 278(40):38194-205.) Anti-FGFR-3 antibodies that bind to both wild type and mutant forms of FGFR-3 have been disclosed. (Martinez-Torrecuadrada, J., et al., *Clin. Cancer Res.* 2005 Sep 1;11(17):6280-90; Trudel S., et al., *Blood* 2006 May 15;107(10):4039-46.) Anti-FGFR-3 antibodies that inhibit ligand mediated activation of FGFR-3 signaling, and inhibit FGFR-3-mediated tumor growth have been disclosed. (Trudel S., et al., *Blood* 2006 May 15;107(10):4039-46.) Anti-FGFR-3 antibodies that enhance the anti-tumor effects of cisplatin when given as combination therapy have been disclosed. (Deevi, D. et al., *AACR* 2007 Oct. 21-24; Wang, W., et al., *EORTC* 2008 Oct. 22-26.)

However, there is a need in the art for an antibody antagonist that is capable of one or more of the following: is highly specific to both splice forms of FGFR-3, (FGFR-3(IIIb) and FGFR-3(IIIc)), that internalizes FGFR-3 and that preferably also induces

X-18531

2

degradation of FGFR-3(IIIb) and FGFR-3(IIIc) or mutant forms thereof, and that enhances therapeutic efficacy and reverses chemo-resistance when used in combination with a chemo cytotoxic agent. Additionally, the antibody is preferably also active to mutant forms of FGFR-3, blocks FGF ligands from binding to FGFR-3, inhibits ligand-induced FGFR-3 signaling pathways, inhibits FGFR-3-mediated cellular activities, or inhibits tumor growth *in vitro* and *in vivo*.

The antibody of the invention has solved these needs. The antibody is highly specific to both splice forms of FGFR-3, (FGFR-3(IIIb) and FGFR-3(IIIc)), internalizes FGFR-3 and preferably also induces receptor degradation upon binding to FGFR-3 receptors or receptor mutants in cells thereof, enhances therapeutic efficacy and reverses chemo-resistance when used in combination with a chemo cytotoxic agent, as well as is active to mutant forms of FGFR-3, blocks FGF ligands from binding to FGFR-3, inhibits ligand-induced FGFR-3 signaling pathways, inhibits FGFR-3-mediated cellular activities, and inhibits tumor growth *in vitro* and *in vivo*.

15 The invention relates to an isolated antibody that specifically binds to human FGFR-3(IIIb) and FGFR-3(IIIc).

Preferably, the antibody is a human antibody having a  $K_D$  of about  $1 \times 10^{-8}$  M or less at room temperature (20-25°C).

20 Preferably, the antibody specifically binds to human FGFR-3 domain 2 (SEQ ID NO 12).

Preferably, the antibody of the invention that specifically binds to human FGFR-3(IIIb) and FGFR-3(IIIc), comprising a CDRH1 having the sequence GYMFTSYGIS (SEQ ID NO 1), a CDRH2 having the sequence WVSTYNGDTNYAQKFQG (SEQ ID NO 2), a CDRH3 having the sequence VLGYYDSIDGYYYGMDV (SEQ ID NO 3), a 25 CDRL1 having the sequence GGNNIGDKSVH (SEQ ID NO 4), a CDRL2 having the sequence LDTERPS (SEQ ID NO 5), and a CDRL3 having the sequence QVWDSGSDHV (SEQ ID NO 6).

30 Preferably, the antibody may comprise a variable heavy amino acid sequence of EVQLVQSGAEVKKPGASVKVSCKASGYMFTSYGISWVRQAPGQGLEWMGWVS TYNGDTNYAQKFQGRVTVTTDTSTSTAYMELRSLRSEDTAVYYCARVLGYYDSI DGYYYGMDVWGQGTTVTVSS (SEQ ID NO 7) and a variable light amino acid

X-18531

3

sequence of

QSVLTQPPSLSVAPGKTATFTCGGNNIGDKSVHWYRQKPGQAPVLVMYLDTERP  
SGIPERMSGNSFGNTATLTITRVEAGDEADYYCQVWDSGSDHVVFGGGTKLTVL  
G (SEQ ID NO 8).

5 Preferably, the antibody may comprise a variable heavy amino acid sequence of  
EVQLVQSGAEVKPGASVKVSCKASGYMFTSYGISWVRQAPGQGLEWMGWVS  
TYNGDTNYAQKFQGRVTVTDTSTSTAYMELRSLRSEDTAVYYCARVLGYYDSI  
DGYYYGMDVWGQQGTTVTVSS (SEQ ID NO 7) or a variable light amino acid  
sequence of

10 QSVLTQPPSLSVAPGKTATFTCGGNNIGDKSVHWYRQKPGQAPVLVMYLDTERP  
SGIPERMSGNSFGNTATLTITRVEAGDEADYYCQVWDSGSDHVVFGGGTKLTVL  
G (SEQ ID NO 8).

The antibody heavy constant region may be from human IgG1, or an FGFR-3-binding fragment of the antibody. Preferably, the antibody comprises a heavy chain of  
15 SEQ ID NO: 9 and a light chain of SEQ ID NO: 10. Preferably, the antibody comprises a heavy chain of SEQ ID NO: 9 and a light chain of SEQ ID NO: 10, or an FGFR-3-binding fragment of the antibody.

The antibody may also comprise two heavy chains of SEQ ID NO: 9 and two light chains of SEQ ID NO: 10. The antibody may also comprise two heavy chains of SEQ ID  
20 NO: 9 and two light chains of SEQ ID NO: 10. Preferably, the antibody comprises two heavy chains of SEQ ID NO: 9 and two light chains of SEQ ID NO: 10, or an FGFR-3-binding fragment of the antibody.

The antibody may comprise a neutralizing human FGFR-3 binding fragment.

In a preferred aspect, the invention is directed to an isolated antibody or a  
25 fragment thereof, wherein said antibody competes for binding to the extracellular domain of FGFR-3 in a competition ELISA assay with a competing antibody, wherein said competing antibody binds FGFR-3 with a  $K_D$  of about  $1 \times 10^{-8}$  M or less at room temperature (20-25°C).

The invention further relates to an antibody that binds to mutant forms of FGFR-3.

30 The present invention relates to a pharmaceutical composition comprising the antibody or fragment, and a pharmaceutically acceptable carrier, diluent or excipient.

X-18531

The present invention also relates to a product containing an antibody or fragment and an additional anti-cancer agent for treatment in combination for simultaneous, separate or sequential use in therapy.

In another aspect of the invention, the antibody or fragment is for use as a medicament. In another aspect of the invention, the antibody or fragment is for use in the treatment of cancer. In another aspect of the invention, the antibody or fragment is used as a medicament where the cancer is bladder or multiple myeloma.

In another aspect of the invention, the antibody or fragment is used in the treatment of cancer together with another agent. The antibody or fragment of the invention may be administered simultaneously, separately, or sequentially with an effective amount of another agent to the patient. The invention may comprise a pharmaceutical composition comprising a compound together with a pharmaceutically acceptable carrier and optionally other therapeutic ingredients.

The invention also relates to a method of treating cancer in a patient comprising administering to the patient an effective amount of the antibody of the invention. The cancer may be bladder or multiple myeloma. In another aspect, the invention includes a method of treating cancer in a patient comprising administering simultaneously, separately, or sequentially an effective amount of the antibody of the present invention and another agent to the patient. The other agent may be cisplatin.

Accordingly, the antibody of the invention binds to naturally occurring and mutant forms of FGFR-3 and induce degradation of FGFR-3, are capable of inhibiting tumors by acting upon the tumor cells as well as stromal components, have broad therapeutic value in treating cancer.

The term "antibody" includes immunoglobulin molecules comprising four polypeptide chains, two identical heavy (H) chains and two identical light chains (L), interconnected by a disulfide bond. Individual chains can fold into domains having similar sizes (110-125 amino acids) and structures, but different functions.

An "isolated antibody" is an antibody that (1) has been partially, substantially, or fully purified from a mixture of components; (2) has been identified and separated and/or recovered from a component of its natural environment; (3) is monoclonal; (4) is free of other proteins from the same species; (5) is expressed by a cell from a different species; or (6) does not occur in nature. Contaminant components of its natural environment are

X-18531

materials which would interfere with diagnostic or therapeutic uses for the antibody, and may include enzymes, hormones, and other proteinaceous or non-proteinaceous solutes. Examples of isolated antibodies include an antibody that has been affinity purified, an antibody that has been made by a hybridoma or other cell line in vitro, or a human antibody derived from a transgenic mouse.

The term "monoclonal antibody," as used herein, refers to an antibody obtained from a population of substantially homogeneous antibodies, e.g., the individual antibodies comprising the population are substantially identical except for possible naturally occurring mutations or minor post-translational variations that may be present.

10 Monoclonal antibodies are highly specific, being directed against a single antigenic site (also known as determinant or epitope). Furthermore, in contrast to conventional (polyclonal) antibody preparations which typically include different antibodies directed against different determinants, each monoclonal antibody is directed against a single determinant on the antigen. The modifier "monoclonal" indicates the character of the antibody as being obtained from a substantially homogeneous population of antibodies, and is not to be construed as requiring production of the antibody by any particular method.

15

The term "human antibody," as used herein, includes antibodies having variable and constant regions corresponding to human germline immunoglobulin sequences as described in Kabat et al., Chothia et al., and Martin, *supra*. The human antibody of the invention may include amino acid residues not encoded by human germline immunoglobulin sequences (e.g., mutations introduced by random or site-specific mutagenesis in vitro or by somatic mutation in vivo), for example in the complementarity-determining regions (CDRs). The human antibody can have at least one position replaced with an amino acid residue, e.g., an activity enhancing amino acid residue which is not encoded by the human germline immunoglobulin sequence. However, the term "human antibody," as used herein, is not intended to include antibodies in which CDR sequences derived from the germline of another mammalian species, such as a mouse, have been grafted onto human framework sequences.

30 The phrase "recombinant human antibody" includes human antibodies that are prepared, expressed, created or isolated by recombinant means, such as antibodies expressed using a recombinant expression vector transfected into a host cell, antibodies

X-18531

isolated from a recombinant, combinatorial human antibody library, antibodies isolated from an animal that is transgenic for human immunoglobulin genes, or antibodies prepared, expressed, created or isolated by any other means that involves splicing of human immunoglobulin gene sequences to other DNA sequences. Such recombinant 5 human antibodies have variable and constant regions derived from human germline immunoglobulin sequences.

The light chain can comprise one variable domain (abbreviated herein as VL) and/or one constant domain (abbreviated herein as CL). The light chains of antibodies are either kappa ( $\kappa$ ) light chains or lambda ( $\lambda$ ) light chains. The expression on VL, as 10 used herein, is intended to include both the variable regions from kappa-type light chains ( $V\kappa$ ) and from lambda-type light chains ( $V\lambda$ ). The heavy chain can also comprise one variable domain (abbreviated herein as VH) and/or, depending on the class or isotype of antibody, three or four constant domains (CH1, CH2, CH3, and CH4). In humans, the 15 isotypes are IgA, IgD, IgE, IgG, and IgM, with IgA and IgG further subdivided into subclasses or subtypes (IgA<sub>1-2</sub> and IgG<sub>1-4</sub>).

The present invention includes antibodies of any of the aforementioned classes or subclasses. Human IgG is the preferred isotype for the antibody of the present invention. Three regions, called hypervariable or CDRs, are found in each of VL and VH, which are supported by less variable regions called framework regions (abbreviated herein as FR).

20 Amino acids are assigned to a particular CDR region or domain in accordance with Kabat convention (Kabat, et al., Ann. NY Acad. Sci. 190:382-93 (1971); Kabat, et al., Sequences of Proteins of Immunological Interest, Fifth Edition, U.S. Department of Health and Human Services, NIH Publication No. 91-3242 (1991)) or Chothia convention (C. Chothia and A.M. Lesk, J. Mol. Biol. 196 (4): 901-917 (1987)) or by Martin, (Martin, 25 A.C.R. Accessing the Kabat Antibody Sequence Database by Computer PROTEINS: Structure, Function and Genetics, 25 (1996), 130-133.)

Each VH and VL is composed of three CDRs and four FRs, arranged from amino-terminus to carboxy-terminus in the following order: FR1-CDR1-FR2-CDR2-FR3-CDR3-FR4. The portion of an antibody consisting of VL and VH domains is designated 30 Fv (Fragment variable) and constitutes the antigen-binding site. Single chain Fv (scFv) is an antibody fragment containing a VL domain and a VH domain on one polypeptide chain, wherein the N terminus of one domain and the C terminus of the other domain are

X-18531

joined by a flexible linker (see, e.g., U.S. Patent No. 4,946,778 (Ladner et al.), WO 88/09344 (Huston et al.)).

Fragments have binding characteristics that are the same as, or are comparable to, those of the whole antibody. Suitable fragments of the antibody include any fragment 5 that comprises a sufficient portion of the hypervariable (i.e. complementarity determining) region to bind specifically, and with sufficient affinity to inhibit growth of cells. Such fragments may, for example, contain one or both Fab fragments or the F(ab')2 fragment. Preferably the antibody fragments contain all six complementarity determining regions of the whole antibody, although functional fragments containing fewer than all of 10 such regions, such as three, four or five CDRs, are also included. Preferred fragments are single chain antibodies, or Fv fragments. More preferred fragments are bivalent. Single chain antibodies are polypeptides that comprise at least the variable region of the heavy chain of the antibody and the variable region of the light chain, with or without an interconnecting linker. Thus, Fv fragments comprise the entire antibody combining site. 15 These chains may be produced in bacteria or in eukaryotic cells.

Fab (Fragment, antigen binding) refers to the fragments of the antibody consisting of VL CL VH CH1 domains. Those generated following papain digestion simply are referred to as Fab and do not retain the heavy chain hinge region. Following pepsin digestion, various Fabs retaining the heavy chain hinge are generated. Those fragments 20 with the interchain disulfide bonds intact are referred to as F(ab')2, while a single Fab' results when the disulfide bonds are not retained. F(ab')2 fragments have higher avidity for antigen than the monovalent Fab fragments.

Fc (Fragment crystallization) is the designation for the portion or fragment of an antibody that comprises paired heavy chain constant domains. In an IgG antibody, for 25 example, the Fc comprises CH2 and CH3 domains. The Fc of an IgA or an IgM antibody further comprises a CH4 domain. The Fc is associated with Fc receptor binding, activation of complement-mediated cytotoxicity and antibody-dependent cellular-cytotoxicity (ADCC). For antibodies such as IgA and IgM, which are complexes of multiple IgG like proteins, complex formation requires Fc constant domains.

30 The hinge region separates the Fab and Fc portions of the antibody, providing for mobility of Fabs relative to each other and relative to Fc, as well as including multiple disulfide bonds for covalent linkage of the two heavy chains.

X-18531

Thus, an antibody of the invention includes, but is not limited to, naturally occurring antibodies, human antibodies, recombinant human antibodies, monoclonal antibodies, digestion fragments, bivalent fragments such as (Fab')2, monovalent fragments such as Fab, single chain antibodies, single chain Fv (scFv), single domain antibodies, multivalent single chain antibodies, diabodies, triabodies, and the like that bind specifically with antigens.

An antibody of the present invention is specific for FGFR-3. Antibody specificity refers to selective recognition of the antibody for a particular epitope of an antigen. The antibody may exhibit both species and molecule selectivity, or may be selective with respect to molecule only and bind to FGFR-3 of more than one species. The antibody of the invention may bind to human, murine, rat, dog and/or rabbit FGFR-3. Preferably, the antibody binds to human FGFR-3. Antibody formats have been developed that retain binding specificity but that also have other characteristics.

An antibody of the present invention, for example, can be monospecific, bispecific or multispecific. Bispecific antibodies (BsAbs) are antibodies that have two different antigen-binding specificities or sites. Multispecific antibodies have more than two different antigen-binding specificities or sites. Where an antibody has more than one specificity, the recognized epitopes can be associated with a single antigen or with more than one antigen.

Specificity of the FGFR-3 antibodies can be determined based on affinity and/or avidity. Affinity, represented by the equilibrium constant for the dissociation of an antigen with an antibody ( $K_D$ ), measures the binding strength between an antigenic determinant and an antibody-binding site. Avidity is the measure of the strength of binding between an antibody with its antigen. Avidity is related to both the affinity between an epitope with its antigen binding site on the antibody, and the valence of the antibody, which refers to the number of antigen binding sites of a particular epitope.

Antibodies typically bind with a dissociation constant ( $K_D$ ) of about  $10^{-5}$  to about  $10^{-11}$  mol/liters (e.g.,  $K_D < 100$  M). Any  $K_D$  less than about  $10^{-4}$  mol/liter is generally considered to indicate nonspecific binding—the lesser the value of the  $K_D$ , the stronger the binding strength between an antigenic determinant and the antibody binding site.

X-18531

In certain aspects, the antibody of the invention binds to FGFR-3 with a  $K_D$  of preferably about  $1 \times 10^{-8}$  M or less, more preferably about  $1 \times 10^{-9}$  M or less, more preferably about  $1 \times 10^{-10}$  M or less, and most preferably about  $1 \times 10^{-11}$  M or less. See Table 1 below.

5 **Table 1: Binding affinities of Antibody 1 to human and murine FGFR-3 splice variants.**

	$K_D$ (M)
Human FGFR-3(IIIb)	$7.2 \times 10^{-10}$
Human FGFR-3(IIIc)	$1.4 \times 10^{-10}$
Murine FGFR-3(IIIb)	N.D.
Murine FGFR-3(IIIc)	$2.2 \times 10^{-10}$

In certain aspects, the antibody of the present invention preferably has a  $K_D$  of about  $5.0 \times 10^{-10}$  M to about  $1.5 \times 10^{-11}$  M, about  $1.0 \times 10^{-10}$  M to about  $1.0 \times 10^{-11}$  M or about  $1.5 \times 10^{-11}$  M to about  $7.5 \times 10^{-10}$  M.

10 As used herein, the terms "blocks binding" and "inhibits binding," used interchangeably, refer to blocking/inhibition of binding of a cytokine to its receptor, resulting in complete or partial inhibition or reduction of a biological function of the cytokine/receptor signal pathway. Blocking/inhibition of binding of FGF to FGFR-3 is 15 assessed by measuring the complete or partial inhibition or reduction of one or more *in vitro* or *in vivo* indicators of FGF activity such as, receptor binding, an inhibitory effect on cell growth, chemotaxis, apoptosis, intracellular protein phosphorylation, or signal transduction. The ability to block the binding FGF to FGFR-3 may be measured by 20 ELISA as described herein. The antibody of the invention is an antagonist that blocks the FGFR-3 receptor in ligand-induced activation in live cells. Binding assays can be carried out using a variety of methods known in the art, including, but not limited to, ELISA. As 25 used herein, "competes for binding" refers to the situation in which an antibody reduces binding or signaling by at least about 20%, 30%, 50%, 70% or 90% as measured by a technique available in the art, e.g., competition ELISA or  $K_D$  measurement with BIAcore, but is not intended to completely eliminate binding.

The heavy chain amino acid sequence is described in SEQ ID NO. 9. The light chain amino acid sequence is described in SEQ ID NO. 10. In another aspect, the

X-18531

10

antibody of the invention has one, two, three, four, five, or all six complementarity-determining regions of any one of the CDRs of Antibody 1.

The antibody of the present invention also includes those for which binding characteristics have been improved by direct mutation, methods of affinity maturation, 5 phage display, or chain shuffling. Affinity and specificity can be modified or improved by mutating CDR and/or framework residues and screening for antigen binding sites having the desired characteristics (see, e.g., Yang et al., *J. Mol. Biol.* 254:392-403 (1995)). One way is to randomize individual residues or combinations of residues so that 10 in a population of otherwise identical antigen binding sites, subsets from two to twenty amino acids are found at particular positions. Alternatively, mutations can be induced over a range of residues by error using PCR methods (see, e.g., Hawkins et al., *J. Mol. Biol.*, (1992) 226:889 96). In another example, phage display vectors containing heavy 15 and light chain variable region genes can be propagated in mutator strains of *E. coli* (see, e.g., Low et al., *J. Mol. Biol.* 250:359 68(1996)).

15 An in vitro selection process may then be suitably used to screen these additional variable region amino acid sequences for Fab fragments having the claimed cross reactivity and in vitro. In this way further Fab fragments are identified that are suitable for preparing a humanized antibody in accordance with the present invention. Preferably the amino acid substitution within the frameworks is restricted to one, two or three 20 positions within one or each of the framework sequences disclosed herein. Preferably amino acid substitution within the CDRs is restricted to one to three positions within one or each CDR, more preferably substitution at one or two amino acid positions within one or each CDR is performed. Further preferred, amino acid substitution is performed at one or two amino acid positions in the CDRs of the heavy chain variable region. A suitable 25 methodology for combining CDR and framework substitutions to prepare alternative antibodies according to the present invention, using an antibody described herein as a parent antibody, is provided in Wu et al., *J. Mol. Biol.*, 294:151-162.

The antibody of the invention may be produced by methods known in the art. These methods include immunological methods described by Kohler and Milstein in 30 *Nature* 256:495-497 (1975) and Campbell in "Monoclonal Antibody Technology, The Production and Characterization of Rodent and Human Hybridomas" in Burdon et al., Eds., *Laboratory Techniques in Biochemistry and Molecular Biology*, Volume 13,

X-18531

11

Elsevier Science Publishers, Amsterdam (1985); as well as by the recombinant DNA method described by Huse et al. in *Science* 246:1275-1281 (1989).

Human antibodies can also be produced using various techniques known in the art, including phage display libraries (Hoogenboom and Winter, *J. Mol. Biol.* 227:381 (1991); Marks et al., *J. Mol. Biol.* 222:581 (1991)). The techniques of Cole et al. and Boemer et al. are also available for the preparation of human monoclonal antibodies (Cole et al., *Monoclonal Antibodies and Cancer Therapy*, Alan R. Liss, p.77 (1985) and Boemer et al., *J. Immunol.* 147(1):86-95 (1991)). The antibody of the invention secreted by subclones may be isolated or purified from culture medium or ascites fluid by conventional immunoglobulin purification procedures such as, for example protein A-Sepharose, hydrolyapatite chromatography, gel electrophoresis, dialysis, or affinity chromatography.

The polynucleic acid that encodes for the antibody of the invention is obtained by standard molecular biology techniques.

The invention also includes host cells for transformation of vectors and expression of antibodies. Preferred host cells include mammalian cells, such as NSO (non-secreting (o)) mouse myeloma cells, 293 and CHO cells, and other cell lines of lymphoid origin such as lymphoma, myeloma, or hybridoma cells. Other eukaryotic hosts, such as yeast, can be used.

Vectors for expressing proteins in bacteria, especially *E. coli*, are known. Such vectors include the PATH vectors described by Dieckmann and Tzagoloff in *J. Biol. Chem.* 260:1513-1520 (1985). These vectors contain DNA sequences that encode anthranilate synthetase (TrpE) followed by a polylinker at the carboxy terminus. Other expression vector systems are based on beta-galactosidase (pEX); lambda PL; maltose binding protein (pMAL); and glutathione S-transferase (pGST). See *Gene* 67:31 (1988) and *Peptide Research* 3:167 (1990).

Vectors useful in yeast are available. A suitable example is the lambda ZAP plasmid. Suitable vectors for expression in mammalian cells are also known. Such vectors include well-known derivatives of SV-40, adenovirus, retrovirus-derived DNA sequences and shuttle vectors derived from combination of functional mammalian vectors, such as those described above, and functional plasmids and phage DNA.

X-18531

12

The vectors useful in the present invention contain at least one control element that is linked to the DNA sequence or fragment to be expressed. The control element is inserted in the vector in order to control and regulate the expression of the cloned DNA sequence.

5 Following expression in a host cell maintained in a suitable medium, the polypeptide to be expressed may be recovered from the medium and purified by methods known in the art. If the polypeptide or peptide is not secreted into the culture medium, the host cells are lysed prior to isolation and purification.

10 This invention further provides a pharmaceutical composition comprising the antibody, polynucleic acid, vector or host cell of this invention together with a pharmaceutically acceptable carrier, excipient or diluent. The pharmaceutical composition may comprise an additional therapeutic agent. The additional agent may be a chemotherapeutic agent, for example, cisplatin.

15 Carrier as used herein includes pharmaceutically acceptable carriers, excipients, or stabilizers which are nontoxic to the cell or mammal being exposed thereto at the dosages and concentrations employed. Often the physiologically acceptable carrier is an aqueous pH buffered solution. In another aspect of the invention, anti-FGFR-3 antibodies or antibody fragments can be chemically or biosynthetically linked to anti-tumor agents or detectable signal-producing agents, particularly when the antibody is internalized. An 20 antibody to FGFR-3 can inhibit activation of the receptor (phosphorylated FGFR-3) as well as activation of the down-stream signaling molecules, including phosphor-MAPK and phosphor-AKT in several cancer cells, such as bladder cancer cells, which results in inhibition of their proliferative ability.

25 The antibody of the present invention can bind to naturally occurring FGFR-3 or its splice forms or mutants thereof. "Splice forms" of FGFR-3 means the forms of the exons encoding the third IgG-like domain of FGFR-3 called FGFR-3(IIIb) and FGFR-3(IIIc). Mutant FGFR-3 includes those forms of the receptor altered by DNA replication or errors in translation. The mutations can be gain-of-function mutations that heighten the activity of the mutant receptors through mechanisms such as constitutive activation, 30 prolonged half-life and increased ligand sensitivity.

The antibody of the present invention can bind to wild-type FGFR-3 domain 2 (SEQ ID NO 12). An arginine residue at position 173 of the human and mouse FGFR-3

X-18531

13

sequences is not shared by the other family members, suggesting that this residue is likely responsible for the FGFR-3 specificity exhibited by Antibody 1.

The antibody of the present invention induces degradation of FGFR-3. Degrade means disintegrate the receptor so that it can no longer perform its signaling function.

5 The antibody of the present invention can neutralize activation of FGFR-3. Neutralizing a receptor means inactivating the intrinsic kinase activity of the receptor to transduce a signal. Neutralization for example may occur by an antibody blocking access of certain epitopes to a ligand, or by changing conformation of FGFR-3 in a certain manner so that the ligand, particularly FGF, cannot activate the receptor even though it 10 can bind to the receptor. Down regulation may occur when cells that express FGFR-3 decrease the number of FGFR-3 receptors on their surface, for example, by inducing internalization or degradation of the receptor, or inhibiting the expression of FGFR-3. Hence, neutralizing has various effects, including inhibition, diminution, inactivation 15 and/or disruption of growth (proliferation and differentiation), angiogenesis (blood vessel recruitment, invasion, and metastasis), and cell motility and metastasis (cell adhesion and invasiveness).

One measure of FGFR-3 neutralization is inhibition of the tyrosine kinase activity 20 of the receptor. Tyrosine kinase inhibition can be determined using well-known methods; for example, by measuring the autophosphorylation level of recombinant kinase receptor, and/or phosphorylation of natural or synthetic substrates. Thus, phosphorylation assays are useful in determining neutralizing antibodies in the context of the present invention. 25 Phosphorylation can be detected, for example, using an antibody specific for phosphotyrosine in an ELISA assay or on a western blot. Some assays for tyrosine kinase activity are described in Panek et al., J. Pharmacol. Exp. Ther. 283:1433-44 (1997) and Batley et al., Life Sci. 62:143-50 (1998).

In addition, the antibody of the invention can inhibit signaling by the tumor cells 30 themselves since many tumor cells have FGFR-3 on their cell surface. The antibody of the invention can be used to treat a mammal in need thereof. "Treating" a disease includes inhibiting the disease, arresting or retarding its development; relieving the disease, or causing regression of the symptoms of the disease.

The antibody and compositions of the invention can be used to treat cancer. The cancer may be refractory or first line. Cancers include, but are not limited to, brain, lung,

X-18531

14

squamous cell, bladder, gastric, pancreatic, breast, head, neck, renal, kidney, ovarian, prostate, colon, colorectal, esophageal, gynecological (ovarian, endometrial), prostate, stomach, or thyroid cancer, leukemia, and lymphoma. Additionally, cancers that may be treated by the antibody and compositions of the invention include multiple myeloma, 5 colorectal carcinoma, Ewing's sarcoma, choriocarcinoma.

Administration is achieved by any suitable route of administration, including injection, infusion, orally, parenterally, subcutaneously, intramuscularly or intravenously.

The method of treatment described herein may be carried out with the antibody being administered with another treatment, such as anti-neoplastic agents. The anti-10 neoplastic treatment may include small organic molecules. Examples of such small organic molecules include cytotoxic and/or chemotherapeutic agents such as taxol, doxorubicin, actinomycin-D, cisplatin, methotrexate, irinotecan (CPT-11), gemcitabine, oxyplatin, fluorouracil (5-FU), leucourin (LU), cisplatin, paclitaxel, docetaxel, vinblastine, epothilone, cisplatin/carboplatin and Pegylated adriamycin. A preferred 15 treatment of the invention is administration of the antibody with cisplatin.

The anti-neoplastic agent can also be radiation, the source of the radiation can be either external (external beam radiation therapy -- EBRT) or internal (brachytherapy -- BT) to the patient being treated. The dose of anti-neoplastic agent administered depends on numerous factors, including, for example, the type of agent, the type and severity of 20 the tumor being treated and the route of administration of the agent. The present invention is not limited to any particular dose.

The administration of the FGFR-3 antibodies with other antibodies and/or treatments may occur simultaneously, or separately, via the same or different route, at the same or different times. Further, the antibody may be conjugated with one or more of the 25 other agents for administration.

The methods of treatment described herein can be used to treat any suitable mammal, including primates, such as monkeys and humans, horses, cows, cats, dogs, rabbits, and rodents such as rats and mice. Preferably, the mammal to be treated is human.

30

## EXAMPLES

The following examples are offered for illustrative purposes only, and are not intended to limit the scope of the present invention in any way. The examples do not

X-18531

15

include detailed descriptions of conventional methods, such as those employed in the construction of vectors and plasmids, the insertion of genes encoding polypeptides into such vectors and plasmids, or the introduction of plasmids into host cells. Such methods are well known to those of ordinary skill in the art and are described in numerous 5 publications including Sambrook, J., Fritsch, E. F. and Maniatis, T. (1989) Molecular Cloning: A Laboratory Manual, 2nd Edition, Cold Spring Harbor Laboratory Press.

**Example 1**

**Generation of FGFR-3 specific antibody antagonist**

10 Recombinant human FGFR-Fc, recombinant human FGFs, custom-synthesized primers, restriction enzymes and DNA polymerases may be obtained from vendors or prepared by known methods.

Pan a naïve human Fab bacteriophage library against the human FGFR-3 extracellular domain with tubes coated with 10 µg FGFR-3(IIIc) extracellular domain (ECD)-Fc recombinant proteins according to published panning protocols. Elute the 15 retained phages from the panning process and infect bacterial host cells with the retained phages. Collect phages produced by the host cells. Repeat the above procedures one more time. Transfer single colonies of infected host cells into 96-well plates containing 100 µl/well of 2xYTAK, and grow phage in presence of 10 µl M13KO7 helper phage (5x1010pfu/ml). Incubate plates at 37°C for 30 min without shaking followed by 30 min 20 with shaking (100 rpm). Prepare cell pellets by centrifugation at 2,500 rpm for 10min, re-suspended in 200 µl of 2xYTAK, and incubate at 30°C with shaking (100 rpm) for overnight. Centrifuge the plates at 2,500 rpm for 10 min. Transfer supernatants in fresh plates and mix with 6x blocking buffer (18% milk/PBS) for 1 hr. Screen phage clones 25 using the ELISA binding and blocking assays as described below. Select phage clones that bind to FGFR-3(IIb) or FGFR-3(IIIc), then from this pool, select those that block the receptors from binding to FGF-1 ligand. Determine DNA sequences of the clones that both bind and block the receptor according to standard sequence techniques. Each unique DNA sequence is kept and the corresponding phage clone is designated as a FGFR-3 blocker phage candidates. Prepare soluble Fabs from these phage candidates. Repeat 30 ELISA binding and blocking assays using purified Fabs to confirm blocking activity. Engineer the confirmed Fab blockers into full size antibodies by cloning the CDRs (SEQ ID NO. 1-6) into a human IgG1 framework according to published techniques. Use

X-18531

16

ELISA binding assay to determine the binding of Antibody 1 to FGFR-1 (IIIb), FGFR-1 (IIIc), FGFR-2 (IIIb), FGFR-2 (IIIc), and FGFR-4 extracellular domain recombinant soluble proteins. Select antibodies that show high affinity binding to both b and c splice forms of FGFR-3, but low affinity binding to other FGFR receptors.

5

**Example 2****Antibody 1**

Antibody 1 may be biosynthesized in a suitable mammalian expression system using well-known methods and it can be purified by well-known methods.

## ASSAYS

### 5 ELISA binding assay

Coat recombinant FGFRs at a concentration of 1 $\mu$ g/ml in PBS on 96-well plates at room temperature for 2 hrs. Wash the plates 3 times with 0.2% Tween20/PBS, and block with 5% milk/PBS for 2 hrs before use. Add phages, Fabs or antibodies to the plate and serially dilute in 0.2% Tween20/PBS. Incubate the plate at room temperature for 2 more hrs. Detect the captured molecules using an appropriate commercial secondary antibody and detect according to suppliers' instructions.

### ELISA blocking assay.

Coat recombinant FGFs on Immulon® 2B microtiter plates (ThermoLab Systems, Franklin, MA) at concentrations of 0.5-2  $\mu$ g/ml for 2 hrs at room temperature. Wash the plates with 0.2% Tween20/PBS, and block with 5% milk/PBS for 2 hrs before use. Serially dilute phages, Fabs, or antibodies with 5  $\mu$ g/ml heparin, 5% milk, PBS. Add FGFR-3(IIIb) or (IIIc) ECD (extracellular domain) Fc tagged soluble recombinant proteins to a final concentration of 1  $\mu$ g/ml. Incubate the mixture at room temperature for 1 hr before transferring to the FGF-1 coated plates, and incubate at room temperature for an additional 2 hrs. Wash plates 3 times with 0.2% Tween20/PBS. Detect the bound receptors using an anti-human Fc monoclonal antibody coupled with horse radish

X-18531

18

peroxidase (HRP) solution prepared according to supplier's instructions. Blocking activities lead to decreased signals.

**Binding affinity of Antibody 1 to human and mouse FGFR-3(IIIb) and FGFR-3(IIIc)**

Determine the binding kinetics of the antibody to FGFR-3(IIIb) and (IIIc) using a BiaCore® 3000 biosensor (BiaCore, Inc., Piscataway, NJ) at room temperature following the standard protocols suggested by the manufacturer. The summary of results set forth in Table 1 indicates that the antibody binds to both b and c-splice forms of human FGFR-3 as well as cross-reacting fully with mouse FGFR-3(IIIc) receptor with affinities less than  $10^{-9}$  M.

**Specificity of Antibody 1 to membrane bound FGFR-3**

Clone cDNA of murine FGFR-3(IIIc) into a pBABE expression vector containing the puromycin selection gene. Perform retroviral expressions of resulting plasmids in L6 cells. Cells are selected and cultured in DMEM medium containing 10% FBS and 2  $\mu$ g/ml puromycin. Suspend the FGFR-3 expressing L6 cells in 1% BSA/PBS.

Add Antibody 1 to the final concentrations of 1-30  $\mu$ g/ml. After a 1-hour incubation on ice, wash cells in 1% BSA/PBS and incubate with an appropriate secondary detecting antibody or Fab fragments in the same buffer for 1 hour on ice. Stain control samples only with this secondary antibody. Analyze all samples using a FACSvantage SE flow cytometer (BD Biosciences). Antibody 1 is specific to FGFR-3 as shown by producing positive staining signals only when FGFR-3-transfected cells (R3-L6) are used, but not when the FGFR-3 negative L6 parental cells are used.

Human embryonic kidney (HEK) 293 cells, 293fetin, FreeStyle 293 Medium and OptiMEM Medium may be purchased from Invitrogen (Carlsbad, CA). Protein-A affinity purification media may be purchased from GE Healthcare. Generate a DNA construct for FGFR(IIIb)-Fc.

*Production of FGFR-3(IIIb)-Fc, FGFR-3(IIIb)-Fc Ig domain truncates, and single residue alanine mutants of FGFR-3(IIIb)-Fc.*

FGFR-3(III)b domain boundaries may be defined based on the FGFR-3(IIIb) extracellular domain3D model as well as the crystal structures of the FGFRs, which are known. Five

X-18531

19

truncated FGFR-3(IIIb) ECD constructs are designed, namely D1 (25-148), D2 (149-245), D3 (250-372), D1-2 (25-245) and D2-3 (149-372) along with wild-type FGFR-3(IIIb) D1-3 (25-372). The constructs are subcloned into a pGS vector with a Fc tag engineered at the 3' end of the multiple cloning site and the sequences confirmed.

5 Twenty FGFR-3(IIIb) residues in proximity to the putative ligand binding region, as well as those implicated in heparin binding and receptor-receptor dimerization are selected based on the FGFR-3(IIIb) ECD model and the FGFR-3(IIIc) structure as known. FGFR-3(IIIb) ECD single residue alanine mutants are generated via overlapping PCR using the full length FGFR(IIIb) ECD construct as the template, and subsequently subcloned into 10 the pGS-Fc vector. The domain truncates and alanine mutants are expressed transiently in 293 cells following transfection using 293fectin™ (Invitrogen). Culture supernatants are harvested 6 days post-transfection and Fc containing the proteins are purified by passage over a protein-A affinity column, buffer exchanged into PBS, quantitated and evaluated by SDS-PAGE analysis to confirm structural integrity.

15

*FGFR-3(IIIb)-Fc Mesoscale binding assay:* A purified solution of Antibody -1 is diluted to a concentration of 2mg/ml in PBS. MSD Sulfo-TAG NHS-Ester (MesoScale Discovery, #R91AN2), a ruthenium-tris-bipyridine N-hydroxysuccinimide ester, is reconstituted with cold distilled water to a concentration of 10nmol/ul. A 12:1 molar ratio 20 of MSD Sulfo-TAG NHS-Ester to Antibody 1 is used for the reaction. Incubations are performed at room temperature, protected from light, for 2 hours. The unreacted MSD Sulfo-TAG NHS-Ester is removed from the conjugated Antibody 1 using a desalting resin. Ruthenium conjugated Antibody 1 is stored at -80°C. Concentration of the conjugated Antibody 1 is determined using bovine serum albumin for the standard curve.

25

Truncated, mutant or wild type FGFR-3(IIIb)-Fc is diluted in phosphate buffered saline PBS to 5µg/mL. Standard 96 well plates are coated with 25ng/well of receptor and incubated for 1 hr at room temperature. To block non-specific binding in the wells, 150 µL of 5% MSD Blocker A (MesoScale Discovery, #R93Ba-1) is added to each well. The plates are incubated for 1 hr at room temperature. Blocking solution is removed and 30 plates are washed five times with 200 µL of PBS, pH 7.4, 0.02% Tween®-20. A three-fold dilution series (250 – 0.001 nM) of the ruthenium-labeled Antibody 1 is added in a volume of 25 µL in triplicate for each protein being tested. After a one hour incubation at

X-18531

20

room temperature with mild agitation and protected from light, free ruthenium-labeled antibody is removed by performing another five washes with PBS, pH 7.4, 0.02% Tween-20, 200  $\mu$ L per well. After this wash, 150  $\mu$ L of 1X read buffer (MesoScale Discovery, #R92TC-2) is added to each well. Upon electrochemical stimulation, ruthenium label on 5 the bound antibody emitted luminescent light at 620 nm. Electrochemiluminescence ECL signals are detected by a charge-coupled device camera in a SECTOR Imager 2400 plate reader (MesoScale Discovery, #1250) and expressed as ECLU. ECL signals are plotted in GraphPad Prism software version 5.0. KD values are calculated by nonlinear regression curve fit analysis of the software's One Site – Specific Binding function.

10 Binding of ruthenium-labeled Antibody 1 to wild type FGFR-3(IIIb)-Fc is used as a standard for the relative binding affinity analysis of the truncated or mutant FGFRs, plotted as a percentage of the wild type.

*Mab B9 ELISA binding assay:* The wells of a 96 well ELISA microtiter plate are coated 15 overnight with 200n g of an anti-FGFR-3 monoclonal antibody, B9 (Santa Cruz sc-13121), in 100  $\mu$ L of PBS, pH 7.2 with mild agitation at 4°C. After coating, the antibody solution is decanted and the wells are blocked with 100  $\mu$ L of phosphate buffer saline with 0.1% Tween (PBST), 5% Bovine serum albumin (BSA) for 2 hours at room 20 temperature with mild agitation. After blocking, the wells are washed 5 times with 200  $\mu$ L PBST. A three-fold dilution series (100 – 0.006 nM) of the mutant or wild type FGFR-3(IIIb)-Fc is then added in 100  $\mu$ L of PBST, 1% BSA in triplicate for each protein being tested and incubated with mild agitation for 1 hour at room temperature. The wells are washed again 5 times with 200  $\mu$ L PBST. A 1:5000 dilution of horse radish 25 peroxidase (HRP)-conjugated anti-mouse IgG in 100  $\mu$ L of PBST, 5% BSA is incubated in each well for 1 hour at room temperature with mild agitation. The wells are washed a final 5 times with 200  $\mu$ L PBST then developed with 100  $\mu$ L of 3,3',5,5'-Tetramethylbenzidine peroxidase (TMB) chromogenic substrate for 5 minutes. The reaction is stopped with 100  $\mu$ L of 1N  $H_2SO_4$  per well. Absorbance is measured 30 spectrophotometrically at 450 nm. Absorbance readings are plotted in GraphPad Prism® software version 5.0. KD values are calculated by nonlinear regression curve fit analysis of the software's One Site – Specific Binding function. Binding of B9 to the wild type

X-18531

21

FGFR-3(IIIb)-Fc is used as a standard for the relative binding affinity analysis of the truncate or mutant FGFRs, plotted as a percentage of the wild type.

*Molecular modeling of human FGFR-3(IIIb):* To help guide the mutagenesis studies, a three-dimensional model of the domains 2 and 3 of the FGFR-3(IIIb) ECD is generated using SWISS-MODEL®. The sequences of human FGFR-3(IIIb), and human FGFR-3(IIIc) are aligned using the CLUSTALW® method, and the model is constructed using the X-ray crystal structure of FGFR-3(IIIc) as the template (Protein Data Bank code 1RY7).

10

*The epitope of Antibody 1 is contained within the second immunoglobulin-like (Ig) domain of FGFR-3:* The ligand-binding sites of the FGFR receptor family are contained within the three N-terminal Ig domains which define the extracellular domain (Chellaiah, et al., J. Biol. Chem. 1999 Dec. 3; 274(49):34785-34794). To determine which of the three Ig domains contains the epitope of Antibody 1, a panel of domain truncates is employed. DNA sequences encoding the human Ig domains are truncated in various forms and expressed as homodimeric fusion proteins with human Fc tags. The encoded proteins are purified from conditioned supernatant of transiently transfected cells and the homodimeric structure of each purified domain truncate is confirmed by SDS-PAGE.

20

The truncates are then tested for binding to Antibody 1 in a mesoscale binding assay (Meso Scale Discovery, Gaithersburg, MD). While Antibody 1 showed no detectable binding to truncates D1 and D3, it showed significant binding to truncates D1-2 and D2 as determined in a mesoscale binding assay (Meso Scale Discovery, Gaithersburg, MD) and by BIACore™ (Pharmacia, Piscataway, NJ). B9 recognizes a conformationally

25

sensitive epitope in domain 1 of the receptor therefore those truncates containing domain 1 would be expected to bind the antibody if the overall structure was not disturbed. The D1 and D1-2 truncates showed significant binding to control Mab B9, confirming the structural integrity of those two proteins as determined in a mesoscale binding assay (Meso Scale Discovery, Gaithersburg, MD) and by BIACore™ (Pharmacia, Piscataway,

30

NJ). The truncate binding data revealed that the second Ig domain of FGFR-3 is sufficient for binding Antibody 1 and thus contains residues critical to the epitope.

X-18531

22

*Identification of amino acids of FGFR-3 within the epitope recognized by Antibody 1:* A three-dimensional model of the domains 2 and 3 of the FGFR-3(IIIb) ECD was generated based on the crystal structure of FGFR-3(IIIc). Twenty amino acids (D160, K161, K162, L163, L164, V166, P167, P220, R223, D244, N170, T171, R158, R173, R175, 5 K205, R207, L246, E247, S249) within the second domain of FGFR-3 that are in proximity to or directly involved in ligand binding, receptor dimerization or heparin binding are identified based on the molecular model and single residue alanine mutations are generated.

The wild-type sequence of FGFR-3 domain 2 is determined (SEQ ID NO 12).

10 Each amino acid indicated is mutated individually to alanine by site-directed mutagenesis and expressed in the context of FGFR(IIIb)-Fc protein encoding the full ECD. The encoded mutant proteins are purified from conditioned supernatant of transiently transfected cells and the homodimeric structure of each purified mutant is confirmed by SDS-PAGE.

15 A residue is considered critical to the epitope if the alanine mutation described above leads to a significant loss of binding to Antibody 1. All mutant proteins that show significant loss of binding are then tested for binding to Mab B9 to check for gross changes in overall protein structure. Of the 20 positions examined, the substitution of Alanine for Arginine at position 173 (R173A) leads to almost complete loss of binding to 20 Antibody 1 (>90% decrease of binding compared to WT); whereas the other substitutions retained binding (<20% decrease of binding compared to WT). Subsequent testing showed that binding to Mab B9 was not affected by the R173A substitution, suggesting that position 173 constitutes a critical residue for the specific recognition of the receptor by Antibody 1. The affinity of Antibody 1 for the R173A mutant is determined by 25 BIAcore® analysis. The binding of Antibody 1 to the R173A mutant is 7-fold poorer than the affinity of the antibody for the wild-type protein.

Sequence comparison reveals that the Arginine residue at position 173 of the human and mouse FGFR-3 sequences is not shared by the other family members, suggesting that this residue is likely responsible for the FGFR-3 specificity exhibited by 30 Antibody 1.

X-18531

23

**FGFR-3 antibody antagonist blocks FGFR-3(IIIb) and FGFR-3(IIIc)-mediated FGF binding and cell signaling**

Results from the aforementioned ELISA blocking assay show that Antibody 1 blocks FGF-1/FGFR-3 binding with an IC<sub>50</sub> within the range of 1-10 nM. Use FGFR-3 expressing L6 cells described above to test the activities of this antibody on FGFR-3 signaling in live cells. Quiesce the FGFR-3 expressing L6 cells overnight in media with very low concentration of serum (0.1%). The next day divide cells into five samples of equal size. Treat sample 1 and 2 for 1 h with an isotype-matched non-specific control antibody (200 nM) and Antibody 1 (200 nM), respectively. Expose samples 3 for 15 min with 0.6 nM of FGF-9. Treat samples 4 and 5 first for 1 h with an isotype-matched non-specific control antibody (200 nM) and Antibody 1 (200 nM), respectively, then expose for 15 min with 0.6 nM of FGF-9. After these treatments and exposures, lyse the cells and subject them to SDS-PAGE and western blot. Probe for the activation of FGFR-3 with an anti-phospho-Tyrosine antibody. Antibody 1 alone neither increased nor decreased the signals of activated FGFR-3 and MAPK, and FGF-9 ligand exposure increases the signals of activated FGFR-3 and MAPK to the same degree. These results thus demonstrate that Antibody 1 is an antagonist that blocks the FGFR-3 receptor in ligand-induced activation in live cells.

**Cell surface FGFR-3 is internalized upon binding to Antibody 1.**

Antibody 1 triggers the internalization of FGFR-3, constituting a mechanism of down-modulating the receptor signaling. To test this, label the antibody with the commercially available Alexa Fluor® dye (Invitrogen), in order to trace the location of the Antibody 1/FGFR-3 complex. Conjugate Antibody 1 and an isotype matched nonspecific control antibody with the fluorescent dye. Quiesce the FGFR-3 expressing L6 cells overnight in media with very low concentration of serum (0.1%).

Divide the cells into 8 samples of equal size and seed into wells of a 6-well tissue culture plate. These samples are subjected to three distinct procedures: 1) Binding, in which cells are incubated with 1 mL of 200 nM conjugated antibodies for 1h at 4°C. The temperature is prohibitory low for endocytosis but conducive to antibody-antigen interaction; 2) Internalizing, in which cells are incubated with 1 mL of 200 nM conjugated antibodies for 1h at 37°C. This temperature will allow endocytosis; 3) Stripping, in which cells are treated with 1 mL of 0.2 M glycine-0.15 M NaCl, pH3 for 30

X-18531

24

min at 4°C. In this condition, antibodies that are not internalized can no longer bind to the surface receptor and are released into the media. The eight FGFR-3 transfected L6 cell samples are treated according to the following description: Sample 1 is incubated with the conjugated control antibody (200 nM, 1 mL) for 1 h at 4°C; Sample 2 is 5 incubated with the conjugated control antibody (200 nM, 1 mL) for 1 h at 4°C, followed by stripping; Sample 3 is treated with the conjugated control antibody (200 nM, 1 mL) for 1 h at 37°C; Sample 4 is treated with the conjugated control antibody (200 nM, 1 mL) for 1 h at 37°C followed by stripping; Sample 5 is treated with conjugated Antibody 1 (200 nM, 1 mL) for 1 h at 4°C. Sample 6 is treated with conjugated Antibody 1 (200 nM, 1 10 mL) for 1 h at 4°C followed by stripping; Sample 7 is treated with conjugated Antibody 1 (200 nM, 1 mL) for 1 h at 37°C. Sample 8 is treated with conjugated Antibody 1 (200 nM, 1 mL) for 1 h at 37°C followed by stripping. After these treatments, all cells are washed three times with 1 mL of ice-cold PBS and subject to the Odyssey Infrared Imaging system for the detection of relative fluorescent intensity. The readouts of sample 15 1-8 are as follows: 1.5, 0.6, 1.1, 1, 3.3, 1.5, 5, and 5.8. The conditions under which Samples 1 and 5 are treated allows antibody-cell surface binding but not internalization. The conditions under which Samples 2 and 6 are treated allow neither cell-surface 20 binding nor internalization. The conditions under which Samples 3 and 7 are treated allow cell-surface binding and internalization. The conditions under which Samples 4 and 8 are treated allows internalization but not cell-surface binding. The signals generated by Samples 1-4, as well as Sample 6 are considered background due to non-specificities.

Perform an "acid wash" step on some samples following the incubation to strip off surface-bound antibodies without affecting those that had been trafficked inside the cells. 25 This enables the quantification of internalized antibodies. A similarly labeled control antibody (non-specific hIgG) is not retained regardless of incubation temperature or the washing step. Although Antibody 1 is retained at both temperatures before the wash, only those incubated at 37°C remain afterward; demonstrating the internalization of the antibody by the cells.

30

**Antibody 1 induces FGFR-3 receptor degradation in cells.**

X-18531

25

OPM-2 is a cell line originally isolated from cancer cells of multiple myeloma. OPM-2 cells are known to express FGFR-3 receptors harboring a gain-of-function K650E point mutation. Quiesce the OPM-2 cells in low serum culture media (0.1% FBS) for overnight. The next day, divide these cells into 5 groups. Group 1 is lysed immediately, 5 and the lysate is kept at -20°C until the time of western blot analysis. This group is therefore designated as Time 0 hr sample. Group 2-5 each has 3 samples of equal size, named as Sample A, B and C of Group 2, 3, 4, and 5. Samples A of Group 2-5 are not subjected to any further treatment, but are incubated at 37°C. Samples B of Group 2-5 are treated with 30 ng/ml FGF-1 at 37°C. Samples C of Group 2-5 are treated with 30 10 ug/ml Antibody 1 at 37°C. All samples of Group 2 are lysed after 1 hr of treatment, and the lysates are kept at -20°C until the time of western blot analysis. This group is designated as the Time 1 hr samples. All samples of Group 3 are lysed after 4 hr of treatment, and the lysates are kept at -20°C until the time of western blot analysis. This group is designated as the Time 4 hr samples. All samples of Group 4 are lysed after 8 hr 15 of treatment, and the lysates are kept at -20°C until the time of western blot analysis. This group is designated as Time 8 hr samples. All samples of Group 5 are lysed after 24 hr of treatment, and the lysates are kept at -20°C until the time of western blot analysis. This group is designated as Time 24 hr samples. When all lysates are ready, they are subjected to SDS-PAGE followed by Western Blot experiment. The FGFR-3 signals of 20 Group 1 and all samples of Group 2 are similar. In Group 3, FGFR-3 signals of Samples A and C are similar to that of Group 1; yet signal of Sample B is significantly lower. In Group 4, the FGFR-3 signal of Sample A is similar to that of Group 1; yet signals of Samples B and C are significantly lower. In Group 5, the FGFR-3 signal of Sample A is lower than that of group 1; yet signals of Samples B and C are nearly absent. Therefore, 25 similar to FGF-1, which is known to induce FGFR degradation, Antibody 1 is capable of inducing FGFR-3 degradation in a time-dependent manner; a feature that we believe has not been shown to date.

**Antibody 1 induces depletion of mutant FGFR-3 receptor from cell surface**

30 Most FGFR-3-activating mutations identified in bladder cancer are located in the extracellular domain of the receptor. These mutations (e.g. R248C or S249C) give rise to a new, unpaired cysteine residue, leading to formation of disulfide-linked FGFR-3 dimers

X-18531

26

in a ligand-independent manner. The most frequent mutations are S249C, Y375C and R248C, which together account for 91% of all FGFR-3 mutations in bladder cancer. In addition, S249C on FGFR-3(IIIc) also leads to constitutive activation of FGFR3(IIIc). Antibody 1 can internalize and deplete not only wild type (WT) FGFR-3, but also the 5 most prevalent tumor-associated FGFR-3 mutants.

To generate NIH-3T3 and Ba/F3 cell lines stably expressing each of the three most common FGFR3 mutant variants and the WT FGFR-3, clone cDNA encoding full-length human FGFR-3(IIIb) or (IIIc) into pMSCVpuro retraviral vector (Clontech Laboratories, Mountain View, CA) to generate pMSCVpuro-FGFR-3(IIIb) or (IIIc). Specific 10 mutations, i.e., S249C, Y375C and R248C, are introduced into the cDNA via QuickChange (Stratagene, La Jolla, CA). To generate NIH3T3 and Ba/F3 stable cells expressing WT or mutant FGFR-3, various pMSCVneo constructs are transfected into packaging cells Phoenix-Eco (ATCC, Manassas, VA) with Lipofectamine (Invitrogen). The retroviruses are collected and used to infect NIH-3T3 and Ba/F3 cells. After selection 15 with 2  $\mu$ g/ $\mu$ l puromycin for two weeks, cell expressing WT or mutant FGFR-3 are stained with Alexa Fluor 488-conjugated anti-human FGFR-3 and analyzed using fluorescence-activated cell sorting (FACS).

For Antibody 1-induced internalization/depletion of mutant and WT FGFR-3 from cell surface, wells of 6-well tissue culture plates (Costar, #3598) are seeded with  $1.5 \times 10^5$  20 NIH-3T3-FGFR-3 mutant in 2 mL of culture medium (DMEM (Invitrogen); 10% (v/v) FCS (Invitrogen); 2 mM L-glutamine (Invitrogen); 100 U/500mL penicillin G, and 100  $\mu$ g/500 mL streptomycin (Invitrogen)). The plates are incubated for 24 hours at 37°C under 95% relative humidity and 5% (v/v) CO<sub>2</sub>. Antibody 1 is then added to the wells at a final concentration of 5  $\mu$ g/mL. After 2-hour treatment, the culture medium is removed 25 from the wells and replaced with 1 mL of enzyme-free cell dissociation solution (Chemicon, #S-014-B). The cells are collected into centrifuge tubes after being incubated for 5 min. at room temperature, and washed once in culture medium followed by one more wash in binding buffer (DPBS with 1% (w/v) BSA and 0.01% (w/v) sodium azide). Before staining cells, an FGFR-3 antibody that recognizes a different epitope from 30 Antibody 1 is labeled by using an Alexa Fluor 488 Monoclonal Antibody Labeling Kit (Molecular Probes, Eugene, OR) according to the supplier's instructions. 100  $\mu$ L of

X-18531

27

binding buffer containing 2  $\mu$ g/mL of the Alexa Fluor 488-labeled antibody are added to the cells, which are then incubated for 60 min. on ice. The cells are then washed once with binding buffer and resuspended in DPBS containing 2  $\mu$ g/mL propidium iodide (to stain the dead cells). The amount of FGFR-3 molecules remaining on the cell surface is 5 analyzed by FACS analysis, and 10,000 events are acquired for each sample.

The mean fluorescence intensity on the cell surface reflects the quantity of FGFR-3 molecules that remain on the cell surface after treatment with Antibody 1. The percentage of depletion of FGFR-3 on the cell surface is calculated by using the mean fluorescence intensity of Antibody 1 treated cells divided by the mean fluorescence 10 intensity of human IgG1 treated cells. Antibody 1 significantly reduced both WT and mutant FGFR-3 from cell surfaces.

For the Ba/F3-FGFR3 cell proliferation assay, 80,000 cells/well are seeded in RPMI 1640 medium supplemented with 10% FBS. Antibody 1 is added at a concentration of 0.005 to 10  $\mu$ g/ml with heparin (StemCell Technologies, Vancouver, 15 Canada). After incubation for 72 hrs, cells were pulsed with 20  $\mu$ l (2  $\mu$ Ci)/200  $\mu$ l of methyl-<sup>3</sup>H thymidine for 6 hours at 37°C, 5% CO<sub>2</sub>. The cells were harvested and counted for <sup>3</sup>H thymidine incorporation. Antibody 1 significantly inhibited Ba/F3-FGFR-3- R248C proliferation.

**FGFR-3 antibody antagonist inhibits FGF-signaling in FGFR-3 expressing tumor 20 cells in vitro.**

Identify tumor cell lines that express wild type or mutant FGFR-3 (IIIb and/or IIIc) using flow cytometry in which Antibody 1 is the primary antibody. Three bladder tumor cell lines, RT112, RT4 and BFTC905 show significant FGFR-3 expression. OPM-2 cells, known to express FGFR-3 receptors harboring a gain-of-function K650E point 25 mutation, also display high level of expression in this study. Two additional cell lines, GEO and FADU, are found to express moderate but still significant levels of the receptor. The FGFR-3 signaling pathway in these tumor cells is characterized using western blot.

OPM-2 is a cell line derived from human multiple myeloma tumors. Quiesce the 30 cells in low serum culture media (0.1% FBS) overnight. The next day, divide these cells into four samples of equal size. Set aside and keep sample 1 at 37°C for 1 h as the control

X-18531

28

sample. Incubate sample 2 with 200 nM of Antibody 1 at 37°C for 1 h. Set aside sample 3 at 37°C for 1 h, then expose the same sample with 0.2 nM of FGF-9 ligand at 37°C for 15 min. Incubate sample 4 with 200 nM of Antibody 1 for at 37°C for 1 h, then expose the same sample with 0.2 nM of FGF-9 at 37°C for 15 min. Next, lyse all four samples 5 and subject them to SDS-PAGE followed by Western blotting. Probe the activation of FGFR-3 with an anti-phospho-Tyrosine antibody. Probe the activation of down-stream effector molecule MAPK with an anti-phospho-MAPK antibody. Probe the activation of down-stream effector molecule Akt with an anti-phospho-Akt antibody. The signals of phosphor-FGFR-3 from Samples 2 and 4 are comparable to that from Sample 1, which 10 represents the un-stimulated state of the receptor. The signal of Sample 3 is more than tripled that of Sample 1. It can be concluded that Antibody 1 antagonizes the effect of FGF-9 on FGFR-3 activation. The signals of phosphor-MAPK from Samples 2 and 4 are comparable to that from sample 1, which represented the un-stimulated state of the receptor. The signal of Sample 3 is more than doubled that of Sample 1. It can be 15 concluded that Antibody 1 antagonizes the effect of FGF-9 on MAPK activation. GEO is a cell line derived from human colorectal tumors. Quiesce the cells in low serum media (0.1% FBS) overnight. The next day, divide these cells into six samples of equal size. Set aside and keep sample 1 at 37°C for 1 h as the control sample. Incubate sample 2 with 200 nM of 200 nM isotype-matched non-specific control antibody at 37°C for 1 h. 20 Incubate sample 3 with 200 nM of Antibody 1 at 37°C for 1 h. Set aside sample 4 at 37°C for 1 h, then expose the same sample with 0.67 nM of FGF-1 ligand at 37°C for 15 min. Incubate sample 5 with 200 nM control antibody for at 37°C for 1 h, than expose 25 the same sample with 0.67 nM FGF-1 at 37°C for 15 min. Incubate sample 6 with 200 nM Antibody 1 for at 37°C for 1 h, than expose the same sample with 0.67 nM FGF-1 at 37°C for 15 min. Lyse all six samples and subject them to SDS-PAGE followed by Western blotting. Probe the activation of FGFR-3 with an anti-phospho-Tyrosine antibody. Samples 1, 2 and 4 have similar low levels of phosphor-FGFR-3, whereas sample 3 alone has significantly higher signals corresponding to all three kinds of molecules. Therefore, 1) FGF-9 exposure increases phosphorylation of FGFR-3; 2) 30 Antibody 1 antagonizes these increases, and 3) Antibody 1 alone does not have any agonist activity.

X-18531

29

RT-112 is a cell line derived from human bladder tumors. Quiesce the cells in low serum culture media (0.1% FBS) for overnight. The next day, divide these cells into four samples of equal size. Set aside and keep sample 1 at 37°C for 1 h as the control sample. Incubate sample 2 with 200 nM of Antibody 1 at 37°C for 1 h. Set aside sample 5 3 at 37°C for 1 h, then expose the same sample with 1.3 nM of FGF-1 ligand at 37°C for 15 min. Incubate sample 4 with 200 nM of Antibody 1 for at 37°C for 1 h, then expose the same sample with 0.13 nM of FGF-1 at 37°C for 15 min. Next, lyse all four samples and subject 10% of each lysed sample to SDS-PAGE followed by Western blotting. Probe the activation of down-stream effector molecule MAPK with an anti-phospho-10 MAPK antibody. Probe the activation of down-stream effector molecule Akt with an anti-phospho-Akt antibody. Subject the other 90% of each lysate to an immunoprecipitation experiment. Mix the sample with a commercial anti-FGFR-3 antibody at 4°C for 4-16 hrs to allow the antibody to collect the FGFR-3 receptors in the lysates, and then retrieve the anti-FGFR-3 antibody-bound FGFR-3 by mixing 20 µg of 15 protein A-protein G beads mixture (50:50, V:V) to the samples at 4°C for overnight. Wash these beads 3 times with PBS, before subjecting them to SDS-PAGE and Western blotting. Probe the activation of FGFR-3 with an anti-phospho-Tyrosine antibody. Samples 1, 2 and 4 have similar low levels of phosphor-FGFR-3 and phosphor-MAPK, whereas sample 3 alone has significantly higher signals corresponding to all three kinds 20 of molecules. Therefore, 1) FGF-1 exposure increases phosphorylation of FGFR-3, and MAPK; 2) Antibody 1 antagonizes these increases, and 3) Antibody 1 alone does not have any agonist activity. Sample 4 alone has lower phosphor-Akt signal than the rest, indicating that Antibody 1 may antagonize Akt signaling as well.

Use GEO cells to prepare the six samples described above, then lyse and subject 25 them to SDS-PAGE followed by Western blotting as above. However, probe the activation of down-stream effector molecule MAPK with an anti-phospho-MAPK antibody. Probe the activation of down-stream effector molecule Akt with an anti-phospho-Akt antibody. Samples 1, 2, 3 and 6 have similar low levels of phosphor-MAPK, whereas Samples 4 and 5 have significantly higher signals corresponding to all 30 three kinds of molecules. Therefore, 1) FGF-1 exposure increases phosphorylation of

X-18531

30

MAPK; 2) Antibody 1 antagonizes this increases, and 3) Antibody 1 alone does not have any agonist activity.

**Antibody 1 inhibits tumor cell growth and survival in vitro**

5 A cell proliferation assay is used to show the inhibitory effects of Antibody 1 on the growth of tumor cells. Quiescent monolayer RT112 cells in low serum culture media (0.1% fetal bovine serum, 5 µg/mL heparin) for 24-72 hrs. Divide cells into 4 samples. Add FBS (Fetal Bovine Serum) to Sample 1 to the final concentration of 10% (V:V). Leave Sample 2 in the starving media. Add FGF-1 to Sample 3 to the final concentration 10 of 1 nM. Add Antibody 1 to Sample 4 to the final concentration of 200 nM, incubate at 37°C for 1 hr. Next, add FGF-1 to the final concentration of 1 nM. After preparing 15 Samples 1-4 as described above, incubate the samples in a tissue culture incubator set at 37°C and with 5% CO<sub>2</sub> (v:v) for 48 hours. Detect cell growth using standard <sup>3</sup>H-thymidine incorporation assays. Tumor cell growth is doubled when RT112 cells in vivo 15 are stimulated with 1 nM exogenous FGF-1. The experiment also shows that Antibody 1 effectively reduces this exogenously stimulated growth.

A soft agar assay, also known as colony formation assay or colonogenic assay, is used to show the inhibitory effects of Antibody 1 on the survival of tumor cells. RT112 cells grown in soft-agar containing 200 nM Antibody 1 (in 10 % FBS culture media) 20 form ~50 % few colonies than those grown in soft-agar containing 10% FBS culture media alone, or containing 200 nM isotype-matched nonspecific control antibody (in 10 % FBS culture media). This shows the anti-survival effects of Antibody 1 on the tumor cells.

25 **Antibody 1 shows anti-tumor effects on FGFR-3-bearing solid tumors.**

Develop RT112 and GEO xenograft tumor models by routine methods in which 1-20 million tumor cells mixed with 0-100% Matrigel are injected subcutaneously to each female athymic nude mouse. Start antibody treatment once the mean volume of the subcutaneous tumors is approximately 400 mm<sup>2</sup>. The two tumor cell lines RT112 and 30 GEO corresponding xenograft tumors both are effectively inhibited by the three times weekly 40 mg/kg Antibody 1 i.p. injection treatment compared to the same type of tumors

X-18531

31

in the control cohorts. To demonstrate that these effects are emanated from the rendering of the FGFR-3 signaling pathway, conduct an efficacy study using a Orthotopic PC-3 tumor model in which the tumor cells are devoid of FGFR-3 signaling as suggested by the negative results from a Western Blot analysis of the FGFR-3 receptor phosphorylation.

5 Orthotopic PC-3 model was generated by injecting luciferase transfected PC-3 cells (PC-3LP) directly into the dorsal lobe prostates of Nu/nu mice (male, 7-8 weeks, 1 X 10<sup>6</sup> cells/mouse) through surgery. Two weeks after cell implantation, bioluminescence images of the animals are captured in the ventral position (animals laying on back) and quantified using the IVIS system according to manufacturer's instructions (Caliper Life Sciences, Hopkinton, MA). Mice with successful implants are randomized into groups to receive various testing agents i.p. on a predetermined schedule. Signals captured by IVIS are used as surrogates of tumor burden, and are recorded weekly. Statistical analyses are performed using repeated ANOVA. Antibody 1 shows no significant effect on the growth of the PC-3 tumors. Therefore Antibody 1 inhibits the growth of those solid

10 tumors that possess functional FGFR-3 signaling pathways.

15

**Antibody 1 shows anti-tumor effect on myeloid tumors with mutant FGFR-3 receptors**

OPM-2 and KMS-11 are FGFR-3 expressing multiple myeloma cell lines. In addition, receptors in both cell lines are mutants harboring single point-mutations: K650E in OPM-2 and Y373C in KMS-11. The two mutations are gain-of-function mutations and heighten the activity of the mutant receptors through mechanisms such as constitutive activation, prolonged half-life and increased ligand sensitivity. Develop an OPM-2 xenograft model by routine methods in which 1-20 millions of tumor cells mixed with 0-100% Matrigel are injected subcutaneously to each female athymic nude mouse.

20 Start injection treatment once the mean volume of the subcutaneous tumors is approximately 400 mm<sup>2</sup>. Treat 3 times weekly. Measure tumor volumes 3 times weekly. Make final measurement after 4 weeks of treatment. Mean tumor size of the Antibody 1 treated animals is 64% smaller than that of the control group. Perform Student t-test. The

25 P value is less than 0.0001. Therefore the finding is highly significant. A KMS-11 bone engraftment model is established according to Xin X , et al., Clin Cancer Res. 2006 Aug 15;12(16):4908-15. Start antibody treatment 1 week after the tumor cell injections. Treat

30

X-18531

32

3 times weekly. Measure signals emitted by the tumor cells several times during the study. Make final measurement after 33 days after the first injection. Mean signal from Antibody 1 treated animals is 1/4 of that from the control animals. Conduct Long-rank (Mantel-Cox) Test. The P value is 0.0002. Therefore the finding is highly significant. In 5 both models, three times weekly 40 mg/kg Antibody 1 i.p. injections treatment significantly inhibits tumor growth compared to the control cohorts. Antibody 1 appears to be the first to demonstrate in vivo anti-tumor activity against tumor cells that possess K650E as well as those that possess Y373C mutant forms of FGFR-3.

10 **Antibody 1 enhances the therapeutic efficacy of cytotoxic agents.**

Cisplatin is a widely used cytotoxic agent in cancer therapies. It causes DNA cross-linking and induces cell apoptosis. The therapeutic benefit of combining cisplatin with FGFR-3 antibody in three bladder xenograft models is explored. Develop RT112, RT4 and BFTC905 xenograft tumor models by routine methods in which 1-20 million 15 tumor cells mixed with 0-100% Matrigel are injected subcutaneously to each female athymic nude mouse. Start antibody treatment once the mean volume of the 20 subcutaneous tumors is approximately 400 mm<sup>2</sup>. Use 40 mg/kg three times weekly injections of Antibody 1 and the maximal-tolerated-dose (MTD) of cisplatin. Measure tumor volumes 3 times weekly until the end of the studies. A summary of the data of RT112 tumor model are recorded in the following table:

Table 3: Individual RT-112 Tumor Volumes (mm<sup>3</sup>) -- Cisplatin Treatment

Treatment	Day 1	Day 8	Day 15	Day 22	Day 29	Day 36	Day 42

±S.E.M.	12.6	16.2	21.7	22.1	52.1	81.2	97.7	137.6

10 Conduct RM ANOVO statistical test. Compare the efficacy of cisplatin treatment vs. that of cisplatin-Antibody 1 combination. The P value is 0.0209. Therefore the effect of Antibody 1 on the increased efficacy of cisplatin is highly significant.

15 None of the animals died of the treatments during the entire courses of these studies, suggesting that adding Antibody 1 to MTD of cisplatin enhances the efficacy of the latter without significantly worsening the adverse effects of the two drugs.

X-18531

35

## WE CLAIM:

1. An isolated antibody that specifically binds to human FGFR-3(IIIb) and FGFR-3(IIIc).
2. The antibody of claim 1, which is a human antibody having a  $K_D$  of about  $1 \times 10^{-8}$  M  
5 or less at room temperature (20-25°C).
3. The antibody of either of claims 1-2 that specifically binds to human FGFR-3 domain  
2 (SEQ ID NO 12).
4. The antibody of any one of claims 1-3 that specifically binds to human FGFR-3,  
comprising a CDRH1 having the sequence GYMFTSYGIS (SEQ ID NO 1), a  
10 CDRH2 having the sequence WVSTYNGDTNYAQKFQG (SEQ ID NO 2), a CDRH3 having the sequence VLGYYDSIDGYYYGMDV (SEQ ID NO 3), a CDRL1 having the sequence GGNNIGDKSVH (SEQ ID NO 4), a CDRL2 having the sequence LDTERPS (SEQ ID NO 5), and a CDRL3 having the sequence  
QVWDSGSDHV (SEQ ID NO 6).
- 15 5. The antibody of any one of claims 1-4, wherein the antibody comprises a variable  
heavy amino acid sequence:  
EVQLVQSGAEVKKPGASVKVSCKASGYMFTSYGISWVRQAPGQGLEWMGW  
VSTYNGDTNYAQKFQGRVTVTIDTSTSTAYMELRSLRSEDTAVYYCARVLG  
YYDSIDGYYYGMDVWGGQGTTVTVSS (SEQ ID NO 7) and a variable light amino  
20 acid sequence:  
QSVLTQPPSLSVAPGKTATFTCGGNNIGDKSVHWYRQKPGQAPVLMYLD  
ERPSGIPERMSGNSFGNTATLTITRVEAGDEADYYCQVWDSGSDHVVFGGGT  
KLTVLG (SEQ ID NO 8).
6. An antibody as claimed in any preceding claim, comprising a heavy chain of SEQ ID  
25 NO: 9 and a light chain of SEQ ID NO: 10.
7. An antibody as claimed in any preceding claim, comprising two heavy chains of SEQ  
ID NO: 9 and two light chains of SEQ ID NO: 10.
8. A neutralizing human FGFR-3-binding fragment of the antibody of any of claims 1-7.
9. An isolated antibody or a fragment thereof, wherein said antibody competes for  
30 binding to the extracellular domain of FGFR-3 in a competition ELISA assay with a  
competing antibody according to any one of claims 5 to 8, wherein said competing

X-18531

36

antibody binds FGFR-3 with a  $K_D$  of about  $1 \times 10^{-8}$  M or less at room temperature (20-25°C).

10. The antibody of claim 9 that specifically binds to mutant FGFR-3.
11. A pharmaceutical composition comprising an antibody or fragment, as claimed in any 5 one of claims 1-9 and a pharmaceutically acceptable carrier, diluent or excipient.
12. A product containing an antibody or fragment, according to any one of Claims 1-9, and an additional anti-cancer agent for treatment in combination for simultaneous, separate or sequential use in therapy.
13. An antibody or fragment as claimed in any one of claims 1-9 for use as a medicament.
- 10 14. An antibody or fragment as claimed in any one of claims 1-9, for use in the treatment of cancer.
15. An antibody or fragment as claimed in claim 13, wherein the cancer is bladder or multiple myeloma.
